Proceedings of the  
Tenth Congress of  
the European Society  
for Research in  
Mathematics Education

**Editors:** Thérèse Dooley and Ghislaine Gueudet

**Organised by:** Institute of Education, Dublin City University

**Year:** 2017

**e r m e**

european society for research in mathematics education

## Editors

Thérèse Dooley, CASTeL, Institute of Education, Dublin City University, Ireland.

Ghislaine Gueudet, CREAD, ESPE de Bretagne, University of Brest, France.

## Editorial Board

Mario Sánchez Aguilar; Gilles Aldon; Paul Andrews; Samuele Antonini; Jonas Bergman Ärleback; Fatma Aslan-Tutak; Michal Ayalon; Anna Baccaglini-Frank; Arthur Bakker; Berta Barquero; Christiane Benz; Angelika Bikner-Ahsbahr; Irene Biza; Lisa Björklund Boistrup; Nina Bohlmann; Orly Buchbinder; Susana Carreira; Renato Carvalho; Sona Ceretkova; Renaud Chorlay; Anna Chronaki; Kathy Clark; Alison Clark-Wilson; Jason Cooper; Seán Delaney; Pietro Di Martino; Javier Díez-Palomar; Ove Gunnar Drageset; Paul Drijvers; Ingvald Erfjord; Eleonora Faggiano; Daniel Frischemeier; Torsten Fritzlar; Eirini Geraniou; Imène Ghedamsi; Inés María Gómez-Chacón; Alejandro Gonzalez-Martin; Katalin Gosztönyi; Corinne Hahn; Mariam Haspekian; Thomas Hausberger; Kirsti Hemmi; Dave Hewitt; Jeremy Hodgen; Paola Iannone; Jenni Ingram; Eva Jablonka; Uffe Thomas Jankvist; Darina Jirotkova; Keith Jones; Gabriele Kaiser; Sibel Kazak; Iveta Kohanová; Sebastian Kuntze; Snezana Lawrence; Aisling Leavy; Esther Levenson; Peter Liljedahl; Thomas Lingefjord; Božena Maj-Tatšis; Mirko Marracci; Francesca Martignone; Michaela Maschietto; Tamsin Meaney; Joris Mithalal; Reidar Mosvold; Reinhard Oldenburg; Maurice O'Reilly; Marilena Pantziara; Birgit Pepin; Kirsten Pfeiffer; Alon Pinto; Núria Planas; Valentina Postelnicu; Caterina Primi; Elisabeth Rathgeb-Schnierer; Sebastian Rezat; Miguel Ribeiro; Kirsti Rø; Elisabetta Robotti; Ornella Robutti; Frode Rønning; Mirosława Sajka; Charalampos Sakonidis; Judy Sayers; Stanislaw Schukajlow; Marcus Schütte; Gerard Sensevy; Nathalie Sinclair; Jeppe Skott; Heidi Strømskag Måsøval; Andreas Stylianides; Gabriel Stylianides; Rukiye Didem Taylan; Amanjot Toor; Fabrice Vandebrouck; Michiel Veldhuis; Olov Viirman; Kjersti Wæge; Geoff Wake; Hans-Georg Weigand; Constantinos Xenofontos

# TABLE OF CONTENTS

<u>Foreword: CERME10 in lovely Dublin</u> <i>Susanne Prediger, Viviane Durand-Guerrier</i>	1
<b>Introduction</b>	
<u>Introduction to the Proceedings of the Tenth Congress of the European Society for Research in Mathematics Education (CERME10)</u> <i>Thérèse Dooley, Ghislaine Gueudet</i>	3
<u>Statistical overview of CERME10</u> <i>Maurice O'Reilly</i>	6
<b>Plenary Lectures</b>	
<u>From advanced mathematical thinking to university mathematics education: A story of emancipation and enrichment</u> <i>Elena Nardi</i>	9
<u>Young children's early mathematical competencies: Analysis and stimulation</u> <i>Lieven Verschaffel, Joke Torbeyns, and Bert De Smedt</i>	31
<b>Plenary Panel</b>	
<u>Solid findings in mathematics education: What are they and what are they good for?</u> <i>Marianna Bosch, Tommy Dreyfus, Caterina Primi, Gerry Shiel</i>	53
<u>Solid findings in mathematics education: A necessary discussion</u> <i>Marianna Bosch</i>	53
<u>What are solid findings in mathematics education?</u> <i>Tommy Dreyfus</i>	57
<u>Solid findings in mathematics education: A psychometric approach</u> <i>Caterina Primi</i>	63
<u>Can the outcomes of PISA 2015 contribute to evidence-based decision making in mathematics education?</u> <i>Gerry Shiel</i>	68

<b>TWG01: Argumentation and proof</b>	<b>78</b>
<b><u>Introduction to the papers of TWG01: Argumentation and proof</u></b>	<b>79</b>
 <u>Meta-mathematical knowledge about proof</u> <i>Nadia Azrou</i>	 83
<u>Conceptualizing reasoning-and-proving opportunities in textbook expositions: Cases from secondary calculus</u> <i>Andreas Bergwall</i>	 91
<u>Cognitive unity of theorems, theories and related rationalities</u> <i>Paolo Boero</i>	 99
<u>Supporting classroom implementation of proof-oriented tasks: Lessons from teacher researcher collaboration</u> <i>Orly Buchbinder</i>	 107
<u>A framework for classifying mathematical justification tasks</u> <i>Boon Liang Chua</i>	 115
<u>An application of Habermas' rationality to the teacher's actions: Analysis of argumentation in two classrooms</u> <i>AnnaMarie Conner</i>	 123
<u>Evolution of proof form in Japanese geometry textbooks</u> <i>Marion Cousin and Takeshi Miyakawa</i>	 131
<u>Pre-service middle school mathematics teachers' interpretation of logical equivalence in proof by contrapositive</u> <i>Esra Demiray and Mine Işıkşal Bostan</i>	 139
<u>Issues of a quasi-longitudinal study on different types of argumentation in the context of division by zero</u> <i>Christian Fahse</i>	 147
<u>The flow of a proof - Establishing a basis of agreement</u> <i>Mika Gabel and Tommy Dreyfus</i>	 155
<u>Fostering and investigating students' pathways to formal reasoning: A design research project on structural scaffolding for 9th graders</u> <i>Kerstin Hein and Susanne Prediger</i>	 163
<u>Misconceptions and developmental proof</u> <i>Kirsti Hemmi, Erika Julin and Ray Pörn</i>	 171
<u>Primary and secondary students' argumentation competence: A case study</u> <i>Eugenia Koleza, Nikolaos Metaxas and Klio Poli</i>	 179
<u>Proofs and refutations in school mathematics: A task design in dynamic geometry environments</u> <i>Kotaro Komatsu and Keith Jones</i>	 187

<u>Can teacher trainees use inductive arguments during their problem solving activity?</u> <i>Eszter Kónya and Zoltán Kovács</i>	195
<u>Principles towards justification: A focus on teacher actions</u> <i>Joana Mata-Pereira and João Pedro da Ponte</i>	203
<u>A reference for studying the teaching of logic</u> <i>Zoé Mesnil</i>	211
<u>Revisiting Odysseus' proving journeys to proof: The 'convergent-bounded' question</u> <i>Andreas Moutsios-Rentzos and Faidra Kalozoumi-Paizi</i>	219
<u>Play and pre-proving in the primary classroom</u> <i>Maria Pericleous and David Pratt</i>	227
<u>Proof-based teaching as a basis for understanding why</u> <i>David Reid and Estela Vallejo Vargas</i>	235
<u>Mathematical reasoning in the written argumentation of primary students</u> <i>Silke Ruwisch</i>	243
<u>An expanded theoretical perspective for proof construction and its teaching</u> <i>John Selden and Annie Selden</i>	251
<u>Tool-based argumentation</u> <i>Kalliopi Siopi and Eugenia Koleza</i>	259
<u>Learning with the logic of inquiry: game-activities inside Dynamic Geometry Environments</u> <i>Carlotta Soldano and Ferdinando Arzarello</i>	267
<u>Reasoning-and-proving in geometry in school mathematics textbooks in Hong Kong</u> <i>Kwong-Cheong Wong</i>	275
<u>An exploratory teaching style in promoting the learning of proof</u> <i>Xiaoheng Yan, John Mason and Gila Hanna</i>	283
<u>Looking for the roots of an argument: Textbook, teacher, and student influence on arguments in a traditional Czech classroom</u> <i>Jana Žalská</i>	291
<u>Identifying phases and activities in the proving process of first-year undergraduates</u> <i>Katharina Kirsten</i>	299

<b>TWG02: Arithmetic and number systems</b>	<b>301</b>
<b><u>Introduction to the papers of TWG02: Arithmetic and number systems</u></b>	<b>302</b>
<u>A conception of between-state ratio in fraction form</u> <i>Gulseren Karagoz Akar</i>	306
<u>The double nature of didactic models in conceptualizing the evolution of number systems: A mathematical model and a learning tool</u> <i>Marita Barabash and Raisa Guberman</i>	314
<u>Dealing with large numbers: What is important for students and teachers to know?</u> <i>Christine Chambris and Frédérick Tempier</i>	322
<u>Working memory, number sense and arithmetical performance: Relations between these domains</u> <i>Luciana Vellinho Corso and Beatriz Vargas Dorneles</i>	330
<u>Number estimation in children: An assessment study with number line estimation and numerosity tasks</u> <i>Beatriz Vargas Dorneles, Mariana Lima Duro; Nohemy Marcela Bedoya Rios; Camila Peres Noguez and Clarissa dos Santos Pereira</i>	338
<u>Do lower-achieving children profit from derived facts-based teaching of basic multiplication? Findings from a design research study</u> <i>Michael Gaidoschik, Kora Maria Deweis and Silvia Guggenbichler</i>	346
<u>Fostering rational numbers understanding through percentage</u> <i>Helena Gil Guerreiro and Lurdes Serrazina</i>	354
<u>The fostering of flexible mental calculation in an inclusive mathematics classroom during Mutual Learning</u> <i>Laura Korten</i>	362
<u>Opportunities to acquire foundational number sense: A quantitative comparison of popular English and Swedish textbooks</u> <i>Anna Löwenhielm, Gosia Marschall, Judy Sayers and Paul Andrews</i>	371
<u>Seeking symmetry in distributive property: Children developing structure sense in arithmetic</u> <i>Andrea Maffia and Maria Alessandra Mariotti</i>	379
<u>Models' use and adaptation aiming at conceptual understanding of decimal numbers</u> <i>Cristina Moraes and Lurdes Serrazina</i>	387
<u>Middle school students' difficulties in proportional reasoning</u> <i>Oznur Soyak and Mine Isiksal</i>	395
<u>Number line as a conceptual and didactical resource for teaching fractions using applets</u> <i>Carlos Valenzuela García, Olimpia Figueras, David Arnau and Juan Gutiérrez-Soto</i>	403
<u>How middle-grade students explain ordering statements within real life situation? An example of temperature context</u> <i>Aysenur Yilmaz and Mine Isiksal-Bostan</i>	411

<b>TWG03: Algebraic thinking</b>	<b>419</b>
<b><u>Introduction to the papers of TWG03: Algebraic thinking</u></b>	<b>420</b>
 <u>The effect of two intervention courses on students' early algebraic thinking</u> <i>Maria Chimoni and Demetra Pitta-Pantazi</i>	424
<u>Grade 6 students' abilities to represent functional relationships</u> <i>Isil Isler, Susanne Strachota, Ana Stephens, Nicole Fonger, Maria Blanton, Angela Gardiner, and Eric Knuth</i>	432
<u>An APOS perspective of the understanding of the concept of vector subspace</u> <i>Lillias H.N Mutambara and Sarah Bansilal</i>	440
<u>Four-component decomposition of sense making in algebra</u> <i>Alik Palatnik and Boris Koichu</i>	448
<u>'Father Woodland': A learning environment to facilitate the development of algebraic thinking</u> <i>Ioannis Papadopoulos and Nafsika Patsiala</i>	456
<u>Aspects of proficiency in elementary algebra</u> <i>Guido Pinkernell, Christian Düsi and Markus Vogel</i>	464
<u>Functional thinking and generalisation in third year of primary school</u> <i>Eder Pinto and María C. Cañadas</i>	472
<u>Didactic transposition in school algebra: The case of writing equations of parallel and perpendicular lines</u> <i>Valentina Postelnicu</i>	480
<u>Students' and teachers' mental solving of algebraic equations: From differences to challenges</u> <i>Jérôme Proulx, Marie-Line Lavallée-Lamarche, &amp; Karl-Philippe Tremblay</i>	488
<u>Introduction to equation solving for a new generation of algebra learners</u> <i>Ann-Sofi Røj-Lindberg, Ann-Maija Partanen and Kirsti Hemmi</i>	496
<u>An insight into the sources of multiple referents for the unknown in the algebraic solving of word problems</u> <i>Carlos Soneira, José Antonio González-Calero and David Arnau</i>	504
<u>Key ideas as guiding principles to support algebraic thinking in German primary schools</u> <i>Anna Susanne Steinweg</i>	512
<u>Constraints to a justification of commutativity of multiplication</u> <i>Heidi Strømskag and Anita Valenta</i>	520
<u>Shape patterning tasks: An exploration of how children build upon their observations when asked to construct general terms</u> <i>Aisling Twohill</i>	529

<u>Multiple models for teaching logarithms - with a focus on graphing functions</u> <i>Christof Weber</i>	537
<u>Hierarchical and non-hierarchical clustering methods to study students algebraic thinking in solving an open-ended questionnaire</u> <i>Benedetto Di Paola, Rosario Battaglia and Claudio Fazio</i>	545
<u>Conceptualizing the core of the function concept – A facet model</u> <i>Carina Zindel</i>	547
<u>A classical dot pattern-based approach to algebraic expressions in a multicultural classroom</u> <i>Marc Sauerwein and Malte Mink</i>	555
<u>An instructor-generated concept framework for elementary algebra in the tertiary context</u> <i>Claire Wladis, Kathleen Offenholley, Jae Ki Lee, Dale Dawes, Susan Licwinko</i>	557

<b>TWG04: Geometry</b>	<b>559</b>
<b><u>Introduction to the papers of TWG04: Geometry education</u></b>	<b>560</b>

<u>Learning to use a protractor: Touch screen tablet or not?</u> <i>Cécile Allard and Edith Petitfour</i>	564
<u>Constructing draggable figures using GeoGebra:</u> <u>The contribution of the DGE for geometric structuring</u> <i>Lina Brunheira and João Pedro da Ponte</i>	572
<u>Geometric constructions in a dynamic environment (GeoGebra):</u> <u>The case of in-service teachers</u> <i>Dorit Cohen, Anatoli Kouropatov, Regina Ovodenko, Maureen Hoch and Sara HersHKovitz</i>	580
<u>Transitioning from definitions to proof: Exploring non-Euclidean geometry in a college geometry course</u> <i>Rebecca Dibbs and Janessa Beach</i>	588
<u>Teaching geometry to students (from five to eight years old)</u> <u>“All that is curved and smooth is not a circle”</u> <i>Jacques Douaire and Fabien Emprin</i>	597
<u>Dialogic processes in collective geometric thinking:</u> <u>A case of defining and classifying quadrilaterals</u> <i>Taro Fujita, Jonathan Doney and Rupert Wegerif</i>	605
<u>Double perspective taking processes of primary children – adoption and application of a psychological instrument</u> <i>Cathleen Heil</i>	613

<u>Traveling in spatiality, in spatial sense</u>	621
<i>Catherine Houdement</i>	
<u>Autism and mathematics education</u>	629
<i>Michiel Klaren, Birgit Pepin and Marieke Thurlings</i>	
<u>Learning sine and cosine in French secondary schools</u>	637
<i>Ratha Loeng</i>	
<u>The Pythagorean theorem in mathematics laboratory</u>	645
<i>Michela Maschietto, Stefano Barbieri, Francesca Scorcioni</i>	
<u>The design of a teaching sequence on axial symmetry, involving a duo of artefacts and exploiting the synergy resulting from alternate use of these artefacts</u>	653
<i>Antonella Montone, Eleonora Faggiano and Maria Alessandra Mariotti</i>	
<u>Hide and think: Limiting the obvious and challenging the mind in geometry</u>	661
<i>Chrysi Papadaki</i>	
<u>What influences grade 6 to 9 pupils' success in solving conceptual tasks on area and volume</u>	669
<i>Veronika Tůmová</i>	
<u>Shapes recognition in early school: How to develop the dimensional deconstruction?</u>	677
<i>Céline Vendeira and Sylvia Coutat</i>	
<u>The construction and study of the ellipse through Huzita-Hatori axioms: An investigative activity in analytic geometry classes</u>	685
<i>Fabiana Chagas de Andrade, Thais de Sales Ribeiro and Bruna Mayara Batista Rodrigues</i>	
<u>A scale on cognitive configurations for tasks requiring visualization and spatial reasoning</u>	687
<i>Teresa F. Blanco, Pablo G. Sequeiros, Cristina Núñez, María Salgado</i>	
<u>Diagrams in students' proving activity in secondary school geometry</u>	689
<i>Keith Jones and Kotaro Komatsu</i>	
<u>QED-Tutrix: Creating and expanding a problem database towards personalized problem itineraries for proof learning</u>	691
<i>Michele Tessier-Baillargeon, Nicolas Leduc, Ludovic Font, Philippe R. Richard and Michel Gagnon</i>	
<u>Children's block-building: How do they express their knowledge of geometrical solids?</u>	693
<i>Susanne Wöller and Simone Reinhold</i>	

<b>TWG05: Probability and statistics education</b>	<b>695</b>
<b><u>Introduction to the papers of TWG05:</u></b>	
<b><u>Probability and statistics education</u></b>	<b>696</b>
<u>Errors or didactic resources: A teacher education task in the context of probability</u>	700
<i>Laura Afeltra, Maria Mellone, Piera Romano and Roberto Tortora</i>	
<u>Negotiating the content and the teaching of statistics:</u>	
<u>Two complementary processes in teachers' professional development</u>	708
<i>Dionysia Bakogianni</i>	
<u>Common patterns of thought and statistics: Accessing variability through the typical</u>	716
<i>Christian Büscher</i>	
<u>Do attitudes toward statistics change during an introductory statistics course?</u>	
<u>A study on Italian psychology students</u>	724
<i>Francesca Chiesi and Caterina Primi</i>	
<u>Informal statistical inference and pre-service primary school teachers:</u>	
<u>The development of their content knowledge and pedagogical content</u>	
<u>knowledge during a teacher college intervention</u>	732
<i>Arjen de Vetten, Judith Schoonenboom, Ronald Keijzer and Bert van Oers</i>	
<u>Chilean primary-school students' levels in reading pictograms</u>	740
<i>Danilo Díaz-Levicoy, Pedro Arteaga, and Carmen Batanero</i>	
<u>Conditional probability as a decision-making tool: A didactic sequence</u>	748
<i>Raimundo Elicer and Eduardo Carrasco</i>	
<u>Stepwise development of statistical literacy and thinking in a statistics</u>	
<u>course for elementary preservice teachers</u>	756
<i>Daniel Frischemeier &amp; Rolf Biehler</i>	
<u>Variables characterizing correlation and regression problems in the</u>	
<u>Spanish high school textbooks</u>	764
<i>María M. Gea, Carmen Batanero, Pedro Arteaga and J. Miguel Contreras</i>	
<u>Middle school mathematics teachers' pedagogical content knowledge</u>	
<u>in relation to statistical reasoning</u>	772
<i>Rukiye Gökce and Sibel Kazak</i>	
<u>Using sport-related socially open-ended problems to coordinate</u>	
<u>decision-making, variability modeling and value awareness</u>	780
<i>Orlando González and Somchai Chitmun</i>	
<u>Insights into the approaches of young children when making informal</u>	
<u>inferences about data</u>	788
<i>Aisling M. Leavy</i>	
<u>Students' conception of a sample's relation to the population</u>	
<u>when constructing models of resampling</u>	796
<i>Jeffrey A. McLean and Helen M. Doerr</i>	

<u>At-distance college-level training in statistical methods: Prospects and considerations</u> <i>Maria Meletiou-Mavrotheris, Efi Paparistodemou and Ana Serrado Bayes</i>	804
<u>Insights from students' reasoning about probability when they design their own Scratch games</u> <i>Efi Paparistodemou, Maria Meletiou-Mavrotheris and Christina Vasou</i>	812
<u>Using spreadsheets to teach probability in French high school</u> <i>Bernard Parzysz</i>	820
<u>Technology will solve student's probability misconceptions: Integrating simulation, algorithms and programming</u> <i>Annarosa Serpe and Maria Giovanna Frassia</i>	828
<u>High school students' first experiences with the sampling distribution: Toward a distributive perspective of sampling and inference</u> <i>Eleazar Silvestre and Ernesto Sanchez</i>	836
<u>Using student models to generate feedback in a university course on statistical sampling</u> <i>Sietske Tacoma, Paul Drijvers and Peter Boon</i>	844
<u>Undergraduate students' perceptions of learning introductory statistics through producing a statistical picture book</u> <i>Natthapoj Vincent Trakulphadetkrai</i>	852
<u>Enhancing statistical literacy</u> <i>Marianne van Dijke-Droogers, Paul Drijvers and Jos Tolboom</i>	860
<u>Implementing the statistical investigative process with real data: Effects on education in secondary schools</u> <i>Martin Andre</i>	868
<u>Metaphorical representations of multifaced statistical concepts: An access to implicit dominant interpretation by teachers?</u> <i>Corinne Hahn</i>	870
<u>Non-mathematics majors doing statistics: Factors behind performance</u> <i>Theognosia Michailidou</i>	872
<u>Relating theoretical and empirical probability - Developing students' conceptions of probability and chance in primary school</u> <i>Kristina Penava</i>	874

<b>TWG06: Applications and modelling</b>	<b>876</b>
<b><u>Introduction to the papers of TWG06: Applications and modelling</u></b>	<b>877</b>
 <u>Developing a classification scheme of definitions of Fermi problems in education from a modelling perspective</u>	 884
<i>Jonas Bergman Ärlebäck and Lluís Albarracín</i>	
<u>Levels of analysis of a mathematical modelling activity: Beyond the questions-answers dialectic</u>	892
<i>Berta Barquero, Nacho Monreal and Noemí Ruíz-Munzón</i>	
<u>Mathematical modelling as a prototype for interdisciplinary mathematics education? – Theoretical reflections</u>	900
<i>Rita Borromeo Ferri and Nicholas Mousoulides</i>	
<u>Mathematical modelling of dynamical systems and implementation at school</u>	908
<i>Martin Bracke and Jean-Marie Lantau</i>	
<u>Creating a color palette: The model, the concept, and the mathematics</u>	916
<i>Susana Carreira and Ana Margarida Baioa</i>	
<u>Examining the role of group work as an effective instructional strategy when teaching problem solving</u>	924
<i>Eamonn Clohessy and Patrick Johnson</i>	
<u>Modelling problems in German grammar school leaving examinations (Abitur) – Theory and practice</u>	932
<i>Gilbert Greefrath, Hans-Stefan Siller, Matthias Ludwig</i>	
<u>The investigation of mathematical problem-solving processes of fifth grade students in small groups</u>	940
<i>Firdevs İclal Karatas, Öznur Soyak and Ayşenur Alp</i>	
<u>Geometric modelling inspired by Da Vinci: Shaping and adding movement using technology and physical resources</u>	948
<i>Diego Lieban and Zsolt Lavicza</i>	
<u>Choosing a Mathematical Working Space in a modelling task: The influence of teaching</u>	956
<i>Elizabeth Montoya Delgadillo, Fernanda Viola and Laurent Vivier</i>	
<u>Fifth-grade students construct decimal number through measurement activities</u>	964
<i>Abolfazl Rafiepour &amp; Azam Karimianzade</i>	
<u>Teachers' beliefs about mathematical modelling: An exploratory study</u>	972
<i>Paola Ramirez</i>	
<u>Didactical activities to engineering training: Methodological proposal</u>	980
<i>Avenilde Romo, Santiago Tolentino and Rebeca Romo-Vázquez</i>	
<u>Mathematical modelling in an archaeological context: Their complementarity as essential tool for inquiry</u>	988
<i>Gemma Sala, Vicenç Font, Berta Barquero and Joaquim Giménez</i>	

<u>Strategies for fostering students' reading comprehension while they solve modelling problems</u>	996
<i>Madlin Schmelzer and Stanislaw Schukajlow</i>	
<u>Methodology for designing didactical activities as an engineering project of a tactile sensorial therapeutic ramp</u>	1004
<i>Luis Siero, Avenilde Romo and Arturo Abundez</i>	
<u>The use of heuristic strategies in modelling activities</u>	1012
<i>Peter Stender and Gabriele Kaiser</i>	
<u>Metacognitive modelling competencies in small groups</u>	1020
<i>Katrin Vorhölder, Alexandra Krüger, and Lisa Wendt</i>	
<u>Product orientation in modeling tasks</u>	1028
<i>Wolfgang Bock, Martin Bracke and Patrick Capraro</i>	
<u>Modeling tasks and mathematical work</u>	1031
<i>Charlotte Derouet, Alain Kuzniak, Dominique Laval, Elizabeth Montoya Delgadillo, Laurent Moutet, Assia Nechache, Bernard Parzysz, Laurent Vivier</i>	
<u>Mathematical modeling and competencies for biology students</u>	1033
<i>Yannis Liakos</i>	
<u>Phenomenological analysis of the line: A study based on the Didactical Analysis of mathematical knowledge</u>	1035
<i>Guillermo Ramírez-Montes and Fabián Gutiérrez-Fallas</i>	

## **TWG08: Affect and mathematical thinking** **1037**

<u>Introduction to the papers of TWG08:</u>	
<u>Affect and mathematical thinking</u>	1038

<u>Positioning and emotions in learning algebra: The case of middle-achieving students</u>	1042
<i>Wajeeh Daher, Osama Swidan, Amani Masarwa</i>	
<u>The role of affect in failure in mathematics at the university level: The tertiary crisis</u>	1050
<i>Pietro Di Martino and Francesca Gregorio</i>	
<u>Primary future teachers' expectations towards development courses on mathematics teaching</u>	1058
<i>Silvia Funghi</i>	
<u>Regression trees and decision rules applied to the study of perplexity: Issues and methods</u>	1066
<i>Inés M<sup>a</sup> Gómez-Chacón, J. Tinguaro Rodríguez</i>	

<u>Impact of long-term regular outdoor learning in mathematics – The case of John</u>	1074
<i>Annika Grothérus and Emilia Fägerstam</i>	
<u>Finnish educators' conceptions of the social-emotional needs of mathematically gifted high school students</u>	1082
<i>Eeva Haataja and Anu Laine</i>	
<u>The qualitative differences in generative characteristic of the aesthetic sensibility: Analysis of learners' problem solving</u>	1090
<i>Hayato Hanazono</i>	
<u>Identifying subgroups of CERME affect research papers</u>	1098
<i>Markku S. Hannula and Enrique Garcia Moreno-Esteva</i>	
<u>Tracing mathematics-related belief change in teacher education programs</u>	1106
<i>Çiğdem Haser and Işıl İşler</i>	
<u>Teaching self-regulation strategies with SOLVE IT to two students with learning disabilities: Effects on mathematical problem-solving performance</u>	1114
<i>Keffe Paraskevi, Dermitzaki Irini, Tzivinikou Sotiria and Stathopoulou Charoula</i>	
<u>To err is human. The management and emotional implications of teacher error</u>	1122
<i>Elizabeth Lake</i>	
<u>Students' images of mathematics: The role of parents' occupation</u>	1130
<i>Ciara Lane</i>	
<u>Emotions and problem solving by prospective primary school teachers</u>	1138
<i>Gareth Lewis</i>	
<u>On the edges of flow: Student engagement in problem solving</u>	1146
<i>Peter Liljedahl</i>	
<u>Exploring daily emotions of a mathematics teacher in a classroom: The case of Christian</u>	1154
<i>Gustavo Martínez-Sierra, Yuridia Arellano-García, Antonia Hernández-Moreno and Cristian Nava-Guzmán</i>	
<u>The suitability of rich learning tasks from a pupil perspective</u>	1162
<i>Elisabet Mellroth</i>	
<u>Upper secondary mathematics teachers' beliefs expressed through metaphors</u>	1170
<i>Marilena Pantziara, Marianna Karamanou and Alexandra Petridou</i>	
<u>Multiple solutions for real-world problems, and students' enjoyment and boredom</u>	1178
<i>Stanislaw Schukajlow and Kay Achmetli</i>	
<u>Self-efficacy and mathematics performance: Reciprocal relationships</u>	1186
<i>Karin Elisabeth Sørli Street, Lars-Erik Malmberg and Gabriel J. Stylianides</i>	
<u>Personal meaning and motivation when learning mathematics: A theoretical approach</u>	1194
<i>Neruja Suriakumaran, Christoph Duchhardt and Maike Vollstedt</i>	

<u>Mathematical memory revisited:</u>	
<u>Mathematical problem solving by high-achieving students</u>	1202
<i>Attila Szabo</i>	
<u>The mathematical values in the Turkish Middle School Mathematics</u>	
<u>Applications Course Curriculum</u>	1210
<i>Gülçin Tan-Şişman and Büşra Kirez</i>	
<u>A case study on Finnish pupils' mathematical thinking:</u>	
<u>Problem solving and view of mathematics</u>	1218
<i>Hanna Viitala</i>	
<u>Exploring affective reactions of children to Scratch programming and mathematics:</u>	
<u>The case of Kim</u>	1226
<i>Johanna Carvajal</i>	
<u>Documenting metacognitive activity in qualitative interviews with high</u>	
<u>school graduates</u>	1228
<i>Sebastian Mungenast</i>	

## **TWG09: Mathematics and language** **1230**

### **Introduction to the papers of TWG09: Mathematics and language** **1231**

<u>Rethinking students' comments in the mathematics notebook</u>	1235
<i>Matías Arce, Tomás Ortega and Núria Planas</i>	
<u>The duck is the biggest – kindergartners talking about measurement and magnitudes</u>	1243
<i>Birgit Brandt and Sarah Keuch</i>	
<u>Educating to rationality in a narrative context: An experimentation</u>	1252
<i>Gemma Carotenuto, Cristina Coppola<sup>1</sup> and Roberto Tortora</i>	
<u>Implicit and explicit processes of establishing explaining practices –</u>	
<u>Ambivalent learning opportunities in classroom discourse</u>	1260
<i>Kirstin Erath</i>	
<u>Young children's appropriation of mathematical discourse:</u>	
<u>Learning subtraction in a plurilingual classroom</u>	1268
<i>Marie Therese Farrugia</i>	
<u>Language in argumentation and solution of problems with graphs</u>	1276
<i>Pier Luigi Ferrari</i>	
<u>Talking with objects</u>	1284
<i>Marei Fetzer and Kerstin Tiedemann</i>	
<u>Occasions for productive interactions in inclusive mathematics</u>	
<u>classrooms that arise following mistakes</u>	1292
<i>Uta Häsel-Weide</i>	

<u>Revisiting the roles of interactional patterns in mathematics classroom interaction</u> <i>Jenni Ingram, Nick Andrews and Andrea Pitt</i>	1300
<u>Constructing mathematical meaning of the cosine function using covariation between variables in a modeling situation in Cabri</u> <i>Faten Khalloufi-Mouha</i>	1308

## **TWG10: Diversity and mathematics education: Social, cultural and political challenges** **1420**

### Introduction to the papers of TWG10: Diversity and mathematics education: Social, cultural and political challenges 1421

<u>Incepted neoliberal dreams in school mathematics and the ‘Chilean experience’</u>	1425
<i>Melissa Andrade-Melina</i>	
<u>“It is only a test” – social aspects of displaying knowledge in mathematics for second language learners</u>	1433
<i>Anette Bagger</i>	
<u>Subjective theories of teachers in dealing with heterogeneity</u>	1441
<i>Elisa Bitterlich, Judith Jung and Marcus Schütte</i>	
<u>Teaching practices in a mathematics classroom and their connection to race and racism in the United States</u>	1449
<i>Sabrina Bobsin Salazar</i>	
<u>The context of workplaces as part of mathematics education in vocational studies: Institutional norms and (lack of) authenticity</u>	1457
<i>Lisa Björklund Boistrup and John Keogh</i>	
<u>Exploring Roma learning mathematics: A socio-mathematical view</u>	1465
<i>Javier Díez-Palomar</i>	
<u>(Wanting to do) Ethical research in a shifting context</u>	1473
<i>Andrea Eikset, Trude Fosse, Troels Lange, Johan Lie, Magni Hope Lossius, Tamsin Meaney and Elena Severina</i>	
<u>How Sámi teachers’ development of a teaching unit influences their self-determination</u>	1481
<i>Anne Birgitte Fyhn, Tamsin Meaney, Kristine Nystad and Ylva Jannok Nutti</i>	
<u>Class, ‘ability’ groups and mathematics in English secondary schools: A review</u>	1489
<i>Colin Jackson</i>	

<u>Content-related and social participation in inclusive mathematics education</u> <i>Judith Jung and Marcus Schütte</i>	1497
<u>The socio-politics of teacher explanation in mathematics education</u> <i>David Kollosche</i>	1505
<u>Polish parents' views on mathematics education in Swedish preschools</u> <i>Dorota Lembrér</i>	1513
<u>The mathematics teacher's quasi-Darwinism: Problematising mathematics education research</u> <i>Alex Montecino</i>	1521
<u>Towards cultural responsiveness in mathematics education</u> <i>Swapna Mukhopadhyay and Brian Greer</i>	1529
<u>Mathematics at the enterprise: Industry, university and school working together to facilitate learning</u> <i>Hans Kristian Nilsen and Anne Vegusdal</i>	1537
<u>"No, it just didn't work": A teacher's reflections on all-attainment teaching</u> <i>Hilary Povey and Colin Jackson</i>	1545
<u>Diversity in an inclusive mathematics classroom: A student perspective</u> <i>Helena Roos</i>	1553
<u>School mathematics education through the eyes of students in Ghana: Extrinsic and intrinsic valuing</u> <i>Wee Tiong Seah, Ernest Kofi Davis and Monica E. Carr</i>	1561
<u>Integrating critical theory and practice in mathematics education</u> <i>David Swanson and Laura Black</i>	1569
<u>Cultural diversity as a resource or an obstacle for teaching practices in multicultural milieu: Experience of a training course for Italian teachers about Chinese Shuxue</u> <i>Benedetto Di Paola and Giovanni Giuseppe Nicosia</i>	1577
<u>Reflections of Fröbel in discourses about mathematics in Scandinavian early childhood education and care</u> <i>Andrea Eikset</i>	1579
<u>Collaborative learning in multigrade mathematics education at primary level</u> <i>Rachel-Ann Friesen</i>	1581
<u>Supporting young children's mathematical register learning in two languages: ICT possibilities</u> <i>Troels Lange and Tamsin Meaney</i>	1583
<u>Bangladeshi rural secondary madrasa (Islamic school) children's participation in higher mathematics optional course: A close look through gender lens</u> <i>K.M. Nabiul Alam</i>	1585
<u>Culturally-inspired mathematics and science education</u> <i>Shipra Sachdeva, Per-Odd Eggen and Halvor Hoveid</i>	1587
<u>Being in the diversity and going through the infinity</u> <i>Cássia Aline Schuck and Cláudia Regina Flores</i>	1589

<b>TWG11: Comparative studies in mathematics education</b>	<b>1591</b>
<b><u>Introduction to the papers of TWG11:</u></b>	
<b><u>Comparative studies in mathematics education</u></b>	<b>1592</b>
<u>Beginning teachers' perspectives on linear equations: A pilot quantitative comparison of Greek and Cypriot students</u>	1594
<i>Paul Andrews and Constantinos Xenofontos</i>	
<u>Comparing the practices of primary school mathematics teacher education Case studies from Japan, Finland and Sweden</u>	1602
<i>Yukiko Asami-Johansson, Iiris Attorps and Anu Laine</i>	
<u>The lexicon project: Examining the consequences for international comparative research of pedagogical naming systems from different cultures</u>	1610
<i>David Clarke, Carmel Mesiti, Yiming Cao, &amp; Jarmila Novotna</i>	
<u>A comparison of Kosovar and Polish pre-service teachers' knowledge of fractions</u>	1618
<i>Jeta Kingji-Kastrati, Mirosława Sajka and Eda Vula</i>	
<u>Finnish teaching materials in the hands of a Swedish teacher: The telling case of Cecilia</u>	1626
<i>Tuula Koljonen</i>	
<u>Algorithmics in secondary school: A comparative study between Ukraine And France</u>	1634
<i>Simon Modeste and Maryna Rafalska</i>	
<u>Ten years of mathematics education: Preparing for the supermarket?</u>	1642
<i>Mona Nosrati and Paul Andrews</i>	
<u>Visual attention while reading a multiple choice task by academics and students: A comparative eye-tracking approach</u>	1650
<i>Mirosława Sajka</i>	
<u>A cross-national study of lower secondary mathematics teachers' content knowledge in the USA and Russia</u>	1658
<i>Mourat Tchoshanov, Maria Cruz Quinones, Kadriya Shakirova, Elena Ibragimova and Liliana Shakirova</i>	
<u>Explanations as tools for evaluating content knowledge for teaching: A cross-national pilot study in Cyprus and Greece</u>	1666
<i>Constantinos Xenofontos and Paul Andrews</i>	
<u>Research on mathematical literacy in schools - Aim, approach and attention</u>	1674
<i>Frode Olav Haara, Oda Heidi Bolstad and Eirik S. Jenssen</i>	
<u>Kids Inspiring Kids for STEAM (KIKS)</u>	1676
<i>Maitane P. Istúriz, Ignacio González-Ruiz, Jose M. Diego-Mantecón, Tomás Recio, José B. Búa, Teresa F. Blanco, María J. González and Irene Polo</i>	
<u>The teaching and learning of relations and functions: A comparative study of Norwegian and Ethiopian textbooks</u>	1678
<i>Solomon A. Tesfamichael and Geir H. Botten and Øyvind A. Lundebj</i>	

<b>TWG12: History in mathematics education</b>	<b>1680</b>
<b><u>Introduction to the papers of TWG12:</u></b>	
<b><u>History in mathematics education</u></b>	<b>1681</b>
<u>Arithmetical problems in primary school: Ideas that circulated in São Paulo/Brazil in the end of the 19th century</u>	1685
<i>Luciane de Fatima Bertini and Andreia Fernandes de Souza</i>	
<u>Mathematics in the initial pre-service education of primary school teachers in Portugal: Analysis of Gabriel Gonçalves proposal for the concept of unit and its application in solving problems with decimals</u>	1693
<i>Rui Candeias</i>	
<u>Mathematical analysis of informal arguments: A case-study in teacher-training context</u>	1701
<i>Renaud Chorlay</i>	
<u>Primary source projects in an undergraduate mathematics classroom: A pilot case in a topology course</u>	1709
<i>Kathleen Clark, Daniel Otero and Nicholas A. Scoville</i>	
<u>A course in the philosophy of mathematics for future high school mathematics teachers</u>	1717
<i>Elizabeth de Freitas</i>	
<u>Variational strategies on the study of the existence and uniqueness theorem for ordinary differential equations</u>	1725
<i>Rodolfo Fallas-Soto and Ricardo Cantoral</i>	
<u>Understanding didactical conceptions through their history: A comparison of Brousseau's and Varga's experimentations</u>	1732
<i>Katalin Gosztanyi</i>	
<u>Historical methods for drawing anaglyphs in geometry teaching</u>	1740
<i>Rainer Kaenders and Ysette Weiss</i>	
<u>Teaching kinematics using mathematics history</u>	1748
<i>Alfredo Martínez, Olimpia Figueras and François Pluvinage</i>	
<u>The concept of infinity – different meanings through the centuries</u>	1756
<i>Regina D. Möller and Peter Collignon</i>	
<u>Analyzing some algebraic mistakes from a XVI century Spanish text and observing their persistence among present 10th grade students</u>	1764
<i>Antonio M. Oller-Marcén and Vicente Meavilla</i>	
<u>Multiple perspectives on working with original mathematical sources from the Edward Worth Library, Dublin</u>	1772
<i>Maurice O'Reilly</i>	

<u>Inquiry-based teaching approach in mathematics by using the history of mathematics: A case study</u>	1780
<i>Areti Panaoura</i>	
<u>Classification and resolution of the descriptive historical fraction problems</u>	1788
<i>Maria T. Sanz Garcia and Bernardo Gómez</i>	
<u>Mathematics at the Royal Danish Military Academy of 1830</u>	1796
<i>Asger Senbergs</i>	
<u>Design research with history in mathematics education</u>	1804
<i>Bjørn Smestad</i>	
<u>“Sickened by set theory?” – About New Math in German primary schools</u>	1812
<i>Tanja Hamann</i>	
<u>The role of genetic approach and history of mathematics in works of Russian mathematics educators (1850-1950)</u>	1814
<i>Ildar Safuanov</i>	

## **TWG13: Early years mathematics** **1816**

### **Introduction to the papers of TWG13: Early years mathematics** **1817**

<u>Aspects of numbers challenged in toddlers’ play and interaction</u>	1821
<i>Camilla Björklund</i>	
<u>Perception, cognition and measurement of verbal and non-verbal aspects of the cardinal concept in bodily-spatial interaction</u>	1829
<i>Morten Bjørnebye, Thorsteinn Sigurjonsson and Tor Solbakken</i>	
<u>Kindergarten children’s argumentation in reflection symmetry: The role of semiotic means</u>	1837
<i>Svanhild Breive</i>	
<u>Making numbers: Issues in using manipulatives with young children</u>	1845
<i>Sue Gifford, Rose Griffiths and Jenni Back</i>	
<u>A kindergarten teacher’s revealed knowledge in orchestration of mathematical activities</u>	1853
<i>Per Sigurd Hundeland, Ingvald Erfjord and Martin Carlsen</i>	
<u>Young children’s aesthetic development in the context of mathematical explanation</u>	1861
<i>Esther Levenson and Many Raman-Sundström</i>	
<u>Discovering regularities in a geometrical objects environment</u>	1869
<i>Bozena Maj-Tatsis and Ewa Swoboda</i>	
<u>Combining historical, foundational, and developmental insights to build children’s first steps in mathematics</u>	1877
<i>Ana Millán Gasca, Elena Gil Clemente, Ilaria Colella</i>	

<u>How do preschool teachers characterize their own mathematics teaching in terms of design and content?</u>	1885
<i>Hanna Palmér and Camilla Björklund</i>	
<u>“Two, three and two more equals seven” – Preschoolers’ perception and use of structures in sets</u>	1893
<i>Priska Schöner and Christiane Benz</i>	
<u>A framework for designing inquiry-based activities (FIBA) for early childhood mathematics</u>	1901
<i>Chrysanthi Skoumpourdi</i>	
<u>The role of gestures in supporting mathematical communication for students with language delays</u>	1909
<i>Helen Thouless</i>	
<u>Preschool teachers’ variations when implementing a patterning task</u>	1917
<i>Dina Tirosh, Pessia Tsamir, Ruthi Barkai, and Esther Levenson</i>	
<u>Teaching intervention for developing generalization in early childhood: The case of measurement</u>	1925

<u>Discussing school mathematical narratives in early childhood future teacher education</u>	1933
<i>Yuly Vanegas, Joaquín Giménez and Marjorie Samuel</i>	
<u>Early years mathematics learning – Comparing traditional and inclusive classroom settings</u>	1942
<i>Andrea Peter-Koop and Miriam M. Lüken</i>	
<u>Making maps in kindergarten</u>	1944
<i>Geir Olaf Pettersen and Monica Volden</i>	
<u>Learning of numerosity through a designed activity with dice and towers</u>	1946
<i>Reinert A. Rinvold</i>	
<u>Kindergarten class – inquiry and magnets</u>	1948
<i>Ana Filipa Silva, Conceição Costa and António Domingos</i>	
<u>Slow down, you move too fast!</u>	1950
<i>Jorryt van Bommel and Hanna Palmér</i>	

## TWG14: University mathematics education 1952

### Introduction to the papers of TWG14: University mathematics education 1953

- Undergraduates' reasoning while solving integration tasks:  
Discussion of a research framework 1961  
*Aaltje Berendina Aaten, Johan Deprez, Gerrit Roorda and Martin Goedhart*
- A categorisation of the resources used by undergraduates when studying mathematics 1969  
*Marinos Anastasakis, Carol Robinson and Stephen Lerman*
- An analysis of freshmen engineering students' notes during a preparatory mathematics course 1977  
*Chiara Andrà*
- The transition from high school to university mathematics:  
A multidimensional process 1985  
*Amalia-Christina Bampili, Theodossios Zachariades and Charalampos Sakonidis*
- "Points", "slopes" and "derivatives": Substantiations of narratives about tangent line in university mathematics students' discourses 1993  
*Irene Biza*
- Teaching didactics to lecturers: A challenging field 2001  
*Ignasi Florensa, Marianna Bosch, Josep Gascón and Noemí Ruiz-Munzon*
- High school teachers' choices concerning the teaching of real numbers: A case study 2009  
*Laura Branchetti*
- Proof and formalism: The role of letters' logical status 2017  
*Faïza Chellougui*
- A mathematics educator and a mathematician co-teaching mathematics – Affordances for teacher education 2025  
*Jason Cooper and Orit Zaslavsky*
- The organization of study in French business school preparatory classes 2033  
*Lynn Farah*
- How mathematicians conjecture and prove: An approach from mathematics education 2041  
*Aurora Fernández-León, Rocío Toscano-Barragán and José María Gavilán-Izquierdo*
- Students' interpretation of the derivative in an economic context 2049  
*Frank Feudel*
- Exploring tensions in a mathematical course for engineers utilizing a flipped classroom approach 2057  
*Helge Fredriksen, Said Hadjerrouit, John Monaghan and Ragnhild J. Rensaa*
- A micro-model of didactical variables to explore the mathematical organization of complex numbers at upper secondary level 2065  
*Imène Ghedamsi*

<u>How are Calculus notions used in engineering?</u> <u>An example with integrals and bending moments</u>	2073
<i>Alejandro S. González-Martín and Gisela Hernandes Gomes</i>	
<u>Students' view of continuity:</u> <u>An empirical analysis of mental images and their usage</u>	2081
<i>Erik Hanke and Ingolf Schäfer</i>	
<u>Using the theory of instrumental genesis to study students' work with</u> <u>a digital tool for applying integrals in a kinematic simulation</u>	2089
<i>Ninni Marie Hogstad and Ghislain Maurice Norbert Isabwe</i>	
<u>Investigating the discursive shift in the learning of Group Theory:</u> <u>Analysis of some interdiscursive commognitive conflicts</u>	2097
<i>Marios Ioannou</i>	
<u>Theorising university mathematics teaching:</u> <u>The teaching triad within an activity theory perspective</u>	2105
<i>Barbara Jaworski, Despina Potari and Georgia Petropoulou</i>	
<u>Praxeological analysis: The case of ideals in Ring Theory</u>	2113
<i>Julie Jovignot, Thomas Hausberger and Viviane Durand-Guerrier</i>	
<u>University students' understandings of concept relations and preferred</u> <u>representations of continuity and differentiability</u>	2121
<i>Kristina Juter</i>	
<u>Engineering mathematics between competence and calculation</u>	2129
<i>Birgit Griesse and Michael Kallweit</i>	
<u>The association between engineering students' self-reported</u> <u>mathematical identities and average grades in mathematics courses</u>	2137
<i>Eivind Kaspersen, Birgit Pepin, and Svein Arne Sikko</i>	
<u>A praxeological approach to Klein's plan B: Cross-cutting from</u> <u>calculus to Fourier analysis</u>	2145
<i>Margo Kondratieva and Carl Winsløw</i>	
<u>The interface between mathematics and engineering – problem solving processes</u> <u>for an exercise on oscillating circuits using ordinary differential equations</u>	2153
<i>Jörg Kortemeyer and Rolf Biehler</i>	
<u>Self-efficacy of engineering students in the introductory phase of studies</u>	2161
<i>Ronja Kürten</i>	
<u>Q<sup>2</sup> game used in a task design of the double quantification</u>	2169
<i>Thomas Lecorre</i>	
<u>A framework for goal dimensions of mathematics learning support in universities</u>	2177
<i>Michael Liebendörfer, Reinhard Hochmuth, Rolf Biehler, Niclas Schaper,</i> <i>Christiane Kuklinski, Sarah Khellaf, Christoph Colberg, Mirko Schürmann, Lukas Rothe</i>	
<u>A vector is a line segment between two points? - Students' concept</u> <u>definitions of a vector during the transition from school to university</u>	2185
<i>Tobias Mai, Frank Feudel and Rolf Biehler</i>	

<u>What can calculus students like about and learn from a challenging problem they did not understand?</u>	2193
<i>Ofer Marmur and Boris Koichu</i>	
<u>“What you see and don’t see, shapes what you do and don’t do”: Noticing in first year mathematics lectures</u>	2201
<i>Maria Meehan, Ann O’Shea, and Sinéad Breen</i>	
<u>To be or not to be an inflection point</u>	2209
<i>Regina Ovodenko and Pessia Tsamir</i>	
<u>Math teaching as jazz improvisation: Exploring the ‘highly principled but not determinate’ instructional moves of an expert instructor</u>	2217
<i>Alon Pinto</i>	
<u>Identifying discussion patterns of teaching assistants in mathematical tutorials in Germany</u>	2225
<i>Juliane Püschl</i>	
<u>French engineers’ training and their mathematical needs in the workplace: Interlinking tools and reasoning</u>	2233

## **TWG15: Teaching mathematics with resources and technology 2324**

### **Introduction to the papers of TWG15:**

#### **Teaching mathematics with resources and technology 2325**

Real uses of ICT in classrooms: Tensions and disturbances in mathematics teachers' activity 2334

*Maha Abboud and Janine Rogalski*

Out- and in-sourcing, an analysis model for the use of instrumented techniques 2342

*Henrik P. Bang, Niels Grønbaek and Claus R. Larsen*

The development of pre-service teachers' TPACK for the use of digital tools 2350

*Nimer Baya'a, Wajeeh Daher, Rawan Anabousy and Ahlam Anabousy*

Beyond a positive stance: Integrating technology is demanding on teachers' mathematical knowledge for teaching 2358

*Nicola Bretscher*

What influences in-service and student teachers use of MathCityMap? 2366

*Iwan Gurjanow, Matthias Ludwig and Joerg Zender*

Exploring a framework for technology integration in the mathematics classroom 2374

*Patrik Gustafsson*

Preparing preservice teachers to use instructional technology: How much development can happen in one semester? 2382

*Janet M. Herrelko*

Maths teachers' adventure of ICT integration: From an open online course towards an online teacher community 2390

*Judith Hohenwarter Selay Arkün Kocadere and Markus Hohenwarter*

The effect of GeoGebra collaborative and iterative professional development on in-service secondary mathematics teachers' practices 2398

*Houssam Kasti and Murad Jurdak*

"One of the beauties of Autograph is ... that you don't really have to think": Integration of resources in mathematics teaching 2406

*Lina Kayali and Irene Biza*

Identifying and assessing quality criteria for dynamic mathematics materials on platforms 2414

*Barbara Kimeswenger*

Teachers designing e-books to foster creative mathematical thinking: the case of curvature 2422

*Angeliki Kolovou and Chronis Kynigos*

Planning geometry lessons with learning platforms 2430

*Andreas Lindenskov Tamborg*

<u>What can we assess using multiple choice problems that involve learner generated examples?</u>	2438
<i>Shai Olsher and Michal Yerushalmy</i>	
<u>Analysing MOOCs in terms of their potential for teacher collaboration: The French experience</u>	2446
<i>Monica Panero, Gilles Aldon, Jana Trgalová and Luc Trouche</i>	
<u>Using a flipped classroom approach in the teaching of mathematics: A case study of a preservice teachers' class</u>	2454
<i>Theodosia Prodromou</i>	
<u>'Walking a graph' – primary school students' experimental session on functions and graphs</u>	2462
<i>Svein Arne Sikko, Øistein Gjøvik, Jardar Cyvin, Maria I.M. Febri and Ragnhild L. Staberg</i>	
<u>PÉPITE Online automated assessment and student learning: The domain of equations in the 8th grade</u>	2470
<i>Stéphane Sirejacob, Françoise Chenevotot-Quentin and Brigitte Grugeon-Allys</i>	
<u>Analysing MOOCs in terms of their potential for teacher collaboration: The Italian experience</u>	2478
<i>Eugenia Taranto, Ferdinando Arzarello, Ornella Robutti, Virginia Alberti, Sara Labasin, Sara Gaido</i>	
<u>Coaching and engaging. Developing teaching with CAS in High School</u>	2486
<i>Henrik P. Bang, Niels Grønbæk and Claus R. Larsen</i>	
<u>A study of the development of mathematics student teachers' knowledge on the implementation of CAS in the teaching of mathematics -a praxeological analysis</u>	2488
<i>Louise Meier Carlsen</i>	
<u>A study investigating how mathematics teachers view and use tablets as a teaching tool</u>	2490
<i>Kinga Petrovai</i>	
<u>The role of automated reasoning of geometry statements in mathematics instruction</u>	2492
<i>Francisco Botana, Tomás Recio and M. Pilar Vélez</i>	
<u>A study of the Cornerstone Maths project teachers' classroom practices: Geometric similarity using the Cornerstone Maths software</u>	2494
<i>Ali Simsek and Nicola Bretscher</i>	
<u>Resource systems of English teachers as they appropriate mastery approaches</u>	2496
<i>Michael Achile Umameh</i>	

# TWG16: Learning Mathematics with Technology and Other Resources 2498

## Introduction to the papers of TWG16: Learning Mathematics with Technology and Other Resources 2499

<u>A computer-based collaboration script to mediate verbal argumentation in mathematics</u>	2507
<i>Giovannina Albano, Umberto Dello Iacono and Maria Alessandra Mariotti</i>	
<u>(Legitimate peripheral) computational thinking in mathematics</u>	2515
<i>Laura Broley, Chantal Buteau and Eric Muller</i>	
<u>Examining motivation in mobile app-supported math trail environments</u>	2523
<i>Adi Nur Cahyono and Matthias Ludwig</i>	
<u>Mathematical gestures: Multitouch technology and the indexical trace</u>	2531
<i>Elizabeth de Freitas and Nathalie Sinclair</i>	
<u>Learning mathematics with technology. A review of recent CERME research</u>	2539
<i>Ana Donevska-Todorova and Jana Trgalová</i>	
<u>Number, arithmetic, multiplicative thinking and coding</u>	2547
<i>Krista Francis and Brent Davis</i>	
<u>Investigating the integration of a digital resource in the mathematics classroom: The case of a creative electronic book on reflection</u>	2555
<i>Eirini Geraniou and Manolis Mavrikis</i>	
<u>Preliminary testing of apps in mathematics, based on international collaborative work</u>	2563
<i>Øistein Gjøvik and Iveta Kohanová</i>	
<u>Khan Academy as a resource for pre-service teachers: A controlled study</u>	2571
<i>James Gray, Christine Lindstrøm and Kristian Vestli</i>	
<u>Constructing the shortest path on a cylindrical surface</u>	2579
<i>Chronis Kynigos and Ioannis Zantzios</i>	
<u>Using dynamic worksheets to support functional thinking in lower secondary school</u>	2587
<i>Edith Lindenbauer and Zsolt Lavicza</i>	
<u>Students' use of movement in the exploration of dynamic functions</u>	2595
<i>Giulia Lisarelli</i>	
<u>Representing the one left over:</u> <u>A social semiotic perspective of students' use of screen casting</u>	2603
<i>Carol Murphy and Nigel Calder</i>	
<u>Interactive Virtual Math: A tool to support self-construction graphs by dynamic events</u>	2611
<i>Sonia Palha and Stephan Koopman</i>	

<u>Meaning-generation through an interplay between problem solving and constructionism in the C-book technology environment</u>	2619
<i>Ioannis Papadopoulos, Dimitris Diamantidis, and Chronis Kynigos</i>	
<u>Three ways that use ICT to enlarge students' roles in learning</u>	2627
<i>Jean-Jacques Salone</i>	
<u>Nature and characteristics of digital discourse in mathematical construction tasks</u>	2636
<i>Florian Schacht</i>	
<u>Using dynamic and interactive technological tools to support conceptual learning of equations among low-achieving students</u>	2644

## **TWG17: Theoretical perspectives and approaches in mathematics education research** **2682**

### **Introduction to the papers of TWG17: Theoretical perspectives and approaches in mathematics education research** **2683**

Abstraction in Context and Documenting Collective Activity 2692  
*Michal Tabach, Chris Rasmussen, Tommy Dreyfus and Rina Hershkowitz*

Meta-theoretical aspects of the two case studies of networking theoretical perspectives:  
Focusing on the treatments of theoretical terms in different networking strategies 2700  
*Yusuke Shinno*

On dialectic and dynamic links between the Mathematical Working  
Space model and practice in the teaching and learning of mathematics 2702  
*Alain Kuzniak and Assia Nechache*

The Mathematical Working Space model: An open and adaptable  
theoretical framework? 2710  
*Charlotte Derouet, Alain Kuzniak, Assia Nechache, Bernard Parzysz, Laurent Vivier*

Learning research in a laboratory classroom: Complementarity and  
commensurability in juxtaposing multiple interpretive accounts 2713  
*Man Ching Esther Chan and David Clarke*

The perspective of indexicality: How tool-based actions and gestures  
contribute to concept-building 2721  
*Daniela Behrens and Angelika Bikner-Ahsbahr*

Towards argumentative grammars of design research 2730  
*Arthur Bakker*

When a critical aspect is a conception: Using multiple theories to design  
dynamic computer environments and tasks to promote secondary students'  
discernment of covariation 2738  
*Heather Lynn Johnson, Evan McClintock, Peter Hornbein, Amber Gardner  
and Daniel Grieser*

Combining two theories in the design for learning about integrals 2746  
*Anatoli Kouropatov and Tommy Dreyfus*

Learning Through Activity: A developing integrated theory of  
mathematics learning and teaching 2754  
*Martin A. Simon*

'Grundvorstellungen' and their application to the concept of extreme points 2763  
*Anna-Katharina Roos*

Mathematics teachers' re-sourcing and use of social media:  
Can the 'prosumer' concept convey what's going on? 2771  
*Yvonne Liljekvist*

<u>Analyzing verbal interactions in mathematics classroom:</u> <u>Connecting two different research fields via a methodological tool</u>	2773
<i>Mariam Haspekian, Eric Roditi</i>	
<u>Networked theories for a didactical study of communities of mathematics teachers</u>	2781
<i>Jean-Philippe Georget and Hussein Sabra</i>	
<u>An analytical tool for identifying what works with children with mathematics learning difficulties</u>	2789
<i>Esmeralda Zerafa</i>	
<u>When the theoretical model does not fit our data:</u> <u>A process of adaptation of the Cognitive Demand model</u>	2791
<i>Clara Benedicto, Angel Gutiérrez and Adela Jaime</i>	

## **TWG18: Mathematics teacher education and professional development** **2799**

### **Introduction to the papers of TWG18: International research on mathematics teacher education and professional development** **2800**

<u>Upper secondary teachers' stages of concern related to curricular innovations before and after a professional development course on teaching probability and statistics including the use of digital tools</u>	2804
<i>Rolf Biehler and Ralf Nieszporek</i>	
<u>Characteristics of pre-service primary teachers' noticing of students' thinking related to fraction concept sub-constructs</u>	2812
<i>Ángela Buforn, Ceneida Fernández, Salvador Linares and Gloria Sánchez-Matamoros</i>	
<u>Analysing mathematics teacher learning in Lesson Study - a proposed theoretical framework</u>	2820
<i>Stéphane Clivaz and Aoibhinn Ni Shuilleabhain</i>	
<u>Innovating teachers' practices: Potentiate the teaching of mathematics through experimental activities</u>	2828
<i>Maria Cristina Costa and António Domingos</i>	
<u>From emergency sirens to birdsong – Narratives of becoming a mathematics teacher</u>	2836
<i>Elisabeta Eriksen, Bjørn Smestad, Annette Hessen Bjerke, Camilla Rodal and Yvette Solomon</i>	
<u>Core practices and mathematical tasks of teaching in teacher education: What can be learned from a challenging case?</u>	2844
<i>Janne Fauskanger and Reidar Mosvold</i>	

<a href="#"><u>Characteristics of a learning environment to support prospective secondary mathematics teachers' noticing of students' thinking related to the limit concept</u></a>	2852
<i>Fernández, C., Llinares, S., Callejo, M.L., Moreno, M. and Sánchez-Matamoros, G.</i>	
<a href="#"><u>Evaluation of a discovery, inquiry- and project-based learning program</u></a>	2860

## **TWG20: Mathematics teacher knowledge, beliefs and identity 3219**

### **Introduction to the papers of TWG20:**

### **Mathematics teacher knowledge, beliefs, and identity 3220**

The reasons underlying mathematics teachers' decisions about the teaching objectives of a mathematical task 3224

*Miriam Amit and Hodaya (Liora) Hoch*

Differences in the forms of content teachers are seen to offer over time: Identifying opportunities for teacher growth 3232

*Nick Andrews*

How do prospective teachers imagine mathematical discussions on fraction comparison? 3240

*Kristin Krogh Arnesen, Ole Enge, Yvonne Grimeland and Torkel Haugan Hansen*

A novice high school teacher's perception on the effect of content course taken as preservice 3248

*Fatma Aslan-Tutak and Tugay Durak*

Study of primary school teacher's practices for a lesson after a Lesson Study process in mathematics 3256

*Valérie Batteau*

Developing student teachers' professional knowledge of low attainments' support by "learning-teaching-laboratories" 3264

*Ralf Benölken*

Didactic assessment over a final work of a master for mathematics teachers in service 3272

*Adriana Breda, Luis R. Pino-Fan, Vicenç Font, Valderez Marina do Rosário Lima*

Describing a secondary mathematics teacher's specialised knowledge of functions 3280

*Dinazar Escudero-Avila, Eric Flores-Medrano, and José Carrillo*

Use of analogies in teaching the concept of function: Relation between knowledge of topics and knowledge of mathematics teaching 3288

*Gonzalo Espinoza-Vásquez, Diana Zakaryan and José Carrillo Yañez*

Pre-service teachers using the Knowledge Quartet as a tool to analyse and reflect on their own teaching 3296

*Sindre Syversen Flesvig, Tim Rowland and Elisabeta Eriksen*

Subject professional association activity: What can it offer teachers of mathematics and their students? 3304

*Jennie Golding*

Subject matter knowledge and pedagogical content knowledge in the learning diaries of prospective mathematics teachers 3312

*Jani Hannula*

<u>The role of definitions on classification of solids including (non)prototype examples: The case of cylinder and prism</u>	3320
<i>Mine Işıksal-Bostan and Seçil Yemen-Karpuzcu</i>	
<u>Preparing teachers for teaching: Does initial teacher education improve mathematical knowledge for teaching?</u>	3328
<i>Dun Nkhoma Kasoka, Arne Jakobsen and Mercy Kazima</i>	
<u>A preservice secondary school teacher's pedagogical content knowledge for teaching algebra</u>	3336
<i>Florence Mamba, Reidar Mosvold, and Raymond Bjuland</i>	
<u>Analysis of mathematics standardized tests: Examples of tasks for teachers</u>	3344
<i>Francesca Martignone</i>	
<u>An exploration of challenges of engaging students in generative interaction with diagrams during geometric proving</u>	3352
<i>Lisnet Mwadzaangati</i>	
<u>An investigation of middle school mathematics teachers' knowledge for teaching algebra</u>	3360
<i>Nurbanu Yılmaz and Ayhan Kürşat Erbaş</i>	
<u>Is teacher knowledge affecting students' transition from primary to second-level mathematics education?</u>	3368
<i>Niamh O'Meara, Mark Prendergast, Lorraine Harbison and Clare O'Hara</i>	
<u>Intertwining noticing and knowledge in video analysis of self practice: The case of Carla</u>	3376
<i>Miguel Ribeiro, Edelmira Badillo, Glória Sánchez-Matamoras, Miguel Montes, Genaro de Gamboa</i>	
<u>Investigating Lesson Study as a practice-based approach to study the development of mathematics teachers' professional practice</u>	3384
<i>Anita Tyskerud, Janne Fauskanger, Reidar Mosvold, &amp; Raymond Bjuland</i>	
<u>First year student teachers dealing with non-routine questions in the context of the entrance examination to a degree in Primary Education1</u>	3392
<i>Aitor Villarreal, Lluís Albarracín and Núria Gorgorió</i>	
<u>Anticipating students' thinking through Lesson Study: A case study with three prospective middle school mathematics teachers</u>	3400
<i>Nadide Yılmaz, İ. Elif Yetkin Özdemir and Bülent Çetinkaya</i>	
<u>Mathematics teachers' knowledge and professional development in a Lesson Study context</u>	3408
<i>Vanessa Crecci, Miguel Ribeiro, Dario Fiorentini</i>	
<u>Combining two frameworks: A new perspective on mathematics teacher knowledge</u>	3410
<i>Knud Thorbjørn Sloth and Ingi Heinesen Højsted</i>	
<u>Teachable moments at elementary school mathematics level</u>	3412
<i>Amanjot Toor and Joyce Mgombelo</i>	

<b>TWG21: Assessment in mathematics education</b>	<b>3414</b>
<b><u>Introduction to the papers of TWG21: Assessment in mathematics education</u></b>	<b>3415</b>
 <u>Formative assessment - and the component of adjusted teacher instruction</u> <i>Catarina Andersson</i>	3419
<u>Written documentations in final exams with CAS</u> <i>Johannes Beck</i>	3427
<u>Teachers' formative assessment practices: The case of an IBME- centered course</u> <i>Maud Chanudet</i>	3436
<u>Ireland's Junior Certificate mathematics examination through the lens of the PISA and TIMSS frameworks: Has Project Maths made any difference?</u> <i>Rachel Cunningham, Seán Close and Gerry Shiel</i>	3444
<u>Designing and analysing the role of digital resources in supporting formative assessment processes in the classroom: The helping worksheets</u> <i>Annalisa Cusi, Francesca Morselli and Cristina Sabena</i>	3452
<u>Enhancing formative assessment in mathematical class discussion: a matter of feedback</u> <i>Annalisa Cusi, Francesca Morselli and Cristina Sabena</i>	3460
<u>Mathematics students' attitudes to group-based project exams compared to students in science and engineering</u> <i>Bettina Dahl</i>	3468
<u>A case for a new approach to establishing the validity of comparative judgement as an assessment tool for mathematics</u> <i>Ben Davies</i>	3476
<u>Cognitive demand of mathematics tasks set in European statewide exit exams – are some competences more demanding than others?</u> <i>Christina Drüke-Noe and Svenja Mareike Kühn</i>	3484
<u>A vertical analysis of difficulties in mathematics by secondary school to level: Some evidence stems from standardized assessment</u> <i>Federica Ferretti and Alessandro Gambini</i>	3492
<u>The Italian national education assessment system: Building mathematics items</u> <i>Rossella Garuti, Cristina Lasorsa and Stefania Pozio</i>	3500
<u>Using external assessments for improving assessment practice of primary school teachers: A first study and some methodological questions</u> <i>Nadine Grapin and Nathalie Sayac</i>	3508
<u>Using assessment for learning to enhance mathematics education in the primary school: Irish students' perspectives</u> <i>Ann Marie Gurhy</i>	3516

<u>Assessment of students' thinking when working with graphs of functions – Promoting pre-service teachers' diagnostic competence</u>	3524
<i>Rita Hofmann and Jürgen Roth</i>	
<u>Preservice mathematics teachers' views about planning the assessment</u>	3532
<i>Gözde Kaplan and Çiğdem Haser</i>	
<u>From paper and pencil- to computer-based assessment: Some issues raised in the comparison</u>	3540
<i>Alice Lemmo, Maria Alessandra Mariotti</i>	
<u>Teddy Bear Preschool Mathematics Assessment: Validation of a constructivist game- and story-based measure</u>	3548
<i>Sally Moomaw</i>	
<u>Examining difficulties in initial algebra: Prerequisite and algebra content areas for Irish post-primary students</u>	3556
<i>Aoife O'Brien and Máire Ní Ríordáin</i>	
<u>Analysing students' graphicacy from a national test</u>	3564
<i>Oduor Olande</i>	
<u>Assessment in mathematics as a lever to promote students' learning and teachers' professional development</u>	3572
<i>Julia Pilet and Julie Horoks</i>	
<u>It's different, it's difficult, it's unknown': Letting go of levels</u>	3580
<i>Nick Pratt and Julie Alderton</i>	
<u>Towards an empirical validation of mathematics teachers' intuitive assessment practice exemplified by modelling tasks</u>	3588
<i>Xenia-Rosemarie Reit</i>	
<u>Mathematics teachers' assessment of accounts of problem solving</u>	3596
<i>Anna Teledahl</i>	
<u>Using classroom assessment techniques in Chinese primary schools: Effects on student achievement</u>	3604
<i>Xiaoyan Zhao, Marja van den Heuvel-Panhuizen and Michiel Veldhuis</i>	
<u>The complexity of mathematical thought and the quality of learning: Portfolio assessment</u>	3612
<i>Fernando Luís Santos and António Domingos</i>	

## TWG22: Curricular resources and task design in mathematics education 3614

### Introduction to the papers of TWG22: Curricular resources and task design in mathematics education 3615

Tensions between resource perspectives and trends in the design and dissemination of digital resources 3619

*Zenon Borys and Jeffrey Choppin*

Tasks to develop flexible multiplicative reasoning 3627

*Joana Brocardo, Jean Marie Kraemer, Fátima Mendes, Catarina Delgado*

The role of design in conceptual change: The case of proportional reasoning 3635

*Noa Cohen- Eliyahu*

From textbook to classroom: A research on teachers' use of pedagogical resources in the context of primary school in the French speaking part of Switzerland 3643

*Audrey Daina*

Children's performance on a mathematics task they were not taught to solve: A case study 3650

*Seán Delaney*

Critical evaluation and design of mathematics tasks: Pre-service teachers 3658

*Majella Dempsey and Ann O'Shea*

Agency as a tool in design research collaborations 3666

*Andreas Eckert*

Factors impacting on the collaborative design of digital resources 3674

*Nataly Essonnier, Berta Barquero, Christian Mercat, Mohamed El-Demerdash, Jana Trgalova, Mario Barajas and Pedro Lealdino Filho*

Programming for 3rd graders, Scratch-based or unplugged? 3683

*Aaron Gaio*

Principles of redesigning an e-task based on a paper-and-pencil task: The case of parametric functions 3691

*Galit Nagari Haddif*

Context based tasks on differential equations to improve students' beliefs about the relevance of mathematics 3699

*Dié Gijsbers and Birgit Pepin*

Teachers' collective documentation work: A case study on tolerance intervals 3707

*Ghislaine Gueudet and Veronica Parra*

Pre-service teachers' reflections on task design and implementation 3716

*Hulya Kilic, Oguzhan Dogan, Zuhail Yilmaz and Pelin Donmez*

<u>Students' utilizations of feedback provided by an interactive mathematics e-textbook for primary level</u>	3724
<i>Sebastian Rezat</i>	
<u>Documentational trajectory: A tool for analyzing the genesis of a teacher's resource system across her collective work</u>	3732
<i>Katiane de Moraes Rocha and Luc Trouche</i>	
<u>Designing for responsibility and authority in experiment based instruction in mathematics: The case of reasoning with uncertainty</u>	3740
<i>Abdel Seidouvy and Andreas Eckert</i>	
<u>Promoting prospective elementary teachers' knowledge about the role of assumptions in mathematical activity</u>	3748
<i>Andreas J. Stylianides and Gabriel J. Stylianides</i>	
<u>Asymptotes and asymptotic behaviour in graphing functions and curves: An analysis of the Croatian upper secondary education within the anthropological theory of the didactics</u>	3756
<i>Aleksandra Čižmešija, Ana Katalenić and Željka Milin Šipuš</i>	
<u>Using variation theory to explore the reteaching phase of Lesson Study</u>	3758
<i>Thérèse Dooley and Tugba Aysel</i>	
<u>Changes in the images and arguing from the mathematics textbooks for the secondary school in Argentina along 67 years</u>	3760
<i>Viviana Carolina Llanos and María Rita Otero</i>	
<u>Teacher's pedagogical design capacity and mobilization of textbook</u>	3762
<i>Ljerk Jukić Matić</i>	
<u>How to design educational material for inclusive classes</u>	3764
<i>Anna Noll, Jürgen Roth and Markus Scholz</i>	
<u>The application of the Universal Design for Learning framework to task design in order to support lower attaining children in the primary school mathematics classroom</u>	3766
<i>Caitríona Wynne and Lorraine Harbison</i>	

## **TWG23: Implementation of research findings in mathematics education** **3768**

### **Introduction to the papers of TWG23: Implementation of research findings in mathematics education** **3769**

Research findings associated with the concept of function and their  
implementation in the design of mathematics textbooks tasks 3776

*Mario Sánchez Aguilar, Apolo Castañeda and Rosa Isela González-Polo*

Designing a research-based test for eliciting students' prior  
understanding on proportional reasoning 3784

*Linda Marie Ahl*

'Explicit teaching' as an effective method of acquiring problem  
solving strategies - the case of 'working backwards' 3792

*Miriam Amit and Yelena Portnov-Neeman*

Using a Models and Modeling Perspective (MMP) to frame and  
combine research, practice- and teachers' professional development 3801

*Jonas Bergman Ärlebäck*

Providing a tool for lesson planning in pre-service teacher's education 3809

*Tone Bulien*

From theory to praxis 3817

*Lisser Rye Ejersbo and Morten Misfeldt*

The notion and role of "detection tests" in the Danish upper secondary  
"maths counsellor" programme 3825

*Uffe Thomas Jankvist and Mogens Niss*

Students' video tutorials as a means for supporting and analysing their  
reflections on the limit concept 3833

*Tinne Hoff Kjeldsen and Morten Blomhøj*

Implementation enterprise through the lens of a theory of diffusion of  
innovations: A case of online problem-solving forums 3841

*Boris Koichu and Nelly Keller*

From theory through collaboration into practice: Designing a  
problem- solving curriculum for grade 6 students 3849

*Ana Kuzle*

Theoretical constructs for early intervention programs in  
mathematics: Who cares? – A Danish example 3857

*Lena Lindenskov & Katrine Kirsted*

<a href="#"><u>Characterizing theories aimed at supporting teachers' mathematical classroom practices</u></a>	3865
<i>Per Nilsson, Andreas Ryve and Maria Larsson</i>	
<a href="#"><u>Mapping the logics in practice oriented competence development</u></a>	3873
<i>Andreas Lindenskov Tamborg, Benjamin Brink Allsopp, Simon Skov Fougat and Morten Misfeldt</i>	
<a href="#"><u>Rehearsals in work with in-service mathematics teachers</u></a>	3881
<i>Anita Valenta and Kjersti Wæge</i>	
<a href="#"><u>Incorporating mathematical problem solving in the Chilean school curriculum</u></a>	3889
<i>Eugenio Chandia and Maria Luz Montes</i>	

## **TWG24: Representations in mathematics teaching and learning** **3891**

<a href="#"><u>Introduction to the papers of TWG24:</u></a>	
<a href="#"><u>Representations in mathematics teaching and learning</u></a>	3892

<a href="#"><u>Representing subset relations with tree diagrams or unit squares?</u></a>	3896
<i>Katharina Böcherer-Linder, Andreas Eichler and Markus Vogel</i>	
<a href="#"><u>Enactive metaphors in mathematical problem solving</u></a>	3904
<i>Daniela Diaz-Rojas and Jorge Soto-Andrade</i>	
<a href="#"><u>Diagrams and mathematical events: Encountering spatio-temporal relationships with graphing technology</u></a>	3912
<i>Francesca Ferrara and Giulia Ferrari</i>	
<a href="#"><u>Emerging and developing multiplicative structure in students' visuospatial representations: Four key configuration types</u></a>	3920
<i>Carla Finesilver</i>	
<a href="#"><u>Identifying key visual-cognitive processes in students' interpretation of graph representations using eye-tracking data and math/machine learning based data analysis</u></a>	3928
<i>Enrique Garcia Moreno-Esteva, Sonia White , Joanne Wood and Alexander Black</i>	
<a href="#"><u>Epistemic and semiotic perspectives in the analysis of the use of digital tools for solving optimization problems in the case of distance teacher education</u></a>	3936
<i>Veronica Hoyos</i>	

<u>Continuity of the students' experience and systems of representation, an example of teaching and learning in mathematics first grade students</u>	3944
<i>Sophie Joffredo-Le Brun, Mireille Morellato, Gérard Sensevy, &amp; Serge Quilio</i>	
<u>Visuo-spatial abilities and geometry: A first proposal of a theoretical framework for interpreting processes of visualization</u>	3952
<i>Elisa Miragliotta and Anna Baccaglini-Frank</i>	
<u>Middle school students' employments of gestural signs: A case study</u>	3960
<i>Samet Okumus and Karen Hollebrands</i>	
<u>Preservice mathematics teachers' types of mathematical thinking: Use of representations, visual-spatial abilities, and problem solving performances</u>	3968
<i>Beyza Olgun and Engin Ader</i>	
<u>Teaching mathematics with multimedia-based representations – what about teachers' competencies?</u>	3976
<i>Julia Ollesch, Fabian Grünig, Tobias Dörfler and Markus Vogel</i>	
<u>Children's drawings for word problems – design of a theory and an analysis tool</u>	3984
<i>Barbara Ott</i>	
<u>How the representations take on a key role in an inclusive educational sequence concerning fraction</u>	3992
<i>Elisabetta Robotti</i>	
<u>Using manipulatives in upper secondary math education – a semiotic analysis</u>	4000
<i>Marit Hvalsøe Schou</i>	
<u>The use of artifacts and different representations by producing mathematical audio-podcasts</u>	4008
<i>Christof Schreiber and Rebecca Klose</i>	
<u>The role of representations in promoting the quantitative reasoning</u>	4016
<i>Lurdes Serrazina and Margarida Rodrigues</i>

## **Foreword: CERME10 in lovely Dublin**

Susanne Prediger<sup>1</sup>, Viviane Durand-Guerrier<sup>2</sup>

<sup>1</sup>Dortmund, Germany, [prediger@math.uni-dortmund.de](mailto:prediger@math.uni-dortmund.de)

<sup>2</sup>Montpellier, France, [viviane.durand-guerrier@univ-montp2.fr](mailto:viviane.durand-guerrier@univ-montp2.fr)

Since its beginnings in 1998, ERME, the European Society for Research in Mathematics Education was dedicated to supporting the so-called “three C’s”: communication, cooperation, and collaboration among researchers in Europe and beyond. The major occasion for the ERME spirit to come to life is the biannual congress, CERME. In this year, the 10<sup>th</sup> congress of ERME, CERME10, took place in Dublin from February 1<sup>st</sup> to February 5<sup>th</sup>, 2017.

The congress took place in Dublin in Croke Park, the stadium that is home of the Irish national sports of Gaelic football and hurling. Although the conference was bigger than ever, the 774 participants felt few compared to the 80 000 people who fit into the stadium on large sporting and other occasions. However, our local chair, Thérèse Dooley, her co-chair Maurice O’Reilly and all their colleagues did a fantastic job in making us feel at home and not lost in the huge venue. Their hospitality and engagement were praised by all participants.

The program of the congress was organized by the International Program Committee, chaired by Ghislaine Gueudet and the vice-chair Andreas Eichler in a very well structured, transparent and highly efficient way. Under their guidance, the IPC developed a substantial program with two very interesting plenaries, one presented by Elena Nardi (entitled “From Advanced mathematical thinking to university mathematics education: A story of emancipation and enrichment”) and the other by Lieven Verschaffel (entitled “Towards a more comprehensive model of children’s number sense”). In a panel on “Solid findings in mathematics education: What are they and what are they good for?” this ‘hot’ topic was discussed from different perspectives. Marianna Bosch, Tommy Dreyfus, Caterina Primi, and Gerry Shiel made up the panel. All of the plenary activities contributed substantially to the success of the conference.

However, the core and the heart of each CERME are the seven sessions in the Thematic Working Groups, which offer the main place for the spirit of inclusion realized in communication and cooperation. The 23 Thematic Working Groups were organized by 84 group leaders, an impressive number of people who invest their energy and time in the success of the congress. Several external conference organizers expressed their surprise that during the sessions, nobody was wandering around in the corridors. Of course not, we said, they are communicating and cooperating! And we become aware again that this intensity of work is specific, and perhaps even unique, to CERME.

Most of the CERME group leaders have taken this responsibility for several years and have established a long-term collaboration with substantial academic outcomes. This group of people engaged in the enormous effort of managing the process of quality development for 474 submitted papers and 94 posters, numbers much larger than ever before.

CERME is not only getting larger from congress to congress, but also increasingly international. The 774 participants came from 29 European countries and 23 Non-European countries. The top ten

countries in terms of numbers of participants were Germany (127), United Kingdom (60), Norway (55), France (47), Italy (47), Ireland (41), Spain (39), Sweden (38), Israel (32), and the US (30). Austria, Belgium, Croatia, Cyprus, Czech Republic, Denmark, Faroe Islands, Finland, Greece, Hungary, Iceland, Kosovo, Malta, Netherlands, Poland, Portugal, Russia, Slovakia, Switzerland, Turkey, and Ukraine were included in the European countries. Among the non-European countries were Algeria, Argentina, Australia, Bangladesh, Brazil, Cameroon, Canada, Chile, Hong Kong, Kenya, Iran, Japan, Lebanon, Malawi, Mexico, New Zealand, Nigeria, Singapore, South Africa, Thailand, and Tunisia. It must be the specific style of the congress and the ERME spirit which attracts so many people from all over the world!

With the increasing numbers and diversity, the challenge of compiling proceedings is getting more and more complex. We thank the chairs who served as editors for this complex process and for finalizing it so quickly.

Such a huge and complex congress as CERME could not be conducted without the engagement of more than 15% of all participants (including TWG leaders, IPC members, LOC members and ERME board members). We thank everybody who has contributed to the ongoing work behind the scenes which allowed the congress to be a real success. Specific thanks go to Ghislaine Gueudet, Andreas Eichler, Thérèse Dooley and Maurice O'Reilly for their hard work with a wonderful outcome.

We encourage interested researchers to meet us at the next CERME that will take place from February 5<sup>th</sup> to February 10<sup>th</sup> 2019, in Utrecht (the Netherlands).

Susanne Prediger, ERME President since February 2017

Viviane Durand-Guerrier, ERME President until February 2017

# Introduction to the Proceedings of the Tenth Congress of the European Society for Research in Mathematics Education (CERME10)

## About CERME10

The Tenth Congress of European Research in Mathematics Education (CERME 10) took place in Dublin (Ireland) from 1<sup>st</sup> to 5<sup>th</sup> February 2017. Ghislaine Gueudet (France) was the chair of the International Programme Committee (IPC) which comprised Thérèse Dooley (Ireland, chair of the local Programme Committee), Andreas Eichler (Germany, co-chair), Marianna Bosch (Spain), Markku Hannula (Finland), Jeremy Hodgen (UK), Konrad Krainer (Austria), Despina Potari (Greece), Kirsti Rø (Norway), Cristina Sabena (Italy), Michiel Veldhuis (Netherlands), Nad'a Vondrová (Czech Republic). Thérèse Dooley and Maurice O'Reilly were chair and co-chair respectively of the Local Organizing Committee (LOC).

CERME10 hosted 23 Thematic Working Groups, listed in the table below. The TWGs 21, 22, 23 and 24 were new groups, created following a call launched just after CERME9, and a selection process involving the CERME10 IPC and the ERME board. They all have been very successful, and will be part of CERME11 in February 2019. TWG7 (Mathematical potential, creativity and talent) has unfortunately been cancelled, due to a lack of contributions; while TWG14 has been split in two for the conference, because of the large number of papers received.

TWG	Leader
TWG1: Argumentation and proof	Gabriel Stylianides (UK)
TWG2: Arithmetic and number systems	Elisabeth Rathgeb-Schnierer (Germany)
TWG3: Algebraic thinking	Reinhard Oldenburg (Germany)
TWG4: Geometry	Joris Mithalal (France)
TWG5: Probability and statistics education	Corinne Hahn (France)
TWG6: Applications and modelling	Susana Carreira (Portugal)
TWG8: Affect and mathematical thinking	Pietro Di Martino (Italy)
TWG9: Mathematics and language	Núria Planas (Spain)
TWG10: Diversity and mathematics education: Social, cultural and political challenges	Lisa Björklund Boistrup (Sweden)
TWG11: Comparative studies in mathematics education	Paul Andrews (Sweden)
TWG12: History in mathematics education	Renaud Chorlay (France )

TWG13: Early years mathematics	Ingvald Erfjord (Norway)
TWG14a: University mathematics education	Alejandro Gonzalez Martin (Canada)
TWG 14b: University mathematics education	Irene Biza (United Kingdom)
TWG15: Teaching mathematics with resources and technology	Alison Clark-Wilson (UK)
TWG16: Students' learning mathematics with resources and technology	Hans-Georg Weigand (Germany)
TWG17: Theoretical perspectives and approaches in mathematics education research	Angelika Bikner Ahsbals (Germany)
TWG18: Mathematics teacher education and professional development	Stefan Zehetmeier (Austria)
TWG19: Mathematics teacher and classroom practices	Charalampos Sakonidis (Greece)
TWG20: Mathematics teacher knowledge, beliefs and identity	Miguel Ribeiro
TWG21: Assessment in mathematics education	Paola Iannone (UK)
TWG22: Curricular resources and task design in mathematics education	Birgit Pepin (The Netherlands)
TWG23: Implementation of research findings in mathematics education	Uffe Thomas Jankvist (Denmark)
TWG24: Representations in mathematics teaching and learning	Elisabetta Robotti (Italy)

## Editorial information

These proceedings are available as a complete volume online on the ERME website and each individual text is also available on the HAL open archive, where it can be found through keywords, title or author name. This has been the practice since CERME9, to increase the visibility of the huge work done in CERME conferences.

This volume begins with texts corresponding to the three plenary activities of CERME10: the presentation by Elena Nardi on University Mathematics Education; that by Lieven Verschaffel on Early Mathematics; and the panel on Solid Findings in Mathematics Education, chaired by Marianna Bosch and involving Tommy Dreyfus, Catarina Primi and Gerry Shiel.

After the plenaries, the reader will find 23 chapters corresponding to the work done in the TWGs of CERME10 (we remind the reader that TWG7 has been cancelled; moreover, TWG14 was split in two for the conference, but all the papers are in the same section in these proceedings).

These chapters follow a similar structure: they start with an introduction; then the long contributions (8-page papers) are presented – in alphabetical order by first author's name – and finally the short

contributions (2 pages). However, TWG17 has chosen a different order, corresponding to subthemes in the group.

There are two kinds of introductions to the TWGs, according to the team's choice: short introductions (4 pages) presenting the contributions; or long introductions (8 pages), which propose, in addition, an analysis of the current research on the theme of the TWG, and perspectives for the future. TWGs 6, 14, 15, 16, 17, 19 and 23 have chosen this form of long introduction.

The publication of these proceedings is the result of a collaborative work, involving CERME10 IPC, the TWG leaders and co-leaders, and the LOC co-chair. We warmly thank all these people for their involvement, and hope that this volume will contribute to the development of mathematics education research in Europe and beyond.

## Statistical overview of CERME10

Maurice O'Reilly

Dublin, Ireland, maurice.oreilly@dcu.ie

CERME evolves over time, and so it is of interest to gather and present some quantitative data on the number of participants and on the scientific output at CERME10. The table opposite shows the number of submissions to these proceedings (excluding the TWG introductions and the plenary papers) along with other submissions that were made online by December 2016 but were not included here. The numbers of long and short contributions are noted. Of course, each TWG had more participants than the number of submissions, since (i) many papers had several authors and (ii) there were other participants who did not submit. The entries in the table are explained in its footnotes.

The data for the table comes from two sources: the submissions made online (to the CERME10 website) by mid-December 2016, and the registration and attendance database for the congress. The final column shows the 768 (distinct) participants at CERME10, allocating each to exactly one TWG. Although over 80 participants were active in more than one TWG, care was taken to ensure that no participant was included more than once (by fine-tuning the 'Additional authors' column appropriately). This was facilitated by taking into account the TWG explicitly chosen by each participant at registration. The foreword states that there were 774 participants; this figure includes the six presenters at the plenary sessions.

Of the 565 submissions made in advance of CERME – comprising 466 (long) papers and 99 posters (or short contributions) – the attrition by the time these proceedings have been edited was only 22 (about 3.9%). This low figure underscores the observation mentioned in the foreword that “nobody was wandering in the corridors”. Contributions to the proceedings as a proportion of the total number of participants was 0.71 (= 543/768), this figure varying from 0.56 (for TWG2) to 0.82 (for TWG16). Another indicator of the intensity of the work at CERME is the low number of participants (84) who did not contribute papers – although they did contribute to the lively discussion! This was 10.9% of the total number of participants, with extremes ranging from 3.0% (for TWG10) to 20.0% (for TWG24). Yet another perspective on the hard work undertaken in the context of the congress is illustrated by the number (451) of 'long' papers as a proportion of all contributions: 83% overall, with a minimum of 71% (for TWG14) and an impressive maximum of 100% (for TWG2).

It has already been noted (in the foreword) that participants at CERME10 were drawn from 52 countries. It is part of the 'CERME spirit' to support academics who would normally have limited access to CERME (either from underrepresented or economically weak countries). This is made possible through the Graham Littler Fund which draws from those who can afford, in support of those who cannot. For CERME10, 46 participants were awarded grants totaling €21 100 (€12 300 for registration and €8 800 for travel and accommodation).

It is hoped that the data provided on these two pages helps quantify important aspects of CERME10, putting the scientific output in perspective.

TWG	Submissions		Contributions to the Proceedings		Additional authors	Additional participants	Total number of participants in each TWG
	to Proceedings	Online only	Long	Short

<b>Total</b>	<b>543</b>	<b>22</b>	<b>451</b>	<b>92</b>	<b>119</b>	<b>84</b>	<b>768</b>

**Submissions** were made **online** by mid-December 2016, most of which are published in these **proceedings** (as either **long** or **short contributions**).

In each TWG, the number of submissions is augmented by ‘**Additional authors**’ indicating the number of participants at CERME10 who contributed to (long or short) papers. The ‘**Additional participants**’ attended CERME10 but were not authors of these papers.

The ‘**Total number of participants in each TWG**’ is then the sum of all the submissions along with the additional authors and participants.

# From advanced mathematical thinking to university mathematics education: A story of emancipation and enrichment

Elena Nardi

University of East Anglia, UK, [e.nardi@uea.ac.uk](mailto:e.nardi@uea.ac.uk)

*Between CERME1 and CERME9 there have been approximately two hundred and fifty papers with their focus directly, or a little less so, on the teaching and learning of mathematics at university level, starting from about a dozen in CERME1 and rising to several dozens in CERME9. ERME recognised the increasing significance of this emerging field with the launch of Working Group 14 (Advanced Mathematical Thinking) in CERME4 in 2005 which evolved into Thematic Working Group 14 (University Mathematics Education) in CERME7 in 2011. In this lecture, I draw on my experience as researcher in this field, and as participant in both groups (and inaugural leader of the latter), to identify epistemological – theoretical, substantive and methodological – trends in the transition from the one to the other. I aim that the story I tell is one of gradual emancipation from a relatively limited initial focus on cognitive aspects of the student learning experience in university mathematics to the grander vista of issues – also inclusive of pedagogical, institutional, affective and social issues – that studies presented at CERME nowadays address. I also aim that the story I tell is one of enrichment as the depth and diversity of said vista has been accomplished also through thoughtful appropriation of results from those earlier studies.*

*Keywords: University mathematics education, developmental / cognitive and sociocultural approaches to the teaching and learning of mathematics.*

## Introduction

In tandem with ERME, the area of research that is the focus of this plenary, *University Mathematics Education* research, has also been evolving rapidly in the last twenty years or so. Here I focus on some of the milestones of this evolutionary journey, with the particular emphasis that I promised in the above title and abstract. Before proceeding to these though, here is a bit of a pre-ample: Figure 1 presents a still from a scene in the film *A Serious Man* (2009) directed by Ethan and Joel Coen.

**Fig.1.** Still taken from *A Serious Man* (2009): <https://www.youtube.com/watch?v=7iggyFPls4w>

This is a typical imagining in popular culture of how mathematics teaching looks like at university. I will not go much further with a discourse analysis of what the still (or the scene, or the film itself) may convey. In what I see as some contrast, Figure 2 presents a sequence of images, taken from the publicity materials of my own institution's department of mathematics.

**Fig. 2. Still taken from UEA promotional video:** <https://www.youtube.com/watch?v=gRzVX8c1be4>

The students and the lecturer in these images work together, they are not physically too far from each other and there is a range of resources – from chalk to digital – present. The sequence illustrates how institutions may wish to present the kind of learning experience that potential incomers into a department of mathematics are likely to be offered.

To me, there is a clear contrast between the movie still from *A Serious Man* and these two images from the UEA promotional video. It is a contrast between a widespread perception of university mathematics lectures as the ultimate form of transmissive pedagogies – with all the repercussions of alienation and distancing these pedagogies may entail – and the aspiration (institutional but not only) for a more approachable, more inclusive and more engaging learning experience in university mathematics that is tailored to individual student needs.

As university lecturers today – in mathematics and in other disciplines – we lecture. But we also do much more: we coordinate seminars, we conduct individual or small group tutorials, we run workshops and drop-in clinics, we supervise dissertations, we advise students on academic and on pastoral matters and we assess students in a variety of ways (all the way from closed-book examinations to mini-projects and oral presentations). Our professional worlds are far from monotonous. In fact, they require us to be quite versatile.

I see as of little surprise, and rather pleasing, that the versatility of our jobs is being reflected in the diversity of University Mathematics Education research that is now presented at CERME. This diversity of focus – but also theoretical perspective and methodology – is to me a sign of richness. In fact, here I have taken the liberty of endorsing a metaphor, which originates in currently dominant theories of evolution and conservation (Figure 3). These theories equate species diversity with resilience. The story I tell here relies somewhat on whether this is a convincing metaphor.

**Fig. 3. Image from:** <https://conservationbytes.com/2014/01/08/more-species-more-resilience/>

I tell this story in five parts: *The “early years”, CERME 1, 2, 3; The AMT years, CERME 4, 5, 6; The UME years, CERME 7, 8, 9; CERME10, the split<sup>1</sup> ...; and, Taking stock / What next / Coming soon...* Before starting, I need to post a health warning though: that a lecture of this kind errs on the side of being impressionistic – and of course quite personal<sup>2</sup> too. I thank you in advance for your tolerance.

My own trajectory in CERME – and outside – mirrors some of the milestones and trends that this plenary aims to map out. I was present in 1999 at CERME1, in Osnabrueck, assisting with the coordination of Group 5, *Mathematical thinking and learning as cognitive processes*. To those more familiar with the increasingly sociocultural and discursive take that my work has been taking over the years, this commitment to Group 5 may sound a little surprising. It is not. I start Part I with an anecdote on exactly this.

## Part I: The “early years”, CERME 1, 2, 3; UME research evidenced in several TWG groups

My 1996 doctorate’s title (Nardi, 1996) is *The novice mathematician’s encounter with mathematical abstraction: Tensions in concept image construction and formalization*. The statement of intentions in this doctorate are clear:

Mathematics is defined as an abstract way of thinking. Abstraction ranks among the least accessible mental activities. In [the UK educational context where the study took place], the encounter with mathematical abstraction is the crucial step of the transition from informal school mathematics to the formalism of university mathematics. This transition is characterised by cognitive tensions. This study aimed at the *identification and exploration of the tensions in the novice mathematician’s encounter with mathematical abstraction*. (Nardi, 1996: Abstract)

However, the study’s stated theoretical perspective is a little more perplexing. It is declared as “consisting of cognitive and sociocultural theories on learning”. And, the two key parts of findings in the final chapter promise an account of the novice mathematician’s encounter with mathematical abstraction “as a personal meaning-construction process and as an enculturation process” (ibid.).

It is quite easy, in hindsight, to be skeptical about the risky eclecticism of the approach – some may see this as standing on a fence, or, even, as pick-and-mix nonsense. But, I keep reminding myself that the study started in 1992 and was completed in 1996. It was therefore conducted at a time when

---

<sup>1</sup> Continuing with the biology inspired metaphors, I use the word “split” deliberately. Cell splitting is the process of subdividing a congested cell into smaller cells. Cell splitting or division is associated with reproduction and the creation of an entire new organism. This process is typically seen as increasing many of the capacities of a cellular system. In fact, in Parts III and IV, I aim to show the inevitability of cell splitting, emanating from the substantive, theoretical, and methodological diversity of UME research presented in CERME these days. It is in these parts that the main point of this lecture, signposted in the abstract by the words **emancipation** and **enrichment**, will, I hope, come through.

<sup>2</sup> I also need to thank at this juncture two overlapping groups of colleagues: my CERME 7, 8 and 9 TWG14 co-leaders and my co-authors of the 20-year anniversary ERME book in which UME research has been allocated a chapter (Winsløw et al., in press). Since 2010, when the UME TWG group was formed – for its first appearance in CERME7, in 2011 – these colleagues, have become what I like to call my academic family of friends.

the various shades of constructivism that form its theoretical backbones were then taking shape themselves. To signpost this a little more emphatically, allow me the gentle reminder that the seminal paper *Constructivist, emergent and sociocultural perspectives in the context of developmental research* (Cobb & Yackel, 1996) – a paper and a programme more broadly that impacted upon our debate around the co-determinants of mathematical learning in immense ways – appeared in *Educational Psychologist* in 1996, the year that my doctorate was completed. I often use this excuse when the slightly embarrassing thought comes to me that my study wanted to have its cake and eat it too!

So, here are some recollections from the early years, and, to start with, CERME1, that I see as pertinent for today: UME papers can be found in several groups but mostly in TWG1 (*Nature and content of mathematics and its relation to teaching and learning*) and TWG5 (*Mathematical thinking and learning as cognitive processes*). There is a pronounced epistemological focus on several papers – Grenier and Payan (1999) is one example – and there is a strong tendency in the few papers present to give a prominent position to the mathematical context and content of, for example, proposed course designs. Belousova and Byelyavtseva's (1999) paper on course design in Numerical Methods comes to mind; as do the Cabri designs for Linear Algebra put forward by Tommy Dreyfus, Joel Hillel and Anna Sierpinska (1999). There is also a tendency to consider this mathematical content regardless of whether this is present in school or university mathematics: there are, for example, propositions in this first CERME about using CAS (Computer Algebra Systems) for teaching functions; or, courseware for the teaching of Geometry from across school to university, and all the way to Differential Geometry.

There are two contributions to CERME1 though which, for me, stand out even more than those I sampled in my last comments. Both pre-empt the publication of two volumes that proved influential in the following years, in different, yet distinct ways. One is Leone Burton's (1999) preliminary analyses of interviewed mathematicians' epistemological perspectives which culminated in her monograph (Burton, 2004), *Mathematicians as Enquirers*. The other is Jean-Luc Dorier's paper (with Aline Robert, Jacqueline Robinet and Marc Rogalski, 1999) that sets the scene for the volume *On the teaching of linear algebra* (Dorier et al., 2000).

Both papers foreshadow – and I daresay contributed towards shaping – trends in UME research that became prominent in the years that followed. Burton's work signals a broadening of the UME church to include in its focus the university teacher (most other work at the time concerns the student or the mathematics alone). Dorier's work, and that of his colleagues, signals the still then not so imminent end of what I see as a shortcoming of UME research that is still present today, albeit to a lesser extent: the perception of research into university mathematics teaching practice as an a-theoretical aside of well-intended practitioners who are unaware of the epistemological and methodological underpinnings of mathematics education as an academic discipline. This work is distinct for its robust theoretical grounds and for its keen eye for intervention design, trial and evaluation – in a nutshell, for its systematic character. In this sense, of scope and ambition, it shares some common ground with another, powerful at the time – and still today –programme: that of APOS which originated in the USA and which was at the time also pushing the boundaries of work in UME beyond elementary Calculus and into Abstract Algebra.

Continuing with my observing trends that were to become influential in later years, within TWG5 (*Mathematical thinking and learning as cognitive processes*), which I mentioned earlier and which I assisted coordinating under the leadership of Inge Schwank, there are two themes that made an appearance – timidly and managing to occupy a small portion of the discussions only: the role of motivation in cognition (I see here inklings of evidence on the burgeoning importance of research on affect) and the emerging importance of theories of situated cognition. An observation that stands out from these discussions was made in the paper by Pier Luigi Ferrari (1999): in advanced mathematical thinking, wrote Pier Luigi at the time, some learner behaviours cannot be accounted for simply in terms of semantics. His paper presented an argument that brings the role of language – ordinary and mathematical – and of communicational structures to the fore.

CERME2 and CERME3 are the two CERMEs that I missed. Nonetheless, returning to the proceedings after all these years, there are several papers presented in CERME2 and a couple of dozen papers in CERME3 that can be found across several Working Groups and contain implicit references to advanced mathematics, often as extensions of what is typically found in the school syllabus that each paper revolves around.

In CERME2 these papers are mostly found in Working Group 5 (*Mathematical thinking and learning as cognitive processes*) and Working Group 1 (*Creating experience for structural thinking*). Mathematical thinking (including a growing focus on proof and proving) is at the heart of these papers which are only implicitly and only occasionally concerned with the institutional, curricular and pedagogical context of university level Mathematics Education. There is concern in these papers with internal mental structures. Nad'a Stehlíková and Darina Jirotková's paper (2001) is a good example: it focuses explicitly on processes of building an inner mathematical structure, which the authors abbreviate as IMS and which they acknowledge as hard to observe. They then resort to introspective, self-reporting accounts of mathematical thinking. John Mason's (1998) "researching from the inside" features largely as a theoretical influence on the paper. Nad'a Stehlíková will carry on in this strand of work also in CERME3.

These works concern the learning of mathematics often at the cusp of the transition from school to (what is in many places) university mathematics. One example of this trend is Bettina Pedemonte's (2001) study of cognitive unity, or break, in the context of constructing mathematical arguments and proofs. Another is the paper by Baruch Schwarz, Rina Hershkowitz, and Tommy Dreyfus (2001) which presents a perspective on abstraction as always occurring in context and which focuses on three epistemic actions (Recognising, Building-With and Constructing, RBC). Its theoretical close relatives are an eclectic mix and include elements of Activity Theory (Alexei Nikolaevich Leontiev) and the construct of situated abstraction per Richard Noss and Celia Hoyles (1996).

In tandem with abstraction, there are two studies of mathematical intuition that I would like to close my reference to CERME2 with. One (Tsamir, 2001) regards infinite sets and another (Chartier, 2001) regards geometrical intuition as a stepping stone to the study of Linear Algebra. Both refer extensively – and in some sense stand on the solid shoulders of – the essential work on mathematical intuition by Ephraim Fischbein. The analysis in (Chartier, 2001) is also embedded in curricular and pedagogical aspects of the experiences of the post-graduate students who are its focus and draws out of the students' responses the kinds of geometrical intuition – helpful and less helpful

– they bring into their practice of Linear Algebra. Those links between mathematical encounters of the students in earlier and later phases of their studies will be a focus for Ghislaine Gueudet (then Chartier) also in CERME3.

Transitions, for example from Algebra to Analysis – as in the work also in CERME2 by Michela Maschietto (2001), even though technically concerning secondary school – is a theme that features strongly in CERME ever after. I note though that both Gueudet and Maschietto had their CERME2 work presented in Working Group 7 (*Metaphors and Images*) and that Maschietto's paper has an explicit focus on the concept of limit. This is a mathematical topic which, to this day, is a flagship topic for much UME research. In CERME3, for example, there are five papers with this focus, with three of the studies carried out in a computational environment. Again, UME research can be found interspersed in five (on my count) Working Groups: 1. Metaphors and images (including embodied cognition); 3. Building structures in mathematical knowledge; 4. Argumentation and proof; 6. Algebraic thinking; 7. Geometrical thinking. Colleagues such as Uri Leron, Ted Eisenberg, Cécile Ouvrier-Buffet contribute investigations that can be seen as closely relevant to those of us doing research in a university mathematics education context. However, these are works pitched beyond the context of the investigations at their heart. Participants are often called “subjects” and it is sometimes several pages into the papers that the reader learns whether these participants are school pupils, university undergraduates or pre-service teachers. This is a particularly evident tendency in the more explicitly psychologically-oriented works in Working Group 3 (*Building structures in mathematical knowledge*) and a little less pronounced in those in the rapidly growing Working Group 4 (*Argumentation and proof*) which had more than a dozen papers in it.

A clear exception to this rule is a paper that was not presented in any of the working groups I listed above: it was presented and discussed in Thematic Group 8 (*Social interactions in mathematical learning situations*) and, to me, it has an incredibly modern, up to date feel to it. It embodies several of the characteristics that were to become more salient in much later CERMEs. The paper is by Andreas Andersson (2003, later Ryve) and it involves observations of engineering students as they interact during mathematical activity. It also deploys the then just-emerging tools from the work of Anna Sfard and her colleagues (e.g. 2002). The tools are used to record patterns in participants' communication (*preoccupational analysis* for social aspects of the communication and *focal analysis* for patterns in the mathematical content of the communication). Both the explicit focus on a group of university students (and actually non-mathematics specialists) and the discursive tools deployed in the data analysis render the paper – retrospectively – a solid foreshadower of things to come, in CERME and elsewhere.

## Part II: The AMT years, CERME 4, 5, 6

The quality and quantity of work I sampled so far from the first three CERMEs resulted in the recognition by ERME of the increasing significance of research in this area. Group 14 (*Advanced Mathematical Thinking*) was launched in CERME4 in 2005 with Joanna Mamona-Downs, Maria Meehan and John Monaghan as its inaugural leaders and attracted twelve papers.

There is a clear trend emerging from the bulk of these twelve papers: many of these works focus squarely on the students and their habits or preferences in mathematical thinking. The perspective is

largely developmental and dualist. Several papers explore perceived differences between the intuitive and the abstract, the procedural and the conceptual, processes and objects. The prevailing theoretical constructs are Richard Skemp's *instrumental and relational understanding* (1976), Shlomo Vinner and David Tall's *concept image – concept definition* (1981), Eddie Gray and David Tall's *procepts* (1994), APOS theory (Dubinsky, 1991) and Anna Sfard's *theory of reification and process – object duality* (1991).

These dualities prevail in the analysis in many of the papers – especially in studies that concern the mathematical topics of Calculus and Analysis, and proof and proving. Matthew Inglis and Adrian Simpson (2005) capture this well in their paper about dual process theory: intuition, formalism/abstraction. Students in these analyses – which have a strong developmental / cognitive flavour – appear frequently not at ease with the latter (formalism) and uncertain about the validity of the former (intuition). But, we are now well into the 2000s and the broader field is moving briskly towards what Steve Lerman (2000) had labelled a “social turn”. (A note here: I find myself agreeing more though with the later labelling, by Eva Jablonka and Christer Bergsten (2010), of “social brand”, and Lerman's own acknowledgment in the same volume that plurality is not a problem per se in mathematics education.) While attending CERME4, I was also preparing a review (Nardi, 2005) of Carolyn Kieran's, Ellice Forman's and Anna Sfard's 2002 volume *Learning Discourse: discursive approaches to research in mathematics education*. There was a palpable sense in the CERME4 sessions that this extended and accentuated tendency to use developmental/cognitive frameworks, rather than exploring connections between students' learning behaviours and the institutional, pedagogical and curricular context in which these behaviours manifest themselves, was leaving much more to desire from the presented analyses.

The paper by Erhan Bingolbali and John Monaghan (2005) on the impact of departmental settings for engineering and mathematics undergraduates' engagement with the notion of derivative, expressed this desire very well. The paper had a good go at exploring the dialectic between departmental setting, lecturers' teaching and student 'positioning'. Even better was the 2008 ESM paper by these authors, poignantly entitled *Concept image revisited*.

The paper that Paola Iannone and I presented at CERME4 (2005) also expresses, in a rudimentary form, this desire for more substantial exploration of the dialectic relationship between lecturers' and students' ways of communicating mathematically in writing and in speaking. We used the term “genre speech” (Bakhtin, 1986). The paper draws on the larger data pool that three years later became *Amongst Mathematicians* (Nardi, 2008) and has – a little over-ambitiously I admit – a multiple purpose. To explore the “genre speeches” of university mathematics is one. The other one is to bring to the fore an example of a “co-learning partnership” between university mathematics lecturers and mathematics education researchers. I note that “co-learning partnership” is a term that I had become familiar with from the work of my doctoral supervisor and research collaborator Barbara Jaworski (2003), who is also to be credited for introducing me to CERME in the first place! The rapprochement between the communities of university mathematicians and mathematics education researchers became a staple theme in much of the work that I became involved with in the years that followed – and it is one of the defining characteristics of the work that the UME group has showcased and also nurtured. More on this follows later.

Joanna Mamona-Downs continued to lead the AMT group in CERME5 too and the group grew bigger – about 50% bigger! But was it also healthier? I recall vividly the vibrancy of the sessions and also the fact that substantial findings were shared. Two strands made an impression on me at the time: the emerging strand of studies on students' generation of examples, non-examples and counter examples – for example by Maria Meehan (2007) – also emerging out of the then freshly published work in this area by Anne Watson and John Mason (2005). I also recall an emerging focus on studies that explore the easing of the transition from school to university – for example, in terms of the mathematical reasoning required. Matthew Inglis and Adrian Simpson (2007) at the time brought to our attention differences between 'vernacular logic' and 'mathematical logic' and belief biases in reasoning.

Closer to the focus that my work was gearing towards at the time, I also recall Winsløw and Møller Madsen's (2007) adaptation of ATD, the anthropological theory of the didactic, and their examination of the relationship between mathematicians' research activities and their teaching practices. Paola Iannone and I (2007) continued to report analyses from our interview study with university mathematicians: this time we chose to report a slice of our data that concerned the interplay between syntactic and semantic knowledge in proof production (Weber & Alcock, 2004).

With Lara Alcock, and also Matthew Inglis and Rina Zazkis, I was delighted to act as helper to Joanna Mamona-Downs and to observe the many elements of continuity from CERME4 – but also the elements of what I, to this day, see as evidence of healthy controversy. Mamona-Downs (2007), in her synopsis of the group's work captures this well. Here she lists the pertinent questions we were asked to engage with:

- (1) Is the perceived discontinuity between secondary and tertiary mathematics due to institutional and pedagogical practices, or is it caused by factors concerning the character of University Mathematics that demand new habits of behavior in reasoning?
- (2) What ways are there to ease the transition?
- (3) If AMT is taken as thinking skills needed for Advanced Mathematics, how are they beyond those required at school?
- (4) What commonalities or differences in mental processes are there in the two levels? (p.2228)

She then notes that our group discussion was:

“rather diffused and mostly sidestepped the questions despite their fundamental significance. It was dominated by the view of some that the research field of AMT has largely changed its main focus from cognitive-based studies starting in the early nineteen eighties, to the tendencies found nowadays based more on societal and affect factors that make the long established work 'obsolete'. Others countered strongly this position on the basis of the existence of different scientific 'paradigms', in the sense of Kuhn, and on much of the actual output of recent educational research. Opinions were often put in a partisan spirit. [...] A discussion was raised concerning the possibility that some tasks accessible to school students might pose the same kinds of problems in their resolution for undergraduates, and so it could be claimed that these tasks might be considered within the scope of AMT.” (p.2228)

No consensus was found possible in the group at CERME5 as this quotation from Mamona-Downs suggests:

“Several participants declared that the two interpretations are complementary and that there was no compelling reason not to retain the traditional name 'Advanced Mathematical Thinking' as an umbrella term [while there were] a few participants who felt that the themes stated in the program were mostly steered towards cognitive factors.” (p.2228-9)

And, I recall, for example, the paper from Corine Castela (2007) offering evidence and taking a clear stance that this persistent focus on cognitive approaches may not be the most inclusive – or fertile – way forward for the group.

This tendency to question whether UME research was appropriately congregating under the AMT umbrella continued in CERME6. The AMT group maintained its size and also, as the group leaders (Roza Leikin, Claire Cazes, Joanna Mamona-Dawns, Paul Vanderlind) observe in their notes on the proceedings (2009), attracted papers firmly focused on the latter of the two ways of interpreting AMT (advanced thinking in mathematics, A-MT or thinking about advanced mathematics, AM-T). As I was reporting a study about prospective and practising teachers' perspectives on proof, I attended the proof group on that occasion. So I missed the wealth of findings in the CERME6 AMT papers on conceptual attainment, approaches to proof and proving, problem solving, instructional approaches and processes of abstraction. It is fair to say though that UME research was gaining even more critical mass with about twenty five papers across six groups!

One of these is Barbara Jaworski's (2009) paper which proposes the exploration of university mathematics teaching practice through a sociocultural perspective that embroiders elements of *Activity Theory* and the *Communities of Practice Theory*. There will be a stream of papers thereafter in CERME with a focus on the practices and perspectives of the university mathematics teacher.

My own work in this period, a part of it also with Barbara Jaworski, illustrates this focus rather emphatically. In a nutshell, I would describe my research programme dating from 1990s to the mid-2000s as as shifting from studies of university **mathematics students' learning** of particular mathematical topics (as outlined earlier: Nardi, 1996; 2000) to a progressively growing focus on **university mathematics teachers' perspectives/practices** in mathematics and mathematics teaching (Nardi, Jaworski & Hegedus 2005; Nardi, 2008). These two sets of work illustrate the shift of my focus progressively towards university mathematics teachers' pedagogical and epistemological perspectives. UMTTP (University Mathematics Teaching Project) resulted in the 4-level Spectrum of Pedagogical Awareness (Nardi et al., 2005). *Amongst Mathematicians: Teaching and learning mathematics at University Level* (Nardi, 2008) was published in 2008, following a gestation period of several years that had started also in CERME with the presentations, with Paola Iannone, that I mentioned earlier.

*Amongst Mathematicians* (Nardi, 2008) tells the story of a co-learning partnership that illustrated research between mathematics educators and mathematicians with these five key characteristics: ***collaborative, mathematically focussed, context-specific, non-prescriptive and non-deficit*** as possible. In addition to reporting university mathematicians' pedagogical and epistemological perspectives, the book served a broader purpose too. It is written in the rather unconventional format of a dialogue between two fictional, yet data grounded characters – M, mathematician, and RME, researcher in mathematics education – and is intended as reflection on the perceived benefits,

obstacles and desires of the relationship between the two. Such conversations were of course not new. For example, Anna Sfard (1998) reported her discussion with Shimshon A. Amitsur, in the form of a dialogue and a range of authors from a variety of national and institutional contexts, including Michèle Artigue and Gerry Goldin, were writing at the time about this relationship. A common observation in these accounts was about its fragility. Research which consolidates and propels the rapprochement between the communities of mathematicians and mathematics educators remains a focus of my work today (e.g. Nardi, 2016) and it is fair to say that CERME, in the mid-2000s provided one of the first fora for kickstarting this work.

Let me conclude my reflections on what I labelled as “the AMT” years with a brief reference to a set of works that somehow foreshadow developments within the UME community in CERME: in the Modelling TWG, Berta Barquero, Marianna Bosch and Josep Gascón (2009) offered an ATD account of the institutional constraints hampering the teaching of mathematical modelling at university level. They coin the term “applicationism”, an epistemological perspective which proposes a strict separation between mathematics and other disciplines (especially the natural sciences) and sees mathematical tools as built to be applied to solve problems in other disciplines – with this application not causing any change in the discipline of mathematics or for the discipline in which the application is made. As UME research is rapidly growing in the area of teaching mathematics to non-mathematicians, works such as this, in CERME6 and earlier, now acquire added significance.

### **Part III: The UME years, *CERME 7, 8, 9***

The proposal to the ERME board for the launch of *TWG14: University Mathematics Education* was born out of two main sources. First was my reading and writing at the time: While writing *Amongst Mathematicians*, my search across the literature was broad. In fact, as Michèle Artigue (2016) has noted in her INDRUM2016 plenary, there is a synthesis feel to the book. A more explicit, deliberate synthesis of hitherto developments in research into the teaching and learning of university mathematics that was the chapter that Artigue (Artigue, Batanero & Kent, 2007) co-authored with Carmen Batanero and Philip Kent for the second NCTM Handbook. Secondly, at PME, in Morelia (Nardi & Iannone, 2008) and in Thessaloniki (Nardi et al., 2009), two Working Sessions / Discussion Groups that I had co-ordinated with colleagues many of whom ended up co-leading the UME TWG in CERME, had attracted many colleagues and had generated vital, urgent discussions.

I recall that this sensation of vibrancy and urgency was not universally shared outside the bubble of researchers in this area. I recall that when we proposed the launch of the group, we were gently reminded by members of the board that we would need to attract at least eight papers to make the new group viable! I recall that we – the inaugural co-leaders of TWG14 – were nudging each other that, if each one of us submitted a paper, we would only need to find three more to be able to launch the group! We were of course wrong.

I need to make two brief notes at this juncture: first, that the account of the group’s work since 2011 borrows heavily from the collectively authored texts in the CERME7, 8 and 9 proceedings (Nardi et al., 2011; 2013; 2015); second, that, given the volume of work presented at these conferences, I will

from now on stay largely away from extensive exemplification from specific papers. I will instead focus on the themes that mark the “emancipation” and “enrichment” themes promised in the title.

Our rationale for a UME TWG ((Nardi et al., 2011) was in a nutshell as follows.

Research on university level mathematics education is a relatively young field, which embraces an increasingly wider range of theoretical approaches (e.g. cognitive/developmental, socio-cultural, anthropological and discursive) and methods/methodologies (e.g. quantitative, qualitative and narrative). Variation also characterises research in this area with regard to at least two further issues:

- the *role of the participants*, students and university teachers, in the research – from ‘just’ subjects of the research to fully-fledged co-researchers; and,
- the *degree of intervention* involved in the research – from external, non-interventionist research, to developmental/action research in which researchers identify problems and devise, implement and evaluate reforms of practice (Artigue et al, 2007).

2011 marked the 20<sup>th</sup> anniversary of the publication of *Advanced Mathematical Thinking* edited by David Tall (1991). This is a volume that is often heralded as a first signal of the emergence of this new area of research. A few years later, a second signal was given by the 1998 ICMI study that resulted in *The teaching and learning of mathematics at university level*, edited by Derek Holton (2001). In the meantime, Advanced Mathematical Thinking (AMT) groups ran both in previous CERME and PME conferences; sessions exclusively on university mathematics education have been part of the EMF (*Espace Mathématique Francophone*) conferences since 2006; the RUME, UMT and Delta conferences emerged in the USA, the UK and South Africa respectively; the International Conferences on the Teaching of Mathematics at University Level were launched in 1998; etc. The UME TWG emerged out of the above developments and out of the realisation that this is a distinct area of mathematics education research.

The distinctiveness of UME research can be attributed to several characteristics.

Firstly, the classic distinction between ‘teacher’ and ‘researcher’ does not always apply in UME as researchers in mathematics education in this area are often university-level teachers of mathematics themselves. In particular, there is a growing group of mathematicians specializing in research on mathematics education at university level, where expertise and experience in advanced mathematics is really an asset (if not a necessity). Secondly, mathematics education theories and research methods find new uses, and adaptations, at the university level. These adaptations are often quite radical as the post-compulsory educational context is different in many ways – including the voluntary presence of students, the important role of mathematics as a service subject, the predominance of lecturing to large numbers of students, the absence of national programmes for university education, the required shift to the distinctly different practices of university mathematics, to mention but a few. In this sense, UME is a distinct area of mathematics education research, not merely a mirror of mathematics education research at a more advanced educational level. Finally, in recent years, research in this area has been growing in different parts of the world. TWG14 is one forum where evidence of this growing research activity from Europe and beyond has been accumulating.

Across CERME7, 8 and 9, the WG14 Calls for Papers invited contributions from as wide a range of research topics as possible. Here is, for example, the list from CERME9: the teaching and learning of advanced topics; mathematical reasoning and proof; transition issues “at the entrance” to university mathematics, or beyond; challenges for, and novel approaches to, teaching (including the teaching of students in non-mathematics degrees); the role of ICT tools (e.g. CAS) and other resources (e.g. textbooks, books and other materials); assessment; the preparation and training of university mathematics teachers; collaborative research between university mathematics teachers and researchers in mathematics education; and, theoretical approaches to UME research.

We opted for widening participation as much as possible, both in terms of the substantive, methodological and theoretical takes of the proposed papers but also in terms of the disciplinary background and experience of the proposers. The 21, 29 and 45 (31 long 14 short) papers accepted for publication in the respective proceedings met those terms.

Across the WG14 discussions, certain themes and questions emerged as crucial. These included: exploring whether UME needs to generate new theories or adapt already existing ones; attending to issues of both theory and practice; acknowledging that research on teaching and learning in higher education develops also outside mathematics education, and benefiting from these developments; working towards the generation of new theories while valuing already accumulated knowledge in the field; etc. One oft-repeated observation was that, beyond staple references to classic constructs from the AMT years, several works presented in TWG14 employ (often in tandem with the above) approaches such as the *Anthropological Theory of the Didactic* (Chevallard, 1999) and discursive approaches, such as Anna Sfard’s (2008) theory of *commognition*.

In CERME7 (Nardi, et al., 2011), we noted that an area of growth has certainly been studies that examine the different role of mathematics in courses towards a mathematics degree, courses for pre-service teachers, as a ‘service’ subject (physics, biology, economics etc.). While a substantial number of papers remains in the increasingly well-trodden area of students’ perceptions of specific mathematical concepts (again calculus prevails in these), a focus on university teachers and teaching is also emerging, if often a little timidly, and diplomatically, resulting in descriptive, openly non-judgemental studies. In conjunction with those studies, a genre of collaborative studies, with mathematicians engaged as co-researchers, also seems to be on the rise. We signal the emerging trends in the CERME7 papers as: *Transitions; Affect; Teacher practices; Mathematical topics*.

In CERME8 (Nardi et al., 2013), we noted the appearance of new mathematical topics: infinite series and abstract algebra. We also noted that some of these papers are written by research mathematicians, using a mathematical, epistemological, or historical analysis, and drawing on their teaching experience. Others present research that makes use of different theoretical frameworks, and methodological tools, to analyse students’ difficulties with these specific topics, to better understand the teaching of a specific topic and the consequences of this teaching, or to formulate propositions for the design of teaching to overcome these difficulties. The range of approaches vary from developmental ones (such as *concept image – concept definition*), to models for abstraction (such as

the *RBC model*), to analysis of discourse (*theory of commognition*) and the consideration of institutional matters (*anthropological theory of the didactic*)<sup>3</sup>.

After CERME8, the team – in collaboration with TWG14 participants and others – worked towards a *Research in Mathematics Education* Special Issue on *Institutional, sociocultural and discursive approaches to research in university mathematics education* which focused on research that is conducted in the spirit of the following theoretical frameworks: *Anthropological Theory of the Didactic*, *Theory of Didactic Situations*, *Instrumental and Documentational Approaches*, *Communities of Practice and Inquiry* and *Theory of Commognition*. As we noted in the Editorial of the RME Special Issue (Nardi et al., 2014), there is a clear surge of sociocultural and discursive approaches – and the number of papers using ATD and TDS is also remarkable. An emerging focus seems to be also on systematic investigations of innovative course design and implementation and there is certainly a rise in the number of studies that examine the teaching and learning of mathematics in the context of disciplines other than mathematics, such as engineering and economics. Furthermore, this time we welcomed more colleagues from outside Europe and also noted the rise in the number of papers on assessment and examination<sup>4</sup>.

In CERME9 (Nardi et al., 2015), there was a notable shift in terms of numbers of papers (two to one) in favour of the second of our two umbrella themes: *Teaching and learning of specific topics in university mathematics; Teachers' and students' practices at university level*. The breadth of topics covered especially in the latter is also telling: curriculum and assessment; innovative course design in UME; student approaches to study; relating research mathematicians' practices to student practices; views and practices of mathematics lecturers; and, methodological and theoretical contributions to UME research.

In CERME9 we also observed the further strengthening, maturity and increasingly more robust theorizing of studies into teaching practices. And, we also noticed in several papers the establishing of promising liaisons across different theoretical perspectives such as a discursive take on *mathematical knowledge for teaching* or an anthropological take on *documentational approaches*.

The critical – and growing – mass and quality of the work presented at CERME9 TWG14 led to the launch of an ERME Topic Conference, [INDRUM2016](#), a conference of the newly established *International Network for Didactic Research in University Mathematics* (Montpellier, March 31 – April 2, 2016)<sup>5</sup>. The conference attracted more than 80 submissions and more than 100 participants. [INDRUM2018](#) is currently in preparation.

---

<sup>3</sup> By the way, we closed our CERME8 text for the proceedings with a *Concluding note on rigour and quality* of UME research. While there is no space here to elaborate, I invite the reader to what I see as pertinent observations from the TWG14 team about these issues in CERME at large.

<sup>4</sup> In CERME10 there is a new TWG on assessment that spans across educational levels led by former TWG14 co-leader Paola Iannone.

<sup>5</sup> I chaired this conference with the tireless Carl Winsløw. Its launch and its 2016 success (Montpellier, France) relied heavily on the sterling work of ERME president Viviane Durand-Guerrier and the commitment of Thomas Hausberger.

## Part IV: CERME10, the split...

There were 47 UME papers and 16 UME posters accepted for presentation and discussion in CERME10. Their presentation and discussion was in two isomorphic groups: TWG14A and TWG14B. From CERME11, it is expected that papers may be invited for two, also thematically distinct, groups – and the debate on possible configurations for this dominated some of the discussions at the conference. One way forward that I personally favour is for a grouping by the following distinction: studies that concern the transition to university studies of mathematics and the transition from university studies into the (various forms of) workplace; and, studies that concern the teaching and learning of mathematics while at university. The challenge of debating the numerous configurations of how the (new) group(s) can be (re)defined is certainly non-negligible. Isn't this a most wonderful place to find ourselves though, having to manage the now critical mass and quality of UME research present in CERME?

## Part V: Taking stock / What next / Coming soon...

As I am drawing to a close, I would like to ask the question: what did we want to achieve with the establishment of TWG14? Have we achieved these objectives? Are we going to? For example: did we manage to encourage fledgling topics in UME research? Have we planted the seed for new ones?

In the sprawling vista of works that I aimed to sample in this lecture – and I am fully aware of the wafer thin way in which I have done so – I have aimed to identify trends in UME research (overall, in CERME, in my own work) that signify the benefits (the **richness!**) of opening up, of widening our substantive, theoretical and methodological horizons (the what, the how and the why of our research). Most of my examples have aimed to illustrate the benefits that **emancipation** from an individualistic, narrowly psychological, cognitive perspective has brought to UME research.

There are still though foci that have not yet merited our sufficient attention. One such research focus that seems to me to be not within the radar of current works is UME research is on more advanced topics in mathematics – and by that, I mean mathematics that is typically taught beyond the first two years of university studies.

On a less deficit tone, I am generally satisfied that we have come a long way but I also acknowledge that there is an even longer way to go. It is fair to say that, within the various UME communities around the world, we have gone (or are still going) through what I would like to label as a dismissive phase: that all so-called traditional pedagogies are “bad”, lecturing in particular. I am observing – but I am also asking that we do so even better – that we become more nuanced and embracing of possibility. We are starting, for example, to recognise that lecturing can serve some purposes rather well; that it can be complemented by formats more tailored to the serving of students' individual needs; that there are interactive lecture formats that give participants the buzz of community belonging and building and prepare students for the less cocooned, less protected world of work where interaction, team work and communication are key. We are finding out that not all interaction and all the time is good per se and that there are particular types of communal engagement with mathematics that work better than others. TWG14 papers have been offering the evidence base for these claims, steadily and cumulatively. In a way, I find the choice made by the

mathematics department in my institution (see earlier snip in Figure 2) to include in its promotional materials images of lectures and also to close its promotional video (<https://www.youtube.com/watch?v=gRzVX8c1be4>) with a close-up of white chalk on a blackboard (Figure 4) somewhat refreshing. We are perhaps starting after all to embrace diversity in the ways that the students need to experience mathematics!

I believe the answers to the questions with which I started this section are reservedly optimistic and affirmative. In Part II, I showed an outline of my own research programme over the years and I am pleased to be able to say that most of the items there – and what followed these – have emerged out of collaborations with colleagues in CERME, including research plans for the immediate future.

CERME has indeed been a platform where I am trialling new topics for research. My CERME8 paper (Nardi, 2013) offers analyses of the challenges of teaching a graduate course on mathematics education to students with a variety of backgrounds, including bachelor degrees in pure mathematics, and native languages other than the language of instruction. The paper also outlines key didactic techniques and principles to cope with these challenges. It finally morphed into the more substantial analyses present in a paper included in the inaugural issue of IJRUME (Nardi, 2015) which examined ways to facilitating paradigm shifts in the supervision of mathematics graduates upon entry into mathematics education.

CERME has also been a platform where I have trialled new approaches to analysing data. In fact, I credit CERME for allowing me the creative space to have a go – and converse about – discursive, particularly commognitive, approaches to the analyses of my data. My CERME7 paper (Nardi, 2011) outlined interviewed mathematicians' perspectives on their newly arriving students' verbalisation skills; and, observed that discourse on verbalisation in mathematics tends to be risk-averse and not as explicit in teaching as necessary. At CERME9, Bill Barton and I (Nardi & Barton, 2015) presented a *commognitive* analysis of a “low lecture” episode (student-led inquiry oriented discussion on open-ended problems) to illustrate crucial steps of student enculturation into mathematical ways of acting and communicating, including a shift away from the lecturer's ‘ultimate substantiator’ role. Finally, both the papers I am involved in as co-author in CERME10 (Virman & Nardi, 2017; Thoma & Nardi, 2017) present commognitive analyses in contexts that said analyses are now just about starting to appear (teaching mathematics to non-mathematicians; analyses of closed-book examination tasks and student/lecturers' assessment discourses).

Returning to the anecdote that I started with, a somewhat self-deprecating recollection of the theoretical ambivalence of my doctoral work, I see my own research programme as an illustration of the **richness emanating from the emancipation**, from what I now see as a narrow, individualistic perspective in my earlier work. To me there is nothing vacantly rhetorical about the three Cs in the CERME spirit: COMMUNICATION, COOPERATION, COLLABORATION. The growth of my research programme through each one of these is to me unshakeable evidence of the pragmatic strength of these three words. In TWG14 these words have taken shape as specific actions. Here are two: (1) Certainly, we have assisted with the arrival of several new researchers in this field, some of whom are currently co-leaders; many have used the reviewing process as a stepping stone for their writing (from poster to conference paper then to completing theses and journal papers). (2) We have engaged practitioners of university mathematics teaching who now see themselves also as UME

researchers. To do so, we deploy the reviewing process and the discussions at the conference to convey the rigour that is required for UME research (in terms of engaging with theory, prior research and methodology) and to bridge the epistemological differences between the academic disciplines of mathematics and education.

I invite the reader to the collections of papers published in the TWG14 sections of the Proceedings, the 2014 *Research in Mathematics Education* Special Issue that followed CERME8, the proceedings of the 2016 *INDRUM* conference and the imminent (publication expected in 2018) *International Journal for Research in Undergraduate Mathematics Education* Special Issue that is following INDRUM2016 as testimonials of the growth and diversity I have tried to map here. And there is more to come: INDRUM2018 will be hosted by MatRIC at the University of Agder (Kristiansand, Norway) in April 2018 and its Scientific Committee aims to follow it up with a state-of-the-art volume soon after. And, of course, there is the UME chapter (Winsløw et al., in press) in the ERME 20<sup>th</sup> Anniversary Book that we aim to celebrate in CERME11, in 2019. The promise of UME research on the global scene is further corroborated by the healthy growth of the [RUME](#) and [DELTA](#) conferences, and the respective group within [EMF](#). In closing, I return to the words of Michèle Artigue whose thoughtful INDRUM2016 plenary (Artigue, 2016) triggered the focus of the synthesis and analysis presented here:

“The emergence of the [UME] field was [...] characterized by the domination of cognitive and constructivist perspectives. I consider as a strength of our field the fact that we have succeeded in emancipating ourselves from these perspectives, whose limitations are evident, but also the fact evidenced by the consideration of most research publications, that this emancipation went along a reconstruction of their main outcomes, thus making possible some form of incorporation of these outcomes in the new paradigms.”

Michèle Artigue, from *Mathematics education research at university level: Achievements and challenges*, INDRUM2016 plenary lecture (p.19)

# Young children's early mathematical competencies: Analysis and stimulation

Lieven Verschaffel, Joke Torbeyns, and Bert De Smedt

University of Leuven, Belgium, [lieven.verschaffel@kuleuven.be](mailto:lieven.verschaffel@kuleuven.be)

*In this paper we take a critical look at the state-of-the-art in the research domain of early mathematical development and education. We start with a brief review of the influential and successful (neuro)cognitive research in this domain - which is heavily focused on the development and teaching of children's (non-symbolic and symbolic) magnitude representation and strongly dominated by the theory of an approximate number system (ANS). We confront and complement this (neuro)cognitive approach with various other lines of research that may help to provide a more comprehensive picture of the development and stimulation of children's early mathematical competence and how it relates to their later mathematical proficiency at school.*

*Keywords: Early mathematics, approximate number system, number concepts, mathematical patterns and structures, preschool education.*

## Introduction

The past 10-15 years have witnessed the emergence of a remarkably productive and highly influential line of research on children's early numerical magnitude representation, its development, its relation to school mathematics, and its assessment and stimulation (Torbeyns, Gilmore & Verschaffel, 2015).

The starting point of this line of research - which has its origins in cognitive (neuro)psychology -, is the idea that young children, like many other species, are equipped with some foundational innate core systems to process quantities. This "starter's kit" is thought to involve (a) an "object tracking system" that has a limit of three or four objects and is thought to underlie "subitizing" (= to immediate and accurate estimate of one to four objects without serial enumeration), and (b) an "analogue number system" – for the internal representation of numerical magnitudes as Gaussian distributions of activation on a "mental number line" with increasingly imprecise representations for increasing magnitudes (Dehaene, 2011) - allowing them to compare non-symbolic quantities that are too numerous to enumerate exactly or to perform some very basic approximate arithmetic on these quantities (Andrews & Sayers, 2015; Butterworth, 2015).

With these foundational core number sense systems, these magnitudes are represented non-verbally and non-symbolically, but, over development and through early (mathematics) education, verbal and symbolic representations are gradually mapped onto these foundational representations, to evolve into a more elaborated system for number sense (Torbeyns et al., 2015).

People's numerical magnitude representations are commonly assessed via magnitude comparison and/or number line estimation tasks, of which there exist both non-symbolic and symbolic versions (Butterworth, 2015; Andrews & Sayers, 2015; Torbeyns et al., 2015). Examples are shown in Figure 1.

**Figure 1: Example of a non-symbolic magnitude comparison and a symbolic number line estimation task**

During the past decade, several research teams have set up correlational, cross-sectional and longitudinal studies to determine the contribution of children's numerical magnitude understanding - sometimes in combination with other specific early numerical competencies (such as subitizing, counting or numeral recognition) - to their concurrent and/or later overall mathematical achievement or to specific parts of it such as mental arithmetic or algebra (see, e.g., Bailey, Geary, & Siegler, 2014; De Smedt, Verschaffel, & Ghesquière, 2009; Jordan, Glutting, & Ramineni, 2010; Nguyen, Watts, Duncan, Clements, et al., 2016; Reeve, Reynolds, Humberstone, & Butterworth, 2012). These studies have demonstrated that children's numerical magnitude understanding is positively related to their concurrent and future mathematics achievement in general or in particular subdomains of mathematics.

Two recent meta-analyses have yielded a good overview of the outcomes of this research on the association between various measures of children's numerical magnitude understanding and their concurrent and future mathematics achievement. Schneider, Beeres, Coban, Merz, et al. (2017) performed a meta-analysis on the research about the association between performance on the magnitude comparison task and measures of mathematical competence. Their literature search yielded 45 articles reporting 284 effect sizes found with 17,201 participants. The results support the view that magnitude processing is reliably associated with mathematical competence as measured at least up to the end of the elementary-school years and by a wide range of mathematical tasks, measures and subdomains. Furthermore, the effect size was significantly higher for the symbolic than for the non-symbolic magnitude comparison task and decreased very slightly with age. So - the authors conclude - symbolic magnitude processing might be a more eligible candidate than non-symbolic magnitude processing to be targeted by diagnostic screening instruments and interventions for school-aged children and for adults. The association was also higher for mathematical competences that rely more heavily on the processing of magnitudes (i.e., early mathematical abilities and mental arithmetic ) than for others (i.e., more general curriculum-based tests).

Schneider, Merz, Stricke, De Smedt, et al. (submitted) performed a similar meta-analysis for the association between people's score on the other main task to assess numerical magnitude processing skills, namely the number line estimation task, and mathematical competence. Using exactly the

same analytic procedure, and working with a set of 37 studies, they found that the correlations with mathematic competence - both in general and for particular parts of the curriculum - were significantly higher for number line estimation than for symbolic magnitude comparison or for non-symbolic magnitude comparison. Whereas the correlations did not substantially increase with age for comparison, an increase with age was found for number line estimation, which suggests that different underlying cognitive systems and processes are involved in magnitude comparison vs. number line estimation.

Furthermore, researchers working within this research tradition have tried to stimulate children's mathematical skills with (game-based) intervention programs that were (primarily or exclusively) aimed at enhancing their numerical magnitude understanding before or at the beginning of formal instruction in number and arithmetic in elementary school. While some intervention studies have resulted in positive effects (e.g., Kucian, Grond, Rotzer, Henzi, et al., 2011; Ramani & Siegler, 2011; Wilson, Dehaene, Dubois, & Fayol, 2009), the overall results are mixed (Torbeyns et al., 2015).

Being well aware of the prominence of this line of research in the international research of early mathematics education, the IPC of the 23<sup>rd</sup> ICMI study on "Whole number arithmetic" invited one of the leading scholars in that line of research, namely Brian Butterworth, as a plenary speaker of the conference, which took place in June 2015 in Macau, China. In his plenary lecture Butterworth (2015) presented a very informative overview of this cognitive (neuro)scientific line research, and strongly defended this research in the working groups and panels wherein he participated. However, at that conference, it also became clear that the dominant picture of early mathematical competences and education in current mainstream (neuro)cognitive research is dangerously narrow. In the present paper, we will try to broaden that picture in multiple ways. In doing so, we will partly rely on recent and current work done in our own research group, but also on the work of many colleagues who have been active in the field of early mathematics education during the past decade(s).

## **The ordinal and measurement aspect of number**

A first important feature of the line of research summarized above is its focus on the cardinal aspect of number, or, to state it differently, its neglect of other constituent aspects of number, particularly its (1) ordinal and (2) measurement aspect. Hereafter we discuss these two neglected aspects.

The distinction between the *ordinal* and cardinal aspect of number knowledge is well known. Whereas cardinality refers to the capacity to link number symbols to collections, e.g., to know that four or 4 is the correct representation to denote a group of four objects, ordinality refers to the capacity to place number words and numerals in sequence; for example, to know that 4 comes before 5 and after 3 in the sequence of natural numbers. Given the wide recognition of the importance of ordinality for the constitution of number since Piaget (1952) developed his theory of children's concept of number, it is remarkable that, until recently, the ordinality aspect of number seems largely neglected in the above mainstream cognitive neuroscientific conceptualization, assessment and instruction of early numerical abilities.

Interestingly, recent neuroscientific evidence shows that accessing ordinal information from numerical symbols (e.g., decide whether three numbers are in order of size) relies on a different

network of brain regions and shows qualitatively different behavioral patterns when compared to the cardinal processing of magnitudes or numerical symbols or to the ordinal processing of perceptual magnitudes (Lyons & Beilock, 2011, 2013). And, how well a child is able to reason about ordinal relations between number symbols has been found to be one of the strongest predictors of mathematical skill such as mental arithmetic (Lyons, Price, Vaessen, Blomert, & Ansari, 2014) – much stronger, by the end of the first grade of elementary school, than non-symbolic or symbolic cardinal processing as measured by the numerical magnitude comparison task. So, the idea that emerges from this recent neuroscientific research is that children’s sense of ordinality of number symbols may be distinct from their sense of cardinality and, in terms of developing skills needed for success in mathematics, that ordinality may even be the more significant one (Sinclair & Coles, 2015, see also Vogel, Remark, & Ansari, 2015).

This line of research pointing to the importance of ordinality also led math educators to criticize the mainstream neuroscientific view on how children’s early number sense may be stimulated. The latter view suggests that working on linking symbols to sets of objects may reinforce the very way of thinking that young children need to overcome to become successful in school mathematics. But this is the current practice in many countries, where the emphasis in early mathematics education is firmly on linking number symbols to collections of objects - whether this is done through subitizing or counting. Based on the above theoretical and empirical arguments, Sinclair and Coles (2015, p. 253) asserted that this emphasis on cardinal awareness in learning number is misplaced and argued that what young children above all need is “support to work with symbols in their relationship to other symbols”. This plea for paying more attention to the importance of ordinality has led these authors to the design of an innovative iPad app, *TouchCounts* (Sinclair & Jackiw, 2011) wherein the way numerosities are built, labeled and manipulated does not primarily require sense of cardinality but rather ordinality.

The cardinal emphasis on number knowledge has also been attacked from another, more radical, perspective. In his plenary address at the ICMI23 conference, Bass (2015) described an approach to developing concepts of number using the notion of quantity *measurement*. This approach is not new, of course, and is quite well-known among mathematics educators (see e.g., Brousseau, Brousseau, & Warfield, 2004), even though it has, to the best of our knowledge, hardly led to actual and wide-scale implementation in national curricula.

It has been articulated most prominently by Davydov (1990), a Soviet psychologist and educator, who developed, together with his colleagues, in the 1960s and 1970s, a curriculum for number and arithmetic based on this measurement approach. This curriculum delayed the introduction of number instruction until late in the first grade. Early lessons rather concentrated on “pre-numerical” material: properties of objects such as color, shape, and size, and then quantities such as length, volume, area, mass, and amount of discrete objects, but without yet using number to enumerate “how many”. So, in this approach number is not intrinsically attached to a quantity; rather it arises from measuring one quantity by another, taken to be the “unit:” How “much” (or many) of the unit is needed to constitute the given quantity?

The discrete (counting) context in which whole numbers are typically developed in most approaches to early and elementary mathematics education is characterized by the use of the single-object set as

the unit, so that the very concept of the unit, and its possible variability, is rarely subject to conscious consideration. According to Bass (2015, p. 11), “this choice is so natural, and often taken for granted, that the concept of a chosen unit of measurement need not enter explicit discussion. If number is first developed exclusively in this discrete context, then fractions, introduced later, might appear to be, conceptually, a new and more complex species of number quite separate from whole numbers. This might make it difficult to see how the two kinds of numbers eventually coherently inhabit the same real number line. Indeed, this integration entails seeing the placement of whole numbers on the number line from the point of view (not of discrete counting, but) of continuous linear measure.” (see also Behr, Harel, Post, & Lesh, 1992, for a similar argument coming from the research literature on rational numbers).

According to Bass (2015), this measurement approach has a lot of advantages over the counting based approach, especially if one takes a broader long-time mathematics educational perspective. First, it is a way of providing coherent connections in the development of rational numbers. A second advantage is that it makes the geometric number line continuum present from the start of the school curriculum as a useful mathematical object and concept. Third, the approach provides opportunities for some early algebraic thinking.

The above analysis suggests that it is important to balance cardinal, ordinal and measurement aspects of number in early mathematics education. This requires some serious reflection on the ingrained ways in which cardinality is now privileged in early mathematics education as well as further creative explorations of how the two other elements of ordinality and measurement can be mobilized to promote the development of a broad and balanced number concept.

### **Arithmetic reasoning skills**

It is apparent that the mainstream analysis of early mathematics-related competences has capitalized on measures that emphasize children’s *numerical* competences, i.e., their subitizing skills, counting skills, the ability to compare numerical magnitudes, and the ability to position numerical magnitudes on an empty number line. While such measures provided empirical evidence for the multi-componential nature and importance of young children’s early numerical competences for future mathematical development, they reflect also in another way a restricted view on children’s early mathematical competences.

Starting from Piaget’s (1952) logical operations framework, there is a recent renewed research attention to children’s early arithmetic reasoning skills, such as their understanding of the additive composition of number or their additive and multiplicative reasoning skills, as well as to their importance for later mathematical learning at school (e.g., Clements & Sarama, 2011; Nunes, Bryant, Barros, & Sylva, 2012; Robinson, 2016).

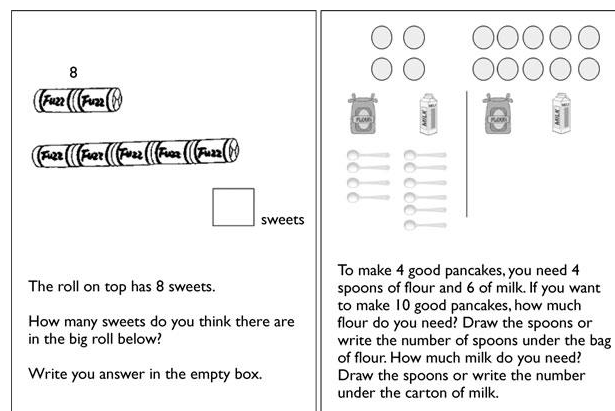

As documented in her extensive review of this research, Robinson (2016) points out that the research on children’s conceptual understanding of these arithmetic concepts is heavily focused on additive concepts, that is, concepts involving the operations of addition and/or subtraction. Various principles including the additive composition of number but also the arithmetical properties such as the commutativity, the associativity, the addition-subtraction inverse, and the addition-subtraction complement principle have been intensively studied, sometimes also in relation to children’s actual

use of these principles in their mental arithmetic (Baroody, Torbeyns, & Verschaffel, 2009; Verschaffel, Bryant, & Torbeyns, 2012). Quite a number of these studies already involve young children at or even before the age of 6-7 years old.

Similar multiplication and division principles have also been investigated, however, to a much lesser extent and with a more restricted developmental range, from late middle childhood to adulthood (Larsson, 2016; Robinson, 2016), which is not surprising given that, for most children, these operations are typically not yet formally introduced in the first grades of elementary school.

Only a few of these studies have explicitly addressed the question of how young children's emergent understanding of these additive and multiplicative principles is predictively related to their (later) achievement in school mathematics, in similar ways as has been done for the numerical aspects of early mathematical competence reviewed in the previous section. The limited available evidence from these few studies suggests that early mathematical reasoning of this sort makes a separate and specific contribution to achievement in school mathematics, even up to several years later (Nunes, Bryant, Evans, Bell, et al., 2007; Nunes et al., 2012).

As an illustration, we refer to the study of Nunes et al. (2012), which used data collected in the context of the Avon Longitudinal Study of Parents and Children (ALSPAC) involving about 4000 pupils, to assess whether arithmetic reasoning makes an independent contribution, besides calculation skills, to the longitudinal prediction of mathematical achievement over five years. Arithmetic reasoning was assessed at the start of children's elementary education (i.e., at 7 years) using a test that included three types of items: additive reasoning about quantities, additive reasoning about relations, and multiplicative reasoning items (see examples in Figure 2).

**Figure 2: Examples of items from Nunes et al.'s (2012) arithmetic reasoning test**

The outcome measures of mathematical achievement were standardized assessments designed to measure school standards by the end of elementary school. Hierarchical regression analyses were used to assess the independence and specificity of the contribution of arithmetic reasoning vs. arithmetic skill to the prediction of achievement in mathematics, science, and English at the end of elementary school, using age, intelligence, and working memory as controls in these analyses. Arithmetic reasoning and skill made independent contributions to the prediction of mathematical achievement, but arithmetic reasoning was by far the stronger predictor of the two. These

predictions were also specific, in so far that these measures were more strongly related to mathematics than to science or English.

In sum, according to Nunes et al. (2012), their findings provide a clear justification for making a distinction between arithmetic reasoning and numerical, counting and calculation skills. The implication for diagnosis and intervention in early mathematics education is that arithmetic reasoning should receive a greater emphasis from the early years in primary school on.

## **Understanding patterns and structures**

In another attempt to identify and explain common underlying early bases of mathematical development and its stimulation, other researchers have looked at mathematical patterns and structures (Lüken, 2012; Mulligan & Mitchelmore, 2009; Mulligan, Mitchelmore, & Stephanou, 2015; Rittle-Johnson, Fyfe, Loehr, & Miller, 2015)

In what can be considered as one of the most enduring, systematic and influential research programs in this respect, based on a series of related studies with diverse samples of 4- to 8-year-olds, Mulligan and colleagues have identified and described a new construct, Awareness of Mathematical Pattern and Structure (AMPS) (Mulligan & Mitchelmore, 2009; Mulligan et al. 2015), that has been shown to be related to children's later mathematics achievement in school.

Mathematical pattern involves any predictable regularity involving number, space, or measure such as number sequences and geometrical patterns, whereas structure refers to the way in which the various elements are organized and related, such as iterating a single 'unit of repeat' (Mulligan & Mitchelmore, 2009). AMPS involves structural thinking based on recognizing similarities, differences and relationships, and also a deep awareness of how relationships and structures are connected.

An interview-based assessment instrument was developed and validated, the Pattern and Structure Assessment - Early Mathematics (PASA) (Mulligan et al., 2015). The PASA yields an overall AMPS score as well as scores on five individual structures: sequences, shape and alignment, equal spacing, structured counting, and partitioning. Some examples of tasks are sequences that have to be extended (e.g., a sequence of colored pearls on a string or a series of triangular dot configurations of increasing size) or structured counting tasks (e.g., counting by two's, counting the number of cells in a partly covered rectangular pattern). Based on the child's response, which may include drawn representations and verbal explanations of patterns and relationships, five broad levels of structural development were identified and described: pre-structural, emergent, partial, structural, and advanced structural (Mulligan & Mitchelmore, 2015). Validation studies indicated that high levels of AMPS were correlated with high performance on standardized achievement tests in mathematics with young students (Mulligan et al., 2015).

In alignment with the assessment of AMPS, an innovative, challenging alternative learning program, the Pattern and Structure Mathematics Awareness Program (PASMAT) was developed and evaluated longitudinally in the kindergarten (= the first year of formal schooling in Australia). This study first showed that kindergartners are capable of representing, symbolizing and generalizing mathematical patterns and relationships, albeit at an emergent level (Mulligan,

Mitchelmore, English, & Crevensten, 2013). The study also tracked and described children's individual profiles of mathematical development and these analyses showed that core underlying mathematical concepts are based on AMPS, and that some children develop these more readily and in more complex ways than others. Finally, this study also involved an attempt to provide an empirical evaluation part involving 316 kindergartners from two schools with and two schools without the PASMMap program. Highly significant differences on PASA scores were found for PASMMap children in comparison to children from the control schools, also for those children labeled as low ability, both at the posttest and the retention test, when children had already moved to Grade 1. On the other hand, there was no significant impact of PASMMap on improving children's mathematical achievement as measured by a general mathematics achievement test.

Other researchers have also performed analyses of (1) elementary school children's perceptions and understandings of patterns and structures, providing nice descriptions and accounts of young children's abilities and difficulties with respect to various mathematical patterns and structures tasks, (2) the predictive value of their mastery of pattern and structure for their later mathematical, i.e. algebraic proficiency, and (3) how instruction on patterns and structures can not only transfer to similar and other patterns and structures, but also to other mathematical domains such as ratios, and mathematics achievement in general (for an overview, see Rittle-Johnson, Fyfe, Loehr, & Miller, 2015).

Of course, the idea that patterns and structures play an important role in the learning of mathematics, and should play an important role in its teaching, is not new (Orton, 1999). After all, is the definition of "mathematics as a science of patterns" (Müller, Selter, & Wittmann, 2012) not one of our favorite definitions of what mathematics is all about? The critically new element in the research of the work of Mulligan and associates is that they give it such a prominent role in their diagnostic and teaching materials for early mathematics. In doing so, they contribute to broadening the picture of what (early) mathematics is all about – a picture that is largely undervalued in current early and elementary school mathematics with its strong focus on learning about numbers and arithmetic facts and procedures.

### **Spontaneous focusing tendencies**

The studies and views on the early development of children's mathematical competence reviewed so far typically take a purely "ability" perspective. In doing so, they neglect other aspects of young children's early mathematical competence, such as their attention to or feeling for, numerical magnitudes, mathematical relations, or mathematical patterns and structures. During the past decade, researchers have started to explore children's spontaneous tendency to focus on numerosity (SFON), its development, its cultivation, and its predictive relation to children's later mathematical achievement (Hannula & Lehtinen, 2005). To a lesser extent, similar attempts have been done for quantitative relations (SFOR) and, even much less, mathematical patterns and structures (SFOPS).

These SFON, SFOR or SFOPS tendencies are not about what children think and do *when they are guided to* the mathematical elements, relations or patterns in the situation, but *what they spontaneously focus on* in informal everyday situations. SFON assessment instruments must therefore capture whether children spontaneously use their available number recognition or

quantitative or mathematical reasoning and patterning skills in situations where they are not explicitly guided or instructed to do so. So, the instruments used to assess these spontaneous focusing tendencies must meet several strict methodological criteria (Hannula & Lehtinen, 2005).

As far as SFON is concerned, the most frequently used task so far is the Elsi Bird Imitation task, wherein the child is instructed to imitate the experimenter's play behavior with toys, i.e., feeding berries into the beak of a toy parrot. A SFON score is given on an item as soon as the child is observed doing or saying something that shows that he or she has spontaneously attended to the quantitative aspect of the situation. Meanwhile several other SFON tasks have been developed, such as the Picture Description task, with cartoon pictures displaying both non-numerical and numerical information and the request to tell what is in the picture. If the child spontaneously refers to the exact numerosities - correct or not – in his or her verbal descriptions of the pictures, (s)he gets a SFON score (for an overview and critical discussion of SFON measures, see Rathé, Torbeyns, Hannula-Sormunen, De Smedt, & Verschaffel, 2016).

Observations of children's activities in SFON assessment indicated that already at the age of 3-4 years children can be spontaneously engaged in mathematically relevant practices in their everyday environments (Hannula & Lehtinen, 2005). This research also revealed great inter-individual differences in children's tendency to spontaneously focus on number. It further showed that children's SFON at the age of 5 or 6 is a unique and strong predictor of later development of mathematical skills even up to the end of elementary school. The hypothetical explanation for these findings is that children who spontaneously focus on the numerical aspects of their environment in everyday situations get much more practice of magnitude recognition, number comparison, combining of numbers, etc. than children who only do this when explicitly instructed by parents or teachers. SFON may support the development of numerical skills and more elaborated numerical skills may further strengthen the SFON tendency. However, convincing direct empirical evidence for this explanatory mechanism is still scarce (Rathé, Torbeyns, Hannula-Sormunen, & Verschaffel, 2016).

In many everyday activities exact numerosity is not the only mathematically relevant aspect that can be focused on. In young children's daily life there are many opportunities to focus on more complex quantitative aspects, such as quantitative relations. Children can also recognize and use mathematical or quantitative relations without explicit guidance to do so. Based on a series of studies, McMullen, Hannula, and Lehtinen (2013, 2014) proposed that there is a similar tendency to focus on quantitative relations as SFON, which indicates that instead of mere numerosity children and school pupils can also focus spontaneously on quantitative relations (SFOR). McMullen and colleagues (McMullen, Hannula-Sormunen, Laakkonen & Lehtinen, 2016; McMullen, Hannula-Sormunen, & Lehtinen, 2013; McMullen, Hannula-Sormunen, & Lehtinen, 2014). designed the Teleportation Task to measure SFOR. This task involves a cover story telling that a set of supplies containing three sets of objects was sent from earth through space with a teleportation machine. However, when doing so, the objects are transformed. Children are asked, first, to describe the transformation in their own words in as many ways as possible, and, second, to draw what they expect to happen with a different numerosity of the same objects. When describing or drawing the transformation, learners can pay attention to the various non-mathematical changes (e.g., in terms of

the colors or shapes of the objects), but also to the quantitative relation between the original and final numerosity of the three sets. The results of the longitudinal study of McMullen, Hannula-Sormunen, Laakkonen, and Lehtinen (2016) showed that there were substantial individual differences in students' SFOR tendencies. It also revealed that SFOR tendency had a unique predictive relationship with rational number conceptual development in late primary school students during the 2-year follow-up period.

Interestingly, in their conceptualization of AMPS, Mulligan and Mitchelmore (2009) also tend to go beyond the pure ability aspect of early mathematical competence, by stating that AMPS may consist of "two interdependent components: one cognitive (knowledge of structure) and one meta-cognitive, i.e., "spontaneous" (a tendency to seek and analyze patterns)" (p. 39). According to these authors, both are likely to be general features of how children perceive and react to their environment. However, neither in their assessment nor in their intervention materials, they have already tried to specifically and explicitly address this spontaneous focusing aspect.

## **Early mathematics and executive functions**

In the previous sections, we have discussed various kinds of domain-specific competences that all have been claimed, and in many cases been shown, to be predictively related to general mathematical competence or to knowledge and/or skill in specific subdomains of the mathematics curriculum. However, it is a well-established research finding that formal mathematics achievement is also influenced by domain-general processes, such as sustained attention, inhibitory control, cognitive flexibility, working memory capacity, and - even more generally - intelligence (Bull & Scerif, 2001; De Smedt, Janssen, et al., 2009; Friso-van den Bos et al., 2013; LeFevre et al., 2010; Peng, Namkung, Barnes, & Sun, 2016).). While most of that research evidence comes from research with older participants, there is increasing evidence on the importance of executive functions in early mathematical thinking and learning too.

In one line of research, authors have analyzed the relative importance of general executive skills as compared to the role of domain-specific early numerical competences in predicting concurrent and later mathematical development. For instance, in a longitudinal study wherein we followed children during the first grades of elementary school, we were able to show that working memory at the start of primary education was predictively related to individual differences in mathematics achievement six months later in Grade 1 and one year later in Grade 2 (De Smedt, Janssen, et al., 2009). Interestingly, overviewing the research, Bailey et al. (2014), concluded that the contribution of domain-specific factors, such as children's early numerical competences to their later mathematical development is relatively small compared to these more stable domain-general factors, such as intelligence and working memory.

The relation between these executive functions and mathematical performance may also be more specific in nature. Research has revealed specific relations between certain executive functions, such as inhibition or working memory, on the one hand, and specific mathematical competences, such as mental arithmetic or word problem solving, on the other hand. Robinson and Dubé (2013), for instance, investigated the role of inhibition in children's use of the inversion and associativity shortcuts on mental addition and subtraction (e.g.,  $6 + 23 - 23 = ?$ ). Children who demonstrated the

highest use of conceptually-based shortcuts also scored highest on the Stop-Signal task, a standard measure of inhibitory abilities. This finding suggests that these children were able to inhibit their tendency to routinely solve problems from left-to-right and thereby process all of the presented numbers before executing the clever shortcut strategy.

So far, we have discussed the role of executive functions in children's performance on relatively complex mathematical tasks. However, to make the picture about the role of executive functions even more complicated, these executive functions are also assumed to play a critical function in the early mathematical tasks, such as the magnitude comparison task, the SFON tasks, the mathematical reasoning tasks, and the patterns and structures tasks discussed above. Take, for instance, the non-symbolic magnitude comparison task used to assess the approximate number system (ANS) and which lies at the basis of this whole line of research that has led to the pivotal role of the precision of children's early ANS representations in early mathematics diagnosis and intervention (see Section 1). In this task it is important to ensure that participants are basing their judgements on the numerosity of the visual arrays, rather than possible visual cues such as the size of the dots, or the area that the dot arrays cover. As Gilmore, et al. (2013) have argued, in an attempt to control for this possible confound, researchers introduce an inhibitory control aspect to the task, as for half of the items with which the child is confronted inconsistent visual cues must be inhibited to indicate the correct set. But if the non-symbolic comparison task is, in part at least, a measure of inhibitory control, then it is perhaps unsurprising that it is predictive of school-level mathematics achievement, but for other reasons than claimed by the advocates of this task.

Starting from the above research documenting in various ways the involvement of executive functions in mathematical thinking and learning, researchers have also asked the question about the possibility and efficacy of enhancing mathematical thinking and learning through training of these executive skills. At least for working memory, a recent meta-analysis by Schwaighofer, Fischer, and Bühner (2015) led to the general conclusion that attempts to improve working memory only improved performance on working memory tests but failed to improve mathematics achievement.

So, while there is increasing research evidence that, from a very young age on, an association between mathematics and executive functions exists, this complex and multi-aspectual association and its implications for early mathematics education and assessment is not well understood yet. Numerous questions remain (Robinson, 2016; Van Dooren & Inglis, 2015). As (early) mathematics educators we are traditionally not so much interested in these general executive functions. However, for various reasons related to theory, diagnosis and intervention, it may be unwise to neglect them.

### **The role of parents and early caregivers during the preschool years**

As amply shown in the previous sections, before the start of formal mathematics education - typically at the age of 5-6, children already begin their initial explorations into everyday mathematics at home, progressively developing and refining their mathematical knowledge and skills as well as their mathematics-related orientations, beliefs, and affects. However, there is wide variation - linked in part to socio-economic status (SES) and culture - in the kinds of early mathematical learning experiences children have at home and the ways in which they are stimulated and helped by their parents. Further, in many cultures, the majority of young children spend

significant time in non-parental care, including family childcare and organized preschool education (DREME, 2016). Arguably, the quantity and quality of mathematics learning stimulation in these various settings also vary enormously, impacting children's mathematical development. For evident reasons, mainstream cognitive (neuro)psychological research on early numerical competences has paid little or no attention to these informal mathematical learning environments. But also within the mathematics education research community this topic is "under-studied". Indeed, we know relatively little about the role of parents and early caregivers during the preschool years when compared, on the one hand, to the development and stimulation of children's emergent literacy, and, on the other hand, to mathematics education in the higher educational levels. Fortunately, the last few years have witnessed an increased research interest.

First, several researchers have aimed for an understanding of children's preschool experiences at home and of how these experiences affect their early mathematical development. For instance, starting from the well-documented finding that children's early numerical competence before the start of formal schooling is highly predictive of their acquisition of mathematics in (the first grades of) elementary school, several authors have pleaded for a better understanding of children's preschool experiences at home. In a well-known study by Lefevre, Skwarchuk, et al. (2009), the mathematical skills of  $\pm 150$  Canadian children in Kindergarten, Grade 1, and Grade 2 were correlated with the frequency with which parents reported informal activities that have quantitative components such as board and card games, shopping, or cooking on a questionnaire. The results support claims about the importance of home experiences in children's acquisition of mathematics, given that effect sizes were consistent with those obtained in research relating home literacy experiences to children's vocabulary skills. In a more recent and more sophisticated study, Susperreguy and Davis-Kean (2016) analyzed the relation between the amount of mathematical input that preschool children hear from their mothers in their homes and their early mathematics ability one year later. Forty mother-child dyads recorded their naturalistic exchanges in their homes using an enhanced audio-recording device. Results from a sample of naturalistic interactions during mealtimes indicated that all mothers involved their children in a variety of mathematics exchanges, although there were differences in the amount of input children received. Moreover, being exposed to more instances of mathematics talk was positively related to children's early mathematical ability one year after the recordings, even after control for maternal education, self-regulation, and recorded minutes. Finally, starting from the well-documented finding that early numerical competences amongst children vary widely and from the belief that a better understanding of the sources of this variation may help to reduce SES-related differences in mathematics skills, Ramani, Rowe, Eason, and Leech (2015) examined two sources of this variation in low SES families: (1) caregiver reports of number-related experiences at home, and (2) caregivers' and children's talk related to math during a dyadic interaction elicited by the researchers. Frequency of engaging in number-related activities at home predicted children's foundational number skills, while caregivers' talk during the interaction about more advanced number concepts for preschoolers, such as cardinality and ordinal relations, predicted children's advanced number skills that build on these foundational concepts. So, these findings suggest that the quantity and quality of number-related experiences that occur at home contribute to the variability found in low-income preschoolers' numerical knowledge.

Complementary to these ascertaining studies, several intervention studies reported positive effects on children's early numerical and later mathematics performance at school. Again, we can give only a few examples. In a series of high-impact studies with children from low-income backgrounds, who were found to lag behind their peers from middle-income backgrounds already before the children enter school, Siegler and Ramani (2008) found that playing a research-based designed numerical board game for only a couple of hours already eliminated the differences in the two commonly used measures of understanding of numerical magnitudes, namely numerical magnitude comparison and number line estimation. Moreover, in a subsequent study (Siegler & Ramani, 2009), children who had played the number board game also performed better in a subsequent training on arithmetic problems. Thus, playing number board games was found to increase not only preschoolers' numerical knowledge but also to help them learn their school arithmetic. Van den Heuvel-Panhuizen, Elia, and Robitzsch (2016) report on a very recent field experiment with a pretest-posttest control group design, which investigated the potential of reading picture books to kindergarten children for supporting their mathematical understanding. During three months, the children from nine experimental classes were read picture books. Data analysis revealed that, when controlled for relevant covariates, the picture book reading programme had a positive effect on kindergartners' mathematics performance as measured by a test containing items on number, measurement and geometry. Finally, we refer to one of the best known research-based early mathematics programs, namely the Building Blocks (BB) program of Clements and Sarama (2011). This program, which is organized into five major strands: (numeric, geometric, measuring, patterning, and classifying and data analyzing), consists of daily lessons where children are encouraged to extend and mathematize their daily experiences through sequenced activities, games, and the use of technology. The daily lessons are organized in whole group activities, small group activities, free-choice learning centers, and reflection time. The program is complemented with a parallel in-service teacher training program. Studies on the effectiveness of the BB intervention program (Clements & Sarama, 2007, 2011) demonstrated that 3- and 4-year-olds who received the BB intervention program developed stronger mathematical abilities than children in the control group, with effects lasting up to the end of first grade. Bojorque (2017) recently successfully implemented the BB program in the Ecuadorian context, with significant effects on the quality of the kindergarten teachers' pedagogical actions as well as on children's progression both on a standard mathematics achievement test based on the national K3 curriculum and on their SFON.

The findings emerging from all these observational, correlational, and intervention studies are very informative for the design of educational environments and activities aimed at increasing young children's mathematics learning - far beyond the rather narrowly oriented (computer) games aimed at stimulating children numerical magnitude representations that have been derived from the cognitive neuroscientific line of research. But still a lot of work needs to be done to further advance knowledge on effective ways to increase parents' and professionals' engagement in preschoolers' mathematics learning, particularly in children growing up in poverty and/or in contexts of unfavorable immigration.

## Preschool to elementary school transition

As explained in the previous sections, a large number of factors in the young child and in its home and caretaking environment have a strong impact on the ease with which (s)he will take the step to formal mathematics education at the age of 5-6 (depending on the country or culture) and profit from the elementary school mathematics curriculum. However, the child's mathematical development and achievement will evidently also be significantly affected by the quality of the transition from preschool to elementary school (see also Gueudet, Bosch, diSessa, Kwon, & Verschaffel, 2016).

Interestingly, researchers working on this theme typically take a much broader theoretical stance than the cognitive (neuro)scientific researchers who look for the elements in children's domain-specific and domain-general competences that are predictively related with success in school mathematics. Their inspiration comes from socio-cultural, sociological, anthropological, and critical mathematical theories (Dockett, Petriwskyj, & Perry, 2014; Perry, McDonald, & Gervasoni, 2015).

The transition from prior-to-school to school mathematics is primarily conceived by these researchers as a set of processes whereby individuals "cross borders" or undergo a "rite of passage" from one cultural c.q. educational context or community to another and, in doing so, also change their role in these contexts or communities. Dockett et al. (2014, p. 3) provide the following summation of this approach: "While there is no universally accepted definition of transition, there is acceptance that transition is a multifaceted phenomenon involving a range of interactions and processes over time, experienced in different ways by different people in different contexts. In very general terms, the outcome of a positive transition is a sense of belonging in the new setting." There is growing research evidence that developing practices that promote effective transitions, and that strive for giving agency of all involved and rely on the "Funds of Knowledge" available in children's home and local environments, results in positive effects - although most of this research is more qualitative and descriptive in nature and thus not primarily interested in following strict experimental designs and providing "hard" statistical data. A nice overview of this broader transition perspective is provided by Perry et al. (2015).

In an interesting newly funded project, Andrews and Sayers have begun to examine how two systems, England and Sweden, facilitate the early mathematical competences, and more specifically their foundational number sense (FoNS) (Andrews & Sayers, 2015), of children starting in Grade 1. Currently the project team is comparing the FoNS opportunities found in commonly used textbooks in the two countries (Löwenhielm, Marschall, Sayers, & Andrews, 2017a). Simultaneously the team has been interviewing first grade teachers in the two countries about their role as well as their perceptions of their pupils' parents' roles in the development of children's FoNS-related competence. Initial analyses (Löwenhielm, Marschall, Sayers, & Andrews, 2017b) have identified both similarities and considerable differences in the relationship between the school and home environment between the two countries.

It is a general complaint among stakeholders of early mathematics education that mathematics learning in preschool is often disconnected from the first grades of elementary school. This disconnect, which is particularly relevant for lower SES and immigrant children, can lead to

children experiencing uneven instructional practices, which can compromise their mathematical development in elementary school. So, policy makers, curriculum developers, teacher trainers, etc. should work toward creating greater alignment of and coherence between preschool and elementary school mathematics education, using research-based insights and recommendations. Unfortunately, there is still limited research on the impact of these policies and practices on the learning experiences and learning outcomes of children moving from preschool through the early elementary grades.

## **Professional development of caregivers and teachers**

In the previous section, we emphasized the importance of a high-quality mathematical learning environment in the preschool years, the first years of elementary school, and the transition between the two. Evidently, this requires highly professional (mathematics) teachers, i.e., “teachers who know the content, who understand children’s thinking, who know how to engage in pedagogical practices that support learning, and who see themselves as capable math teachers” (DREME, 2016, p. 4).

At the same time, many teachers and caregivers in the early care and education field may not be adequately equipped to provide appropriate math-related experiences and instruction to these young children. Research suggests that many practitioners working with preschool, kindergarten and early grade children (1) are themselves not competent in mathematics, (2) have important shortcomings in the pedagogical content knowledge, particularly with respect to the components of the early math curriculum beyond counting, number, and simple addition and subtraction, and/or (3) do not see themselves as competent in mathematics (see e.g., Lee, 2010). And, even if practitioners are mathematically capable and do view themselves as such, they may still hold pedagogical reservations against teaching mathematics to young children, believing that early childhood programs should focus primarily on social emotional and literacy goals (Platas, 2008).

While these problems have shown to be partly due to these professionals’ restricted mathematical talents and negative earning histories in elementary and secondary education, research also indicates that the nature of the pre-service and in-service training they received does not greatly help to overcome these problems. As DREME (2016, p. 4) argues: “Professional teacher preparation programs rarely address how to identify the wide range of informal mathematical understandings that young children bring with them to the classroom, or how to translate these into intentional, individualized math experiences for children with diverse backgrounds and needs.” Indeed, surveys of early childhood education degree programs (e.g., Maxwell, Lim, & Early, 2006) reveal that early education practitioners are exposed rarely to high-quality pre-service or in-service courses that address children’s mathematical development, or the pedagogical content knowledge necessary for supporting it.

We emphasize that the above analysis is largely based on critical reflections upon the situation in the US. So, the situation may be better in other places in the world, although there are good reasons to restrain from being too optimistic, because the above observations about early math teachers’ professional knowledge and beliefs and previous educational histories seem to hold, at least to some extent, for many other countries too.

To support the training of prospective and practicing early childhood teachers, there is a need of creating and implementing research-based modules for professional development that can be used in a variety of pre-service and in-service settings (DREME, 2016). The way forward for research is to attempt to figure out what are the key levers of professional development that might effect significant change in the quality of early math education and its learning outcomes. Given the above-mentioned depiction of the complex and multi-sided nature of caregivers' and early math teacher's professional knowledge base, it seems reasonable to expect the greatest effect from modules that do not focus on one single aspect of professionalism but work on the development of early math related knowledge, skills and beliefs, and that convey the idea that early mathematics is more than teaching young children some basic number knowledge and counting skills.

## Conclusion

Inspired by developments in the field of neuroscience (e.g., Butterworth, 2015), the past two decades have witnessed the emergence of a very productive and highly influential line of (neuro)cognitive research on children's early number sense, its development, and its relation to school mathematics. Cross-sectional and longitudinal studies have demonstrated that various core elements of children's early mathematical ability - especially their numerical magnitude understanding, their subitizing and counting skills, and their ability to transcode a number from one representation to another - are positively related to concurrent and future mathematics achievement (Torbeyns et al., 2015).

However, other research, most of which is situated in other scientific circles and relying on other theoretical and methodological perspectives, has yielded increasing evidence for uniquely significant relations of mathematical achievement also with (1) young children's understanding of ordinal and measurement aspects of number, (2) their abilities related to mathematical relations, patterns and structures, and (3) their tendency to spontaneously attend to numerosities and to mathematical relations, patterns, and structures in their environment, and has confirmed the important role of domain general executive functions.

Moreover, researchers have started to explore and analyze the rich variety of early mathematical learning environments at home, in preschool and kindergarten settings, as well as the coherence between these informal learning settings and the first years of elementary school mathematics, with special attention to the professional quality of the early caregivers and teachers. Also, they started to set up various kinds of intervention studies aimed at the improvement of the quality of these environments and of the professionals operating in these environments. These studies have yielded evidence on the short- and long-term benefits of such attempts to provide high-quality early mathematics education in preschool settings and in the transition from preschool to elementary school.

While the small-scale, short-term and focused experimental intervention programs derived from the (neuro)cognitive research on early numeracy have their value in enhancing our theoretical insight into numerical cognition and learning, practitioners active in the field of early mathematics education may profit more from the studies describing the design, implementation, and evaluation of large-scale and more broadly conceived intervention programs that combine and balance several

of the elements that have been found to be foundational for future mathematics learning (see Sections 2-6) and that also integrate aspects of teacher development, working with parents, and community building (see Sections 7-9), with the *Building Blocks* program of Clements and Sarama (2007) and the *Pattern and Structure Mathematics Awareness Program* of Mulligan et al. (2013) as the most visible and successful examples. Still, as math educators, we should continue to follow, with an open but critical mind, the cognitive neuroscientific research on mathematical cognition and, equally important, also try to have an impact on their research agenda (De Smedt et al., 2011).

As a result of all this research, there is a lot of practically useful new knowledge, techniques and resources to promote young children's math learning. Still there remains much to learn about how to optimally enhance math learning at home and at school in the preschool years and about how to help teachers to be well prepared for delivering high-quality instruction to those young children, particularly the weaker ones. In this respect, we should applaud - and may-be also strive for an European counterpart – of the recent initiative called the DREME Network in the US, which is aimed at developing new researchers and enticing current elementary math education, child development, and policy researchers to expand their work to include young children's mathematical learning.

### Acknowledgment

The authors want to thank Paul Andrews, Mariolina Bussi, and Jeremy Hodgen for their comments on earlier versions of this paper.

*This paper presents the contributions of the participants at the CERME10 panel, as well as some of the questions raised during the discussion. Our main aim is to examine the notion of solid finding in mathematics education, the theoretical and methodological assumptions underlying their establishing and the degree of agreement (and disagreement) they provoke. We will consider their possible utilities and weaknesses, even jeopardies, taking into account two different standpoints: how solid findings are identified and what kind of common ground they rely upon; what are solid findings for, how can they be useful and what could be their risks or adverse effects. The panellists will adopt different perspectives on the topic, focusing on the specific selection of solid findings proposed by the Committee on Education of the European Mathematical Society, approaching the problem of the methodologies and use of psychometric models; questioning the use of evidence in policy development and curriculum evaluation.*

*Keywords: Mathematics education, solid findings, criteria, empirical proof, concept images, measurement, reliability, validity, invariance, math anxiety, statistics anxiety, PISA.*

### **Solid findings in mathematics education: A necessary discussion**

Marianna Bosch

Proposing to collectively discuss on ‘solid findings’ in mathematics education at CERME10 was certainly motivated by the initiative of the Education Committee of the European Mathematical Society (EMS) to start publishing a series of articles on ‘Solid findings in mathematical education’ in 2011 ([http://www.euro-math-soc.eu/ems\\_education/education\\_homepage.html](http://www.euro-math-soc.eu/ems_education/education_homepage.html)). This can be interpreted as an audacious attempt to establish a stable account of our young discipline, which otherwise might appear as made of too diverse principles, approaches and perspectives. It is thus supposed to facilitate the approach by people from the outside, especially mathematicians and teachers, by giving more visibility of the type of questions approached and the results obtained. Inside the discipline, it also appears as an effort to organise and elaborate a provisional common hard core (in the sense of Lakatos) of sound and relevant knowledge, without denying the provisional and dynamic nature of the considered findings.

Taking the EMS project and its products as initial motivation, the aim of the panel is to examine the notion of solid finding, the theoretical and methodological assumptions underlying studies on solid findings and the degree of agreement (and disagreement) they might provoke. We propose to consider the possible utilities and weaknesses, even jeopardies, of the reports on solid findings, taking into account two different standpoints: (1) how solid findings are identified and what kind of common ground they rely upon; (2) the purpose of solid findings, their potential utility, and also their possible risks or adverse effects.

The aim of the panel was thus to open a debate on controversial questions like:

- (1) What is a solid finding in Mathematics Education? What criteria are used to select them? Who decides whether a finding is solid or not? Are solid findings linked to specific methodologies, theories or approaches? Can they be contested and how? What kind of evidence is required? Is it the same kind of evidence for the different ‘findings’?
- (2) What is the purpose of identifying solid findings? What are they for? How can they be useful? Are they necessary for teacher education? Could they help to give more visibility to our field and to negotiate with educational decision makers? Can there be a risk of disseminating false ‘weak’ solid results instead of disseminating the persistent questions addressed from research in mathematics education – which do not always coincide with those raised by the actors of the educational system (teachers, students, parents, decision makers, etc.)?

During the discussion among the participants at the panel session, the question of the diversity of theoretical perspectives was raised on various occasions. It is clear that solid findings are always anchored in a given research approach or paradigm (a set of close theories sharing the main theoretical principles or assumptions). Agreement on solid findings thus supposes agreement on these main assumptions too. This does not seem to be – at the moment – the historical situation of the research community in mathematics education, where a diversity of approaches coexists without a common shared ground. Not only the type of results provided by these approaches are different, but mainly the type of research questions asked, the methodologies used, and even the empirical units of analysis considered. If solid findings are presented without mentioning the approaches where they have been produced, we run the risk of interpreting solid findings as if they came from an a-theoretical perspective (or from a fully shared one), which is in fact a way of giving preponderance to the already dominant approaches in detriment of the less disseminated ones.

Other questions related the issue of solid findings to the problem of the dissemination of results. If solid findings should be closely contextualised within a given theoretical framework – or research perspective –, how to make them accessible to people not knowledgeable of the framework? To what extent, and under what conditions, could solid findings be extended to include frameworks? The question varies of course if we think about disseminating research outcomes outside the field, or about highlighting what are seen as important milestone in the evolution of the field, for instance to build the basis for productive debates.

Furthermore, participants also indicated that it is important to avoid not only taking the theoretical ‘load’ of solid findings for granted, but also to pay attention to the *values* they implicitly carry on, for instance, about the purpose of education, the purpose of research on mathematics education or

about the corresponding specific epistemology or conception of science. For instance, the choice of the term ‘finding’ seems related to a somewhat naturalistic perspective – the scientific discovery of a pre-existent reality –, while other options such as ‘claims’, ‘proposals’ or ‘questionings’ (in the double sense of raising questions and questioning the status quo) would entail other connotations. In this sense, maybe the dimension of problematizing can also be a possible direction to work with.

In fact, one of the questions from the audience addressed the issue of the relationships between solid findings, persistent phenomena and educational problems: Are solid findings restricted to phenomena that persist? Is it also possible to have a solid finding that eliminates a problem? In other terms, because advancing research also modifies our ways of problematizing reality, solid findings can also make some problems appear as simple difficulties that can be overcome, or as consequences of other factors to be approached. In the other sense, a solid finding can also consist in the awareness that a problem has no solution – at least in the framework where it is formulated.

The establishment of solid findings as such was also referred to by some participants. Some of them wondered if it is possible to identify some steps to help establish solid findings and build upon them more systematically. Others asked about efficient ways of guaranteeing cumulative research efforts, such as the replicability of the solid findings, which was proposed as a possible research avenue to pursue. One should not see naivety in this kind of demands – as if we were asking for ‘recipes’ –, but on the contrary, interpret them in terms of a reflection on the research methodologies followed (in terms of validity, truthfulness, reproducibility, etc.) and the level of exigence put on them. To enrich the debate, some participants provided related materials or counterexamples to this kind of reflexion, such as the U. S. webpage “What Works in Education” (<http://ies.ed.gov/ncee/wwc/>) or the special issue of the International Journal of Research & Method in Education (2016) *Is the Educational ‘What Works’ Agenda Working? Critical Methodological Developments*, including a paper on review procedures to optimise reviews’ impact and uptake (Green, Taylor, Buckley, & Hean, 2016).

The three contributions that form the core of this paper address some of the issues raised from very diverse – and complementary – perspectives. Tommy Dreyfus, a member of the Education Committee of the EMS and co-author of some of the ‘solid findings’ articles, provides a very interesting account of two moments of reflection of our community around the issue of ‘results’ or ‘findings’ in mathematics education, and their related projects. He also presents two examples of ‘solid findings’, showing the criteria used to identify them and also some of the limitations of the efforts made. He argues for a collective effort toward the products of more systematic reviews on different topics or approaches, as a way to increase the impact of research outside the field but, also, to “establish and organize mathematics education as scientific discipline and to determine where we come from, where we are and where we might go as a research community”. From a completely different side, Caterina Primi, an expert in the field of quantitative educational research, addresses the methodology problem – measurement tools to support rigorous research designs – for findings to be ‘solid’ or, in statistical terms, ‘robust’, ‘reliable’ and ‘unbiased’. Even if the example taken and the questions raised are only related to quantitative methods – where statistical tools are more commonly applied –, the reader can do the mental exercise of transposing them to qualitative as well as theoretical studies to see how demanding the research work to make knowledge develop can be. Finally, Gerry Shiel, National (Ireland) Project Manager for the OECD PISA 2015 Study,

tackles what can be called the ‘impact issue’ of educational research, considering the PISA phenomenon, which is maybe the source of the most practical and political pressures nowadays in almost all countries. The relationships between ‘solid finding’ and *evidence-based decision making* provides a rich paradigmatic example and reminds us how intricate is the situation, especially when raw data is proposed without any protection from the procedure followed to generate it and the theoretical framework, including political ideologies, that underlies its generation.

To end this introduction, let me quote the British sociologist Martin Hammersley (2011) who, in his book on methodology, notes how extremely demanding it is to achieve the ‘threshold of likely validity required by academic work’ (p. 8). After presenting ‘dedication’, a ‘heightened sense of methodological awareness’ and ‘objectivity’ as important virtues for the researcher, the author recalls that, besides these individual virtues:

[The] collective character of enquiry places additional obligations on researchers, as regards how they present their work, how they respond to criticism and how they treat the work of colleagues. In large part, what is required is that academic research takes place within an enclave that is protected from the practical considerations that are paramount elsewhere. [...] In other words, academic discussion must be protected from political and practical demands, so that the consequentiality of proposing, challenging, or even just examining particular ideas or lines of investigation is minimised. [...] [While] the ‘findings’ of particular studies should be made public within research communities, they should not be disseminated to lay audiences. What *should* be communicated to those audiences, via literature reviews and textbooks accounts, is the knowledge that has come to be more or less generally agreed to be sound within the relevant research community, through assessment of multiple studies. (Hammersley, 2011, p. 10)

I am not sure if the field of mathematics education has already reached a sufficient level of development to agree on what can be globally accepted as sound and relevant knowledge, and thus to identify, elaborate and disseminate ‘solid findings’ to lay audiences. However, I am certain that the community of research in mathematics education is mature enough to initiate a productive debate on this, as a way to make different research perspectives interact in a productive way. The effort of gathering, summarising, organising, and discussing the research produced about certain big questions or issues – as the one undertaken by the EMS Educational Committee – appears nowadays as an endeavour that cannot be postponed.

## What are solid findings in mathematics education?

Tommy Dreyfus

*Relying on earlier studies by an ICMI Study and the Education Committee of the EMS, the question what the term ‘solid finding’ might mean with respect to mathematics education is discussed and criteria are proposed. Examples are provided for solid findings that mathematics education research has produced.*

### Introduction

Mathematics education as a research community has grown over the past approximately 50 years: ERME, The European Society for Research in Mathematics Education is approaching its 20<sup>th</sup> anniversary in 2018 – CERME1, the first conference took place in Osnabrück, Germany, in August, 1998. PME, the International Group for the Psychology of Mathematics Education has held its 40<sup>th</sup> annual conference in 2016 - the first one took place in 1977 in Utrecht, The Netherlands. JRME, the *Journal for Research in Mathematics Education*, is now producing its 48<sup>th</sup> annual volume, and ESM, *Educational Studies in Mathematics* is currently in its 50<sup>th</sup> year of publication since Volume 1 appeared in 1968. One of the characteristics of research results in (mathematics) education is that they depend on the context in which the research has been designed and carried out. Nevertheless, after 50 years, one would expect the community to be able to make statements that go beyond “it depends on the context and the learning environment”, which is often implicit in the results of even high quality research articles. Review articles could be expected to remedy this situation to some extent but few review articles are published in the domain.

### What are the results of research in mathematics education – ICMI Study 8

The question whether we, as a research community, have obtained results with a certain scope, range or breadth of validity and what these results are, has been approached at least twice, once in the framework of the study conference of ICMI Study 8 in 1996 (ICMI stands for the International Commission on Mathematical Instruction), and a second time in the framework of the Education Committee of the European Mathematical Society (EMS) in 2011.

The task assigned by ICMI to the Study 8 program committee was to discuss *what is research in mathematics education and what are its results*. The title of the book published two years later as outcome of the study is *Mathematics Education as a Research Domain: A Search for Identity* (Sierpinska & Kilpatrick, 1998). Maybe significantly, the word ‘results’ has disappeared in the process. Nevertheless, one of the working groups at the study conference dealt with results (Dreyfus & Becker, 1998). One of the questions the working group dealt with was what counts as result; the term ‘solid’ did not appear. Rather, ‘result’ was interpreted as ‘significant result’.

Working group members agreed that without a question, there can only be facts but no results. Results are more than data: They are based on data collected with questions in mind that have been asked within a theoretical framework, and consist of findings interpreted in that theoretical framework. Effects alone (e.g., statistical differences in achievements between different groups) are not results. In mathematics education, we need to *explain* the differences, not only show them. We

need to identify the variables of the didactic situation in order to combine the different facts into a coherent network of reasons, which informs the circular process of understanding the learning of mathematics and thus improving its teaching. Hence, results are often theoretical as well as experimental. Many of our theoretical frameworks are mathematics-specific (e.g., process, object, procept), and therefore our research questions and results are often domain-specific.

Context was seen as relevant with respect to theory as well as beyond: mathematical context (contents, concepts, symbols, representations and epistemological status), the community, the educational system, among others. Results might be tied not only to the theoretical framework but also to the institution that asked the question. It is not the result itself, but the conditions under which it was obtained, that make it significant.

The contextual nature of results implies that results are neither universal nor eternal, that their validity is situated in space and time, and that we have to be careful when trying to generalize. The validity of a result depends on the interpretation within a theory, and the theory might change with time and place, with mathematical content, learning environment, and so on. Hence results are permanent but their relevance might be ephemeral.

### **Characterising solid findings**

It is on this background that the members of the Education Committee (EC) of the European Mathematical Society (EMS) asked themselves what solid findings mathematics education has produced. While the question was motivated by the intention of the committee to present mathematics education to mathematicians, in particular to EMS members, with an interest in mathematics education, committee members were well aware that the exercise of identifying solid findings contributes to establishing and organizing mathematics education as scientific discipline and to determining where we come from, where we are and where we might go as a research community.

Of course, the first, and possibly most difficult task of the EC was to discuss, agree and explain what they meant by ‘solid findings’. A major difficulty in defining what it means that a result is solid is the context dependence, mentioned above. A second and related difficulty is complexity. As we know well, things are more complex than one might think; we know, for example that the mathematics taught and learned in parallel classes with a similar population according to the same curriculum may be quite different (e.g., Even & Kvatinsky, 2010; Pinto, 2013). A third, and of course also related difficulty is that much of the research in mathematics education is qualitative. Since qualitative empirical research cannot be repeated in a strict sense, reproducibility is replaced by the question how close the results are that one obtains in similar contexts; and the answer to this question of course depends on the metric used to measure closeness. This lack of reproducibility may appear as a serious drawback of mathematics education’s claim to be a scientific discipline; however, reproducibility has recently been shown to be very low even in many hard sciences such as physics, chemistry and engineering (Baker, 2016).

Aware of these difficulties and with the ICMI 8 study characterization of (significant) results as background, the EC has observed that results with the potential of being considered solid usually do not stand alone but have emerged from a line of research consisting of a larger set of related studies.

Solid findings are typically yielded by such a line of studies. Next, the EC has built on three properties of research quality proposed by Schoenfeld (2007 – see there for a much more detailed discussion): trustworthiness, generality and importance. Each of these contributes to the solidity of research results. A characterisation adapted to the purposes of the EC was agreed upon and published in the Newsletter of the EMS (Education Committee of the European Mathematical Society, 2011a). I summarize this characterization here, adapting and supplementing it for the purposes of the present CERME panel.

Trustworthiness includes the explanatory power of research, its rigor and specificity, and whether it makes use of multiple sources of evidence. However, a study may be trustworthy but trivial, in terms of generality or importance.

Generality (or scope) refers to the question: What is the scope or generality of a research result? How widely does this finding, this idea, or this theory apply across content domains, learning contexts, cultures, etc.? For example, did researchers, in different countries and school systems obtain comparable or related empirical results? Do theoretical constructs turn out to be useful beyond the bounds of the individual studies in which they were developed?

Trustworthiness and generality together are expected to impart some predictive power to a result. A result that has no predictive power cannot be considered solid. On the other hand, the difficulties mentioned above, such as context dependence, will usually limit this predictive power. If a result is used to predict an outcome in a new context, and the prediction failed, a trustworthy explanation of the failure may in fact increase the solidity of the result.

Importance addresses the question: Does it matter? What is the (actual or potential) contribution of the research to theory and practice. Of course, importance is to a large extent a value judgment. As in any other field of study, beliefs about what is essential and what is peripheral are not static but change over decades, reflecting trends both within and beyond the discipline. Hence recognition of the significance of the result by experts contributes essentially to the solidity of a result.

The term ‘solid’ may remind the reader of the term ‘robust’ often used in related situations. ‘Robust’ often has a technical meaning that refers to a finding having been repeatedly observed or confirmed in many studies reporting the same or similar results leading to the same (general) conclusions (see Primi, below). The term solid has been chosen intentionally, to refer to results rather than findings, and imply that robustness in the technical sense is not possible, nor maybe desirable, in mathematics education.

While robustness can be defined and hence (dis-)proved, solidity cannot. The above is a characterization or description – not a definition. Hence, solidity cannot be proved but it can definitely be argued by on the basis of the above criteria of significance, trustworthiness, generality and adaptability to context.

## Examples

The second major task of the EC with respect to solid findings was to provide a variety of examples of findings that are solid according to the EC’s characterization. While the selection of the examples to be presented was somewhat eclectic and partly determined by EC members who were willing to write about a topic, the EC as a whole discussed and approved the proposed topics; the EC also

revised every draft several times. As result a sequence of brief articles has been published presenting a rather representative selection including solid findings about cognition and about affect, about teaching and about learning, about elementary school and about university, about specific mathematical contents and about cross domain issues such as the use of technology, and maybe most importantly about theoretical and about empirical results. Most of the issues of the EMS newsletter from Issue 82 (December 2011) to Issue 95 (March 2015) present such a solid finding.

Here, I briefly present two of these, one reason for my choice again being personal preference and the other representativeness, at least in the empirical – theoretical dimension.

### **Do theorems admit exceptions?**

Empirical studies on students' conceptions of proof have found that many students provide examples when asked to prove a universal statement. Universality refers to the fact that a mathematical claim is considered true only if it is true in all admissible cases without exception. A student who seeks to prove a universal claim by showing that it holds in some cases is said to have an *empirical proof scheme*. The same student is also likely to expect that a statement, even if it has been 'proved', may still admit exceptions. There is considerable evidence that many mathematics students, and some mathematics teachers, rely on validation by means of one or several examples to support general statements. The majority of students who begin studying mathematics in high school have empirical proof schemes, and many students continue to act according to empirical proof schemes for many years, sometimes into their college years.

While the issue of empirical proof schemes has already been mentioned by Polya (1945), Bell (1976) may have been the first to report an empirical study about students' proof schemes. Following Fischbein's (1982) seminal investigation on universality, the issue has been re-examined many times, usually with similar results. For example, findings by Sowder and Harel (2003) indicate the appearance of empirical proof schemes among university mathematics graduates.

The phenomenon of empirical proof schemes is general in the sense that it has been found in many cultures, countries, school systems, and age groups. It is persistent in the sense that many students continue to do so even after explicit instruction about the nature of mathematical proof. However, it is also complex. For example, the London proof study (Healy and Hoyles, 2000) showed that even for relatively simple and familiar questions, 14-15 years old high-attaining students' most popular approach was empirical verification but that many students correctly incorporated some deductive reasoning into their proofs and most valued general and explanatory arguments.

How can this pervasive phenomenon be explained? The notion of a "universally valid statement" is not as obvious as it might seem to mathematicians. Mathematical thought concerning proof is different from thought in all other domains of knowledge, including the sciences, as well as everyday experience. In everyday life, the "exception that confirms the rule" is pertinent. Students, in particular young children, have little experience with mathematics as a wonderful world with its own objects and rules. According to Fischbein (1982), the concept of formal proof is completely outside mainstream thinking, and we require students to acquire a new, non-natural basis of belief

when we ask them to prove. These explanations contribute to the trustworthiness of the findings on empirical proof schemes.

In summary, the studies on empirical proof schemes, only a few of which have been referred to here, firmly establish the solidity of the phenomenon of empirical proof schemes. (For a more detailed exposition, see Education Committee of the European Mathematical Society, 2011b.)

### **Concept images in students' mathematical reasoning**

Vinner and Hershkowitz (1980) were the first ones to point out that students' geometrical thinking is frequently based on prototypes rather than on definitions. They have shown, for example, that junior high school students tend to think that the altitude has to reach the base (rather than its extension). Hence, they draw the altitude inside the triangle, even in a triangle with an obtuse base angle. Students' prototype altitude is one that is inside the triangle. This is so, even if the students know and can recite the (general) definition of altitude in a triangle.

Authors from many countries have reported, over the past 35 years, analogous patterns in students' reasoning in other areas of mathematics, even among talented students in elementary school, high school and college. For example, and in spite of 'knowing' the appropriate definitions, students tend to act according to rules such as multiplication makes bigger, inflection points have horizontal tangents, definite integrals must be positive, and sequences are monotonous.

A commonality in these and parallel studies is that students do not base their reasoning on the definition of the concepts under consideration (even though they are often aware of these definitions and can recite and explain them) but rather on what Tall and Vinner (1981) have called their *concept image*: "the total cognitive structure that is associated with the concept, which includes all the mental pictures and associated properties and processes" (p. 152). A student's concept image need not be globally coherent and may have aspects which are at variance with the formal concept definition.

The notion of a student's concept image is complex since it is influenced by all of this student's experiences associated with the concept. These include examples, problems the student has solved, prototypes the student may have met substantially more often than non-prototypical examples, and different representations of the concept including visual, algebraic and numerical ones. Images may deeply influence concept formation. As a consequence, the concept image is personal and continuously changing through the student's mathematical experiences.

How can this pervasive phenomenon be explained? While it is not possible to introduce a concept without giving examples, particular instances of the concept never suffice to fully determine the concept. As a consequence, specific elements of the examples, even if not pertinent to the mathematical definition of the concept, become for the student key elements characterizing the concept. And even if at the stage a concept is introduced a teacher might make an effort to present a rather varied set of examples, as the concept is being used over the coming months or years, some of these properties tend to be reinforced because they appear much more frequently than others that may recede. Examples abound, and the height of a triangle being vertical in the sense explained above is a typical one. Students may see many triangles in which the altitude is inside the triangle, and few in which it is not. They might consider these few cases as exceptions (Lakatos might say

monsters). This explanation contributes to the trustworthiness of the findings on empirical proof schemes.

In summary, a solid finding of mathematics education research, supported by dozens of studies in many different contexts, is that students' mathematical reasoning is frequently based on their concept images rather than on a mathematical concept definition. A more detailed exposition of this solid finding has been published elsewhere (Dreyfus, on behalf of the EC of the EMS, 2014).

## **Conclusion**

The list of solid findings presented by the EC of the EMS is, of course, not exhaustive but limited by the time of service of the committee and the people who served on it. I would like to encourage CERME members (and other researchers) to write and publish articles about solid findings they are aware of and consider important. This might have the desirable effect of producing a type of article lacking almost completely from our literature – review articles. Let me make just one suggestion: Work to raise the awareness of issues and of research on teaching and learning among university lecturers and tutors is necessary; it usually improves students' attitudes but effects on learning are limited. Research in at least four countries (USA, Germany, England, Finland) has shown that work with students has more potential for large scale effects. It seems to me that a suitable review article might not only inform many mathematics educators of an important line of research but might have a considerable effect on university teaching centres, an effect that a single study report could (and should) never have.

In conclusion, the researchers and teams referred to above have shown that mathematics education has, over the past 50 years, produced theoretical and empirical results that are solid in the sense that they have explanatory and predictive power, that they can be applied in contexts beyond those involved in previous studies, and that they are recognised as important contributions that have significantly influenced the research field, for example by providing a theoretical lens that allows to see an observed phenomenon differently from how it was seen before.

## **Acknowledgment**

I am grateful to Günter Törner, chair of the EC of the EMS for initiating and sustaining the discussion about solid findings in mathematics education at and in between the six committee meetings from 2010-2014; I would also like to acknowledge the contribution of the committee members to my thinking about what makes findings solid and about what solid findings mathematics education has produced.

## Solid findings in mathematics education:

### A psychometric approach

Caterina Primi

*The foundation of all rigorous research designs is the use of measurement tools that are psychometrically sound. The purpose of this paper is to present the scales' proprieties such as reliability, validity, and invariance that are fundamental prerequisite for assuring the integrity of study findings. Providing examples of how to assess the psychometric properties of tools used in mathematics research may be helpful for future researches in this topic.*

In the document prepared by the Education Committee of the European Mathematics Society (2011), the description of “solid findings” includes an aspect of “robustness”. That means that findings in the research on mathematics learning and teaching should be repeatedly observed or confirmed in many studies reporting the same or similar results leading to the same (general) conclusions. To achieve this goal rigorous research designs and measurement tools that are psychometrically sound are needed. Starting from these premises I will try to identify the contribution of psychometrics to solid findings in mathematics education.

### Measurement

In many educational measurement situations, the variables of interest such as ability, beliefs, attitudes, and anxiety are not directly observable. As such, they are *latent variables* or *traits*. Indeed, they are easily described but they cannot be measured directly, as can height or weight for example, since these variables are concepts rather than physical dimensions.

To give an example of a measurement process, imagine that a researcher is interested in measuring mathematics anxiety (MA). Mathematical anxiety is commonly defined as an adverse emotional reaction to math or the prospect of doing math (Hembree, 1990). It is a state of nervousness and discomfort brought upon by the presentation of mathematical problems and may impede mathematics performance irrespective of true ability (Ashcraft, 2002; Ashcraft & Moore, 2009). The negative consequences of mathematical anxiety are well-documented (Morsanyi et al, 2017). Students with high levels of mathematical anxiety might underperform in important test situations, they tend to hold negative attitudes towards mathematics, and they are likely to opt out of elective mathematics courses, which also affects their career opportunities. Over the last decade there has been more interest in understanding how and when MA develops (Dowker, Sarkar, & Looiet, 2016; Harari, Vukovic, & Bailey, 2013; Jameson, 2013; Ramirez, Gunderson, Levine, & Beilock, 2013), investigating the incidence of MA, and its effects on primary school samples (e.g. Galla & Wood, 2012; Karasel, Ayda, & Tezer, 2010; Wu, Barth, Amin, Malcarne, & Menon, 2012), as well as its consequent influence on math achievement (Wu et al., 2012). Given the widespread prevalence of MA and its detrimental long-term impact on academic performance and professional development, it is important to measure this construct in a valid and reliable way.

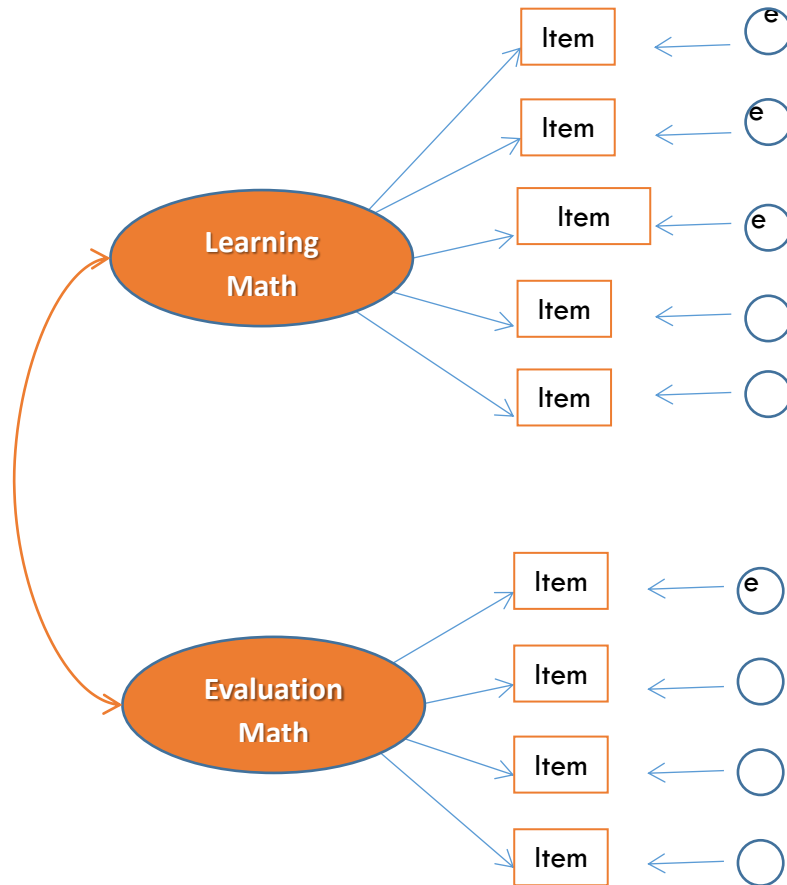

From a measurement prospective it is not possible to directly observe MA. Following the latent trait theory (Lord & Novich, 1968), we can measure something that cannot be observed only by inference from what can be observed. Thus, while the trait itself is not observable, its interaction with the environment produces, at the surface level, observable indicators which can be used to infer the level or degree of the latent trait. Considering MA, although we cannot observe our latent variable, its existence may be inferred from behavioural manifestations or *manifest* variables (for example, as feeling tense, fearful and apprehensive about mathematics). These manifestations make it possible to measure MA asking, for example, a series of questions (the *items* of the instruments) that describe each manifestation (for example, “I feel nervous when I use numbers”). Indeed, a measurement instrument can be constructed using these items with the purpose of assessing the unobservable trait.

However, the primary goal of educational measurement is to determine the level of the latent trait that a person possesses. In general, *scaling* is the process of establishing the correspondence between the observations and the latent variable. Several mathematical approaches have been developed in order to define how to measure a latent trait through item responses, assuming that the latent trait is continuous. These approaches include Classic Test Theory (CTT) and the more recent Item Response Theory (IRT).

Traits, indicators, and their relationships can be represented graphically. Figure 1 represents the measurement structure of the *Abbreviated Math Anxiety Scale* (AMAS; Hopko, Mahadevan, Bare, & Hunt, 2003). This is a two-factor measure of MA that is considered a parsimonious, reliable, and valid scale. The two factors are *Learning Math Anxiety*, which relates to anxiety about the process of learning, and *Math Evaluation Anxiety*, which is more closely related to testing situations. The AMAS is one of the most commonly used measure of MA in college and high school students (for a review, see Eden et al., 2013). The scale has been translated into several languages, and it has been found to be a valid and reliable measure in a variety of populations (Polish version: Cipora, Szczygiel, Willmes, & Nuerk, 2015; Italian version: Primi, Busdraghi, Tomasetto, Morsanyi, & Chiesi, 2014; Persian version: Vahedi & Farrokhi, 2011). Recently, it has also been adapted for children between the ages of 8 to 11 (Italian version: Caviola et al. 2017), and 8 to 13 (English version: Carey et al. 2017).

Looking at the details of Figure 1, the ovals represent latent, unobserved variables, specifically, Learning Math Anxiety and Math Evaluation Anxiety. The squares represent the observed variables (items); five for *Learning Anxiety* (e.g., listening to a lecture in a math class), and four for *Math Evaluation Anxiety* (e.g., thinking about an upcoming math test one day before). The relations between items and the latent traits are represented with arrows that indicate that the traits cause the corresponding indicators. In Figure 1, the error components that we have to take into account in the measurement process are also represented. Any observed score has two parts: The true score part and the error part. Intuitively, we control for the error and we estimate the true score by taking several measures and averaging them. We assume that averaging several measures results in a better estimate of the true score. These ideas are formalized in the concept of *reliability*. We use multiple indicators or items to better measure the trait. This way, we can have more information and reduce the error components, that is, we can maximize the reliability or precision of the measurement tool.

Moreover, verifying the relationships among indicators and the corresponding traits, through a confirmative procedure, such as a confirmatory factor analysis (CFA), we can verify that the measurement tool truly captures the underlying trait, attesting the *validity* of the measurement tool (Zumbo, 2009). Indeed, obtaining evidence of validity is part of the measurement process.

**Figure 1: Model of the Abbreviated Math Anxiety Scale (AMAS)**

## Invariance

Measurement validity also implies that the meaning of the construct and its operationalization is the same in different social and cultural contexts. Testing the invariance of the test concerns the extent to which the psychometric properties of the test generalize across groups or conditions. Therefore, measurement invariance is a prerequisite of the evaluation of substantive hypotheses regarding differences between contexts and groups.

If the research question is, for example, about assessing gender differences in MA, and our test shows that female students have higher math anxiety scores than male students, we would be tempted to interpret test scores in terms of the trait that they are intended to reflect, i.e., that females have greater MA than males. However, it is possible that the test scores do not purely reflect the latent trait, i.e. MA in each group. That is, it is possible that the test is biased in some way.

Bias is used as a general term to represent the lack of correspondence between measures applied to different groups (Van de Vijver & Tanzer, 2004). There are different kinds of bias, for example

*construct bias*, when the meaning of the studied trait varies among groups; *item bias*, when the meaning of the item content is different in certain groups, or *method bias*, when the characteristics of instruments induce measurement errors for particular groups of respondents.

These biases violate the assumption of measurement invariance, which holds that measurement properties should not be affected by group membership (Zumbo, 2009). In other words, the observed scores should depend *only on the latent construct*, and not on group membership. An observed score is said to invariantly measure the construct if it is affected by the true level of the trait in a specific person, rather than by group membership or context (Meredith, 1993). This means that people belonging to different groups, but with the same level of a trait, are usually expected to display similar response patterns on items that measure the same construct. Thus, when studying test invariance, we determine whether the tool functions equivalently in different groups, that is, we test the absence of biases in the measurement process.

A well-known method to assess invariance is multiple group confirmatory factor analysis (MGCFAs) in which the theoretical model is compared to the observed structure in two samples. Testing measurement invariance involves a step-by-step procedure in which nested models are organized in a hierarchical ordering. Specifically, the following invariance models are tested. The *configural* one, which refers to testing whether an instrument exhibits the same structure (Do the groups show the same general factor structure? Same number of factors? Same conceptual definition of latent constructs?). The next model, the *metric* one, tests whether the items function equally across groups. If this invariance is established, the groups can be said to have the same unit of measurement. The final model, the *residual* one, tests if measurement errors are the same across groups, which means that the scale is be equally reliable in both groups.

Applying this method, we tested the equivalence of the AMAS across male and female Italian students (Primi et al., 2015). With regard to the measurement issue, given that the assessment of MA relies on self-report measures, it is important to note that females are more willing to report their feelings of anxiety than males (e.g., Goetz, Bieg, Lüdtke, Pekrun, & Hall, 2013). This finding highlights the importance of employing measures of MA which are invariant across genders. That is, there is a need to test if the items measure the same construct when administered to male and female respondents, controlling for the differences in true group means. Indeed, to compare groups of individuals with regard to MA, one must be sure that the values that quantify the construct are on the same measurement scale.

The issue of measurement invariance has received considerable attention also in cross-cultural research because people from different cultures might have different understanding of the same questions included in an instrument (Milfont & Fischer, 2010). Indeed, testing invariance is of particular concern when using a translated version of a survey instrument, and it is a necessary prerequisite for the translated instrument to be used in cross-cultural research (e.g., Baumgartner & Steenkamp, 1998).

For this reason, we tested the invariance of the Italian version of the Statistical Anxiety Scale (SAS) developed by Vigil-Colet, Lorenzo-Seva, and Condon (2008). Learning statistics is often associated with statistics anxiety, defined as “extensive worry, intrusive thoughts, mental disorganization, tension, and physiological arousal [. . .] when exposed to statistics content, problems, instructional

situations, or evaluative contexts” (Zeidner, 1991, p. 319). In the original validation study, Vigil-Colet et al. (2008) analyzed the internal structure of the SAS using exploratory factor analysis. The results attested a three-factor structure: *Examination Anxiety* (referring to the anxiety involved when taking a statistics class or test), *Interpretation Anxiety* (referring to the anxiety experienced when students are making a decision about or interpreting statistical data), and *Fear for Asking for Help* (referring to the anxiety experienced when asking a fellow student or a teacher for help in understanding specific contents). The primary aim of our work was to confirm this factorial structure of the Italian version using CFA. As confirmation of the same base factor model was not a sufficient condition to establish the equivalence of the Spanish and Italian versions of the SAS, we tested the invariance of the factor model’s parameters between the Italian sample and a comparison Spanish sample. Since the results indicated a substantial equivalence of the Italian and Spanish versions of the SAS, we can use the translated instrument in cross-cultural research, we can make meaningful comparisons between Italian and Spanish students’ statistics anxiety, and we can develop intervention strategies to enhance students’ achievement across Spanish and Italian educational frameworks.

To sum up, if measurement tools are not “invariant”, instruments do not measure the same trait across the different groups or contexts, results are not comparable, and inferences about differences are misleading. As a consequence, methods for investigating biases should be implemented when new measures are created, when existing measures are adapted to new contexts or for different populations, or when existing measures are translated.

## Conclusion

The foundation of all rigorous research designs is the use of measurement tools that are psychometrically sound. Confirmation of the validity and reliability of tools is a prerequisite for assuring the integrity of study findings.

In empirical research, comparisons are often made between distinct population groups, including groups from different cultures, genders, or that speak different languages. These analyses implicitly assume that the measurement of these outcome variables is equivalent across groups, although this assumption often remains untested. Measurement invariance can be tested and it is important to make sure that the variables used in the analysis are indeed comparable across groups.

In conclusion, testing the psychometric properties of tools, such as measurement invariance might help in increasing the robustness of findings across various groups and contexts.

## Can the outcomes of PISA 2015 contribute to evidence-based decision making in mathematics education?

Gerry Shiel

*Drawing on data from the OECD's Programme for International Assessment (PISA), which assesses mathematical literacy and other domains among 15-year olds in over 70 countries every three years, this paper explores the extent to which PISA outcomes in 2015 can be described as 'solid' and hence contribute to evidence-based decision making. It identifies aspects of PISA that render its findings 'solid', but also points to pitfalls that arise in interpreting PISA outcomes related to achievement. The paper concludes by examining how PISA can contribute to thinking about the nature of evidence-based findings in mathematics education.*

### Introduction

A key feature of the educational landscape since 2000 has been the Programme for International Student Assessment (PISA), a study sponsored by the Paris-based Organisation for Economic Cooperation and Development (OECD) that assesses performance in mathematics, reading literacy and science among 15-year olds in over 70 countries every three years. In addition to administering tests to students, PISA administers questionnaires to students, their parents and their school principals. The student questionnaire asks about students' socioeconomic status, their attitudes towards mathematics and other subjects, and their instructional experiences. This paper looks at performance outcomes in the two most recent PISA cycles – 2012, when mathematics was a major assessment domain, and 2015, when mathematics was a minor domain, and PISA moved from a paper-based to computer-based testing in most participating countries.

Interest in the extent to which PISA provides 'solid' or 'evidence-based' findings arises because of the strong impact that PISA has on policy making in many participating countries. In Ireland, for example, a significant drop in performance in mathematics and reading literacy in PISA 2009 led to the implementation of a *National Strategy to Improve Literacy and Numeracy 2011-2020* (DES, 2011). The strategy set out a series of measures designed to improve performance, including plans to enhance initial teacher education, curriculum and assessment. In parallel with the Strategy, revised curricula in mathematics at post-primary level have been rolled out in a phased basis since 2010 in an initiative known as 'Project Maths'. This involves a strong focus on developing students' conceptual understanding in mathematics, and on applying mathematical knowledge in solving problems in context using a range of methods. Ní Shuilleabháin (2013) described Project Maths as 'a philosophical shift in Irish post-primary classrooms from a highly didactic approach with relatively little emphasis on problem solving towards a dialogic, investigative problem-focused approach to teaching and learning mathematics' (p. 23).

A key feature of the National Strategy is the inclusion of national targets for performance in PISA mathematics. In an interim review of the Strategy (DES, 2017), there are targets of 10.5% of students achieving below proficiency level 2 by 2020, and 12.0% achieving levels 5-6. The first of these is quite an ambitious relative to current performance (15% performed below Level 2 in 2015), while the second is more modest (11% performed at Levels 5-6 in 2015).

## Efforts to ensure that PISA findings are solid

The procedures around the development of PISA survey instruments, including the mathematics test, are designed to ensure that findings can be relied on and used by participating countries to enhance teaching and learning, and raise performance standards. The development of the PISA mathematics test and scale encompasses the following:

- An assessment framework is developed and published at the outset of each PISA cycle (e.g., OECD, 2013). The framework provides a definition of mathematical literacy in PISA, and outlines the content areas (mathematical content categories) and processes to be assessed, the contexts in which items are to be embedded and the item formats to be used. Items are then developed in a way that ensures that all elements of the framework are adequately addressed. The assessment framework is a key source of evidence to support the validity of the PISA tests.
- Items based on the framework are submitted by countries, or are developed by the consortium charged by the OECD with implementing PISA. Items are vetted by countries for cultural and linguistic appropriateness and suitable items are forwarded for field trialling.
- The PISA field trial is conducted on a sample of 15-year olds in each participating country, and the performance of items is assessed within and between countries. The outcomes of both classical item analysis and item response theory scaling are taken into account in determining the suitability of items. These items, along with any trend items not field-trialled, are then used to compile test forms for the main study.
- Considerable effort goes into ensuring that items are scored accurately, using scoring guides prepared by the PISA consortium. Many items are marked by two or four scorers, and real-time indices of inter-rater reliability are used to guide the quality of scoring.
- The PISA main study is implemented. Quality control is a key aspect of the Main Study, as countries are held accountable to quality standards (see below).
- Performance on PISA is scaled using Item Response Theory models and links with performance on earlier rounds are established.

A document, *PISA Technical Standards* (e.g., OECD, 2014), is issued in each cycle to guide countries in ensuring that their samples, response rates, security procedures, translation and coding practices are of a sufficiently high standard that their data warrants inclusion in international reports. For example, the 2015 Technical Standards indicate that response rates of 85% at school level and 80% at the student level are required. The achieved samples of countries failing to meet these criteria are examined in detail for potential bias. In some cases, countries have not been included in international reports because of low response rates (e.g., the Netherlands in 2000, and the UK in 2003).

At the end of each PISA cycle, a technical report is prepared by the PISA consortium and is issued by the OECD (e.g., OECD, 2017). It details the procedures used in each aspect of the implementation of PISA, including sample design, field operations, quality control, survey weighting, scaling, proficiency scale construction, and coding reliability.

The consortium charged with implementing PISA establishes expert groups for mathematics, science and reading literacy, and there is also a Technical Advisory Group, which advises the Consortium on its use of scaling and other procedures, and a Questionnaire Expert Group. These groups act as a further check on the quality of the PISA instruments and outcomes.

Hence, PISA has taken several precautions to ensure the quality and solidity of its findings. Notwithstanding the fact that PISA assesses the mathematics that students require for life after they leave school (or mathematical literacy) and for future study, rather than mathematics based on school curricula, the steps taken to ensure that findings are solid are extensive.

### **The introduction of computer-based assessment as a threat to the solidity of PISA findings**

Prior to 2015, PISA implemented computer-based testing in subsets of countries on an optional basis. In 2012, for example, mathematics was assessed on paper in all 65 participating countries, and on computer on an experimental basis in a subsample of 32 countries. In 2015, however, there was a shift to computer-based assessment in most participating countries, with 56 of 73 countries, including all 34 OECD member countries, administering PISA in this format. The remaining countries administered PISA on paper.

The transition to computer-based testing in PISA presented some significant challenges for the OECD. A key component of PISA is the availability of trend data – that is, performance from one PISA cycle to the next must be placed on the same underlying scale so that average performance and performance across proficiency levels in each country and on average across OECD countries can be tracked from cycle to cycle. The task facing the OECD and its contractors<sup>1</sup> was to establish the feasibility of linking performance on the 2015 computer-based tests to scales based on performance on paper-based tests in earlier cycles. This was further complicated by a requirement to continue to provide trend data for countries that administered PISA in paper-based form in 2015.

There were several ways in which the transition to computer-based testing could have been managed, given the imperative to maintain trends. For example, all students (or equivalent samples of students) taking PISA 2015 could have been given paper-based and computer-based tests. Then trends could have been established with reference to performance on the paper-based measures and new computer-based scales could have been devised, based on the computer-based items, and used for trend analysis in the future. This would have eliminated any concerns about mode effects (an advantage or disadvantage arising from implementing PISA on computer).

The approach taken by the OECD and its contractors was to make adjustments in 2015 based on how the same items performed on paper and on computer in the PISA 2015 Field Trial, which took place in all participating countries in spring or autumn 2014. In the case of mathematics, which was a minor domain, items used in earlier PISA cycles (i.e., trend items) were transferred from paper to computer, and equivalent representative samples of students from each country took the paper- and computer-based tests. Hence, the purpose of the mode study was to ascertain whether tasks or items

---

<sup>1</sup> The lead contractor in PISA 2015 was the Educational Testing Service in the US. The lead contractor in all earlier cycles of PISA was the Australian Council for Educational Research.

presented in one mode (i.e., paper) functioned differently when presented in another mode (i.e., computer) and vice versa. For the purpose of analysis, items were pooled across countries, as individual countries did not have sufficiently large samples of students to allow for reliable comparisons of individual items across modes, or for an analysis of item-by-country interactions. Where item parameters were judged to be ‘strongly invariant’ (that is, similar on paper and computer), item parameters were constrained to be the same in the 2015 Main Study (OECD, 2017). In the course of the Field Trial analysis, a subset of items showed mode effects. To account for these effects in the Main Survey, different item parameters were estimated for paired paper- and computer-based items. According to the OECD (2017, Chp. 7, p. 53), ‘this established an invariance model that assumes scalar or strong invariance for the majority of items and metric invariance for a minority of items for which difficulty differences were detected’. A correlation of .95 was found between paper-based and computer-based item parameters for mathematics in the Field Trial, further supporting a link between performance on computer-based tests in 2015 and paper-based tests in earlier cycles, as well as between computer- and paper-based tests administered in 2015.

The PISA 2015 Field Trial yielded other interesting findings that applied to mathematics as well as other domains. For example, across countries, students taking the Field Trial tests on computer had significantly fewer omitted responses than students taking the paper versions. Furthermore, there were fewer effects of cluster position on performance when tests were administered on computer (that is, items administered by computer were more likely to perform in the same way regardless of whether they appeared early or late in the test). However, as Jerrim et al. (in press) note, while the Field Trial did not yield large differences across modes for male and female students, no analyses were conducted to examine potential interactions with variables such as ethnicity or socioeconomic status. They also questioned the representativeness of the samples used in the Field Trial, which, in some countries, could be described as convenience samples. They viewed this as weakening the external validity of the results, given the implications for the adjustments made within Main Study scaling to enhance cross-mode comparability.

### **Overall performance on PISA 2015 mathematics**

The PISA main study took place in all participating countries in 2015. The OECD issued two volumes of findings in December 2016 that included country mean scores in mathematics, and comparisons with performance in earlier cycles. The mean score of students in Ireland in 2015 was 503.7 (OECD, 2016). This was significantly above the average across OECD countries (490.2), and was about the same as in 2012 (501.5), 2006 (501.5) and 2003 (502.8). Indeed, the only year in which average performance moved outside the 501-504 range was in 2009 (487.1).

While the mean mathematics score of students in Ireland was stable in the transition to computer-based assessment, a number of countries saw large declines in performance between 2012 and 2015. These included Korea (down 29.7 score points, though still well above Ireland at 517.4), Chinese Taipei (17.5), Hong Kong (13.3), Poland (13 points), and the Netherlands (10.7 points). On the other hand, a small number of countries experienced increases in achievement, including Sweden (15.7 points), Norway (12.4), the Russian Federation (11.9), and Denmark (11.1).

It is noteworthy, however, that Norway, Denmark and the Russian Federation were among the countries with the highest use of computers by students in mathematics classes in PISA 2012 for

purposes such as entering data on a spreadsheet, drawing a graph of a function, constructing geometric figures, re-writing algebraic expressions and solving equations (OECD, 2015). In contrast, Korea, Hong-Kong China and Ireland were among the countries with the lowest usage of ICTs by students in mathematics classes.

The fact that Ireland's overall performance on PISA 2015 is similar to 2012 can be interpreted in a number of ways:

- It suggests that students in Ireland are equally adept at solving mathematical problems in paper and computer-based formats; indeed, this would suggest that the mode of assessment does not matter, at least for students in Ireland.
- It suggests that students in Ireland improved in their mathematics between 2012 and 2015, but this improvement was largely hidden because of the transition to computer-based testing.

The second of these seems the most likely. PISA 2015 was the first PISA cycle in which all students in Ireland's sample had studied under the Project Maths syllabus. This interpretation is consistent with a finding that students in initial Project Maths schools (24 schools that had implemented Project Maths first) outperformed students in non-initial schools in PISA 2012 mathematics (see Merriman et al. 2013), though the difference was relatively small (4 score points) and not statistically significant.

A further relevant finding relates the optional computer-based assessment of mathematics administered as part of PISA 2012. In that assessment, students in Ireland had a mean score that was not significantly different from the corresponding OECD average score, despite achieving a mean score on paper-based mathematics that was significantly above the corresponding OECD average in the same year (Perkins et al., 2013). Hence, performance on PISA 2015 can be interpreted as being indicative of a possible improvement.

Interestingly, the OECD has continued to hold the position that mode effects in PISA 2015 mathematics were small and did not impact on the performance of participating countries (OECD, 2016, 2017). Implicit in this is the view that performance on computer-based assessment in 2015 can be linked back to performance on paper-based assessment in earlier PISA cycles.

### **Other threats to the solidity of PISA 2015 findings**

The transition to computer-based assessment in PISA is clearly one threat to the validity of scores reported by the OECD for PISA 2015 mathematics. However, there were several other changes to PISA 2015 which could also impact on the interpretation of outcomes, and hence the solidity of PISA findings. The changes – several of which occurred because a new consortium was contracted by the OECD to gather and analyse PISA data – include:

- Changes in the assessment design – the design of PISA 2015 was modified to reduce or eliminate differences in construct coverage for major and minor assessment domains for test takers. In practice, this meant that fewer students took mathematics in PISA 2015, compared with earlier cycles, but more mathematics items were included in the assessment, thereby allowing for broader construct coverage.

- Changes in the calibration sample – prior to 2015, item difficulty in PISA was estimated using the responses of students in the most recent cycle (e.g., in 2012, this comprised data from students who took PISA in 2009). Moreover, the calibration sample in earlier cycles comprised a random sample of 500 students per participating country. In 2015, item parameters were re-estimated using all students in all participating countries in the previous four PISA cycles. This change was implemented to reduce the uncertainty around estimates of the item parameters used in calibration.
- Changes to the scaling model – in earlier PISA cycles, a one-parameter Item Response Theory (IRT) model (with adjustment for partial credit) was used to scale performance. In 2015, item functions based on a two-parameter logistic IRT model for dichotomous data, and a generalized partial-credit model for polytomous data were used in scaling data in the case of new items, while functions based on a one-parameter model were used (as previously) with trend items. Unlike its predecessor, the new approach does not give equal weighting to all items when constructing a score, but assigns optimal weights to tasks based on their capacity to distinguish between high- and low-achieving students.
- Changes in the treatment of differential item functioning across countries – where items performed unexpectedly differently across countries, the calibration in 2015 allowed for a number of country-by-cycle-specific item parameters. In previous cycles, items that showed differential item functioning (e.g., because of differences across languages) were dropped from scaling. The change in 2015 was intended to reduce the dependency of country rankings on the selection of items included in the assessment (for a country) and hence improve fairness (OECD, 2016).
- Changes in the treatment of not-reached items – in PISA 2015, not-reached items (unanswered items at the end of a section, such as at the end of the first and second hour of testing) were treated as not administered when estimating proficiency (i.e., scoring student responses), whereas in previous PISA cycles they were treated as incorrect. A reason for this change was to eliminate the opportunity for countries and test takers to randomly guess answers to multiple-choice questions at the end of a section of the test. As in previous cycles, not-reached items were treated as not administered when computing item parameters (i.e., during scaling).

The OECD (2016) acknowledges that improvements to the PISA test design and to scaling in PISA 2015 can be expected to result in reductions in link error (the error associated with particular sets of items used in a particular cycle) between 2015 and future cycles. However, it also acknowledges that the changes described above may result in increased link error between PISA 2015 and earlier cycles, as past cycles used a different design (paper-based assessment) and used different scaling procedures. Furthermore, the OECD (2016) acknowledges that the change in the treatment of not-reached items could result in higher scores than would have been estimated in earlier PISA cycles for countries with many unanswered items.

## Conclusion

The problem in terms of interpreting trend scores is that any of the changes implemented by the OECD and their contractors in relation to the design and scaling of PISA in 2015 could have impacted on the scale scores achieved by students. Interpretation becomes even more difficult when multiple changes are implemented, as these may interact with one another in complex ways. The OECD has sought to address this in a limited way by rescaling data from earlier PISA cycles using the methods implemented in 2015. Thus, in the case of Ireland, performance on PISA mathematics changed by +2 score points between 2012 and 2015 (see above), but, the change was 6.0 score points when newer scaling methods were applied to the 2012 mathematics data. On average across OECD countries, the impact of changes to scaling procedures was also reported to be small (a published drop of 3.7 score points between 2012 and 2015, and a drop of 2.5 score points following rescaling of the 2012 data) (OECD, 2016). For most countries, differences arising from re-scaling are within the error margins of the original difference scores reported by the OECD.

While the readjustment of scores from PISA 2012 using the new scaling procedures implemented in 2015 may go some way towards reassuring users that PISA outcomes are comparable over time, the sheer number of changes implemented in PISA 2015, including the change to computer-based testing, indicates that particular care should be exercised in interpreting PISA 2015 data.

Efforts to improve the design and scaling of PISA 2015 also contain some lessons for efforts to generate solid data in mathematics education. On the one hand, solid findings can be obtained by implementing the same testing procedures and methodologies on multiple occasions (e.g., pre- and post-intervention). In the words of Beaton (1990), ‘when measuring change, do not change the measure’ (p. 165). On the other hand, at least in the case of longitudinal, multi-year surveys such as PISA, there is an ongoing need to build innovation into all aspects of the project to maintain relevance and deliver more robust measures for the future. One clear danger is that, when mathematics becomes a major assessment domain in PISA 2012, the construct measured will also change, as new items specifically designed to take advantage of the affordances computers, will be introduced for the first time.

### Introduction

The role and importance assigned to argumentation and proof in the last decades has led to an enormous variety of approaches to research in this area. The 27 papers and 1 poster presented in the Thematic Working Group (TWG) “argumentation and proof” come from 18 countries across 4 different continents, and offer a wide spectrum of perspectives. These contributions intertwine educational issues with explicit references to mathematical, logical, historical, philosophical, epistemological, psychological, curricular, anthropological and sociological issues.

Taking into account this diversity, the contributions were presented and discussed in working sessions organized under the following 7 themes: (1) assessments issues of argumentation and proof; (2) theoretical and philosophical issues of argumentation and proof; (3) argumentation and proof in textbooks; (4) tools for analyzing argumentation and proof; (5) intervention studies on argumentation and proof; (6) argumentation and proof at the university mathematics level; and (7) task design in argumentation and proof. Since the themes are intertwined, each paper could be assigned to multiple themes. Therefore, the assignment of papers to themes was guided by a “best fit” approach as well as practical considerations. We will briefly discuss each theme separately.

### Assessment issues of argumentation and proof

This theme included three papers, related to issues of assessment in the area of argumentation and proof: Kónya and Kovács’ paper focused on development of inductive reasoning of prospective teachers by analyzing their problem-solving processes on a carefully selected problem. Hemmi, Julin and Pörn’s paper investigated teachers’ perspectives on the possibility of using students’ common misconceptions, identified in prior research, as a starting point for activities that develop students’ understanding and skills in proof. Demiray and Bostan’s paper investigated pre-service middle school mathematics teachers’ interpretations of statements regarding proof by contrapositive and the reasons for their incorrect interpretations. The discussion of the three papers in the TWG raised several important issues, such as:

*The influence of sociocultural context* should be considered in assessment findings.

*Alternative variations of task design* should be considered in the interpretation of students’ performances.

*Adopting a more positive model.* Should researchers aim to identify students’ competencies rather than misconceptions?

## **Theoretical and philosophical issues of argumentation and proof**

The two papers in this theme addressed implications of Habermas' rationality theory. Conner's paper discussed how Habermas' rationality can be used to analyse how teachers support argumentation processes in their classrooms. Boero's paper showed the added value of analyzing individual student's thinking processes while attempting to prove a statement. The discussion of the papers raised several points, including the following:

*What is the added value of applying Habermas' rationality to a particular kind of analysis, and what would be lost if it was not used?*

*The difficulty of applying the categories of Habermas' rationality to coding data and, in particular, the difficulty in distinguishing between teleological rationality and epistemological rationality.*

## **Argumentation and proof in textbooks**

The five papers presented in this theme were grouped based on their relation to argumentation and proof in textbooks. Žalská's paper described how different types of arguments enacted in one classroom were influenced by the textbook, the teacher beliefs, and the students. Wong's paper presented an examination of geometry chapters in a prominent Hong Kong textbook series and illustrated the limited opportunities for students to engage in the process of generalizing and providing proofs. Cousin and Miyakawa's paper described the evolution of proof in Japanese geometry textbooks and the role of the specificity of Japanese language on that process. Mesnil's paper described a reference for studying and teaching logic in France, while Bergwall engaged the TWG in analysis and discussion of reasoning-and-proving opportunities in Finish and Swedish textbooks on primitive functions. The discussion addressed several important topics, such as:

*The role of language and linguistics in introducing, teaching, and writing proofs; and how the goal of teaching proof is articulated in a curriculum, represented in textbooks, and enacted in classrooms.*

*The role of mathematical logic in the teaching and learning of proving.*

*Definitions in research frameworks.* Caution is required in the interpretation of the findings from different studies which operationalized certain terms in different ways.

*The need for specialized analytical frameworks when examining argumentation and proof opportunities in textbook tasks versus textbook expositions.*

## **Tools for analyzing argumentation and proof**

The five papers in this theme concerned different tools for analyzing argumentation and proof. Ruwisch's paper concerned a one-dimensional model to rate reasoning competences at the primary level, considering both mathematical reasoning and its linguistic realization. With the same goal to better understand primary students' reasoning characteristics, Koleza, Metaxas and Poli used a simplified model of Toulmin's argumentation, drawing also on argumentation schemes described by Walton. The paper by Mata-Pereira and da Ponte aimed to understand how application of design principles regarding tasks and teacher actions can help provide students with opportunities to justify, and presented a framework that accounts for the level of complexity in students' justifications. In a longitudinal study, Fahse explored secondary school students' ways of argumentation on tasks concerning division by zero. He identified three different types of student argumentation and showed

how these relate to students' age. Focusing on teachers' competencies, Chua's paper presented a theoretical framework that classifies justification tasks by their nature, purpose and the expected element to be provided in the justifications. The discussion of the five papers raised some deep issues, including the following:

*The validity versus utility of theoretical frameworks in argumentation and proof.* The utility of a framework depends on how well it is designed to address a particular goal.

*Multi-dimensional models of proof.* Researchers should acknowledge the complexity of proof and specify the aspect(s) of proving that they are focusing on.

*Language and argumentation.* Investigating relations between language and argumentation requires clarifying what we mean by "mathematical language".

*Classroom culture* should be considered in interpretations of research findings.

### **Intervention studies on argumentation and proof**

The five papers in this theme related to implementing proving activities in school mathematics classrooms. Reid and Vallejo Vargas' paper describes an intervention where 3<sup>rd</sup> graders learn division through "proof-based teaching" by developing a shared toolbox of justification principles. The study showed that 3<sup>rd</sup> graders are capable of reasoning deductively from premises when explaining their thinking. The paper by Soldano and Arzarello described students using game activities in Dynamic Geometry Environments (DGEs) to discover geometric properties of the mutual relationship between two circles. The authors found that games helped students to communicate their claims, formulate and check conjectures, and explain their thinking. Siopi and Koleza's paper focused on students' use of a specific tool, a pantograph, to explore geometrical properties of parallelograms. The paper by Pericleous and Pratt examined how a teacher helped students to foreground mathematical argumentation as they investigated geometrical properties within a DGE. Finally, Buchbinder reported on a study on professional development sessions where teachers became familiar with 'proof-task prototypes', applied them in their teaching, and reflected on this application. These activities helped teachers to involve proof-oriented activities in their ordinary mathematics classrooms. The discussion included the following issues:

*What was the contribution of particular tools to students' learning?*

*Students' investigations within DGEs* and the ambiguity of the expression 'play with the software'.

*The need for structured support for teachers to implement proving activities.*

### **Argumentation and proof at the university mathematics level**

The five papers in this theme were concerned with teaching and learning of proof at the university level. Yan, Mason and Hanna's paper suggests an exploratory teaching style to promote the learning of proof, and describes specific pedagogical strategies. Selden and Selden's paper discusses theoretical perspectives for proof construction and its teaching. They suggest including psychological aspects of proving to these perspectives, and how these aspects should be considered in teaching and future research. Moutsios-Rentzos and Kalozoumi-Paizi's paper also considers psychological aspects by describing affective and cognitive experiences of a mathematics undergraduate student while producing a proof under exam-conditions. The innovative methodology of their study is to examine

students' facially expressed emotions during proving activities, as a way to study and influence students' attitudes towards proof. Gabel and Dreyfus' paper describes an attempt to analyze rhetorical aspects of proof presentation. They use Perelman's "New Rhetoric" as a framework to identify ways to analyze and increase the effectiveness of teachers' argumentation in mathematics classrooms. Azrou's paper suggests that students' lack of meta-knowledge about proof, such as features of mathematical proof and how a proof should be organized, influences their competence to write mathematical proofs. The discussions of these papers raised the following issues:

*Phenomena (as behavioural issues)* that have not been previously considered by psychologists or mathematics educators may play a role in students' difficulties to construct proofs.

*The role of emotions and feelings* in proof construction.

### **Task design in argumentation and proof**

Although many papers touched on issues of task design, this was the main topic of the two papers in this theme. Komatsu and Jones's paper explores how task design can facilitate students' engagement with the mathematical activity of proofs and refutations in the context of a DGE. Hein and Prediger's paper explored the role of task design and scaffolding to foster students' learning of deductive reasoning, making explicit the logical structures and unpacking their verbal representations in geometry. The discussion included the following issues:

*Proving something in a particular case:* how can we help students see the generality of the proof?

*The notion of scaffolding.* How can we make explicit to students the logical structure of proving?

*The special place of geometry* in teaching, learning and researching of argumentation and proving.

### **Conclusions**

We think that the TWG on argumentation and proof has offered the participants the richness of diversity in this research domain and the opportunity of fruitful discussions. At the last session of the TWG, the participants engaged in a discussion to identify areas in which they would like, and hope, to see more research in future CERMEs. The following areas were identified:

*The teaching of proof and argumentation* in both school and university settings, including in teacher education. The study of the classroom implementation of tasks rich in argumentation and proof opportunities, scaffolding and responding to unexpected student responses.

*Issues of language in argumentation and proof.* This also includes representations, structure, oral and written language, rhetoric and logic.

*Aesthetics of proof* and ways in which students of all levels of education can improve their attitudes, emotions, and beliefs about proof.

The identification of these areas is aimed at describing the state of the art of the field, without suggesting prioritizing certain areas of research. The TWG is committed to representing the diversity of perspectives and research areas on argumentation and proof in future CERMEs.

# Meta-mathematical knowledge about proof

Nadia Azrou

University Yahia Fares, Medea, Algeria; [nadiazrou@gmail.com](mailto:nadiazrou@gmail.com)

*We deal in this paper with a particular difficulty with proof and proving at the undergraduate level, which concerns knowledge about proof at a meta-level. Some undergraduate students' difficulties or mistakes observed in their proof texts have been related to lack of that meta-knowledge. In order to test this hypothesis, interviews with a sample of students have been performed. Relationships with the didactic contract have been discussed.*

*Keywords: Proof, meta-knowledge, theorem, undergraduate students.*

## Introduction

Most mathematics teaching at all school levels is concentrated on teaching content; at the university level, students learn about functions, differential equations, matrices and integrals, by manipulating definitions and theorems. In order to assimilate the content, students are asked to solve problems and prove statements. The difficulties of students with proof have been largely investigated in research (Moore, 1994; Epp, 2003; Selden & Selden 2007; Harel & Sowder, 1998); some of these difficulties are related with the fact that students do not know mathematics at the meta-level, particularly as it concerns proof (Morselli, 2007; Hemmi, 2008). Several students do not see clearly the difference between a definition and a theorem, the difference between an example and a counter example. Knowledge about proof at the meta-level is neither presented in textbooks nor in courses of specific mathematical disciplines, but it makes one of the most important differences between mathematicians and students. In this paper, we will consider in particular the meta-knowledge about proof (MKP), such as the knowledge of the notion of proof and the rules related to how a proof must be organized. Many researchers acknowledge the fact that high school and university students do not understand what is meant by “proof” and “proving” (e.g. Schoenfeld 1989, Harel & Sowder 1998). “To most undergraduates, convincing their teacher (and thereby earning satisfactory grades) is typically the most important reason for constructing a proof” (Weber, 2004, p. 429) and “unfortunately, many students believe that they either know how to solve a problem (prove a theorem) or they don't, and thus, if they don't make progress within a few minutes, they give up” (Selden & Selden 2007, p. 96); students often believe that non-deductive arguments constitute a proof, or “an argument is a proof if it is presented by or approved by an established authority, such as a teacher or a famous mathematician” (Weber, 2003, p. 3); other different interpretations and conceptions of students regarding proof are described in Harel & Sowder (1998) and in Recio & Godino (2001). Meta-knowledge about proof is used implicitly by mathematicians when they construct proofs, “what may be assumed contextually and what needs to be explicitly proved, using logical deduction and previously established results, is highly non-trivial and, I would suggest, is implicit rather than explicit in the minds of most mathematicians” (Tall, 2002, p. 3). Our focus in this paper will be on the lack of MKP and what it might cause as difficulties to students when constructing proofs. The present study is developed using a past empirical study with undergraduates that consisted of investigating students' difficulties by analyzing their proof texts

responding to different tests (Azrou, 2015). We would like to examine if the following hypothesis is supported by an interview analysis: Is lack of MKP one of the reasons behind the messy proof texts? Moreover, we would like to answer the following question: Why students do not develop MKP?

## **Theoretical framework**

We choose the definition of proof stated by Durand-Guerrier et al. in (Durand-Guerrier, Boero, Douek, Epp, Tanguay, 2012), inspired from the Vergnaud's conceptual fields (Vergnaud, 1990). According to Vergnaud, a concept (in our case proof) is learnt by acquiring three components: the set of different representations (oral, written, formal, etc), the situations of reference (proof in geometry, in algebra, in calculus, etc.) and the operatory invariants (related to the logical structure of proof: legitimated inference rules, status of hypotheses, thesis, axioms, etc). Mastering the MKP is mastering the concept of proof according to Vergnaud, as it was stated by Durand-Guerrier et al. (2012).

We are interested in comparing MKP that students acquire with how they have been presented proofs and how they have been taught MKP by their teachers. As we consider the relationship with the teaching regarding proof and proving, we will be referring to the didactic contract (Brousseau, 1988) that is defined as a set of rules framing the mathematical practices of teachers and students under the constraints of the teacher-students institutional relationships. Most of these rules regarding how, why and what teachers do mathematically (and students should learn to do) are implicit and thereby not declared by teachers, who often suppose that students would assimilate them over time and practice. Often, teachers use some particular intentions and rules with the proofs exposed to students, without being aware of and without feeling the importance of explaining them; consequently, sometimes students are misguided to make correct proofs. Let us take the example of proof writing: 'the processes used by mathematicians are often rough and informal, but students typically see proofs in their final forms, and rarely witness the process of creating a "rough draft", as a result, students often do not know where to begin when writing their own proofs' (Moore, R. C., 1994). We will examine what kind of MKP students learn from their teachers and how they manifest it.

## **Methods**

We are more interested in examining in students' proof texts their MKP considering the three components of the definition of Durand-Guerrier et al. (2012); students' behaviors will be checked regarding definitions and other used mathematical statements (mathematical argument), regarding their modes of reasoning and argumentation and how they expressed them and presented them. Especially, how lack of MKP is manifested through students' proof texts and their interviews. A test composed of open questions (to which the proof cannot be procedural but rather syntactic or semantic (Weber, 2004)) have been submitted to 98 undergraduates during their third academic year, for a complex analysis course in a high level school of engineers in Algeria. The written language is French, but often, Arabic dialect is used, along with French, in the oral form. The analysis of students' proof texts indicates that one of the difficulties behind writing messy and disorganized proof texts to open questions was lack of MKP (Azrou, 2015). To receive further evidence for our findings, interviews were performed with a sample of students. We have chosen

fourteen students to interview whose proof texts contained well-organized, less organized and very disorganized proof texts. Our aim was to investigate, by analyzing students' words, whether they master the concept of proof at a conscious level, in other words if they have a mastery of its operatory invariants (Vergnaud, 1990).

### **A-priori analysis of the test**

The test contained three questions, but in scope of this paper we can only include the first question.

*1- Is it possible to find a holomorphic function that admits 0 as a simple pole such that Residue of  $f$  at 0 is 0 ( $\text{Res}(f, 0) = 0$ )?*

By designing such questions, we aimed at ascertaining if students were able to construct the proof, based on known definitions and theorems, in a clear argumentation form by providing their own way of expressing the answering to the question. The question is about the possibility of having  $(P \Rightarrow Q)$  and its negation  $(P \text{ and } \overline{Q})$  at the same time, which results in a contradiction and thus it is impossible. Logically speaking: the fact that the residue at a point is not 0 is a direct consequence of that point being a simple pole for the function. We have chosen to refer to the point 0 to simplify the formula. There was no doubt that students knew all these concepts because they had used them many times before, but always when performing direct calculations and procedures. However no request of identifying and exploring the links between concepts had been made, especially in a written form.

### **A preliminary analysis of students' proof texts**

We have observed in students' proof texts, among others, the following behaviors related to the concept of proof:

- Lack of justifications: students do not know when the justification is necessary and when it is not; they might give a justification for an obvious fact and miss to justify a non-obvious statement.
- Students turn around confusing the hypothesis and the thesis (forwards and backwards between the premise and the result).
- An example is given instead of a justification to prove that the statement is true.
- Incomplete mathematical statements and/or formulas.
- Missing details that make holes in the proof.
- Lack of organization of proof steps.
- Disconnection between statements.
- Writing the proof text like a draft or a sketch.

### **Examples of students' proof texts**

The following excerpts show some of the difficulties cited before; the language used is French.

### Proof text 1

Exercice 1: Est-il possible de trouver une fonction qui admet (0) comme pôle simple tel que  $\text{Res}(f, 0) = 0$ ? Justifier.

il est impossible de trouver cette fonction exp.  $\text{Res}(f, a) = \lim_{z \rightarrow a} (z-a) f(z)$ . ~~on ne peut pas le trouver~~ ~~non on ne peut pas le trouver~~

$f(z) = \frac{1}{z(z-1)}$   $\lim_{z \rightarrow 0} z \cdot \frac{1}{z(z-1)} = \lim_{z \rightarrow 0} \frac{1}{z-1} = -1$

In this proof, the student responds by saying that such function does not exist and gives an example of a function that does not verify the conditions given by the statement. Clearly, the existence of a function that does not verify the conditions does not tell why these conditions cannot go together. This student considers that giving such example is the proof of the inexistence of functions verifying the two conditions.

### Proof text 2

Exercice 1: Est-il possible de trouver une fonction qui admet (0) comme pôle simple tel que  $\text{Res}(f, 0) = 0$ ? Justifier.

Soit  $z_0$  est pôle simple  $\Rightarrow \lim_{z \rightarrow z_0} f(z) \neq 0 \Rightarrow \text{Res}(f, 0) = \frac{1}{0!} \lim_{z \rightarrow 0} f(z)$

$\Rightarrow \lim_{z \rightarrow z_0} z f(z) = 0 \Rightarrow \lim_{z \rightarrow 0} z f(z) = \lim_{z \rightarrow 0} z f(z) = 0$

The student does not provide an answer to the question, the proof is a series of statements; each one derived from the previous one by an implication, but without any justification; moreover the last three ones are similar but incorrect, they present the simple pole definition, but the limit should be not 0.

### Interviews

Based on the analysis of students' written productions, in the wider investigation this study belongs to, we have conducted interviews to address our previous questions, but also to receive more information about students' points of view. We will present only the questions of the interviews that deal with MKP about proof. The main interview contained three questions, each with three or four sub-questions.

Q1- If your answer would have been addressed to another teacher, would you have written it the same way?

a- What is important, to a teacher, to see in a student response to questions like this one?

b- Do you think another teacher, not familiar with the course, would have understood the answer?

c- How can the teacher know if the answer is right or not?

d- If the question has been proposed in homework, would you have presented it in a different way?

Q3- If a rigorous mathematician would have answered to this question, how would he presented his answer?

a- What is the difference from your answer text and those we find in mathematics books?

b- After this time, looking again to your answer, is there something you would add or change in yours answer or would you keep it as it is?

### Results of interviews

**Q1:** Four students said ‘yes’, while the rest (ten) said ‘no’. They intended their responses to be given especially to their own teacher, so they made their responses intentionally focusing on what is important to the teacher which is, according to them, their reasoning and showing that they got the idea of the process and understood enough the concept at stake in order to get the credit or a part of it. *‘I know that my teacher will understand it even if it’s not complete’.*

**Q1.a:** All students responded that the teacher would check in a proof whether a student got the whole idea of the solution or not: *‘the teacher would see always the method’; ‘the reasoning’; ‘the process of the proof’.*

**Q1.b:** Half of the students said ‘yes’ and the others said ‘no’: *‘no, because we are used to respond to get the credit, so we address the response to our teacher’.*

**Q1.c:** All of them responded mentioning the reasoning of the student (method, the logic in his response, whether it is convincing, if there is no contradiction): *‘the teacher would follow the reasoning of the student to find out if his understanding is clear or not about the concept’.*

**Q1.d:** Twelve students answered ‘no’ and only two students said ‘yes’. They would keep the idea or the method the same but make better the organization or the presentation: *‘I would have changed the way I wrote, ... the organization’; ‘I would have given more details’.*

**Q3:** Two students (good ones) said ‘the same’; one didn’t answer clearly, six said with more details and/or better organization; two said with better reasoning and three said with more symbols: *‘a mathematician would have another goal, mine is to give the response and get the credit’; ‘he would use only symbols till getting the final result, you see, I wrote a lot of comments’.*

**Q3.a:** Twelve students said that they would contain more symbols and less comments; with an academic rigorous style: *‘it’s different’; ‘my answer is addressed to the teacher while mathematics books are addressed to all’; ‘with more symbols and less comments’.*

**Q3.b:** Four students among fourteen answered by keeping their text as they are. Five said they would improve the organization, three said they would add more details and two said they would make the explanation better: *‘I might keep the idea, but I will give more details’; ‘I would write it better’.*

## Data analysis

### Analysis of the written texts

Different students' weaknesses emerge from the analysis of students' written texts (difficulty of communication, lack of justification, using incomplete mathematical statements (or formulas) and lack of organization of the proof); the last three are of particular interest for MKP. Failing to give justification may be caused by the didactic contract supposing that the teacher would not mind it, by a lack of concept mastery or by a lack of meta-knowledge about proof. Mathematical statements are given incomplete because students might suppose that they are clear for the teacher, or because they are not well mastered by them or not important to be given complete in a proof text, which is related to MKP. The lack of organization of the statements displayed by students might be originated in didactic contract, in lack of concepts mastery, but also in lack of MKP.

### Results of interviews analysis

The answers to Q1, Q1.b and Q1.c. confirm that students, when writing their proof texts, intend to address it particularly to their own teacher. The answers to Q1.d show that students are aware of their unclear text and possible missing details. According to them, they have to focus on two important points that have the same objective: how to get the most part of the credit and show to their teacher that they understood the concept at stake by presenting the main idea or the method of the proof; because they believe that the teacher will focus on that. This shapes their meta-knowledge about proof writing. Most answers to the third question and to Q3.a support more details would be given by a rigorous mathematician and mathematics textbooks, students mention that the organization would be better in both cases than theirs – but they reveal how their conception about proofs in mathematics concerns superficial aspects when they say that proofs in textbooks contain more symbols and less comments and words in comparison with their proofs and do not mention the structure of the proof. Answers to question Q3.b confirm that students are aware that their proof texts need improvement – but it must be related to previous consideration about superficial aspects.

## Conclusion

Students' texts and interviews offered strong evidence for students' lack of MKP and its influence on proof writing. Students have many situations of reference for proofs at their disposal but do not master the operatorial invariants of the proof concept and the form of the proof texts as conscious objects. Findings suggest particularly that the influence of the didactic contract is strong. Teachers generally write proofs in a direct linear way, making unfolding the steps till the conclusion. Students learn to do the same: when they first set some ideas about how to solve a problem, they write their first exploratory draft as a final text because they were never shown how to go further to the written proof text. Here, the didactic contract works against to the development of MKP because the contractual knowledge substitutes the knowledge about the concept of proof. An important element emerged in the interviews, which is the intention of the students to write the proof text only for their teachers, which supports our hypothesis of lack of MKP. Students acknowledge that their texts miss details, but do not see that these missing details would make the organization of the different parts of the proof clearer. This shows that the MKP and the didactical contract are strongly related. When students compare their texts with mathematicians' or textbooks' proofs, they only point out to symbols and comments, they do not see that in these perfect proofs, the statements are

linked through a deductive process from the hypothesis to the proof end, the proof text is organized, not only in its form, but also in the structure; avoiding holes, disconnections and missing justifications. This is evidence of students' superficial perception of proof texts, which indicates lack of mastery of proof structure and representation as a concept, which is related to lack at the operatory invariants level. As MKP is also built up through language, we hypothesize that students' weak mastery of French language, especially in the oral form, which should be translated to the written form, might have contributed to their unclear written texts.

Let us examine now why students are not able to develop their MKP; it seems that they are stuck in a constant perception of proof that does not help them to overcome their difficulties, if not causing some of them, and as long as there are not alternative ways of presenting proofs, they will hold on it. "Students need to understand that proofs are not generally conceived of in the order they are written" (Selden & Selden, 2007, p. 114) and that "successful reasoning can be carried out both by relying on the logic and formal structures of syntactic reasoning, and by relying on the informal representations of mathematical objects of semantic reasoning" (CadwalladerOlsker, 2011, p. 48). Changing or adjusting the didactic contract may favor students' autonomy to understand and make proofs; university teachers often mistakenly think that undergraduates understand what a proof is and how to make proofs by following the standard presented proofs. In fact, "while a traditional definition-theorem-proof style of lecture presentation may convey the content in the most efficient way, there are other ways of presenting proofs that may enable students to gain more insight" (Selden & Selden, 2010, p. 411). Teachers should provide samples of proof construction instead of final products, to be clear about what do they expect from students when they are asked to prove and to provide an opportunity to learn how to make proofs. "In general, professors should avoid "dumbing down" their assessments by asking routine questions that can be answered by mimicking. One needs to modify the "didactic contract" in order to achieve this; otherwise, questions requiring genuine problem solving and proving will be considered "unfair" " (Selden & Selden, 2010, p.414). We support that "university teachers should consider including a good deal of student-student and teacher-student interaction regarding students' proof attempts, as opposed to just presenting their own or textbook's proofs" (cf. Selden & Selden, 2007, p. 114). Finally, in order to gain control, students need to master meta-knowledge about proof; "the difficulty of students to reach a structural axiomatic proof scheme suggests that a capstone course including some attention to meta-mathematics as a topic might be of value to mathematics majors" (Harel and Sowder, 1998, p. 280).

# Conceptualizing reasoning-and-proving opportunities in textbook expositions: Cases from secondary calculus

Andreas Bergwall

Örebro University, Sweden; [andreas.bergwall@oru.se](mailto:andreas.bergwall@oru.se)

*Several recent textbook studies focus on opportunities to learn reasoning-and-proving. They typically investigate the extent to which justifications are general proofs and what opportunities exist for learning important elements of mathematical reasoning. In this paper, I discuss how a particular analytical framework for this might be refined. Based on an in-depth analysis of certain textbook passages in upper secondary calculus textbooks, I make an account for analytical issues encountered during this process and identify aspects of reasoning-and-proving in textbooks that might be missed unless the framework is refined. Among them there are characterizations of generality, use of different representations, logical and mathematical structure, and ordering of material and student activities. Finally, implications beyond textbook research are discussed.*

**Keywords:** Reasoning-and-proving, mathematics textbook, upper secondary calculus.

## Introduction and background

Almost two decades ago, Hanna and de Bruyn (1999) pointed out that textbook research with specific focus on reasoning and proving was rare. Even though a number of papers with such a focus have been published in prominent journals since then, the field is still young. While the ultimate goal is to come up with well-founded prescriptions for textbook design, research is still striving to describe the current state of the art for reasoning-and-proving in textbooks (Stylianides, 2014).

Several studies have focused on (potential) opportunities to learn reasoning-and-proving (RP). Textbooks from different stages in mathematics education, from different educational contexts, and from different content areas have been studied (e.g., Davis, Smith, Roy, & Bilgic, 2014; Nordström & Löfwall, 2006; Otten, Gilbertson, Males, & Clark, 2014; Stacey & Vincent, 2009; Stylianides, 2009; Thompson, Senk, & Johnson, 2012). They typically include one or several of the following aspects of RP: generality (are statements justified with proofs or specific cases?), elements of proof-related reasoning (are students asked to make and investigate conjectures, find and correct errors, design counter examples?), proof methods (direct, indirect, by contradiction), purposes of proof (conviction, verification, discovery etc.), levels of formalism, and mathematical structure.

The variety of analytical frameworks developed for textbook studies can make it difficult to compare findings. However, some researchers have purposefully chosen to use frameworks and methods developed by others. For instance, the framework by Thompson et al. (2012) has been used with slight modification by Otten et al. (2014) and Bergwall and Hemmi (2017), and it was the basis for Bergwall (2015). Their framework is similar to the one developed by Stylianides (2009), which also has been used by Davis et al. (2014). While this simplifies comparison of findings, there is a risk that certain aspects of RP always are missed in the analysis. The purpose of this paper is to examine such potential aspects in relation to the framework by Thompson et al. (2012) and to contribute to a more refined conceptualization of opportunities to learn RP in mathematics textbooks.

## Theory and analytical framework

Mathematics textbooks are widely used in classrooms around the world and are important links between national curricula and student learning (e.g., Stein, Remillard, & Smith, 2007). Tasks and expository sections, as they appear in a textbook, are potential sources for opportunities to learn RP. The concept of RP goes beyond formal proof and includes proving elements such as developing, outlining, or correcting an argument; deriving a formula; making or testing a conjecture; and providing a counterexample.

In this paper, I will focus on opportunities to learn RP through justifications in expository sections. I will use the framework and analytical procedure by Thompson et al. (2012). They employ a four item framework for justifications: A general proof is named a *general justification* (G); a deductive justification based on a generic case is named a *specific justification* (S); if the authors explicitly ask the student to provide a rationale it is referred to as *justification left to student* (L); and otherwise there is *no justification* (N). As in Bergwall and Hemmi (2017), I include all non-proof arguments in the S-category.

Stylianides (2009) uses a more refined framework with a separate category for specific justifications that are not generic. Otten et al. (2014) made modifications to the framework by Thompson et al. (2012) and distinguish between specific and general statements. They also have additional categories for justifications that only outline the general proof and for justifications that can be found in past or future lessons. We have adopted Thompson et al. (2012)'s methodology for the present and other studies (Bergwall, 2015; Bergwall & Hemmi, 2017). It has been put forward that mathematics education research needs more of cumulative research (Lesh & Sriraman, 2010) and we want to compare with – and build on – Thompson et al.'s extensive results on US upper secondary textbooks.

## Textbook sample and analytical procedure

Cases for the present paper are chosen from the two most commonly used textbooks in Sweden and the only Finnish textbook available in Swedish (for Finland's Swedish speaking minority): Alfredsson, Bråting, Erixon, and Heikne (2012); Szabo, Larson, Viklund, Dufåker, and Marklund (2012); and Kontkanen, Lehtonen, Luosto, Savolainen, and Lillhonga (2008). I refer to them as SW1, SW2, and FI1 respectively.

In Bergwall and Hemmi (2017), we report our findings from an analysis of all expository sections and students' tasks on integral calculus in these textbooks (and others). In that study, we identified all mathematical statements presented as results and categorized their justifications using the framework described above. Like Thompson et al. (2012), we also checked if there were opportunities for the students to conjecture the result, how the statements were labeled, and what proving methods were used. Like researchers always do during such processes, we encountered a number of analytical difficulties. In the present paper, I will focus on these difficulties and on other issues that became apparent when the textbooks were compared to each other. I consider them a relevant base for discussing the development of frameworks for RP opportunities.

An upper secondary textbook cannot present a general theory for integral calculus. Thus its authors face the problem of what kind of justifications to include. This makes this topic relevant when examining frameworks for opportunities to learn RP. I will illustrate my findings with an analysis of the sections where students first encounter the definition of primitive function, the statement of the

representation formula  $F(x) + C$  for all primitive functions to  $F'$ , and the justification of this result. This particular choice was made since it includes a complete definition-theorem-proof chain for a central concept and a non-trivial result. Furthermore, the textbooks present this particular content quite differently.

## Analysis and results

The analysis and results are presented as follows. I give a condensed description of how each textbook treats primitive functions, following the chronology of that textbook. This description will include all details needed to: (1) make an analysis according to the Thompson et al. (2012) framework, (2) describe analytical difficulties, and (3) make my points about the need to further develop the framework. Aside from the textbook's *definition*, *justification* and *statement*, I describe material placed immediately *before*, *after*, and *in between* them if such exists. This is followed by my *analysis* and description of *analytical difficulties* and *other issues*. Finally, I make a short *summary* of aspects of RP opportunities that could be better incorporated in the framework.

For easier reference, the descriptions of the justifications are presented as numbered lists. Note that the representation formula can be expressed as an equivalence. Therefore the (trivial) statement that  $F(x) + C$  is a primitive function to  $F'(x)$  will be referred to as 'the sufficiency', while the (non-trivial) statement that *all* primitive functions have this form is referred to as 'the necessity'.

### SW1 (Alfredsson et al., 2012, pp. 173-174)

*Before.* There is one exercise where the student, based on graphical representations, shall identify which function has a certain derivative, and another where the student shall draw two different graphs with the same derivative. This is followed by a short note that it now is time to turn the problem of finding the derivative around.

*Definition.* The following text is framed and labelled 'Primitive function': "A function  $F$  is called a primitive function to  $f$  if  $F'(x) = f(x)$ ."

*In between.* The authors write about three questions that need to be answered: How to find *one* primitive function, *all* primitive functions, and *the* primitive function satisfying a certain condition?

*Justification.*

1.  $x^2$  and  $x^2 + 5$  are presented as examples of functions with derivative  $2x$  and the reader is told that "whatever constant  $C$  we add to  $x^2$  we get a primitive function to  $f(x) = 2x$ ".
2. There are plots of the graphs to  $x^2 + 1$ ,  $x^2$ ,  $x^2 - 1$  and  $x^2 - 2$ , and the authors write: "Obviously, graphs to functions with the same derivative must for every  $x$ -value have the same slope. Hence the graphs have the same form, they are only translated in the  $y$ -direction".
3. The authors continue: "This means that if  $f(x) = 2x$  then every function  $F(x) = x^2 + C$ , where  $C$  is a constant, is a primitive function to  $f(x)$ ".
4. The authors ask if there are other functions with derivative  $2x$  and immediately answer that it can be proven that there are no such functions.

*Statement.* The following text is framed and labelled 'Summary': "If  $F(x)$  is a primitive function to  $f(x)$  then  $F(x) + C$ , where  $C$  is a constant, denotes all primitive functions to  $f(x)$ ".

*After.* There are two worked examples illustrating how primitive functions are determined, a table with some elementary primitive functions and then a student exercise set.

*Analysis.* (1) provides two specific cases for the sufficiency ( $x^2$  and  $x^2 + 5$ ), and it is said in words (without explanation) that any additive constant works. The necessity is touched upon in (2). This might be meant as an intuitive argument. But it is merely a formulation in words of the statement itself with no further warrants for the conclusion. The authors also chose to return to the sufficiency in (3) before they return to the necessity in (4), but once again without any argument. This means that in relation to the framework by Thompson et al. (2012) the sufficiency is justified with a specific case (S) and that there is no justification (N) for the necessity.

*Analytical difficulties.* The first difficulty was to decide if this justification should be counted as one or two. In Bergwall and Hemmi (2017), we chose the second alternative. However, if the unit of analysis is the justification of the statement as it is formulated in the textbook one could also choose the first. Then there are at least two alternatives: the justification receives the code N (since there are not justifications for both directions) or the code S (since there is a specific case justification for at least one direction).

The second difficulty was whether (2) should be counted as an intuitive justification of the necessity and receive the code S instead of N, since it seems to have a convincing purpose.

*Other issues.* Even a specific case such as  $x^2 + C$  has some generality to it: the identity  $(x^2 + C)' = 2x$  holds for *all*  $x$ . This indicates that when dealing with functions there is room for a more nuanced way of describing justifications than the categories G and S admit. Also, if the textbook statement had been that  $x^2 + C$  denotes all primitive functions to  $2x$ , then the justification offered for the sufficiency is a general proof.

*Summary.* The analytical framework/method should be developed to better account for opportunities to learn: *the difference between an equivalence and an implication and how such are justified; the roles of different kinds of non-proof justifications, such as intuitive arguments based on visual impressions from a drawing of an “arbitrary” case; and that justifications can be specific in different ways when statements include several kinds of variables (dependent and independent), and that whether a justification is general or not also depends on how general the statement is.*

## **SW2 (Szabo et al., 2012, pp. 154-155)**

*Before.* The authors demonstrate how velocity can be obtained by differentiating the distance function and then state that the opposite problem can be solved by asking which function has a certain derivative. In the margin there is a table with some elementary derivatives.

*Definition.* The following text is framed and labelled ‘Primitive function’: “A function  $F$  is a primitive function to  $f$  if  $F'(x) = f(x)$ .”

*Justification.*

1.  $x^2$ ,  $x^2 + 5$ , and  $x^2 - 4$  are given as examples of functions with derivative  $2x$  and in the margin it is emphasised that the derivative of a constant term is 0.
2. The authors write: “You can add and subtract any constant to a primitive function without altering its derivative. Thus a given function has an infinite number of primitive functions”.

*Statement.* The following text is framed and labelled ‘All primitive functions’: “If  $F'(x) = f(x)$  then  $F(x) + C$ , where  $C$  is a constant, gives all primitive functions to  $f(x)$ .”

*After.* There are two worked examples illustrating how primitive functions are determined followed by a student exercise set.

*Analysis.* The sufficiency is justified with three specific functions in (1). That any constant  $C$  can be added/subtracted is explained in (2). However, it is not clear if the first sentence cited in (2) refers to a primitive function to *any* function or to a primitive function to  $2x$ . In the former case, the argument could have been expressed symbolically as  $(F(x) + C)' = F'(x)$ , which most teachers and mathematicians would have accepted as a proof. In the latter case, the sufficiency is only justified with a specific case. Concerning the necessity, there is neither a justification nor a remark that there is something more to prove. Summing up, this means that there is an ambivalence concerning the sufficiency ((S) or (G)) and that there is no justification (N) for the necessity.

*Analytical difficulties.* The question arises whether (2) is a general proof or not. There are two issues here: The use of words instead of algebraic symbols, and clarity in what the authors refer to.

*Other issues.* When comparing SW1 and SW2, we see at least three differences even though the classifications of the justifications are the same. First, SW1 discusses the necessity and states that it can be shown that there are no other primitive functions, which SW2 does not. But neither textbook clearly expresses the representation formula as an equivalence. Second, SW1 uses graphic representations and describes the meaning of the statement in terms of slope and form which SW2 does not. Third, SW2 is less vague in its labelling and formulations. While SW1 labels the statement “summary” and expresses that  $F(x) + C$  “denotes” all primitive functions, SW2 uses the label “All primitive functions” and expresses that  $F(x) + C$  “gives” all primitive functions.

*Summary.* The analytical framework/method should be developed to better account for opportunities to learn: *what needs to be justified, what has been left out of a certain justification, or if a justification is a proof or not; the role of different forms of representations; and the structure of mathematics, i.e. what part of a mathematics text that is a definition, a statement, and a proof, and what their different roles are.*

### **FI1 (Kontkanen et al., 2008, pp. 7-8)**

*Definition.* The following text is framed and labelled ‘Primitive function’: “Assume that the functions  $f$  and  $F$  are defined in the open interval  $I$ . The function  $F$  is a primitive function to  $f$  for every  $x \in I$ , if  $F'(x) = f(x)$ .”

*In between.* In worked examples, the authors demonstrate how one checks if a certain function is a primitive function to another given function. In one of these examples, it turns out that two different functions can be primitive functions to the same function. However, the algebraic descriptions of these functions are not such that it is obvious that they only differ by an additive constant.

*Statement.* The following text is framed and labelled “theorem”: “Assume that  $F_0$  is a primitive function to  $f$ . Then all functions of the type  $F(x) = F_0(x) + C$  are primitive functions to  $f$ . The function  $f$  has no other primitive functions.”

*Justification.* The justification is labelled “proof” and divided in two steps. First the sufficiency is justified by differentiation of  $F(x) = F_0(x) + C$ . Then the necessity is justified using the fact that if

a derivative is 0 everywhere the function is constant. For this fact, there is a reference to a theory section at the end of the book.

*After.* It is pointed out and illustrated in a diagram that the additive constant  $C$  corresponds to a vertical translation of the graph. The notation  $\int f(x)dx$  is introduced. This is followed by three worked examples on calculation of primitive functions and a set of student exercises.

*Analysis.* The sufficiency and the necessity are both justified with general proofs (G).

*Analytical difficulties:* There are none that have not been mentioned so far.

*Other issues:* In FI1 it is clear that the statement contains two parts even though it is not formulated as an equivalence. The justification is labelled proof (SW1 and SW2 have no labels on their justifications). The justification comes after the statement (not before as in the Swedish books). There is a graphical interpretation of the statement but it is put after the proof (not before as in SW1) and it seems to have the purpose of illustrating the meaning of the statement (and not to justify it as in SW1). FI1 is the only textbook that emphasizes that being a primitive function actually is a global property (i.e. that  $F'(x) = f(x)$  should hold for *all*  $x$  in an interval). However, as in SW1 and SW2 the definition is phrased using the word ‘if’ even though it should be interpreted as ‘if and only if’.

SW1 and SW2 have activities and/or worked examples before the definition which together with their justifications give the student an opportunity to discover and conjecture the statement. In FI1 the section starts with the definition. The indefinite integral notation is used throughout FI1 but is completely avoided in SW1 and SW2.

*Summary.* The analytical framework/method should be developed to better account for opportunities to learn: *mathematical formalism, detail and notation; different purposes with different forms of representation; the conjecturing as well as the verifying nature of mathematical work; and the importance of clear definitions.*

## Discussion

When opportunities to learn RP are studied in textbooks there are several aspects to take into account and there is always a risk that important aspects are left out. The examples mentioned above illustrate a number of such aspects identified when a specific analytical framework was applied to a few textbook passages on primitive functions. Here I chose to discuss the importance of four such aspects of RP and their relevance in a refined framework for RP.

The first aspect is *generality* and relates to opportunities to learn what makes a justification a proof. Students’ difficulties with understanding the difference between a general proof and an example are well-established (e.g., Harel & Sowder, 2007). However, justifications can have different levels of generality, or ‘scope of variation’, which opens up for sub-categories of non-proof justifications (e.g., Bergwall, 2015). Also, a justification must be judged in relation to the statement’s formulation and the level of detail in relevant definitions. Thus an analysis of textbook justifications should include an analysis of statements (which Otten et al. (2014) do) and definitions.

The second aspect concerns *forms of representation* and relates to opportunities to learn how proofs are communicated. Sometimes a justification is better expressed in words but often algebraic symbols bring more precision and detail to the argument. Graphical representations may be used to illustrate

meaning as well as the idea behind an argument. Frameworks should take the use of different forms of representation and their roles and purposes into account.

The third aspect is *structure* and relates to opportunities to learn the role of proof in mathematical theory. Here I include the logical structure of individual definitions, statements and justifications as well as the overall structure of the mathematical theory, with its definitions, theorems and proofs, and the connections between them. To some extent this is captured in an analysis of labeling (as in Thompson et al. (2012)) and references to other lessons (as in Otten et al. (2014)).

The fourth aspect is about *ordering* of the material, including student exercises and worked examples, and relates to opportunities to learn different purposes of proof, and to how justifications can serve different educational purposes. Student investigations, specific cases and intuitive arguments placed before a statements can emphasize the creative and conjecturing side of mathematical work, while formal general proofs placed after the statement can emphasize the verifying and organizing side.

All four aspects have one thing in common. They concern proofs and justifications as objects and not only as processes (e.g., Sfard, 1991). To analyze if textbooks offer opportunities to understand proofs and justifications as objects, the analytical frameworks and methods need to focus on opportunities to learn object properties of proofs and justifications. Generality, forms of representation, structure, and ordering are examples of such properties.

Finally, development of frameworks and methods that better capture important aspects of RP are of importance not only for textbook analysts and textbook authors. Similar frameworks can be used for analyzing lecture scripts and teaching episodes. Hence they can also aid teachers when they plan their lectures and teaching elements. A detailed framework risks being of limited analytical use but is an important contribution when conceptualizing opportunities to learn RP.

# Cognitive unity of theorems, theories and related rationalities

Paolo Boero

DISFOR, Genoa University, Italy; [boero@dima.unige.it](mailto:boero@dima.unige.it)

*The construct of cognitive unity of theorems was introduced twenty years ago to identify suitable conditions for students' "smooth" approach to proving. In this paper the Habermas' construct of rationality, adapted to mathematics education in previous research, is used to identify some factors in the activation of cognitive unity of theorems. In particular, I consider the dependence of cognitive unity on the specific rationality (e.g. analytic geometry rationality, or synthetic geometry rationality) according to which a conjecturing and proving problem is dealt with. The analysis of some examples will provide evidence for it, together with hints for further research.*

*Keywords: Theorems, conjecturing and proving, cognitive unity, proving as rational behavior.*

## Introduction

"Cognitive unity of theorems" (CUTHE) is a construct introduced in Garuti, Boero, Lemut & Mariotti (1996) to account for a phenomenon detected in a grade 8 (13-years-old students) classroom engaged in a conjecturing and proving activity, concerning a theorem of space geometry contextualized and verbally expressed in terms of Sun rays (instead of straight lines) and Sun shadows (instead of shapes projected on a plane according to parallel projection rules). The conjecturing task (see Garuti et al, 1996) may be shortly reported this way: "Is it possible that the Sun shadows of two non-parallel sticks are parallel on the ground? If yes, under which conditions?". After comparison and standard re-phrasing ("if... then...") of their conjectures, students were asked to validate their statements by "general reasoning". We observed that, while trying to validate their conjectures, several students resumed some pieces of personal reasoning (e.g. ways of looking at the Sun rays and the Sun shadows) developed during the production of the conjecture and the search for reasons for its validity, and arranged them in a deductive chain of statements. The ways of looking at the Sun rays and the space relationships had been different for different students; those ways corresponded to the different ways of proving the theorem by them. After having found other theorems (in geometry, and in elementary arithmetic) for which students behaved in a similar way, we defined "cognitive unity of theorem" (CUTHE) what happens for some theorems when:

during the production of the conjecture, the student progressively works out his/her statement through an intensive argumentative activity functionally intermingled with the justification of the plausibility of his/her choices. During the subsequent statement-proving stage, the student links up with this process in a coherent way, organizing some of the previously produced arguments according to a logical chain (Garuti, Boero, & Lemut, 1998, p. 345).

The CUTHE construct was also extended to the case of the relationships between the exploratory phase of proving a theorem, and the subsequent construction of a proof for that theorem (Garuti et al., 1998): indeed, the exploratory phase of proving shares some common aspects with conjecturing (as re-construction of the meaning, and appropriation, of a statement; and identification of elements for its validity). The construct of cognitive unity resulted in various research developments. Pedemonte (2007, 2008) performed studies in which (given a theorem for which CUTHE is accessible to students) the mechanism of arranging arguments produced in the exploratory phase

does not result in a proof for some students, due to their difficulty of re-arranging inductive or abductive arguments into deductive arguments. These difficulties are not likely to emerge in algebraic conjecturing and proving (Pedemonte, 2008), while they frequently emerge in the case of plane geometry (Pedemonte, 2007). Leung and Lopez Real (2003) investigated CUTHE in the case of computer-based learning environments, which change the nature of students' exploration and make CUTHE difficult to activate, finding out ways of activating it in the new situation. Fujita, Jones and Kunimune (2010) studied conditions under which CUTHE may be activated in the field of synthetic geometry: they "analyze the circumstances when students *unite*, or not, their conjecture production and proof construction"; the potential of geometrical constructions for the activation of CUTHE was explored. The quoted studies suggest the opportunity of investigating the conditions for the activation of CUTHE for a given theorem. Boero et al. (1998) started a discussion on it, taking into account both the student (her skills, her knowledge and expertise in a given field of mathematics) and the field of mathematics in which a given statement is dealt with. Douek (1998) analyzed the individual variety of exploration strategies and their effects on conjecturing and proving; at present (personal communication) she is further deepening the idea of subject-relativity of CUTHE, together with the relationships between the quality of student's exploration (including its semiotic features) and the construction of the proof. In this paper I will try to identify some aspects of the relativity of CUTHE referred to a given system of discursive practices that concern the truth of statements, the ways of producing and validating them, and the ways of communicating with others - i.e. a "rationality", according to Habermas (1998).

## **Theoretical assumptions**

### **Mathematical theory**

It is possible to define a mathematical theory (shortly, a theory) by its characteristic components: primitive notions, and definitions related to them; postulates; inference rules to get true statements from the postulates and other statements proved as true. 'Characteristic components' depend on the historical period and, in a given historical period, on epistemological assumptions that may be different, according to different fields of mathematics. The case of Euclidean geometry before and after Hilbert's *Grundlagen der geometrie* is a well-known paradigmatic example of historical change in the ways of considering the requirements of a mathematical theory. In this paper, we will consider the following theories: Synthetic geometry (in particular, Euclidean geometry); Analytic geometry (including the algebraic treatment of conic sections); Elementary, verbal-semantic number theory (evidence for truth and inference rules rely on properties of the concept of number and its representations); Elementary, algebraic-formal number theory (evidence for truth of statements comes from the interpretation of an algebraic expression derived, through suitable syntactic transformations, from the algebraic expression which represents the problem situation).

### **Theorem**

Mariotti (2001) defines a theorem as a statement and its proof with reference to a theory (and related inference rules). The definition results in the possibility of considering different theorems with the same statement (in particular, when different proofs referring to different theories are available). The definition encompasses theorems related to various kinds of theories and related inference rules: Euclid's as well as Hilbert's geometry; analytic geometry; graph theory, with its

reference to visual objects; 19th-century probability theory as well as Kolmogorov's axiomatic theory, etc.; and the different ways of considering proof since the Greeks, including verbal-semantic proofs (like in Euclid) and modern algebraic-formal proofs of arithmetic statements.

### **CUTHE and Habermas' rationality**

In this paper we are interested in CUTHE, one possible aspect of the conjecturing and proving process, in order to identify for which theorems (in Mariotti's sense) it may be easily activated, thus we need a comprehensive frame to deal with the process of proving and its relationships with the product (proof) to be built up in a given theory. Habermas (1998, pp. 310–317) deals with the complexity of discursive practices according to three *interrelated* components, concerning: knowledge at play, and the answer to “why is it true” questions in a given cultural context (*epistemic rationality*); action and its goals, and strategies to achieve them, to be evaluated (*teleological rationality*); communication and related, intentional choices in a given social context on a given subject (*communicative rationality*). In Boero & Planas (2014) a detailed elaboration of the reasons for adapting Habermas' construct to mathematics education is presented, with references to how it has been used in different studies. In the case of proof and proving, according to Mariotti's definition of theorem, the adaptation of the Habermas' construct concerns:

- criteria for validity of inferences and truth of statements within a theory, and their dependence on historical periods, mathematical domains, and institutions and cultures. Inferences may rely on visual evidence, or conceptual meaning, or syntactic transformations, etc.;
- problem solving strategies that may be adopted to reach the goal of proving, along with their effectiveness; strategies may use analogies, abduction, and so on. Strategies and exploration are not constrained within the border of the reference theory;
- the choice and use of appropriate communication means for proof in a given context,

together with the relationships among them, taking into account the goal of the proving process — a proof, conforming to requirements specified for the first and the third components. The expression ‘rationality frame’ will be used to put into evidence the system of epistemic constraints, strategies and forms of communication, which works as reference for proving and proof in a given theory.

### **Examples**

Moving to the school, the role of the following examples is to provide evidence for the hypothesis that CUTHE depends, for the same statement, on the specific rationality frame in which a conjecturing and proving problem is dealt with by the student; and also to provide elements for further investigation. The examples will include some excerpts from students' think aloud solving processes. *Italic* is for written texts. (...) is for omitted sentences. ... is for a pause in oral speech.

#### **Example 1**

The same conjecturing and proving problem was proposed in grades VIII and IX: “Consider all the products of three consecutive natural numbers. What is their GCD? Prove that it is their GCD”. S-A is a grade VIII (13-years-old) student not yet familiar with the use of letters to prove:

Student S-A:  $1 \cdot 2 \cdot 3 = 6$        $2 \cdot 3 \cdot 4 = 24$        $3 \cdot 4 \cdot 5 = 60$        $10 \cdot 11 \cdot 12 = 1320$ ; it is evident that 6 is the GCD of the first three products, because it is the greatest divisor of the first product and a divisor of the other products. Is it a divisor of 1320? ... Yes, 1320 is

an even number divisible by 3 because the sum of its digits is a multiple of 3. Then 6 might be the divisor of all the other products too. But why? Probably, by looking at these four products, all the products are even... But why? OK, one factor is always even! Even numbers go two by two, thus among three numbers one number ... one number at least is even, and they may be two, like in the case of  $2 \cdot 3 \cdot 4$ . Look at, three is there! And a multiple of three is in the last product! Why? In the case of 2, multiples go two by two ... In the case of 3, numbers go three by three. That is the reason! Now I try to write down the general reasoning: *The greatest common divisor is 6 because every product is divisible by 6 because every three consecutive numbers contain one even number (multiple of 2) and one multiple of 3, because multiples of 2 go two by two, and multiples of 3 go three by three* (The teacher writes the following question: *Why greatest?*) (after a while) *Because the first product is divisible by 6, and no greater divisor is there.*

S-A resumes the examples, which conjecturing was based on, to identify *general* reasons for the truth of the conjecture. The intention of proving is related to the emerging conjecture, through “But why?” self-posed questions of epistemic relevance. A narrow intertwining between epistemic, teleological and communicative components of rationality allows the student to move continuously from exploration to the production of the conjecture, to proof construction by exploiting relevant elements got during the exploration, and then to proof writing. We may consider S-A’s solution as an example of CUTHE in the rationality frame of verbal-semantic elementary theory of numbers.

S-B is a grade IX student who tries to solve the problem after some classroom work (about 10 hours) on the use of letters to prove in an algebraic way. Note that he would be free (according to the didactic contract) to choose another way of solving the problem, as other schoolmates do:

Student S-B:  $(n+1)(n+2)(n+3) = (n^2+2n+n+2)(n+3) = (n^2+3n+2)(n+3) = n^3+3n^2+2n+3n^2+9n+6 = n^3+6n^2+11n+6$ . I do not see anything. But if I consider, for instance,  $2 \cdot 3 \cdot 4 = 24$   $3 \cdot 4 \cdot 5 = 60$   $5 \cdot 6 \cdot 7 = 210$  I see that... Yes, I see that 6 is always a divisor, because I see it as  $2 \cdot 3$ , as one half of  $3 \cdot 4$ , as 6 in the products. The same for  $13 \cdot 14 \cdot 15$ . (...) 24 is also divisible by 12, and by 8, but 60 is not divisible by 8, but it is divisible by 12. Let us see 210: (...) not divisible by 12, thus 6 is the only remained candidate! With algebra:  $n^3+6n^2+11n+6 = 6(n^2+1) + n(n^2+11)$ . I do not see anything. Perhaps it is not true!  $16 \cdot 17 \cdot 18$  (...) not a good counter-example! Because 18 is divisible by 6.  $21 \cdot 22 \cdot 23 =$  (the student uses his cellular phone to make calculations; the product is divisible by 6). Perhaps it is easier by considering:  $(n-1)n(n+1) = n(n^2-1)$ ... I see nothing! I am not able to prove it!

S-B tries to solve the conjecturing and proving problem in the rationality frame of elementary algebraic theory of numbers; the difficulty to produce a conjecture in that frame is overcome by moving to the rationality frame of verbal-semantic theory, where afterwards he will also try to dispel a doubt on the truth of the conjecture by considering a further, more elaborated example. Differently from S-A, no effort is addressed to find general numerical regularities that might be exploited to build up a verbal-semantic proof. In terms of rational behavior, this is an example of lack of connection between two different strategies (teleological aspect): to produce the conjecture and afterwards to provide some empirical evidence for it; and to produce a general reasoning for

proving. As a consequence, CUTHE does not work in the rationality frame where it could have been activated (verbal-semantic theory). The same happened with the other students who tried to build up an algebraic - formal proof. Note that an algebraic - formal validation of the statement may be performed either in combinatorics, or in modular arithmetic. Some schoolmates get the conjecture in the rationality frame of verbal-semantic theory of numbers, then they consider the products  $(n+1)(n+2)(n+3)$  or  $(n-1)n(n+1)$  and realize that in these products one number is divisible by three and at least one number is divisible by two; thus proving still relies on semantic considerations related to the number line and the positions of multiples of 2 and 3 in it, like in the case of S-A. The algebraic expression of the product is only a device to favor the transition to a general reasoning. CUTHE works thanks to the intention of finding general regularities and a proof in the same rationality frame of verbal-semantic theory, where the conjecture had been produced.

### Example 2

A conjecturing and proving problem was proposed by the same teacher in grade XI, in three parallel classes, as an individual task: “Among the triangles with a given side and the same perimeter, find the triangle with the greatest area”. Those classes were familiar with conjecturing and proving in number theory (both in a verbal-semantic way and in an algebraic way), and in Euclidean geometry.

The first class at that moment was familiar only with proving in plane Euclidean geometry; according to the conjecturing style of Euclidean geometry, some students (one third of that class) got the conjecture (the solution of the problem is the isosceles triangle) by considering that, after drawing some triangles, an isosceles triangle looks as the “widest” one (students say: “the fattest”) among the drawn triangles (but three students got the conjecture of a right-angled triangle with the same considerations); a few students got the conjecture through a “limit & symmetry” consideration related to the fact that, when the triangle becomes strongly asymmetric, the surface within it becomes very “small”, if we want to keep the same perimeter. During the discussion on the produced conjectures, after disproving (through measures) the conjecture concerning the right angled triangle, some students proposed to consider another triangle with the same height of the isosceles triangle (thus with the same area), and to try to prove that its perimeter is longer than in the case of the isosceles triangle. But a rigorous proof is not easy to build up, and in fact no student built it up, in spite of a long time spent for it in the classroom, by working in small groups (and then at home as well!); a relatively easy proof needs an auxiliary construction and the use of related theorems. The exploration to get the conjecture only suggests a first step of a proving process, and does not provide the ingredients to build up the proof: CUTHE does not work.

The second class had already met conic sections in synthetic geometry (they knew that an ellipse is the locus of points whose sum of distances from two given points is constant, and its basic properties concerning symmetry, axes, etc.). In this class, the conjecture was produced in a similar way as in the first class; but one fourth of students, thanks to the drawings of some triangles with approximately the same perimeter, arrived also to make a link with the ellipse in synthetic geometry. Students shared what had been discovered; then (by working in small groups) four groups out of six were able to solve the proving problem by considering the properties of an ellipse in synthetic geometry. The exploration provided students with a visual link with the ellipse in synthetic geometry, thus bridging conjecturing with proving – even if proving did not rely on the

considerations (“fatness” of triangles) that has generated the conjecture (and thus CUTHE did not work). Here is an excerpt from S-C’s think aloud process:

Student S-C: (...) Now I have a reasonable conjecture. How to prove it? (student C draws three more triangles, with the same side in common with the four previously drawn triangles, and approximately the same perimeter). It is even more evident that the isosceles triangle has the largest area. But it seems to me that all those triangles have something in common. Their free edges are ... Yes! I understand: the same perimeter means that the free edges are on an ellipse. Thus I may try to see if I succeed to build the proof by using the ellipse. (...)

The third class had already constructed, under the teacher’s guide, the equations of a circumference and a parabola by translating into algebraic equations the characteristic conditions of those geometric loci. They had not yet met the equation of an ellipse, or the notion of an ellipse in synthetic geometry. The teacher suggested to use algebra to solve the problem. Student S-D is a representative of those students (about one third of the class) who succeeded in finding the conjecture and proving it. S-D draws three triangles with (approximately) the same perimeter:

Student S-D: I must maximize an expression for the area of the triangle, when  $x$  changes:

The maximum is when  $x=0$ . Perhaps this is the solution! But I have not considered the condition  $a+c=K$ . And what I found is ... it is obvious:  $x=0$  means the rectangle triangle. Obvious: in that case the side of length  $a$  is vertical, namely, maximum height of the triangle. But that side has always the same length. But in this problem  $a$  is related to  $c$ . I should find how to take the condition  $a+c=K$  into account. Perhaps it should be good to compare two expressions for the height of the triangle, perhaps... in order to get the area depending only on  $b$  and  $K$ .

$$h = \sqrt{a^2 - x^2} = \sqrt{c^2 - (b-x)^2} \quad a = K - c \quad K^2 - 2Kc + c^2 = c^2 - b^2 + 2bx - x^2$$

$$a^2 - x^2 = K^2 - 2Ka + a^2 - b^2 + 2bx - x^2 \quad 2Ka = K^2 - b^2 + 2bx \quad a = \frac{K^2 - b^2 + 2bx}{2K}$$

$$a = \frac{K^2 - b^2}{2K} + \frac{bx}{K} \quad T > 0 \quad A = \frac{b}{2} \sqrt{\left(\frac{T + 2bx}{2K}\right)^2 - x^2}$$

Good! Given  $K$  and  $b$ , the area depends only on  $x$  (algebraic calculations follow)

$$A = \frac{b}{4K} \sqrt{T(-4x^2 + 4bx + T)}$$

Now it works: I see the equation of a parabola; ... if  $x=b/2$  I get the the vertex of the parabola, it means the maximum... the maximum of the area. (S-D draws an isosceles triangle) OK, it looks fine: the isosceles triangle looks as the widest one!

We may observe how (as it usually happens in analytic geometry) conjecturing and proving are dealt with at the same time, thus CUTHE works. Exploration is driven by the goal to be attained through algebra, thus the initial figures are not exploited to get a conjecture. The first trial is abandoned after interpretation of the algebraic result, the second one develops and brings to the conclusion. Epistemic control works on formalization, choice of syntactic transformations, and interpretation of results (see Morselli & Boero, 2011, pp. 455–456).

## Conclusion and discussion

The aim of this paper was to elaborate the idea of cognitive unity of theorems (CUTHE) by relating it to the rationality frame available to (or chosen by) students to solve a conjecturing and proving problem. Through the examples (particularly Example 1, S-A and also Example 2, S-D) we have seen how the same statement may be produced in a particular rationality frame and then proved in the same rationality frame by exploiting some elements produced during the conjecturing phase, in a continuous process where the intention to achieve the conjecture and ascertain why it is true drives the attention of the student to relevant aspects of the problem situation, useful to build up the proof. While the same statement of Example 1 resists S-B's effort of proving it in another rationality frame. The same for the statement of Example 2 in the frame of Euclidean geometry.

This paper brings some elements of novelty in the field of research, which deals with the relationships between the exploratory phase of conjecturing and proving (or of proving a given statement), and the phase of proof construction. Through the use of the rationality construct, the hypothesis of dependence of activation of CUTHE on the theory chosen as reference for conjecturing and proving, already briefly presented in Garuti et al (1998), is further elaborated, with a counterpart in some examples from classroom activities. The rationality perspective provides a lens to compare (and distinguish between) different rationalities in mathematics, with different opportunities to validate the same statement by activating CUTHE. The chosen examples (particularly in the case of S-B if compared with S-A and with some S-B's schoolmates) also suggest to move to a deeper consideration of the relationships between the student's intention (i.e. the teleological component of her rational behavior) and the production of those elements, which might be arranged in a deductive chain in order to get a proof. Another, possible research development (related to Douek's present work) concerns a connection with what is called "semantic proof production" in Weber (2005, p. 356–357): in his reported example the student produces a visual-graphic representation of the sequence  $(a_n)=(1,0,1,0,1, \dots)$  and a horizontal band, which 'shows' that the sequence is not convergent to a limit; that "informal representation" suggests and guides "the formal inferences that (she) would draw". CUTHE does not work: elements produced during the exploration are not resumed as steps of the construction of the proof in the rationality frame of formal Calculus. But those elements allow to bridge the exploration of the proving situation with the construction of a proof in terms of the teleological component of rationality, with some analogy with the case of S-C (in Example 2); both cases suggest to widen the idea of CUTHE by including that kind of productive relationships between exploration and proof construction.

# Supporting classroom implementation of proof-oriented tasks: Lessons from teacher researcher collaboration

Orly Buchbinder

University of New Hampshire, USA; [orly.buchbinder@unh.edu](mailto:orly.buchbinder@unh.edu)

*This paper reports on a professional development (PD) which aimed to support secondary teachers in incorporating argumentation and proof-oriented tasks in their classrooms. The teachers interacted with researcher-developed models of proving tasks in a variety of ways, including modifying the tasks to their classrooms contexts, implementing the tasks, sharing and reflecting on the experiences. In the process of modifying proof-oriented tasks by teachers some of the original researcher-intended goals were lost, while other unexpected affordances emerged. This raises important questions regarding modes of teacher-researcher collaborations around proof-oriented classroom interventions, and their potential effectiveness.*

*Keywords: Reasoning and proof, professional development, instructional activities, classroom interventions.*

## Introduction

As the body of knowledge on reasoning and proof grows, the focus of mathematics education research has shifted from examining individual students' conceptions of proof and theorizing about potential causes of students' difficulties with proof towards designing classroom interventions that aim to remediate these difficulties and provide instructional support for students and teachers in classrooms (Stylianides & Stylianides, 2016). In this process teachers play a critical role, as they are responsible for establishing learning environments in their classrooms. In line with the wide recognition of the importance of argumentation and proving to students' mathematical experiences (e.g., Reid & Kipping, 2010) teachers are expected to implement tasks that promote reasoning, and have students construct and critique mathematical arguments (CCSS, 2010).

While many teachers agree, in principle, with this vision of mathematics classrooms, they often find them challenging to implement and maintain over time (Brodie, 2010). Moreover, only a limited number of professional development (PD) settings explicitly focus on argumentation and proving in connection to classroom practices (Brodie, 2010). Hence there is a need to expand the theoretical and practical knowledge of successful strategies for supporting teachers in this area.

This paper reports on an experimental model of a PD intended to support teachers in incorporating argumentation and proving in their classrooms. The following sections describe theoretical grounds underlying a special feature of the PD: teachers modifying researcher-designed proof tasks for implication in their classrooms. I illustrate two such modified tasks and analyze them in terms of affordances for students' learning, and their (mis)alignment with the original designer's intentions. I close by discussing some implications for supporting teachers' implementation of proof-oriented classroom activities.

## Theoretical framework

### Supporting change in teacher practices: the emphasis on argumentation and proving

Research has identified key features of PD settings that have shown to be successful in supporting change in teachers' practices. Among them are: focus on content and pedagogical knowledge, active learning experiences, establishing strong connections to teachers' own classroom contexts, and providing ongoing support for teachers (Copur-Gencturk & Papakonstantinou, 2015). These general features can be adapted to provide targeted support for teaching argumentation and proving, for example, by emphasizing mathematical knowledge for teaching proof (MKT-P).

Building on Stylianides's (2011) notion of "comprehensive knowledge package for teaching proof", Buchbinder et al. (2016) suggest that MKT-P includes 4 types of knowledge. Two types are related to pedagogical content knowledge: (a) knowledge about students' conceptions of proof, and (b) knowledge of pedagogical practices for supporting students' development of correct conceptions of proof. The other two types of MKT-P involve subject matter knowledge: (c) robust knowledge of mathematical content involved in a given task, and (d) meta-mathematical knowledge of proof, such as argument validity, logical connections, types of proof, and the role of examples in proving. These four types of knowledge were addressed in the design of the PD reported in this study. In addition, the PD activities established strong connections to teachers' own classrooms by providing practical tools for teachers to develop and implement proof-oriented instructional tasks in their classrooms.

### Task design

Choosing, adapting and designing mathematical tasks is one of the cornerstones of a teacher's work. With textbooks providing only limited opportunities for students to engage in argumentation and proving (Thompson et al., 2012) teachers have been encouraged to treat textbooks' tasks as a starting point for planning instruction: to modify tasks to increase their cognitive demand or develop their own tasks (Stein et al., 2000). Since PD efforts in this area have seldom specifically targeted argumentation and proving tasks, the knowledge on teachers developing and implementing such tasks has been limited. Adding to this concern, Stylianides and Stylianides (2016) argue that it is unrealistic to expect individual teachers to design their own instructional activities that successfully target persisting difficulties with proving. On the other hand, Kim (2016) has found that teachers regularly tend to omit, replace or substitute instructional activities, even when working with reform-based, research informed curricula, which often compromises the original designer intentions.

This dilemma can be addressed by fostering close collaboration between researcher-designer and the teacher (Cobb et al., 2003). While the researcher-designer brings in strong theoretical and empirical knowledge related to proving, the teacher has an intimate knowledge of specific instructional and institutional context. This partnership model was realized in this study by providing teachers with researcher-developed prototypes of proving tasks to modify and implement in their classrooms.

### Proof-task prototypes

Six prototypes of proving tasks were developed by the author of this paper in a study of secondary students' conceptions of proof. The tasks, which can be used as diagnostic tools and as instructional activities (Buchbinder & Zaslavsky, 2013), were developed in generic form, so they could be adjusted for a variety of mathematical topics, while maintaining the original structure and goals,

such as recognizing the limitation of examples for proving general claims, or understanding the role of counterexamples. In the context of the PD reported herein, teachers received at least one content specific version of each type of task, and a generic template highlighting task structure. Figure 1 shows an algebraic version of the task *True-or-false*; and Figure 2 shows its generic version<sup>1</sup>.

<b>True or False?</b> For each statement below decide whether it is true or false and justify your answer.	
1) Every three numbers $a, b, c$ satisfy the equation: $\frac{a}{b+c} = \frac{a}{b} + c.$	4) There exist four numbers $a, b, c, d$ that satisfy: $\frac{a+c}{b+d} = \frac{a}{b} + \frac{c}{d}.$
2) The (positive) difference between the squares of any two consecutive natural numbers is equal to their sum.	5) There exists a number $a \neq 1$ that satisfies the equation: $a + \left(1 + \frac{1}{a-1}\right) = a \cdot \left(1 + \frac{1}{a-1}\right)$
3) Every two numbers $n, m$ satisfy the equation: $\frac{1}{m} + \frac{1}{n} = \frac{1}{n+m}$	6) There exist three distinct positive integers $a, b, c$ that satisfy $\frac{a+c}{b+c} = \frac{a}{b}$

**Figure 1: Algebraic version of the task *True-or-False***

The task *True-or-false* targets multiple aspects of proving and refuting. It requires distinguishing between universal and existential statements, and recognition that the type of statement affects the role of examples in proving or disproving it. To successfully complete the task, students need to construct general proofs, construct appropriate counterexamples to disprove false universal statements, and come up with supporting examples to prove existential statements.

Statement	Type of statement: U / E	Truth value: T / F	“Always-Sometimes-Never”			Type of justification required
			True for all values	True for some values	True for no values	
1)	U	F		✓		Refutation by a counterexample
2)	U	T	✓			General proof
3)	U	F			✓	Refutation by a counterexample
4)	E	T		✓		Proof by a supporting example
5)	E	T	✓			Proof by a supporting example
6)	E	F			✓	General refutation

**Figure 2: The structure of the task *True-or-False***

The task *Always-Sometimes-Never*, builds on the task *True-or-false* by asking whether the *propositions* of the statements in the latter task are true for all, some, or no values of relevant variables. This often requires construction of additional arguments, e.g., although statement #3 in Figure 1 can be refuted by a single counterexample, one must construct a general argument to show that no values of variables satisfy the statement. Sequencing these tasks allows to contrast quantified

<sup>1</sup> For complete presentation of all 6 types of task prototypes see Buchbinder & Zaslavsky (2013).

statements, which are either true or false, with non-quantified propositions, which truth-value depends on the value of a particular variable. Creating a combination of statements to addresses all these aspects of proving is a complex undertaking, which could be supported by using a generic version of the task (Figure 2). The goal of this study was to explore the potential of using generic task prototypes to support the work of mathematics teachers with respect to incorporating argumentation and proving in their classrooms.

## Methods

**Participants.** The study was conducted with 5 secondary teachers, all female, all from different schools in a Northeastern area in the United States. Their teaching experience varied greatly from 5 to over 30 years. Since the PD was advertised as explicitly devoted to classroom implementation of argumentation and proving tasks, all participating teachers were motivated to introduce such tasks in their teaching, but sought to gain practical skills in this area. Hence, the PD aimed to reinforce already existing teachers' motivation, provide ongoing professional support, and foster teachers' sense of self-efficacy as they transformed their practices.

**The setting.** The PD consisted of 9, two-hour long weekly meetings which took place on the campus of a state university in the Fall of 2015. During the sessions teachers interacted with the 6 types of researcher-developed proof tasks in several ways: they experienced the tasks as learners, examined samples of student work pertaining to these tasks, and analyzed opportunities to learn about argumentation and proving embedded in the tasks. This was done by comparing teachers' own experiences and student work with the generic task prototype to examine the extent that the designer-intended goals have been realized. Throughout the PD teachers were encouraged to try out at least two types of tasks in their classrooms and share their experiences with others.

**Modes of Inquiry and Data Sources.** All PD sessions were videotaped. Each teacher submitted the tasks they had created or modified for their classrooms, sample student work and a two-page report on the task implementation e.g., the mathematical topic, the number of students, and the modes of work: group, individual, whole class, or combined. Teachers were also asked to describe what kinds of learning opportunities they think their tasks afforded, and what challenges they encountered as they created and implemented the tasks. The teachers also completed a short survey assessing the perceived effect of the PD on their classroom practices.

## Results and discussion

### Perceived obstacles for classroom implementation

Although all participating teachers expressed their commitment and motivation to incorporate proof-oriented tasks in their teaching, they also frequently shared concerns about feasibility of such shifts in their practices. Their concerns included whether incorporating proof-oriented tasks would compromise curriculum "coverage", or would take out from the time originally allotted to test preparation; whether students would be willing to take social risks associated with sharing mathematical arguments in public, and to critique the arguments of others; and whether students be willing to engage in proof-oriented tasks that vary in form and content from what they are used to. These types of concerns reflect teachers' professional obligations towards the institution of schooling and towards individual students' social and emotional needs (Herbst & Chazan, 2011).

Of the total 11 proof tasks created by the teachers, 2 were of their own design and 9 were modifications of one of the researcher-designed task types: *Is this a coincidence?*, *True-or-false?* and *Always-Sometimes-Never*. The tasks addressed a variety of mathematical topics in algebra, geometry, number and operation, and logical reasoning. The modes of implementation involved: enrichment activities, practice, exam review, or introducing a new topic. In the following I focus on one teacher, Alison (a pseudonym), to illustrate how she had modified two tasks to fit her classroom context. These tasks were chosen because they stood out as one of the most creative modifications to the researcher-designed task prototypes that occurred within this group of teachers.

### Alison's modification of the tasks *True-or-false?* and *Always-Sometimes-Never*

Alison has more than 20 years of teaching experience and is well-respected in her school. Similar to other teachers she joined the PD with mixed feelings: committed to provide students with proving experiences but sharing the abovementioned concerns. Alison was inspired to create two proof tasks when her students performed poorly on a particular item on an algebra test: a word problem about money invested and interest earned in two bank accounts. The students found it challenging to set up an equation to represent the total amount of money split between the two accounts, using a single variable. Alison used students' test responses to create a sequence of tasks: *Always-Sometimes-Never* (Figure 3) and a follow-up *True-or-false* task (Figure 4).

#### Always, Sometimes or Never?

**Part 1:** Tom invested \$50,000 into two accounts. The first account earns 6% interest and the other account earns 11% interest. How much money did he invest at each rate if his total interest earned from both investments was \$4,900.

The following cards are possible setups to describe the amount of money ( $x$ ) invested for Tom's investments described above. Indicate whether the setups are:

- true for all of values of  $x$ ,
- true for some values of  $x$ ,
- or whether there are no values of  $x$  which satisfy the set-up of the application.

Explain your reasoning.

Figure 2: Six out of 8 items from Alison's task *Always- Sometimes-Never*

**Part II: True or False?**

Given: Tom's investment problem.

- 1) Decide whether each statement is algebraically true or false and explain your reasoning.
- 2) Then justify whether the statement could be used to represent and support Tom's investment.

Show algebraic work and / or use complete sentence(s) to support your position.

Tom invested \$50,000 into two accounts. The first account earns 6% interest and the other account earns 11% interest. How much money did he invest at each rate if his total interest earned from both investments was \$4,900.

#1

	Money invested
1st account	$x$
2 <sup>nd</sup> account	$x$
Total	\$50,000

If  $x$  represents the amount of money in each account, then  $x + x = \$50,000$  for some values of  $x$ .

--

#2

	Money invested
1st account	$x$
2 <sup>nd</sup> account	$x$
Total	\$4,900

If  $x$  represents the amount of money in each account, then  $x + x = \$4,900$  for all values of  $x$ .

--

**Figure 3: Two out of 6 items from Alison's task *True-or-false*?**

Alison's goals in developing this sequence of tasks were to confront students with both correct and erroneous charts for setting an equation representing the money split between the two accounts, and have students analyze, validate or critique the equation setups. In the *Always-Sometimes-Never* task students were to determine whether the equation setups are true for all, some, or no values of  $x$ , where  $x$  is the amount of money in one account. In the *True-or-false* task the same setups were accompanied by conditional statements. Students were to determine whether each equation is algebraically correct, and whether it can be applied to the given word problem. The tasks were implemented with 74 students (4 classes). Students worked in groups of 3 or 4 on the *Always-Sometimes-Never* task in class, and then completed the *True-or-false* task at home.

### Opportunities gained and lost through task modification

The design on Alison's tasks reflects the way she balanced her professional obligations. By using students' test responses as a content of the tasks Alison minimized social anxiety associated with presenting and critiquing mathematical arguments. She also addressed her curriculum goals while engaging students in proof-oriented tasks. The mathematical affordances of Alison's tasks encompass many of the original designer intentions. For example, the task *Always-Sometimes-Never* provided students with opportunities to reason through a variety of correct and incorrect equation setups, and evaluate whether they can be true for all, some or no values of the variable. The use of precise mathematical language echoes the goals of the original design. The two tasks build on each other, with *True-or-false* task emphasizing evaluation of conditional (if not quantified) statements. The tasks reflected additional learning goals Alison had for the students: to distinguish between equations that are mathematically correct but are inappropriate in the context of the problem. Further distinctions could be made between equations that do not account for an implicit problem requirement: the investment in either account cannot be \$0 (equations D, E & F); and equations that do not account for the explicit requirement: the total interest earned must be \$4900, meaning that

equal sums of money cannot be invested in two accounts<sup>2</sup> (equation A). These distinctions came up in students' written responses to the tasks. Alison was very satisfied with students' interactions with the tasks, and indicated that next year she plans to use them to *introduce* the topic of solving word problems, rather than a test review.

Despite the important affordances of Alison's task, many of the original proof-oriented goals of the tasks, such as the limitation of examples for proving general claims, the distinctions between quantified and non-quantified, universal and existential statements, were not realized in the tasks setup. Potentially, Alison's tasks could be used to highlight other issues related to proving, which although not intended by researcher design, arise naturally in the context of her tasks. Justifications for dismissing solutions A, D, E and F (Figure 1) bare resemblance to arguments by contradiction – a proposed equation, assumed as correct, is rejected because it contradicts one of the problem constraints. Such interpretation could pave a way to discuss proof by contradiction in algebra class.

## Conclusions

This paper described an exploratory study that tested a PD model which aimed to support secondary teachers' implementation of argumentation and proving tasks in their classrooms. The researcher-designed tasks served as prototypes after which teachers could model their own tasks. The generic versions of the same tasks provided additional support for teachers by outlining the structure of the tasks and highlighting specific proof-related goals. By using researcher-designed tasks as a starting point for creating their own tasks, teachers became critical partners in designing classroom interventions to promote students' engagement with proving. As teachers collaboratively explored, modified and shared experiences of classroom implementation of their tasks, they negotiated a new understanding of what it means to engage students in argumentation and proving. In the post-PD survey, all participating teachers reported increased confidence in their ability to incorporate argumentation and proving tasks in their teaching. One teacher, called here Jenifer, wrote:

The [PD] classes gave me great ideas to take back to my classroom, to look at proofs very differently than what I had always thought of as a proof. Proofs do not need to be the static, two column proofs from my school experience. They can take a couple of minutes or they could be something to wrestle with for a majority of the block. I liked that the activities were easily manipulated to fit a specific time frame or wanted outcome.

The study also revealed challenges associated with supporting teachers in developing proof-oriented tasks. Alison's tasks show that although she created powerful opportunities for students to engage with argumentation, some of the original researcher-intended goals, specifically related to proving, seem to have been lost. The available data sources do not provide sufficient information as to which aspects of proving were explicitly addressed in class, or whether they were completely overshadowed by discussions of the algebraic content. Hence, future studies should involve classroom observations. Finally, the results of this study concur with those suggesting that changing teacher practices is a gradual process which requires structured support (Brodie, 2010) to help teachers to develop a view of proof-oriented classroom activities as means to balance their professional obligations and enhance students' mathematical learning.

---

<sup>2</sup> Investing \$25,000 at 6% in one account and \$25,000 at 11% in another account would yield a total interest of \$4,250.

# A framework for classifying mathematical justification tasks

Boon Liang Chua

National Institute of Education, Nanyang Technological University, Singapore;

[boonliang.chua@nie.edu.sg](mailto:boonliang.chua@nie.edu.sg)

*The large corpus of research on mathematical reasoning and justification in the mathematics education literature has yielded a wide range of tasks that require a mathematical argument to be established. This paper presents the DIVINE framework that classifies justification tasks by their nature and purpose as well as the expected element to be provided in the justifications. The framework is then used as a theoretical basis for appraising justifications produced by mathematics teachers.*

*Keywords: Mathematical justification, classification framework, teacher competency.*

## Introduction

Mathematical reasoning plays a crucial role in mathematics learning at all grade levels. It is a useful tool for exploring, discovering and understanding new mathematical concepts, for applying mathematical ideas and procedures flexibly to other situations, and for reconstructing previous knowledge in order to generate new arguments (Ball & Bass, 2003). To probe into the mathematical reasoning of students, another tool is needed to make such reasoning visible – justification. With the emphasis in schools worldwide on developing a broad set of competencies that are believed to be an imperative for success in the workplaces in the 21<sup>st</sup> century, greater demands are therefore being placed on students to reason and justify in the learning of mathematics.

Mathematical reasoning and communication are two key process skills in the framework of the Singapore school mathematics curriculum (Ministry of Education (Singapore), 2012) that have been advocated for a long time. The notion of communication refers to the ability of using mathematical language to articulate mathematical ideas and arguments precisely, concisely and logically (Ministry of Education (Singapore), 2012). In this sense, mathematical justification is considered part of communication. But very little is known about the justification ability of Singapore mathematics teachers and students at the secondary level. I am thus interested to find out more about it and commenced the investigation with a survey of the various justification tasks that secondary school students had been tested in the national examinations over the past ten years. The survey has found that the justification tasks are of varied nature and can be classified into different categories.

This paper seeks to address the following questions: What are the different types of justification tasks given to secondary school students? How might justifications for the different types of tasks qualify as acceptable? What elements should be present in an acceptable justification? It presents a theoretical framework for classifying mathematical justification tasks and discusses the expectation required in each type of tasks. The structure of this paper broadly follows these strands of work: (a) a perspective of what justification encompasses, (b) a view of justification tasks and the elements expected in the justifications, and (c) a discussion of justifications produced by Singapore mathematics teachers.

## Theoretical framework

**Justification** According to Simon and Blume (1996), mathematical justification involves “establishing validity [and] developing an argument that builds from the community’s taken-as-shared knowledge” (p. 28). The notion of justification as a means of determining and explaining the truth of a mathematical conjecture or assertion resonates strongly with many other researchers. For instance, it is consistent with Balacheff’s (1988) perception of justification as “the basis of the validation of the conjecture” (p. 225) – a view also supported by Huang (2005) as well. To Harel and Sowder (2007), justification for validation serves two different roles: to *ascertain* the truth of a conjecture, and to *persuade* others that the conjecture is true. Even these two roles have slightly dissimilar intention. In Ellis’ (2007) view, ascertaining the truth is meant to remove one’s own doubts whereas persuading is one’s attempt to remove others’ doubts. As the discussion reveals, expressing justification for the purpose of ascertaining truth is a cognitive process whilst convincing others of the truth is a social process.

The notion of justification focuses traditionally on the notion of proof from the primary to the high school and university levels in the research literature (see e.g., Jones, 2010; Stylianides, 2007). Thus proof is viewed as a type of justification in this regard. So I think the definitions of proof available in the literature can help to deepen our understanding of mathematical justification. A prime example that stands out is Stylianides’ (2007) definition of proof as a mathematical argument made up of a connected sequence of assertions for or against a mathematical claim. This definition echoes Hanna’s (1989) definition of proof as “an argument needed to validate a statement” (p. 20) and is considered by far the most comprehensive meaning of proof.

Mathematical justification encompasses a broad range of arguments besides proof. The types of arguments that students are expected to produce depend on at least two factors: *the cognitive abilities of students* and *the nature of the task*. For primary and secondary school students, particularly those in the lower secondary grades, a justification does not need to measure up to a formal proof. This is because providing a theoretical argument for a mathematical result is sometimes not required in the light of their cognitive level until they reach higher level of study (Hoyles & Healy, 1999). This is illustrated by the justification task on algebra asking lower secondary school students to explain why  $2n - 1$  is an odd number for any positive integer  $n$ . This task presents a mathematical claim (i.e.,  $2n - 1$  is an odd number for any positive integer  $n$ ) and requires the students to provide supporting evidence to show why the claim is true. In short, the nature of such a task is to *validate* the claim. Therefore a reasoned argument within the conceptual reach of the students of this grade level could take the form as follows: with  $n$  being any positive integer, forming two groups of  $n$ , which can be expressed as  $2n$  in notation, thus generates an even number, therefore subtracting one from it will result in an odd number. This justification simply uses everyday language rather than formal mathematical language, and does not draw on any theorems as in a typical theoretical argument.

Clearly not all justification tasks require a theoretical argument. Some lend themselves well to experiential justification, which is mainly supported by specific examples and illustrations. Consider asking students to justify why the rule  $a^m \times a^n = a^{m+n}$  is true for any positive integers  $a$ ,  $m$  and  $n$ . The students can rely on intuitive reasoning using several concrete numerical examples in the justification. This mode of argument may be rejected as an adequate and valid justification of

the rule because it does not cover all cases of the variables  $a$ ,  $m$  and  $n$ . Although such an experiential justification does not involve any theorems and somewhat lacks mathematical sophistication, it does convey to some extent student understanding of why the mathematical claim is true, albeit a far less formal argument than a typical mathematical deductive proof (Becker & Rivera, 2009). But it is such justification that is valued because it “explains rather than simply convinces” (Lannin, 2005, p. 235).

Aside from presenting an explanation for or against a mathematical claim, a justification can also take the form of an *elaboration* of how a mathematical result is obtained, as pointed out by Becker and Rivera (2009). Consider, for instance, the topic of pattern generalisation. Becker and Rivera (2009) and Stylianides (2015) had asked students to justify how they established their general rules for figural patterns. The nature of this type of justification task expects the students to illuminate clearly the method used in rule construction. Like the *validation* task described previously, the justification for the *elaboration* task can also be articulated in two different modes: written as in paper-and-pencil tests and verbalised as in face-to-face interviews. Both modes were evident in Stylianides’ (2015) study.

**Justification tasks** Different types of justification tasks are gleaned from the literature on mathematical reasoning, proof and argumentation. Justification tasks require individuals to make mathematical arguments, a process which is integral to mathematics learning in order for the individuals to make sense of the mathematical concepts and procedures, and learn mathematics with understanding. Additionally, these tasks provide insight into their thinking and reasoning as well. Justification tasks can be classified into what I call *elaboration*, *validation* and *making decision* tasks.

*Elaboration* justification tasks are very popular in the literature and have been widely used in research studies by many researchers, including Becker and Rivera (2009), Lannin (2005) and Stylianides (2015). Such tasks (for e.g., *Pizza Sharing* in Lannin (2005)) require individuals to elaborate the approach that was used to obtain a mathematical result. *Validation* justification tasks are questions that seek arguments to support or refute a mathematical claim. This kind of tasks (for e.g., *Mr. Right Triangle* in Chua (2016)) is used to gain insight into how individuals reason about a mathematical claim. *Making decision* justification tasks offer options for a mathematical situation and individuals have to exercise decision-making power to pick one of the options so as to answer the question. The geometry test item from the study by Küchemann and Hoyles (2006) is a case in point.

Apart from the three types of justification tasks discussed thus far, there is one more type which is seemingly less common in research studies but popular in the Singapore national examinations for secondary school students. Consider the algebra task in Figure 1 that requires individuals to make sense of the given context and then infer the significance of the positive solution of the quadratic equation from the context. Such a task exemplifies what I call an *inference* justification task. It is normally set in a real-world context and seeks an interpretation of a mathematical result.

A stone was thrown from the top of a vertical tower. Its position during the flight is represented by the equation  $y = 50 + 21x - x^2$ , where  $y$  metres is the height of the stone above the ground and  $x$  metres is its horizontal distance from the tower.

Explain what the positive solution of the equation  $0 = 50 + 21x - x^2$  represents.

**Figure 1: Inference task on algebra**

In summary, this sub-section has highlighted four distinct types of justification tasks. All these tasks share a common objective, which is to elicit from someone a mathematical argument for a mathematical claim or result. As they vary in nature from one type to another, the essential elements to be expected in the argument for each type of task are therefore also not the same. In the next section, I introduce the *DIVINE* framework that classifies justification tasks by nature and purpose as well as the expected element to be provided in the justifications, and describe its usefulness. *DIVINE* is the acronym of the four types of justification tasks: making **D**ecision, **I**nfERENCE, **V**alIdation, and **E**laboration.

### The *DIVINE* framework

The conceptualisation and development of the *DIVINE* framework in Table 1 was informed by the literature on mathematical proof, reasoning and justification in the field of mathematics education, by analysis of justifications produced by students and mathematics teachers that I had encountered in the course of my teaching in recent years, and by my own disciplinary knowledge. It describes the *nature* and *purpose* of the justification tasks, and the expected *element* to be provided by individuals in their attempt to produce a correct justification.

Nature of justification tasks	Purpose of justification tasks	Expected element in the justification
Making Decision	Explain whether... Explain which...	a decision about the mathematical claim with evidence to support or refute the claim
Inference	Explain what...	the meaning of the mathematical result, with the key words in the task addressed
Validation	Explain why...	a reason or evidence to support or refute the mathematical claim
Elaboration	Explain how...	a clear description of the method or strategy used to obtain the mathematical result

**Table 1: The *DIVINE* framework**

The term *nature* can be described as the cognitive process that an individual undertakes when doing the justification task. The nature of the tasks places slightly different demands on thinking and reasoning. Making decision, inference, validation and elaboration are the four kinds of cognitive processes that have been identified in this paper. The *purpose* of a justification task refers to the reason for making the mathematical argument. Finally, the expected *element* is used to refer to the details that an individual is supposed to provide in order to give a correct justification.

It should be pointed out that although the expected element in a justification indicates what needs to be given for a particular type of justification task, the resulting justification may not necessarily be accepted as correct. For the justification to be judged as correct, I think it is imperative to also examine three other elements of a mathematical argument: the *mathematics* presented, the *clarity* in the argument and what Stylianides (2007) termed as the *modes of argumentation*. The mathematics presented refers to the mathematical concepts and procedures used in the justification, including the definitions and theorems that are used, the calculation that is shown and so on. The clarity in the argument means presenting the argument in a clear, easy-to-follow, and unambiguous way. The mode of argumentation concerns how a justification is developed. In other words, the form of the justification (such as a logical deduction, a proof by contradiction, exposition) has to be taken into consideration. A brief discussion of the potentiality of the *DIVINE* framework will now follow.

***Usefulness of the framework*** Recognising whether a mathematical justification is correct is a vital task for teachers because they often have to evaluate the validity of students' justifications. But as Chua (2016) had noted, this task is fraught with difficulties as the teachers might not be clear about the rigour of justification. They may accept justifications as correct even when certain elements are missing. Teachers therefore need guidance in teaching justification. So the *DIVINE* framework shows them what essential elements to look out for so that they know whether certain details are still lacking in the justification. Teachers can also discuss the three components of the framework for the various types of justification tasks with the students to enrich their learning and appreciation of justification. In this way, students can develop a deeper understanding of constructing mathematical justification and become more confident in doing it. This pedagogical approach is particularly useful for those students who do not already have the justifying skill and struggle with justification. Additionally, for those who get stuck when attempting a justification task, the framework offers a structure for them to rely on and get unstuck instead of seeking immediate help from their mathematics teachers.

In the remaining sections, examples of justifications by both pre-service and in-service mathematics teachers will be discussed to demonstrate the rigour of the *DIVINE* framework as it currently stands. The pre-service teachers were Year 2 undergraduates undergoing their first course in mathematics pedagogy to prepare them to teach secondary school mathematics. The course content covers problem solving, learning theories and teaching strategies for a range of mathematics topics, including arithmetic, algebra, probability and statistics. The in-service teachers were from the same secondary school who attended my professional development workshop. A vast majority of them have taught mathematics for at least 5 years. The justifications were collected from the various classwork given to the teachers in my lessons. The names of the teachers are changed to protect their privacy. The discussion focuses specifically on *making decision*, *inference* and *validation* types of justification tasks. No *elaboration* task will be illustrated because the teachers were not given such tasks to do in my lessons.

### **Making Decision task: The justifications of Angel, Betty and Carl**

The number pattern item in Figure 2 was given to the pre-service mathematics teachers. Before administering this item, the teachers had learnt the various generalising strategies for deriving the

general rule for both numerical and figural patterns, but not how to deal with justification tasks. This item was therefore given to see how they would handle and justify a *making decision* task.

- The first four terms of a sequence are 5, 9, 13 and 17.
- (a) Find an expression, in terms of  $n$ , for the  $n$ th term of the sequence.
- (b) Explain whether 207 is a term in the sequence.

**Figure 2: Making decision task on number pattern**

Part (a) was answered correctly by all the teachers. They established  $4n + 1$  as the general rule of the sequence. However, the responses for part (b) were more varied, and the justifications produced by Angel, Betty and Carl are described below.

Angel began with the supposition  $4n + 1 = 207$  and then solved the equation to obtain  $n = 51.5$ . He concluded: *Since  $n$  has to be a positive integer, then 207 is not a term.* Betty worked out the difference between 207 and the first term 5 to get 202. Then she wrote: *No. All terms in the sequence are divisible by 4 after being subtracted by 5. 202 is not divisible by 4.* For Carl, he started with the same supposition as Angel and found the value of  $n$ . He then stated:  *$n$  must be a whole number for the given number to be a term in the sequence.* The justifications of Angel and Betty, but not that of Carl, were considered fully correct. Their justifications contain all the vital elements for a *making decision* task: that is, a conclusion supported by evidence. Carl's justification is missing the conclusion, thus judged as partially correct. In all the three examples, the justifications are logical and easy to follow, and the mathematics is correct. Carl's case is a perfect example to illustrate the importance of the *DIVINE* framework. If he had known about the essential elements that he had to show in his justification, he would have constructed a complete and correct justification.

### Inference task: The justifications of David and Eve

The algebra item in Figure 1 was administered to the in-service mathematics teachers. The item tested them on their understanding of the significance of the positive solution of the quadratic equation in the given context. I expected the teachers to explain what the following three parts mean in the context: (i)  $y = 0$ , which in this context means that the stone has hit the ground, (ii) positive, which represents the forward direction of the throw, and (iii) the numerical value of the solution, which refers to the horizontal distance from the tower. However, expecting all three parts was too demanding, so a reasonable justification should address at least (i) and (iii). The mathematics teachers were told to construct the justification that would get them the best mark because they were experienced in-service teachers. The justifications of David and Eve are illustrated below.

David:  $x$  metres is the distance of the stone from the tower, when  $y = 0$  (at ground level).

Eve: when  $y = 0$ , height above ground = 0,  $\therefore$  stone is lying on ground.

David and Eve showed evidence of their attempt to explain the meaning of the positive solution. David's argument was regarded as correct because he justified (i) and (iii) correctly. For Eve, her justification was not deemed correct since she justified only (i). Her case again underscores the importance of knowing the critical elements that are needed in the justification, thus manifesting the usefulness of the *DIVINE* framework.

## Validation task: The justifications of Faith and George

A geometry item involving a triangle with all three sides provided (15 cm, 8 cm and 17 cm) was given to the same group of in-service mathematics teachers mentioned above. They had to justify why the angle opposite the 17-cm side is a right angle. Figure 3 presents the justifications of Faith and George.

Faith established the condition  $AC^2 = AB^2 + BC^2$  by separately working out the values of  $AC^2$  and  $AB^2 + BC^2$ , and noticing that both values were equal (see Figure 3a). Subsequently, she inferred that angle  $ABC$  is a right angle. The mode of argumentation is correct, the justification is logical and easy to understand, but there is a mathematical flaw. The correct warrant to use should be the *converse* of Pythagoras' theorem and *not* Pythagoras' theorem. On the other hand, the mode of argumentation of George's justification (see Figure 3b) was wrong because he began with the wrong supposition by assuming angle  $ABC$  is a right angle, which was what he had to prove. So Faith's justification was judged as partially correct whereas George's justification was wrong.

Handwritten justification by Faith:

$$AC^2 = 17^2$$

$$= 289$$

$$AB^2 + BC^2 = 15^2 + 8^2$$

$$= 289$$

$$\therefore AC^2 = AB^2 + BC^2$$

---

By pyth. theorem,  
 $\angle ABC$  is a right  $\angle$ .

(a) Faith

Handwritten justification by George:

Assume  $\angle ABC$   
 is right  $\angle$ ,

$$17^2 = 15^2 + 8^2 \text{ (pythagoras' theorem)}$$

//

(b) George

Figure 3: Teachers' justifications for *Validation* task on geometry

## What's next and conclusion

The *DIVINE* framework introduced in this paper is still emerging and will need further testing and refinement. For instance, it remains to be seen whether the framework can be put into use with student justifications and justification tasks in other mathematical topics. Furthermore, how do mathematics teachers judge what qualifies as a correct justification? What elements do they expect to see in the justifications? How would their judgement differ from peers and mathematics experts? Such evidence is needed to make the *DIVINE* framework more robust.

# **An application of Habermas' rationality to the teacher's actions: Analysis of argumentation in two classrooms**

AnnaMarie Conner

University of Georgia, United States of America; [aconner@uga.edu](mailto:aconner@uga.edu)

*In this paper, I argue that Habermas' components of epistemic, teleologic, and communicative rationality provide insight into the differences in teachers' support for collective argumentation. I examine the teacher's supportive actions in two different classrooms. In their interactions with students, the teachers emphasize different components of rationality. I suggest that teachers may act in ways to support students' development of components of rationality by asking different kinds of questions and raise the question of whether it is useful to consider the components separately.*

*Keywords: Argumentation, proof, geometry, teaching.*

## **Introduction**

It is generally accepted that argumentation and proof are crucial to the study of mathematics. Argumentation has been shown to be particularly important to the learning of mathematics through social interaction. Numerous examples in the mathematics education literature have unpacked aspects of arguments in elementary and secondary classrooms (e.g., Krummheuer, 1995; Pedemonte, 2007); these cases have focused on the learning of mathematics through participation in argumentation, the similarity of argumentation to the structure of proof, the analysis of proof as argument, and the role of the teacher within argumentation. Recent research has examined "successful" argumentation within classroom discussions (Boero, 2011), argumentation that does not meet expectations (Cramer, 2015), and different aspects of rationality with respect to argumentation (Boero & Planas, 2014).

This paper explores the differences in collective argumentation that can be observed in classrooms. It addresses a temptation to characterize the argumentation in one classroom as productive and that in the other as problematic and suggests an explanation for the teacher's actions in each case can be found in Habermas' (1998) constructs of rationality as described by Boero (2006).

## **Background**

In this paper, we explore the teacher's role in argumentation through the combined lenses of our interpretation of Toulmin's (1958/2003) description of arguments in multiple fields, our framework for teacher support of collective argumentation (Conner, Singletary, Smith, Wagner, & Francisco, 2014), and Boero's (2006) description of Habermas' (1998) components of rationality.

Habermas' (1998) components of rationality have been applied to argumentation in several ways. Boero (2006) analyzed a seventh grade student's argument (and the reactions of teachers to the argument) using three interrelated components introduced by Habermas: epistemic, teleologic, and communicative rationality. Boero gave the following explanation of these components.

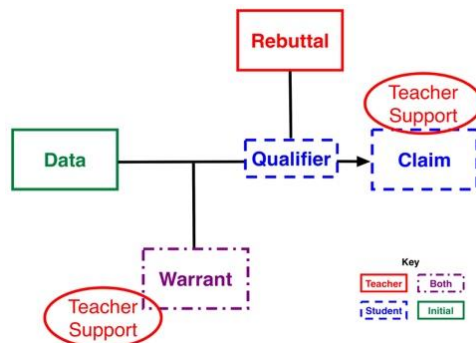

Epistemic rationality is related to the fact that we know something only when we know why the statements about it are true or false...the crucial requirement is that the person has elaborated an evaluation of propositions as true and is able to use them in a purposeful way and to account for their validity. The teleologic rationality is related to the intentional character of the activity, and to the awareness in choosing suitable tools to perform the activity...The communicative rationality

is related to communication practices in a community whose members can establish communication amongst them...rational means that the subject has the intention of reaching the interlocutor in order that he/she can share the content of communication, with an adequate and conscious choice of tools to make it possible. (p. 189–190)

Boero concluded that the student acted in a rational way, using all three components of rationality, while the teachers' behavior did not meet these criteria for rationality.

Recently, multiple researchers have taken up Habermas' components of rationality to examine a range of issues with argumentation (see Boero & Planas, 2014). Within Boero and Planas' (2014) research forum report, Douek introduced the construct of rational questioning, suggesting that teachers can ask students questions in order to "organize the mathematical discussion according to the three components of rationality" (p. 1-210). The teacher plays an essential role in organizing and supporting argumentation in classrooms. In this, Habermas' construct of communicative rationality is key, but the teacher can also influence the teleologic and epistemic rationality of the classroom community.

We follow Krummheuer (1995) in adapting Toulmin's (1958/2003) description of argumentation to collective argumentation in mathematics classrooms. We define collective argumentation broadly as any instance in which students or teachers make a mathematical claim and support it with evidence. Our adaptation of Toulmin's diagrams (see Figure 1) includes the use of color (line style) to denote the contributor(s) of components of an argument and the addition of contributions and actions of the teacher that prompt or respond to parts of arguments (teacher support).

**Figure 1: Adaptation of Toulmin's (1958/2003) Diagram for an Argument**

Our framework for teacher support of collective argumentation includes three main kinds of supportive actions: direct contributions of argument components, questions, and other supportive actions such as gestures or diagrams (Conner et al., 2014). We defined a teacher's support for collective argumentation as any teacher move that prompted or responded to an argument component. We used Toulmin's (1958/2003) model to classify the direct contributions of argument components, and we used an inductive approach to develop categories of questions and other meaningful supportive actions the teacher used. More details about the development of the framework are available in Conner et al. (2014).

## Methods

The analyses in this paper are based on data collected from a project that investigated the beliefs and argumentation practices of a cohort of secondary prospective teachers in the southeastern United States. In particular, the data for this paper include video recordings, field notes, and other artifacts

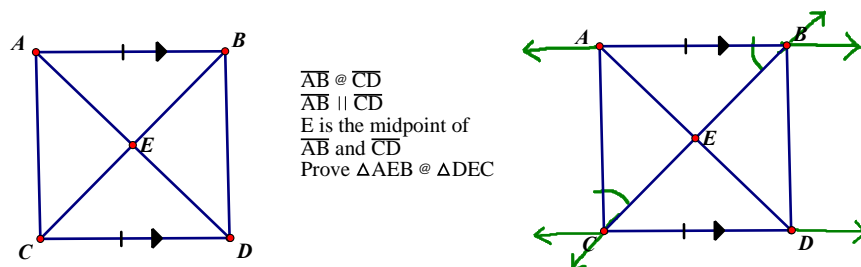

from two days selected from a unit of instruction in each of two student teachers' (Ms. Bell and Ms. Carr, all names are pseudonyms) classrooms. These days were selected as representative of the variety of instructional moves observed in each teacher's instruction. We diagrammed every episode of argumentation from these days of instruction and categorized every supportive action of the teacher that we identified. We used Habermas' (1998) components of rationality to examine the actions of the teacher within our framework categories.

## Episodes from two classrooms

The episodes presented and diagrammed below capture essential qualities of the instruction in each teacher's classroom. For each teacher, we present an excerpt of an episode of argumentation, our interpretation as captured by a partial diagram, and a summary of the teacher's support for argumentation in the class. We then examine the teacher's (and students') actions using Habermas' (1998) components of rationality and argue that the teacher's actions with respect to argumentation reflect her teleologic rationality. That is, we examine the teacher's supportive actions as tools to infer her goals for students' learning and contributions to class and her classroom norms.

### Ms. Carr's Class

This episode occurred when Ms. Carr and her students were at the beginning of a unit on congruence. The students had not yet learned any of the triangle congruence theorems. Thus they were proving figures congruent by their definition of congruence, which required all corresponding sides and all corresponding angles to be congruent. Ms. Carr posed the problem in Figure 2 to her class; the students and she worked together to mark relevant parts of the figure, and when we enter the discussion, they had modified the figure as shown. (They had extended segments BC, AB, and CD, and they marked angle ABE and angle DCE as angles of interest.)

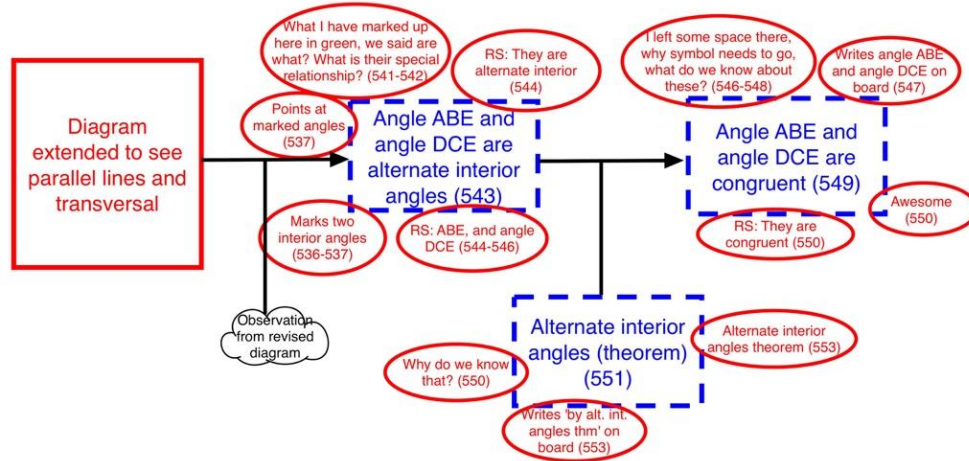

**Figure 2: Initial Problem in Ms. Carr's Class and Modification**

- 541 Ms. Carr: Okay. So, what I have marked up here in green, we said are what? What is their special relationship?
- 543 Alice: They are alternate interior angles.
- 544 Ms. Carr: They are alternate interior. Ok. So, let's write that down. ABE, let's call it, and angle, what is it? Angle DCE...[writes  $\angle ABE$   $\angle DCE$  on board, leaving space between the two angles] [unrelated conversation/interruption] Now, I left some space in there. What symbol needs to go, what do we know about these?
- 549 Students: {congruent} {congruence}
- 550 Ms. Carr: Awesome. They are congruent. Why do we know that?
- 551 Cameron: Because they are alternate interior angles.

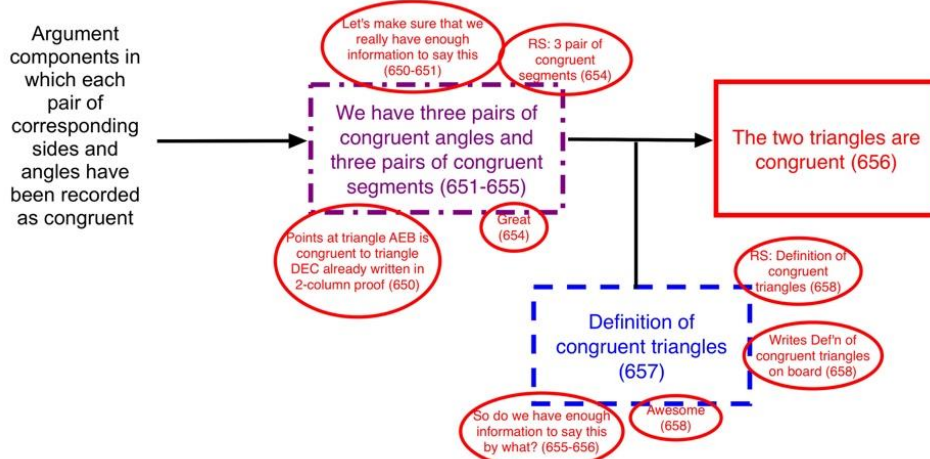

552 Ms. Carr: Alternate interior angles theorem [writes by alt. int. angles thm. on board]

Figure 3 shows the diagram of this excerpt of an argument. Notice that three parts of the argument were contributed by students with a significant amount of support from the teacher. Ms. Carr asked a question that prompted each of the argument components, pointed at or wrote something on the board for each of them, and restated or affirmed each part as well.

**Figure 3: Diagram of First Excerpt of Argument in Ms. Carr's Class**

**Figure 4: Diagram of Second Excerpt of Argument in Ms. Carr's Class**

A little more than five minutes later, Ms. Carr and her students had compiled all of the information about the figure into congruence statements. They ended the proof construction by verifying that they had three pairs of congruent segments and three pairs of congruent angles, warranting the claim that the triangles were congruent with the definition of congruent triangles. In the diagram for this excerpt of argument (Figure 4) we see that the teacher contributed the final claim, the teacher and students jointly contributed the data, and a student contributed the warrant. Ms. Carr prompted both the data and warrant, and she supported each of these components with actions such as repeating, pointing, and writing on the board.

Ms. Carr supported her students in making arguments by contributing many argument components, including approximately one-half of the warrants in her class. In addition, she prompted most argument component by asking questions (primarily factual answer and elaboration questions,

Conner, et al., 2014), and she provided additional support for these argument components using other several kinds of supportive actions (including focusing, evaluating, informing, and repeating actions, Conner, et al., 2014). The importance of Ms. Carr's choices in supporting her students' arguments becomes clear as we reference Habermas' (1998) components of rationality. Ms. Carr asked several questions (line 541, lines 547–548) that requested a factual answer and then asked for elaboration by asking the students to justify that answer in line 550. In this interchange we see an assumption by Ms. Carr of her students' epistemic rationality. She invited them to participate in the argument and indicated by her questions that they should have reasons for their statements. This may be an instance of Douek's rational questioning, as described in Boero and Planas (2014), although Douek's rational questioning seems to presuppose all three aspects of rationality. Ms. Carr seemed to focus on epistemic rationality for her students, while Ms. Carr's own statements and actions indicate a focus on communicative rationality for herself. She repeated or restated (and often wrote the statement on the board) all of the student-contributed components of the arguments. If we consider the teleological rationality of Ms. Carr's actions, they appear to be very goal-directed. Her goal was student understanding of concepts and procedures. In search of that goal, her goal or focus for students was on epistemic rationality. She intended to make sure that they knew the reasons for the statements that were made. Across the class periods, this was evidenced by her many questions prompting argument components as well as her pervasive prompting and providing of warrants for arguments.

### Ms. Bell's Class

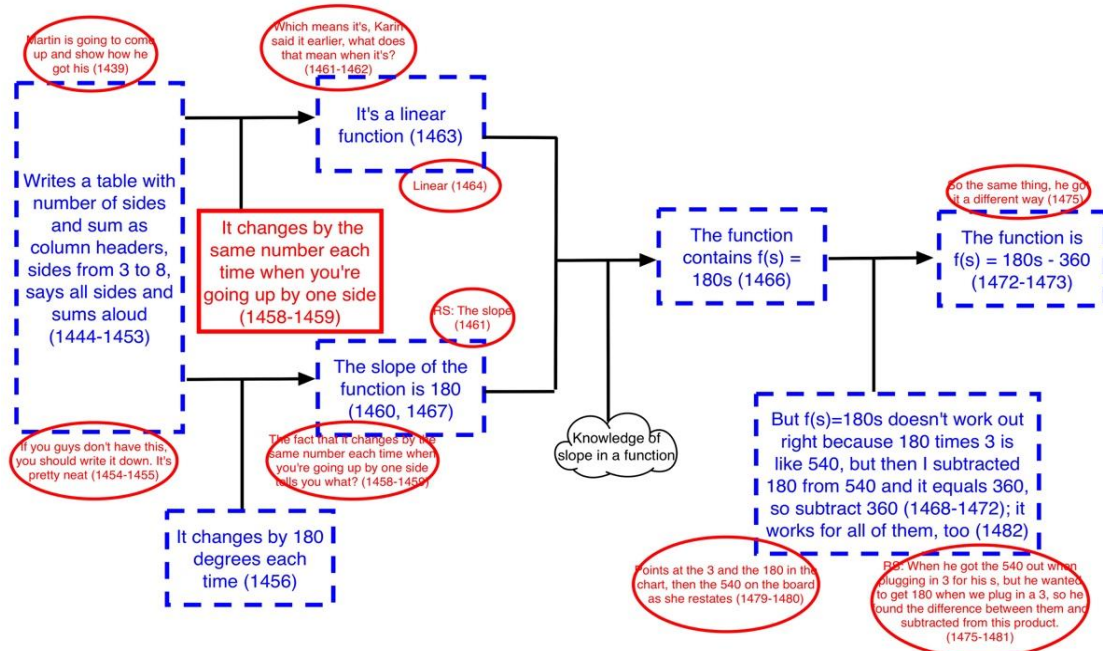

In Ms. Bell's class, the excerpt exemplifying her instruction involved a task in which students had measured the interior angles of several polygons. Students were asked to find a formula for the sum of the interior angles of an  $n$ -sided polygon. The brief snippet of class we examine occurred when a student was presenting his group's work at the end of class. Prior to this excerpt, a student representing a different group presented a solution. Martin, the student in this episode, asked to present his solution because his group found the solution in a different way from the first student.

- 1444 Martin: All right. I had the chart. This is the sides of the figure. That would be the sum of the interior angles.
- ... [Martin talks as he constructs a chart containing numbers of sides and corresponding sums of interior angles for polygons with three to eight sides]
- 1456 Martin: And then it changes by 180 degrees each time.
- 1458 Ms. Bell: So Martin, the fact that it changes by the same number each time, when you're going up by one side, tells you what?
- 1460 Martin: That it has--that that's the slope.
- 1461 Ms. Bell: That's the slope. Which means it's? Karin, you said it earlier. What does that mean when it's?
- 1463 Martin: Linear.
- 1464 Ms. Bell: Linear. It's linear, right? If it changes the same amount each time, when you're going up by 1, it's going to be a linear function.
- 1466 Martin: So I did  $f(s) = 180s$
- 1467 Ms. Bell: What is that 180?
- 1468 Martin: It's the slope. But that doesn't work out right, because 180 times 3 is like
- 1470 Ms. Bell: 540

- 1471 Martin: [writes  $180 \times 3 = 540$ ] 540. But then I just subtracted 180 from 540 and it equals 360. Yeah. So, subtract 360. [Writes  $f(s) = 180s - 360$ ]
- 1475 Ms. Bell: So same thing; he got it a different way. When he got to the 540--so he got this 540 out when he plugging in 3 for his  $s$ , and he got 540. We wanted to get 180 when we plug in a 3. So he said, 'how am I going to get from 540 to 180?' So he found the difference between them and subtracted from this product. Do y'all see that?
- 1482 Martin: It works with all of them too.

Figure 5 shows the diagram of this argument. In this argument, Martin (the student) contributed all of the components except one warrant. Ms. Bell prompted three of the components with questions, and she supported five of the components by restating or rephrasing Martin's contributions. In general, Ms. Bell asked questions of multiple kinds to prompt argument components, and she contributed some components of arguments, but only about one-eighth of the contributed warrants. Students in Ms. Bell's class seemed to contribute more autonomously to arguments, as evidenced by components that were neither prompted by nor responded to by Ms. Bell.

**Figure 5: Diagram of Argument from Ms. Bell's Class**

We see evidence of Ms. Bell's teleologic rationality (Habermas, 1998) in her actions and questions in support of her goal of engaging students in doing mathematics. Ms. Bell modeled actions related to all three components of rationality, and she seemed to encourage all three components of rationality in her students. Ms. Bell's actions show a strong emphasis on developing her students' communicative rationality, not only in her communication with her students (see line 1475 in which she restates the student's argument), but in her encouragement of her student to communicate his ideas more clearly (e.g., line 1458) and in the student's instinctive actions and statements (e.g., lines 1444 and following in which he explained the entries in the chart he drew on the board), which illustrate norms established in this class. Several times after the student gave a claim and warrant, Ms. Bell seemed to slow down the presentation to make sure it was clear to others, enhancing their understanding of communicative rationality. But instead of giving all the information herself, she

asked the student to do so (line 1467). She seemed to be balancing engaging in acts of communicative rationality herself and encouraging her student to do so. In addition, Ms. Bell assumed epistemic rationality in her student and encouraged him to express it (line 1458). The beginning and end of the episode evidence a classroom norm regarding goal-directed behavior and use of appropriate tools (lines 1444–1455; line 1482). The student indicated by his final statement that he had intentionally completed his goal of finding, expressing, and justifying the formula for the sum of the interior angles of a polygon, showing the teacher's encouragement of behavior exhibiting teleologic rationality. This episode illustrates a teacher's use of rational questioning, bringing the students' voices into the discussion and encouraging their implementation and understanding of all three components of rationality (Douek in Boero & Planas, 2014).

## Discussion

The argumentation we observed in the two classes was very different. One classroom was characterized by a focus on students' epistemic rationality and the teacher's communicative rationality. The argumentation in this class seemed to be both somewhat shallow and more formal and proof-like. The other classroom was characterized by a more balanced focus on students' epistemic, communicative, and even teleologic rationality, and we saw the argumentation in this class as somewhat informal but characterized by student autonomy. The second classroom also illustrated some intentionality and awareness of components of rationality (although not with those words) in the interactions, as Douek suggested was necessary (Boero & Planas, 2014). The teachers also used different kinds of tasks in their classrooms. The choice of tasks in each classroom may also be related to the teachers' intentions with respect to the components of rationality; more research is necessary to examine this question.

Differences were observed in the kinds of questions each teacher asked. Ms. Bell asked a wide range of questions, while Ms. Carr asked primarily factual answer and elaboration questions. Perhaps the kinds of questions teachers ask may indicate their focus on a particular component of rationality. It is an open question as to the significance of these components of rationality in a mathematics class, but if we want to encourage students to view mathematics as rational and to act in rational ways when engaging in the study of mathematics, then it seems that it would be helpful for teachers to act in ways that encourage all components of rationality at appropriate points (as Douek suggested, to engage in rational questioning, Boero & Planas, 2014). As Boero (2006) suggested, teachers can model the components of rationality for their students at appropriate times. Perhaps introducing these components of rationality to teachers could provoke a wider focus. Examining the kinds of questions teachers ask in conjunction with their argumentation shows promise for revealing which components of rationality are privileged in their classes. And these components of rationality provide a useful explanatory mechanism for the differences in support for argumentation observed in classrooms. Future research will have to examine how important it is for a teacher to engender all components of rationality and whether it is possible or productive to address each component separately.

# Evolution of proof form in Japanese geometry textbooks

Marion Cousin<sup>1</sup> and Takeshi Miyakawa<sup>2</sup>

<sup>1</sup>Lyons Institute of East Asian Studies, Lyon, France; [cousin\\_marion@yahoo.fr](mailto:cousin_marion@yahoo.fr)

<sup>2</sup>Joetsu University of Education, Joetsu, Japan; [miyakawa@juen.ac.jp](mailto:miyakawa@juen.ac.jp)

*This study discusses the evolution of mathematical proofs in Japanese junior high school geometry textbooks and the conditions and constraints that have shaped them. We analyse the evolution of these proofs from their inception in the Meiji era (1868–1912) to the present. The results imply that features of the Japanese language affected the evolution of proof form in Japan and shaped the use of proofs in Japan as written, but not oral, justification for mathematical statements.*

*Keywords: Secondary school mathematics, history of education, textbook analysis.*

## Introduction

Proving mathematical statements is a very important part of mathematics. However, there were no proofs in the texts of *wasan*, the traditional mathematics dominant until the mid-19<sup>th</sup> century in Japan. In *wasan*, following Chinese tradition, Japanese mathematicians concentrated on elaborating procedures to solve problems rather than proving statements. As one consequence of the educational reforms that accompanied the opening and modernization of the country in the Meiji era (1868–1912), axiomatic Euclidean geometry with mathematical proof was adopted in secondary school mathematics.

Today, Japanese students learn mathematical proof in junior high school, and often face difficulties doing so (MEXT, 2009; Kunimune et al., 2009), as do students in other countries (see Mariotti, 2006; Hanna & De Villiers, 2012). These difficulties vary by country, for two reasons linked to the cultural and social dimensions of teaching. The first involves what is taught; one recent study compared France and Japan and showed that proof to be taught, specifically what constitutes a proof and the functions of proofs, is different between the countries (Miyakawa, 2017). The second reason relates to how students employ and understand justification and argumentation in their daily life, which affect how they approach mathematical proof in the classroom and which differ across cultures (Sekiguchi & Miyazaki, 2000).

The Anthropological Theory of the Didactic (ATD) posits that knowledge taught/learnt in a given *institution* (here, the Japanese educational system and culture) is shaped by a process of ‘didactic transposition’ reflecting the conditions and constraints specific to that institution (Chevallard, 1991; Bosch & Gascón, 2006). In this paper, we study the didactic transposition of proofs in Japan and the effects of the cultural and social dimension. We expect that this will help us better understand the nature of these difficulties and will show the needs for studying this dimension of proof-and-proving in different countries to improve teaching and learning everywhere.

## Methodology

We adopted ATD to frame our research question and determine what should be investigated so as to better understand the cultural and social dimension of proof. The research question we focused on is as follows: *What cultural and social conditions and constraints shape the nature of proof to be taught today in Japan?* To identify these conditions and constraints, we conducted a historical study of the

evolution of the proof in Japanese junior high school geometry textbooks from its first appearance during the Meiji era to the present.

From out of the many textbooks published since the Meiji era in Japan we selected those that were widely used, to construct a representative corpus. Textbooks from the Meiji and Taishō (1912–1926) eras were more important than later ones, since proofs in geometry first appeared in Japan during these periods and since the way they were presented and taught changed more than in later periods. For the Meiji period, we identified major textbooks by consulting prior research (Neoi, 1997; Tanaka & Uegaki, 2015); however, for the Taishō era and up to the Second World War, we had no statistics on the use of textbooks, and so we selected textbooks that remain relatively well known today and that have been the topic of historical studies (Nagasaki, 1992). For the post-war era, we selected one or two textbooks that were widely used from the period following each successive reform of the national curriculum. The current system of selection of textbooks was firmly established by 1965 (Nakamura, 1997, p. 90) and the market share of each textbook series is known thereafter. From that point to the present, the most widely used textbooks have been those published by Keirinkan and by Tōkyō Shoseki.

The process of analysis we followed had three steps. First, we determined the role of the proofs in the geometry teaching approaches employed by the textbooks: Did the textbooks reflect a general strategy concerning proof learning? If yes, what was it? Were proofs important in geometry learning? Second, for each textbook, we analysed the forms (including intermediate steps) of sample proofs (worked examples) related to parallelograms, which were found in most of the textbooks, for overall formatting or organization, use of symbols, and formulation of properties (theorems, definitions, axioms, etc.) and statements. We use the terms *paragraph* and *semi-paragraph* to reflect the extent of sentences versus symbols in a proof, with paragraphs being all written language and semi-paragraphs a mix of words and symbols. Third, we looked at the authors' comments on the proof or on proof learning.

Below, we first describe the proofs one finds in Japanese mathematics textbooks today, and then show what they evolved from and how. However, as this work is currently only at a preliminary stage, our analysis remains general on the evolution of proof form in Japan.

### **Proof in Japanese mathematics textbooks today**

Nowadays, the term 'proof' is introduced in Japanese junior high school mathematics, specifically in grade 8 geometry. Figure 1 shows a sample proof taken from a grade 8 textbook from Keirinkan, proving a property of parallelograms: 'Two pairs of opposite sides in a parallelogram are equal'. The figure provides an image of the proof with our own translation; the translation is quite literal, to maintain data integrity. One may first note the use of mathematical symbols for equality, parallelism, triangles, and angles. Statements (not properties) used as conditions or deduced as conclusions in a deductive step are written all in symbols (e.g.  $\angle BAC = \angle DCA$ ). Deduced statements are given separately from other statements and properties, and some are numbered for use in later steps. In contrast, properties used in deductive steps, such as the condition for congruent triangles, are given as written Japanese phrases, without symbols—not in if-then form as in French mathematics textbooks (Miyakawa, 2017). The proof presented here thus represents the semi-paragraph type, with a mix of natural sentences and symbols; below, we consider the origin and history of such proofs.

(Our translation) Draw the diagonal AC.

In  $\triangle ABC$  and  $\triangle CDA$ ,  
 since the alternate-interior angles of parallel  
 lines are equal,  
 from  $AB \parallel DC$ ,

$$\angle BAC = \angle DCA \dots (1)$$

from  $AD \parallel BC$ ,

$$\angle BCA = \angle DAC \dots (2)$$

And, since AC is common,

$$AC = CA \dots (3)$$

From (1), (2), and (3), a pair of sides and the  
 angles of both sides are equal,

$$\triangle ABC \equiv \triangle CDA$$

since corresponding sides of congruent figures  
 are respectively equal,

$$AB = CD, BC = DA$$

Figure 1. A sample present-day proof from a Keirinkan textbook (Okamoto et al., 2016, p. 133)

## Proofs in geometry textbooks from the Meiji era to the present

Before the Meiji era—that is, before the modernization of Japan—geometry teaching was based on *wasan*, and centred on problem-solving: questions about the measurement of geometric figures were asked, and procedures (sometimes employing algebraic or analytic tools) were applied to acquire the correct answer. Although some *wasan* mathematicians questioned the accuracy of the results yielded by this method, proofs were not used in mathematical texts until the mid-19<sup>th</sup> century, at the beginning of the modernization movement began (for a general view of the evolution of Japanese mathematics and its teaching, see Ueno, 2012, and Baba et al., 2012).

With the *Decree on Education* (*Gakusei*, 1872), the Japanese government abandoned *wasan* teaching and imposed learning of Western-style knowledge and teaching methods (for example, one-on-one teaching was replaced with lecture-type classes in groups). Western textbooks were translated to provide teaching materials for schools of this new type, and the first geometry proofs in Japanese appeared in this context. Since proofs were new to Japan, no convention and no stipulation in the curriculum constrained how they were written or formatted, and the forms used by Western authors and their Japanese translators varied widely. The situation can be quite confusing. For example, in the Japanese translation of an American version of *Legendre's* textbook (Nakamura, 1873), proofs were written in paragraph form only, whereas in translations of other American textbooks (Miyagawa, 1876; Shibata, 1879), symbolic expressions were also mobilized. This situation, and the fact that no author-translators provided any remarks on proofs or reasoning in geometry and sometimes even removed remarks on the nature of mathematical statements that had been present in the original textbooks (see Cousin, 2013) betrays the lack of importance attached by Meiji-era scholars and authorities to proof learning; it also may have occurred partly because of the need for rapid translation of textbooks to meet new requirements, which led translators to focus on developing a basic vocabulary for the new geometry in Japanese and producing textbooks understandable enough for use. We also encountered textbooks from this period in which some functions of proofs were obscured compared to the original source: for example, while the axiomatic systematization function of proofs is emphasized in Davies (1870), the abridged Japanese version of this textbook (Nakamura, 1873) does not preserve this emphasis (see Cousin, 2013).

During the 1880s, Tanaka Naonori (1853–?) compiled works by English, American, and French authors as well as Chinese and Jesuit translators to produce a series of textbooks that were adopted widely in Japanese junior high schools (see Cousin, 2013, pp. 277–282). Tanaka was better trained in Western mathematics than the 1870s author-translators and had teaching experience as well. His proofs used few formulas and provided exposition (the part of the proof where the hypothesis is expressed using specific names for the elements considered in the proposition) and determination (the conclusion expressed using these names) using only symbolic expressions. Moreover, unlike previous authors, Tanaka gave after each statement a reference number corresponding to the property he used to justify it, highlighting the need for systematic justification of every statement in a proof. He was also the first Japanese author to discuss the nature of proof per se, explain its role in geometry (see Cousin, 2013, pp. 305–310), describe inductive and deductive ways of proving, and emphasize that we ‘prove the propositions thanks to the axioms, the postulates and the propositions that already have been proven’ (Tanaka, 1882, p. 15).

In the late 1880s, the publication of textbooks by Kikuchi Dairoku (1855–1917) marked a new stage in Japanese geometry textbook production, and Kikuchi fixed a new Japanese mathematical language and proof form that would remain for decades, as his textbooks were used until the beginning of the Taishō era. In his view, it was important to create a Japanese mathematical language that unified oral and written expression so that geometry proofs could be written in paragraph form, without relying on symbols. Moreover, like Tanaka, he highlighted the systematic aspect of proof by putting on the right-hand side the number of properties used in each deductive step (Figure 2). Kikuchi was clearly influenced by his education in England, where the aim of geometry teaching was to cultivate young spirits to reasoning: ‘Wherever Mathematics has formed a part of a Liberal Education, as a discipline of the Reason, Geometry has been the branch of mathematics principally employed for this purpose. [...] For Geometry really consists entirely of manifest examples of perfect reasoning: the reasoning being expressed in words which convince the mind, in virtue of the special forms and relations to which they directly refer’ (Whewell, 1845, p. 29). Kikuchi provided extensive explanation of

ABCD は平行四邊形、AC  
 は其ノ對角線トセヨ、  
 然ルルハ、(甲) AC ハ之ヲ全ク  
 相等シキニツノ三角形ニ分ツ  
 可シ、  
 (乙) AB ハ DC ニ等シク、BC ハ AD ニ等シカル可シ  
 (丙) 角 ABC ハ角 CDA ニ等  
 シク、角 BCD ハ角 DAB ニ  
 等シカル可シ。  
 直線 AC ガ平行線 AB、  
 CD ニ出會フヲ以テ、  
 錯角 BAC、ACD ハ相等シ、  
 又直線 AC ガ平行線 BC、AD ニ出會フヲ以テ、  
 錯角 BCA、CAD ハ相等シ、  
 然レハニツノ三角形 ABC、CDA ニ於テ、ニツノ角ハ夫々  
 相等シク、其ノ間ニ在ル邊 AC ハ兩形ニ通ス、  
 故ニ(甲)ニツノ三角形ハ全ク相等シク、  
 (乙) AB ハ DC ニ、BC ハ DA ニ等シ、  
 (丙) 角 ABC ハ角 CDA ニ等シ、  
 又角 BCD ハ角 BCA、ACD ノ和ナルヲ以テ、  
 角 CAD、BAC ノ和ニ等シ、  
 即角 DAB ニ等シ。

(Our translation)

Let ABCD be a parallelogram and AC be its diagonal;

Then (1) AC divides it into two completely equal triangles;

(2) AB is equal to DC, BC is equal to AD;

(3) The angle ABC is equal to the angle CDA, the angle BCD is equal to the angle DAB.

Because the line AC intersects with the parallel lines AB and CD, alternate-interior angles BAC and ACD are equal; I, 7.

And because the line AC intersects with the parallel lines BC and AD, the alternate-interior angles BCA and CAD are equal; I, 7.

Now, in the two triangles ABC and CDA, two pairs of angles are respectively equals, and the side AC between them is common to both figures.

So (1) the two triangles are completely equals; I, 10.

(2) AB is equal to CD, and BC is equal to DA;

(3) The angle ABC is equal to the angle CDA: and because the angle BCD is the sum of the angles BCA and ACD, it is equal to the sum of the angles CAD and BAD, which is the angle DAB.

Figure 2. A sample proof from Kikuchi's textbook (Kikuchi, 1889, pp. 53–54)

geometric reasoning, and paid particular attention to the language used and the organization of geometric properties; in doing so, he tried to highlight the importance of the systematization and justification functions of proofs.

However, the form of Kikuchi's proofs (Figure 2) soon came in for criticism by his contemporaries, for being difficult to teach. Nagasawa Kamenosuke (1861–1927), in his own textbook, criticized the paragraph form of Kikuchi's proofs in strong terms: 'Writing proofs of theorems with sentences in a complete and perfect manner is the vice of those who agree with the Euclid movement that came from England' (Nagasawa, 1896, pp. 3–4). Nagasawa instead wrote proofs in a semi-paragraph form very different from Kikuchi's, especially in terms of the use of symbols, as seen in Figure 3. In particular, Nagasawa put more importance on the proof as a written form, and in fact his proofs cannot be used for oral justification due to certain features of the Japanese language and the use of symbols. For example, the statement ' $AB \parallel DC$ ' would usually be read or spoken aloud in Japanese as 'AB hēkō DC' ('AB parallel DC'). However, this is just a pronunciation of each symbol in succession and not a grammatically sound phrase; to be grammatical, it should instead be pronounced as 'AB wa DC ni hēkō' ('AB is parallel to DC'), whose shortened version would be 'AB DC  $\parallel$ ', as an adjective with a *be*-verb should always be placed at the end of a phrase in Japanese. Beginning around the end of the Meiji era, proofs written in semi-paragraphs appeared in many Japanese geometry textbooks (e.g. Nagasawa, 1896; Kuroda, 1917), even Kikuchi's (Kikuchi, 1916), and Kikuchi's goal of a language that unified oral and written expression was abandoned.

<p>定理 28. 平行四邊形ノ兩對邊ハ互ニ 相等シク且其對角線ハ本形ヲ二等分ス、 [特選] <math>\square ABCD =</math> 於テハ、 <math>AB = DC, AD = BC,</math> 及ビ <math>\triangle ABC = \triangle CDA.</math> [證] <math>AC</math>ヲ結ビ付ケヨ、 然ルトキハ <math>AB \parallel DC</math> [假設] ニシテ <math>AC</math>ハ此二平行線ニ交ルガ故ニ、 錯<math>\angle BAC =</math> 錯<math>\angle ACD.</math> [定理 22] 而シテ <math>AD \parallel BC</math> [假設] ナルガ故ニ 錯<math>\angle BCA =</math> 錯<math>\angle DAC,</math> [定理 22] 故ニ <math>\triangle ABC, \triangle CDA =</math> 於テ <math>\angle BAC = \angle DCA,</math> <math>\angle BCA = \angle DAC,</math> 夾邊 <math>AC</math>ハ共通、 <math>\therefore \triangle ABC = \triangle CDA,</math> [定理 7] 即チ <math>AB = DC,</math> <math>AD = BC,</math> <math>\triangle ABC = \triangle CDA.</math></p>		<p>(Our translation) Theorem 28. Two pairs of opposite sides of a parallelogram are equal to each other, and its diagonal divides it into two equal parts. [Exposition] In <math>\square ABCD</math>, <math>AB = DC</math>, <math>AD = BC</math>, and <math>\triangle ABC = \triangle CDA</math>. [Proof] Connect A and C, in such a case, <math>AB \parallel DC</math> [Hypothesis] and because <math>AC</math> intersects with these two parallel lines, alt. int. <math>\angle BAC =</math> alt. int. <math>\angle ACD.</math> [Theorem 22] And because <math>AD \parallel BC</math> [Hypothesis] alt. int. <math>\angle BCA =</math> alt. int. <math>\angle DAC,</math> [Theorem 22] so in <math>\triangle ABC, \triangle CDA,</math> <math>\angle BAC = \angle DCA,</math> <math>\angle BCA = \angle DAC,</math> the side <math>AC</math> is common, <math>\therefore \triangle ABC \cong \triangle CDA,</math> [Theorem 7] So, <math>AB = DC,</math> <math>AD = BC,</math> <math>\triangle ABC = \triangle CDA.</math></p>
---	--	--

Figure 3. A sample proof from Nagasawa's textbook (Nagasawa, 1896, p. 53)

Moreover, until the end of the 19<sup>th</sup> century, although various ways of writing proofs were seen, all textbooks nevertheless followed a classic pattern in the teaching of geometry: theorems and problems were stated one after the other and, beginning in the 1880s, statements in proofs were justified with the reference number of the relevant property. Beginning in the Taishō era, however, the 'practical' approach, meaning one that tried to be more related to ordinary life, gained more and more success, influenced by the work of Treutlein (e.g. 1911), and Japanese authors distanced themselves from the classic pattern. For example, in the first quarter of Kuroda's textbook (1917), measuring instruments were presented and geometric matters were treated without theorems or proofs, while in the latter

part, several practical questions were asked. This evolution of geometry teaching also had an influence on proof form. In Kikuchi (1889), all the statements were expressed without using symbols and the justifications were expressed only by presenting reference numbers for properties (Figure 2), whereas in Yamamoto (1943), new statements were expressed with symbols and the justifications were expressed using literal expressions, without using numbers to refer to properties. Under this practical approach, the systematic aspect of justification in geometry came to be less emphasized.

With the 1942 curriculum reform, the national curricula explicitly adopted this practical approach. The general axiomatic system became less and less explicit in the textbooks, and more and more problems appeared that were related to everyday life. For instance, no proofs at all appeared in 1947's *Secondary Mathematics* (*Chūtō sūgaku*), published by the national Ministry of Education (Monbushō, 1947). Nevertheless, between 1949 and 1955, proofs gradually reappeared in geometry textbooks.

Since the 1960s, proofs have been introduced beginning in the 8<sup>th</sup> grade; however, although the concepts used in geometry teaching in Japan have not changed much in this period, proof form has continued to change, a little. For example, in Kodaira et al. (1974), in the New Math period, properties were always given on the right hand-side, in brackets, and symbols were frequently used (more than in any previous or later textbooks). Later, in Kodaira et al. (1986), the same authors returned to a strategy similar to that observed in the 1940s but also to that used today: symbols were used to express statements in the proofs, but natural language sentences were used to express the properties justifying these statements.

## Discussion and conclusion

The proofs in Japanese mathematics textbooks take the forms they do as a result of the process of didactic transposition, which involves their exposure to different conditions and constraints that affect their nature as proofs. For instance, this study on the evolution of proofs in geometry education in Japan has shown that one factor that significantly affected proof form was certain features of the Japanese language. As mentioned above, Kikuchi tried to develop a Japanese mathematical language unifying oral and written expression, in order to help train students in rigorous logical thinking, adopting the approach of structuring proofs in paragraph form as part of this project; however, our study has shown that Kikuchi's paragraph-form proofs disappeared, as they were viewed as too hard to teach. It was replaced by the semi-paragraph form, which is still used for proofs in Japan today. One consequence is that the distance between the forms of the written proof and the oral justification is still bigger in Japanese education than in English or French, and statements written with symbols cannot be directly used in the oral justification. This leads us to think that Japanese students may experience a proof as a particular written object (like an algebraic equation), a formalism with little relationship to 'actual' oral justification or argumentation. As such a distinction implies, it will be useful to investigate the distance between written proofs and oral justifications across countries, which will help us benefit more fully from existing research results on argumentation and mathematical proofs.

# Pre-service middle school mathematics teachers' interpretation of logical equivalence in proof by contrapositive

Esra Demiray<sup>1</sup> and Mine Işıksal Bostan<sup>2</sup>

<sup>1</sup>Hacettepe University, Faculty of Education, Ankara, Turkey; [esrademiray@hacettepe.edu.tr](mailto:esrademiray@hacettepe.edu.tr)

<sup>2</sup>Middle East Technical University, Faculty of Education, Ankara, Turkey; [misiksal@metu.edu.tr](mailto:misiksal@metu.edu.tr)

*The purposes of this study are to investigate pre-service middle school mathematics teachers' interpretations of logical equivalence in proof by contrapositive and the reasons for their incorrect interpretations. Data analysis indicated that pre-service middle school mathematics teachers were considerably unsuccessful in interpreting logical equivalence of statements. Lack of knowledge related to indirect proof methods, accepting a true statement as false, suggesting to apply direct proof instead of selecting given choices, and thinking contrapositive statements as unrelated could be regarded as the reasons for their incorrect interpretations.*

**Keywords:** *Contrapositive, logical equivalence, pre-service middle school mathematics teachers.*

## Introduction

Proof does not have simple roles in mathematics and mathematics education; it is a fundamental component and includes different forms and methods (Jones, 1997). A review of the literature indicated that there are limited number of studies focusing on particular proof methods (Antonini & Mariotti, 2008; Baccaglini-Frank, Antonini, Leung, & Mariotti, 2013; Bedros, 2003; Stylianides, Stylianides, & Philippou, 2004). According to Stylianides, Stylianides and Philippou (2004), the least attention has been given to proof by contrapositive compared to other proof methods such as mathematical induction, proof by contradiction, and direct proof. Thus, in this study the focus is given to proof by contrapositive. According to Bedros (2003), proof by contrapositive is a method of indirect reasoning. Since a conditional statement  $p \Rightarrow q$  and its contrapositive  $q' \Rightarrow p'$  are logically equivalent, in order to prove a given statement  $p \Rightarrow q$ , the statement  $q' \Rightarrow p'$  can be proved by using direct proof (Bloch, 2000). In other words, when a statement is proved, its contrapositive is also proved (Antonini, 2004). This study focused on the logical equivalence of contrapositive statements, which is the key idea of proof by contrapositive method.

According to Baştürk (2010), students have difficulty in deciding which proof method to use and in applying the selected method. Moreover, students have many more difficulties in indirect proof methods rather than direct proof methods (Antonini & Mariotti, 2008). For example, Dickerson (2008) commented that undergraduate and graduate students have difficulty in understanding the language and logic of indirect proof methods. In the study by Stylianides, Stylianides and Philippou (2004), it was stated that some undergraduate students had difficulty in understanding logical equivalence in contrapositive and used incorrect equivalences such as  $p \Rightarrow q \equiv p' \Rightarrow q'$  in their explanations. Similarly, many students could not distinguish proof by contradiction from proof by contrapositive (Goetting, 1995).

As seen, indirect proofs such as proof by contrapositive have the potential to reveal many difficulties that students possess in relation to proof (Bedros, 2003). Teachers' knowledge of proof plays an important role in developing students' understanding in proof. For instance, when mathematics

teachers present various proof methods in the class, it helps students to enhance their logical thinking and proof abilities (Altıparmak & Öziş, 2005). Therefore, mathematics teachers should have necessary knowledge and experience concerning different proof methods. Since pre-service middle school mathematics teachers are future teachers, their interpretations related to the logic of particular proof methods such as proof by contrapositive are important to investigate. Thus, to examine pre-service middle school mathematics teachers' interpretation of logical equivalence in proof by contrapositive and the reasons for their incorrect interpretations were determined as the purposes of the present study. Moreover, in the teacher education program, pre-service teachers take various mathematics courses and their ability in interpreting proof related concepts might depend on these mathematics courses since some of which place more importance on proof. In relation to this, how pre-service teachers' success levels differ by year level in the program was also investigated. By considering these purposes, the research questions were stated as follows:

1. To what extent are Turkish pre-service middle school mathematics teachers successful in interpreting logical equivalence in proof by contrapositive, and how does their success differ by year level?
2. What are the reasons for Turkish pre-service middle school mathematics teachers' incorrect interpretations?

## Method

Since data were collected at just one point in time from a selected sample in order to describe certain characteristics of the population by asking questions (Fraenkel & Wallen, 2005), this study was designed as a cross-sectional survey. Using convenience sampling methods, the sample for this study was determined as 115 pre-service middle school mathematics teachers attending a state university in Ankara, Turkey. In terms of their year level, 19 were freshmen (16.5%), 25 were sophomores (21.7%), 39 were juniors (33.9%), and 32 were seniors (27.8%).

In Turkey, the middle school mathematics teacher education programs offer mathematics courses such as Calculus, Algebra; mathematics education courses involving Methods of Teaching Mathematics, Practicum; education courses such as Classroom Management; general courses involving Academic Oral Presentation Skills, and elective courses. The first two years of the program mainly consist of mathematics courses while the last two years put more emphasis on education, mathematics education, and elective courses.

This study was conducted as part of a larger study focusing on pre-service middle school mathematics teachers' interpretation of the logic behind proof methods. In this study, the answers given by pre-service teachers to three questions related to the logical equivalence of contrapositive statements were analyzed. These questions were prepared by reviewing the related literature (Knuth, 1999; Saeed, 1996). In more detail, Question 1 (Q1) and Question 2 (Q2) were prepared by the researchers by considering the format of the multiple choice questions in the study undertaken by Knuth (1999). The students were asked to select the correct statement that can be used to start to prove the given statement and explain their answers. The correct choice involves the proposition  $q \Rightarrow p$  as the starting point to prove the proposition  $p \Rightarrow q$  which is known as proof by contrapositive. The other choices were not appropriate to start any proof. The correct choices were identified as (d) for Q1 and (c) for Q2. Questions 1 and 2 are presented below.

<p><b>Q1.</b> Assume that <math>m</math> and <math>n</math> are positive integers. If <math>mn=100</math>, then <math>m \leq 10</math> or <math>n \leq 10</math>. To prove the given statement, which statement can you begin with?</p> <p>a) Assume that <math>m</math> and <math>n</math> are positive integers. If <math>m &gt; 10</math> or <math>n &gt; 10</math>, then <math>mn=100</math>. b) Assume that <math>m</math> and <math>n</math> are positive integers. If <math>m \leq 10</math> or <math>n \leq 10</math>, then <math>mn=100</math>. c) Assume that <math>m</math> and <math>n</math> are positive integers. If <math>m \leq 10</math> and <math>n \leq 10</math>, then <math>mn \neq 100</math>. d) Assume that <math>m</math> and <math>n</math> are positive integers. If <math>m &gt; 10</math> and <math>n &gt; 10</math>, then <math>mn \neq 100</math>. e) None of the above</p> <p>- Why? State your reasons.</p>	<p><b>Q2.</b> Assume that <math>a</math>, <math>b</math> and <math>c</math> are real numbers and <math>a &gt; b</math>. If <math>ac \leq bc</math>, then <math>c \leq 0</math>. To prove the given statement, which statement can you begin with?</p> <p>a) Assume that <math>a</math>, <math>b</math> and <math>c</math> are real numbers and <math>a &gt; b</math>. If <math>c &gt; 0</math>, then <math>ac \leq bc</math>. b) Assume that <math>a</math>, <math>b</math> and <math>c</math> are real numbers and <math>a &gt; b</math>. If <math>c \leq 0</math>, then <math>ac \leq bc</math>. c) Assume that <math>a</math>, <math>b</math> and <math>c</math> are real numbers and <math>a &gt; b</math>. If <math>c &gt; 0</math>, then <math>ac &gt; bc</math>. d) Assume that <math>a</math>, <math>b</math> and <math>c</math> are real numbers and <math>a &gt; b</math>. If <math>c \geq 0</math>, then <math>ac \geq bc</math>. e) None of the above</p> <p>- Why? State your reasons.</p>
---	---

Figure 1: Question 1 and Question 2

Question 3 (Q3) was adapted from the study of Saeed (1996) and involves a discussion about the proofs of two contrapositive statements. In the question, the participants were asked to select the person they agreed with and explain the reasons for their choice. The students' answers were accepted as incorrect if they agreed with Pinar and correct if they agreed with Ahmet.

<p><b>Q3. Statement A:</b> If <math>n^2</math> is an odd integer, then <math>n</math> is an odd integer. <b>Statement B:</b> If <math>n</math> is an even integer, then <math>n^2</math> is even integer.</p> <p><b>Ahmet:</b> I think statement A is true, Pinar. <b>Pinar:</b> Let me see, if <math>n^2=9</math>, then <math>n=\pm 3</math> is odd; if <math>n^2=25</math>, then <math>n=\pm 5</math> is odd. So, statement A seems to be true Ahmet. <b>Ahmet:</b> I also think that statement B is true, Pinar. <b>Pinar:</b> Why? <b>Ahmet:</b> Since <math>n</math> is even, then <math>n=2k</math> where <math>k</math> is some integer. Therefore, <math>n^2 = 4k^2 = 2(2k^2)</math> is also even. <b>Pinar:</b> But Ahmet, this only show the statement B is true, but does not show that statement A is true. <b>Ahmet:</b> This argument also shows that statement A is correct.</p> <p><b>Questions;</b> - Considering the discussion above, who do you agree with? Ahmet _____ Pinar _____ - Why? Explain your reasons.</p>
--

Figure 2: Question 3

To investigate the research questions, descriptive statistics and item-based analysis were conducted. Firstly, pre-service middle school mathematics teachers' interpretations of logical equivalence in proof by contrapositive were analyzed based on the rubric given in Table 1. Then, the reasons for their incorrect interpretations were examined qualitatively by generating themes.

	Answer types in Q1 and Q2	Answer types in Q3
	No answer	No answer
Incorrect answer	Incorrect choice was marked, no explanation was stated	Agreed with no one or both of them
	Incorrect choice was marked, explanation was stated	Agreed with Pinar, no explanation was stated Agree with Pinar, explanation was stated
Correct answer	Correct choice was marked, no explanation was stated	Agreed with Ahmet, no explanation was stated
	Correct choice was marked, explanation was given but not referring to the logical equivalence	Agreed with Ahmet, explanation was given but not referring to the logical equivalence
	Correct choice was marked, explanation was given referring to the logical equivalence	Agreed with Ahmet, explanation was given referring to the logical equivalence

Table 1: Rubric for questions

## Findings

In order to investigate the first research question, pre-service middle school mathematics teachers' answers to Q1 and Q2 were analyzed. The results of 115 pre-service middle school mathematics teachers' answers are presented in Table 2.

Answer types		Question 1		Question 2	
No answer		4 (3.5%)		4 (3.5%)	
Incorrect answer	Incorrect choice was marked, no explanation was stated	12 (10.4%)	50 (43.4%)	12 (10.4%)	55 (47.8%)
	Incorrect choice was marked, explanation was stated	38 (33.0%)		43 (37.4%)	
Correct answer	Correct choice was marked, no explanation was stated	43 (37.4%)	61 (53.1%)	33 (28.7%)	56 (48.7%)
	Correct choice was marked, explanation was given but not referring to the logical equivalence	7 (6.1%)		9 (7.8%)	
	Correct choice was marked, explanation was given referring to the logical equivalence	11 (9.6%)		14 (12.2%)	

**Table 2: Frequencies of the answers to Q1 and Q2**

Table 2 shows that 4 students (3.5%) did not answer to Q1 and Q2. When the answers of the students to Q1 were investigated, it was seen that 50 students (43.4%) answered incorrectly and 61 students (53.1%) selected the correct choice. In addition, 43 students (37.4%) marked the correct choice without stating their reasons and the answers of 7 students (6.1%) were correct but their explanations were not related to logical equivalence. The remaining 11 students (9.6%) answered correctly by providing an explanation based on logical equivalence of contrapositive statements. In terms of year level in the program, freshmen (73.7%) had the highest percentage of correct answers and seniors (40.6%) had the lowest percentage of correct answers in Q1. As an example of a correct answer with an explanation referring to logical equivalence, Participant 52 stated as follows:

$p: mn=100$        $p': mn \neq 100$        $p \Rightarrow q \equiv p' \vee q \equiv q \vee p' \equiv q' \Rightarrow p'$   
 $q: m \leq 10 \vee n \leq 10$        $q': m > 10 \wedge n > 10$   
 $q' \Rightarrow p'$  (If  $m > 10$  and  $n > 10$ , then  $mn \neq 100$ ) (Participant 52, junior)

The analysis of the answers to Q2 showed that 55 students (47.8%) answered incorrectly whereas 56 students (48.7%) answered correctly. Thirty-three students (28.7%) marked the correct choice in the question but did not substantiate their ideas. Moreover, 9 students (7.8%) answered correctly without referring to contrapositive statements, and 14 students (12.2%) answered correctly by referring to the logical equivalence of contrapositive statements. While sophomores (64.0%) had the highest percentage of correct answers, freshmen (36.8%) and seniors (37.4%) had the lowest percentages of correct answers in Q2. To illustrate, Participant 97 answered correctly and explained by referring to logical equivalence in proof by contrapositive.

$p: ac \leq bc$        $q: c \leq 0$   
 Then, proof by contrapositive,  $p \Rightarrow q \equiv p' \vee q \equiv q \vee p' \equiv q' \Rightarrow p'$  (Participant 97, senior)

Since Q3 has a different rubric from the multiple choice questions, pre-service middle school mathematics teachers' answers to Q3 are presented in Table 3.

Answer types		Question 3	
No answer		4 (3.5%)	
Agreed with no one or both of them		3 (2.6%)	
Incorrect answer	Agreed with Pinar, no explanation was stated	16 (13.9%)	75 (65.2%)
	Agree with Pinar, explanation was stated	59 (51.3%)	
Correct answer	Agreed with Ahmet, no explanation was stated	5 (4.3%)	33 (28.7%)
	Agreed with Ahmet, explanation was given but not referring to the logical equivalence	24 (20.9%)	
	Agreed with Ahmet, explanation was given referring to the logical equivalence	4 (3.5%)	

**Table 3: Frequencies of the answers to Q3**

According to Table 3, 4 students (3.5%) did not answer Q3. The answers of 3 students (2.6%) showed that they agreed with neither Pinar nor Ahmet but did not explain their rationale. Moreover, 75 students (65.2%) agreed with Pinar, which is accepted as incorrect answer and 33 students (28.7%) agreed with Ahmet, which is accepted as correct answer. Five students (4.3%) agreed with Ahmet without giving any explanation, 21 students (20.9%) agreed with Ahmet and explained without referring to logical equivalence, and 4 students (3.5%) explained their agreement with Ahmet by referring to logical equivalence of contrapositive statements. Moreover, juniors (38.4%) had the highest percentage of correct answers and sophomores (4.0%) had the lowest percentage of correct answers to Q3. An example of a correct answer, Participant 52 agreed with Ahmet and her explanation was related to logical equivalence used in proof by contrapositive.

$p$ :  $n$  is even                   $q$ :  $n^2$  is even

$p \Rightarrow q$  was proved

$p \Rightarrow q \equiv p' \vee q \equiv q \vee p' \equiv q' \Rightarrow p'$

Thus, if  $n^2$  is odd then  $n$  is odd. Therefore, Ahmet is right. (Participant 52, junior)

For the second research question, pre-service middle school mathematics teachers' explanations for their incorrect answers were analyzed. As presented in Tables 2 and 3, 50 students (43.4%) answered Q1 incorrectly and 38 of them (33.0%) gave explanations for their answers. Fifty-five students (47.8%) answered Q2 incorrectly, of whom 43 (37.4%) explained their answer. Lastly, 75 students (65.2%) answered Q3 incorrectly and 59 of them (51.3%) suggested explanations for their answers. Table 4 shows the reasons behind the students' incorrect interpretations grouped under four categories.

Reasons	Q1	Q2	Q3
R1 Lack of knowledge related to indirect proof methods	30 (26.1%)	35 (30.4%)	-
R2 Accepting a true statement as false	5 (4.3%)	-	-
R3 Suggesting to apply direct proof instead of selecting given choices	3 (2.6%)	8 (7.0%)	-
R4 Thinking that contrapositive statements are unrelated	-	-	59 (51.3%)
Total	38 (33.0%)	43 (37.4%)	59 (51.3%)

**Table 4: Reasons for students' incorrect interpretations**

The first reason for the incorrect interpretations is students' lack of knowledge related to indirect proof methods. As a result of this inadequacy, students thought that one of the choices in the question was related to contradiction or contrapositive; however, this choice was not related to these methods.

For example, in Q2, Participant 7 selected one of the incorrect choices and explained it as an assumption for contradiction.

To prove by contradiction, we have to prove the converse situation. The choice b can be used in this situation. (Participant 7, freshman)

The second reason behind students' incorrect interpretations is that they accepted the given statement as false even though it was true and tried to find counterexamples to refute it. For instance, in Q1, Participant 114 could not see that the given statement was true.

The given statement 'Assume that  $m$  and  $n$  are positive integers. If  $mn=100$ , then  $m \leq 10$  or  $n \leq 10$ .' is not true.

As counterexamples,  $m=12$  and  $n=12$  can be used.

Then,  $mn=12 \cdot 12=144 \neq 100$

Therefore, 'if  $mn=100$  then  $m \leq 10$  and  $n \leq 10$ ' is a true statement. (Participant 114, senior)

The third reason is that students mentioned using direct proof instead of selecting one of the given choices. For instance, the answer of Participant 106 to Q1 is given below:

Firstly, we can assume that  $mn=100$ ; we can try to deduce  $m \leq 10$  or  $n \leq 10$ . We cannot start with the sentences given above. (Participant 106, senior)

The last reason for incorrect interpretations is that students thought that there was no relation between the given contrapositive statements A and B. For example, in Q3, Participant 30 cited that statements A and B were different.

Because the statements are different, one of them starts with an even number and the other one starts with an odd number. The proof of statement A can't be the same with the proof of statement B. (Participant 30, sophomore)

## Discussion

According to the results of pre-service middle school mathematics teachers' answers to questions, it was found that nearly half of the sample answered Q1 and Q2 correctly and almost one third answered Q3 correctly. In other words, students' achievement levels in interpreting logical equivalence in proof by contrapositive were found to be considerably low. The findings revealed that freshmen had the highest achievement level for Q1, sophomores had the highest achievement level for Q2, and juniors had the highest achievement level for Q3. Although seniors were expected to have been the most successful group by considering the number of mathematics courses they took in the program, they were not the most successful in terms of all questions. This result might stem from the fact that seniors did not take any mathematics course in their last year of the program. Therefore, seniors might not remember the details of the logical equivalence used in proof by contrapositive. To avoid this situation, teacher educators could offer elective courses related to logic and proof to enhance prospective teachers' reasoning skills.

Four reasons for the incorrect interpretations were detected from three questions. The first reason is preservice teachers' lack of knowledge related to indirect proof methods. This finding is consistent with the results of Atwood (2001), who stated that students had difficulty in using the words converse, contrapositive, contradiction, and counterexample, and that they might use them interchangeably, which is not correct. Moreover, in the case that where students generally memorize proof methods

instead of understanding the structure of the proof might cause them to have difficulty in related proof methods. Therefore, the participants in this study might use proof by contrapositive and proof by contradiction inaccurately and interchangeably. The second reason why students answer incorrectly is accepting a true statement as false and trying to find counterexamples based on this idea. Some of the terms and signs involved in the given statement in Q1 such as ‘or’ and ‘ $\leq$ ’ might cause students to misunderstand the statement. Thus, students might have had trouble in deciding whether the given statement was true or false and evaluate it as false. The third reason is that students suggested proving the given statement with direct proof instead of selecting one of the given choices in the question. This situation may result from the fact that the majority of the proofs in the textbooks are given as direct proofs (Atwood, 2001). Therefore, students may have a tendency to use direct proofs since they are more familiar with this method. The last reason is that students thought that statements A and B given in Q3 were unrelated. In this study, students might fail to see the relation between proofs of given two contrapositive statements. Therefore, they might think that statement A which involves  $p \Rightarrow q$  and statement B which involves  $q' \Rightarrow p'$  should be proven separately.

In mathematics teacher education programs, proof should be considered as an important theme. Thus, the content or place of mathematics courses in teacher education programs might be revised and developed in order to enhance preservice teachers’ understanding of reasoning, proof, and logical rules behind proof methods. For example, mathematics courses might be taught by paying attention to logical rules behind proof methods. This study pointed out the importance of having knowledge of logical rules in reading and interpreting a given proof statement or conducting proof by using particular proof methods. Moreover, similar findings related to the interpretation of logical equivalence used in proof by contrapositive might be achieved with pre-service mathematics teachers in different countries. Therefore, to compare and to gain a global perspective about pre-service mathematics teachers’ understanding of logical rules behind proof methods, cross-cultural studies could be conducted. Based on the findings of such studies, teacher educators might develop strategies to overcome pre-service mathematics teachers’ current difficulties in logic and proof by considering the characteristics of their teacher education programs.

The results of the study are limited to the data collected with three questions. For further studies, pre-service middle school mathematics teachers’ interpretations of logical equivalence used in proof by contrapositive might be investigated by using alternative questions in various formats. An investigation of the effect of pre-service mathematics teachers’ knowledge of logic on their ability to prove might also be undertaken. Moreover, to analyze the answers of the pre-service mathematics teachers and to determine the reasons for their incorrect interpretations regarding logic in-depth, follow-up interviews might be conducted in future studies.

# Issues of a quasi-longitudinal study on different types of argumentation in the context of division by zero

Christian Fahse

Institute of Mathematics, University of Koblenz-Landau, Campus Landau; [fahse@uni-landau.de](mailto:fahse@uni-landau.de)

*In this study we explore students' ways of argumentation concerning division by zero. The answers of 365 students of four different grade levels in a German secondary school were analyzed on the basis of written texts of the students explaining their results of  $7:0$ . Applying qualitative content analysis (Mayring, 2000), we were able to distinguish three different types of argumentation. The relative frequencies of these different types vary with the increasing age of the students: rich argumentations stagnate, apodictic references to an authority increase.*

*Keywords: Argumentation, reasoning, communication model, division by zero.*

## Motivation and interest of research

Argumentation, besides for instance modelling and problem-solving, is one of the main issues especially characterizing mathematical education. The aim to develop argumentative abilities in mathematics has been reinforced by German authorities since 2003. Consequential, there is a need to measure progress in this field on the level of learning groups and educational systems. Tests like PISA and other test series claim to perform this measuring (OECD 2015, p. 32), even though they are subject to partly strong criticism (e.g., Jahnke & Meyerhöfer, 2007). The tasks used in these tests, pretending to measure argumentative skills, necessarily are very restricted in regard to content and time on task, compared to a creative argumentation process performed in classroom. Furthermore, the dichotomous focus on right or wrong does not seem to be suited for an observation on argumentation.

## The notion of “probe” in educational research

The idea of the main study is to use a so called “educational probe” (Ger. “Sonde”). This can be best described by an analogy: Car insurances ask if the car is parked in a garage. If so, the insurance fee is reduced. This is not done due to causal inference, but for statistical reasons (information from the insurance company HUK-Coburg, Coburg, by telephone, 2011): there is a robust (negative) correlation between parking in a garage and the probability of an accident. A “probe” for detecting abilities is a small bundle of easily carried out measurements, observing the patterns of reactions of learners to some standardized impulse together with an established correlation of those patterns to the intended ability of the learning group.

It is an open question if educational probes exist. As a first step, we try to find candidates for a “probe” on the ability of argumentation; in a second step, we have to validate these probes. A variety of measurements can be taken into account (e. g. videography), but here we concentrate simply on tasks given as impulses and evaluate written texts, thereby e. g. ignoring any social interaction. Several groups of tasks, all roughly of the form “Give your opinion and justify it”, were given to the same students. In this article we consider only the task concerning division by zero (in short: “ $7:0=?$  Justify your opinion.”). This special task was included in the study because of the

variety of possible justifications discussed in the literature (Knifong & Burton, 1980) and observed in classroom practice (author's experiences with eight classes of 6<sup>th</sup> graders).

### **Basic assumptions and research questions**

Argumentative abilities are considered to be of general importance beyond mathematics. Therefore, this study does definitely not focus on proving, and argumentation is not considered as a preliminary step to establish a proof. This decision was a consequence of both, the observed argumentations of the students and a certain communication model which has shown to be compatible with the data.

Furthermore, argumentative and mathematical abilities are considered as different constructs. Therefore, the correctness of the solution of the problem cannot be a primary criterion to discern different types of argumentations. Mistakes have to be tolerated, “misconceptions” can be of a distinct rationality (Prediger, Gravemeijer, & Confrey, 2015, p. 881). This pedagogical view is supplemented by a historic mathematical fact: It is not true that division by zero is not possible or not to define. E. g. the inversion (holomorphic extension of  $1/z$ ) on the Riemann Sphere is a continuous function which imposes  $1/0=\infty$ .

On first sight, one can wonder if short written answers to tasks really make a difference compared to the testing in PISA. The described preponderant disregard of “correctness” of the given result and the completely different evaluation by a qualitative content analysis (QIA, see below) are characteristics of this study, distinguishing it from PISA. The resulting category system is developed by an approach which is in a first step “grounded”, that is, constructed without reference to other theories. This methodical choice was taken because the interest of this study lies in the opportunity to compare our findings to other category systems found in the literature. However, in order to narrow the scope of this article we have to make two limitations: First, we will not report on a comparison between different category systems. Second, neither the analysis of misconceptions of division by zero nor suggestions for classroom practice are points of interest here, but presented in Fahse (2014).

Taking the hypothesis that the ability of deploying argumentation develops over time, an appropriate probe should provide different results for different ages of the learners. The research questions in this mainly descriptive study are:

- What types of mathematical argumentation can be found?
- Does the percentage of these types differ from grade level to grade level?

### **Theoretical background**

In this section we concentrate on literature about types of argumentation and leave aside that on divisions by zero with the following exception: In congruence with our study, Tsamir and Sheffer (2000) analyze argumentation in regard to division by zero. They distinguish between concrete and formal (algebraic) arguments, and favor the formal ones (Tsamir & Sheffer, 2000, p. 94). In contrast Fahse's (2014, p. 24) empirical examples show that the use of concrete models of division can give insight into the problematics of division by zero, even if a “wrong” result is given (different from “division is impossible”, caveat see above). Therefore, in our system, the distinctions of Tsamir & Sheffer can only be considered as subcategories, not as main categories.

Different classifications of argumentation schemes without reference to any special mathematical topic can be found in the literature. Argumentation can be set in contrast to proof (Duval, 1991), or these phenomena can be treated in regard to their mutual relationship. The latter can e.g. be done by analyzing the process that leads to a proof, wherein argumentation is conceived “as a process of producing a conjecture and constructing its proof” (Boero, Douek, Morselli, & Pedemonte, 2010, p. 183). Following Pedemonte (2007), argumentations are based on a system of conceptions and related to conjectures either as “structurant” or as “constructive” argumentation. Furthermore, an argumentation can be abductive, inductive, or deductive (Pedemonte, 2007). These characteristics could be applied to our data, but since our study does not focus on proof they do not adequately describe the variety of justifications found in our study.

Harel & Sowder (1998) use the term “proof schemes” which refers to “what the person offers to convince others” (p. 275). This fits well into the model of argumentation given below. Their way of classification scheme (externally conviction, empirical, and analytical proof schemes as superordinate categories; “analytical” is changed into “deductive” in Harel, 2008, p. 491) will be compared to the findings of our study in another article.

### **Communication models and specification of concepts**

Since essentially different (Brunner 2014, p. 231) definitions exist of the notions argumentation, reasoning (regarded here as synonymous to justification, if referring to one fixed claim), proving and explaining we have to specify these terms. They are not conceived with regard to proof, but to the argumentations notated by the tested students.

Our study uses a model of argumentation that is based on communication theories (Bühler, 1934; Kopperschmidt, 1980, following Habermas (1984)). The sender and receiver refer to a knowledge (and communication) basis assumed to be shared. The objects of justifications are statements that have different grades of plausibility for the two interlocutors. The act of justification performed by the sender is an attempt to augment this grade, conceived as an ordinal structure, on the receiver's side. Therefore, this concept of argumentation is genuinely dialogic. Nevertheless, the receiver can also be an internal entity within the sender, or a universal audience.

In the following, short definitions of the principal terms used in this article are given. The discussion and the comparison of these definitions to those found in the literature go beyond the scope of this article. But for reasons of practicability we suggest to accept these definitions in the frame of this article despite a lacking consensus in the wider scientific community (Brunner 2014, p. 231).

**Argumentation** is conceived as a generic term (Bezold, 2009), including the process of finding hypotheses, and checking common bases of knowledge and communication. **Reasoning** or **justification** is a communicative reaction to a questioning of a statement. The aim of reasoning is to increase the degree of the receiver's acceptance (his attributed epistemic value) of the statement by relating the statement under discussion to the basis of knowledge and communication assumed to be shared (Kopperschmidt, 1980, p. 73). **Proof** is a sequence of argumentative steps relying on an accepted basis of statements approaching the ideal of a complete logical chain of deductive steps (Duval, 1991). A proof can be a justification, but does not necessarily be one. **Explanation** (of “why”, not “how” or “how to do”) is an addressee-oriented justification by the sender with the aim

of creating an “understanding”, which in turn is conceived as a fitting to the (possibly accommodated or enlarged) factual knowledge of the addressee (Kiel, 1999, p. 72; Hanna, 2016, “pedagogical explanations”, p. 2).

Justifications can attempt to explain, but also aim to refer to reliable sources. Furthermore, in this framework, a mathematical proof is only one method of justification and not necessarily effective, depending on the mathematical ability of the sender and receiver. E. g. an algebraic transformation  $7:0 = x \mid 0 \rightarrow 7 = 0$  performed by a student does not really convince another student if their interpretation of the variable  $x$  is uncertain and the concept of equivalence transformation is known, but insufficiently familiar.

## The study

The analysis of the data is not fully completed yet, but we can report first results on selected parts of the study. We asked the students to give the result of the division  $7:0$  and to “justify [their] opinion in a way that someone who doesn't know the answer is able to understand [the result]” (Unabbreviated original task, translated from German). The written answers of a group of  $N=365$  students in grade 7, 9, 11, 13 were analyzed. In regard to the relative abundance of argumentation types we report data from a subgroup of  $N=300$  pupils which did not take part in interventional courses. These were  $N=73, 86, 78, 63$  students in the four grades resp.. In this convenience sample all students were of the same secondary school (“Gymnasium”), and all students of the four chosen grades were tested (absence of students  $< 5\%$ , no denial).

## Method of analysis

First we applied a qualitative content analysis (QCA, Mayring, 2000) with inductive category development. Therefore, we analyzed the student’s written justifications in several steps. The first step was to classify the texts only by similarity without any recourse to theory. In the next steps we aggregated items with an increasing level of abstraction (“feedback loops”) leading to the different types of argumentation described in our coding manual. To ensure reliability this manual was used to perform a separate “deductive category application” (Mayring, 2000, sec. 4.2) by a pair of university students in a second step (Interrater Reliability  $\kappa=.967$ ,  $N=365$ ).

## Results - Three different types of argumentation

We found three types of argumentation: rich, pseudo-factual, and apodictic. A summary is given in Table 1. All examples of student justifications have been translated from German.

### Rich justifications

In this category the content and the way of reasoning are essentially reasonable (see below) even if the results might be wrong, or the justification is partly false or incomplete. The statement of justification is connected to a domain which is relatively complex. Therefore, operations (e.g. changing the mode of representation, calculations) are more likely to be found.

“Essentially reasonable” means that with the same idea a correct argumentation is possible. “ $7 : 0 = 7$ . So, if you have 7 apples and you divide them among 0 persons, you still have 7 apples.” The usage of a model for division in the warrant (Toulmin, 1958) can be regarded as an operation in

which the representation of division is changed from the “algebraic view” to “partitive distribution”. This latter domain is sufficiently complex: it is simply not possible to distribute 7 apples to nobody. The mistake in the original quote, disregarded for the type of argumentation, can be interpreted in the following way: the result of the division does not show what is left, but how much each person gets. Beside partitive interpretation using concrete objects, measurement interpretations of the division: “0 fits infinitely often into 7”, and algebraic calculations are typical examples of rich arguments.

	Rich	Pseudo-factual	Apodictical
Domain	Linked to a mathematically appropriate, well structured domain	Unapt or poorly structured domain, weakly linked	No mathematical domain or tautological
Warrants	Potentially useful/basic concepts	Essentially wrong	No mathematical but social warrants (authorities)
Operations	Operations e. g. change of representation	Few operations	No operations
Need for ...	Mathematical justification		Reliable authority/source
Value (see discussion)	Epistemic (Proof: Logical)	(Similarity)	Informational

**Table 1: Characterization of justification types**

### Pseudo-factual justifications

Mathematical warrants (Toulmin, 1958) are quoted, but these are profoundly incorrect, e.g. if the link to a domain of the common knowledge basis is not reliable (one student used the analogy of  $7^0=1$  - not an appropriate domain (power calculations), and weakly linked by analogy). In others, the cited domain has no sufficient structure, e.g. when including “invented” calculation rules (“all calculations with 0 produce 0 as result”), or making statements about the nature of the task or objects (“there's nothing to calculate”, “0 has no significance”). Because of the lack of rich structure in the used domains only few other acts or operations besides generalizations and analogies can be found. Other texts seem to imitate the logical and symbolic structure of a mathematical justification, or use invented terms.

### Apodictic justifications

Mathematical warrants are not used, but rather references to authorities like the teacher, the calculator, the textbook, or the world-wide-web given instead. A simple tautological repetition of a statement is interpreted as a reference to one's own ultimate knowledge and thus seen as an authority in the sense of: “That's how it is, I know it.” Sometimes it is even stated that no justification is necessary. This shows a utilitarian understanding of mathematics, which can be convenient, e.g. for engineers in the course of their everyday work. Because there is no need for *mathematical* warrants, there are no domains and consequently no operations found. Typical examples: “[...] There is nothing to explain, that's the way it is”, or “The rule says you cannot divide by zero. You just have to learn and remember it.” This type seems to be very close to the authoritative type of Harel &

Sowder (1998). Precautionary it was given a different name, to be able to compare thoroughly the two types.

### Quantitative results

Looking at the increasing grade level of the students, the relative abundances of the used argumentation types accordingly develop as follows: 1) Rich argumentations remain at slightly less than 40%. 2) Pseudo-factual argumentation is reduced to almost a half. 3) Apodictic argumentation almost doubles. There are very few justifications that can be seen as an algebraic proof: Only 4% use multiplication as the inverse of division. Note that the percentages in Figure 1 add up to more than 100% because each text can show more than one type of argumentation. The observed decrease, resp. increase was significant.

**Figure 1: Relative abundance of types with increasing grade and inference-statistical characteristics of the relative abundance of the different types when applying a linear model of increase**

### Discussion

The classification of justifications into different types presented in this study might be useful for the teacher's practice. They offer a framework for the moderation of class discussions. At first sight, there is no valuation concerning the different types. Proof increases the logical value, non-proof justifications try to augment the epistemic value of the statement (Harel, 2007, p. 497). In our model (Table 1), we add the *informational value*, conceived as the reliability of the source, which is increased by apodictic argumentation. This can be important for non-mathematicians, e. g. in the realm of engineering. Also in school, an algebraic argumentation (close to proof) by another student can be considered hard to trust. However, the aim of school education and the standards of mathematical education favor rich argumentations. For the practice of teaching it is recommended that apodictic justifications should *not* be discredited right away, but first discussed: They may be valuable for practical needs (unexamined statements as "black boxes"), but do not initiate an understanding. In contrast, pseudo-factual justifications should be criticized, even though at this point it is an open research question if this argumentation type can be considered a preliminary stage

of rich argumentation practice. As shown in an example in Fahse and Linnemann (2015), pseudo-factual justifications can be very appreciated by fellow students, because they seem to be particularly “mathematical” at first sight. In some cases, they do not increase any value of the statement, but try to augment the acceptance of the *justification* by similarity to genuine mathematical justifications. With the help of our classification, such misleading contributions could be more clearly discerned, both in discussions and written texts. Therefore, it might even be helpful to inform the students of these types (for first experiences, see Fahse & Linnemann, 2015). For teachers, these types could be useful for diagnostic purposes: to gain insight into the individual development of argumentation skills and to foster these abilities.

Taking the special task on division by zero as an educational probe seems to be promising: In all considered grades all three types occurred and were not marginalized. The different grades (and also the 16 different learning groups) showed significantly different distributions of types (not reported here). What is more, there are clear tendencies: The stagnation of the abundance of rich argumentations and the increasing of apodictic ones. One might think that this is caused by the increasing distance (mental and in time) of the students to this topic (taught in 5<sup>th</sup> grade). The following observations, though, question this interpretation: Even in 7<sup>th</sup> grade, the majority of the students does not remember the lessons on this topic, but refer to primary school. Similar questions are topics taught in grade 9 (square-root of negative numbers) and grade 10 ( $7^0$ ,  $\log(0)$ ). Nevertheless, the use of algebra in the answers is rare. More likely, the increase of apodictic reasoning is caused by continuous repetition of the mere algebraic rule without any explanation, and perhaps by a neglect of argumentation as an educational objective. This last hypothesis will persist only if the used probe (division by zero) can be validated as a probe for argumentation ability in general. This will be a topic of future research in our investigations.

*The notion of flow of a proof encapsulates mathematical, didactical and contextual aspects of proof presentation, related to the lecturer's choices regarding the presentation. We explore the relationship between mathematics teaching and rhetoric, suggesting Perelman's New Rhetoric (PNR) as theoretical framework to assess different rhetorical aspects of the flow of a proof. In this paper we relate particularly to the establishment of a shared basis of agreement between the lecturer and the students, and to potential fallacies in this basis. We present examples of analysis of the basis of agreement from a lesson in Number Theory, at the beginning undergraduate level.*

*Keywords: Proof teaching, flow of proof, Perelman's New Rhetoric, mathematical argumentation.*

## Theoretical background

### Mathematics and Rhetoric - "Can two walk together, except they be agreed?"

Mathematics “possesses not only truth, but supreme beauty – a beauty cold and austere, like that of sculpture, without appeal to any part of our weaker nature...” (Russell, 1917, p. 60) and is “independent of us and our thoughts” (ibid, p. 69). This perception of mathematics seems to stand in drastic contrast to rhetoric, the ancient art of persuasion, which over the centuries became mostly related to the study of the ostentatious and artificial aspects of discourse. Yet, over the last few decades, scholars have begun to discuss the mathematics- rhetoric separation and its consequences.

A pioneering effort of associating mathematics and rhetoric was made by Davis and Hersh (1987) who argued “that mathematics is not really the antithesis of rhetoric, but rather that rhetoric may sometimes be mathematical, and that mathematics may sometimes be rhetorical” (p. 54). Davis and Hersh challenged the opinion that mathematics establishes truth “by a unique mode of argumentation, which consists of passing from hypothesis to conclusion by...small logical steps...”, and claimed that “mathematical proof has its rhetorical moments and its rhetorical elements” (ibid, pp. 59–60). They illustrated this by phrases that a college mathematics lecturer may use while presenting a proof (in addition to the expected logical transformations), such as: “It is easy to show ...”, “... simple computation, which I leave to the student, will verify that...”; they identified these phrases as rhetorical means in the service of proof. They acknowledged that the use of such phrases may be related to context, but rejected the myth that behind each theorem stands a flawless, logical proof. For them ‘proof’ is an amalgam of formality, of convincing arguments and of appeals to imagination and intuition.

Another example is the ‘rhetoric of the sciences’ movement, which studies the stylistic forms used by scientists in scientific texts (mathematics included), to persuade others that their claims are valid. So, as in the other sciences, the rhetoric of mathematics plays an essential role in maintaining its epistemological claims (Ernest, 1999). Ernest relates to another aspect of rhetoric in mathematics, namely the importance of persuasion for mathematics instruction.

Reyes (2014) asserts that it should be in the interest of rhetorical scholars to explore mathematics discourse, as it is the basis of techno-science. He analyses conceptual mathematical metaphors as an example for a mode of analysis of mathematics whose roots lie in rhetorical studies. Elsewhere, Reyes studies the rhetorical process during the invention of mathematics, and explores the introduction of infinitesimals by Newton and Leibniz as an example of the role of mathematical rhetoric in mathematical invention, in addition to its role in communicating the mathematics.

In conclusion, inquiry into relations between rhetoric and mathematics is growing in extent and richness. An increasing number of scholars explore the possibilities offered by the use of rhetorical concepts and ideas to gain better understanding of mathematics and mathematical education. Instead of viewing mathematics as a ‘perfected, austere’ product, they re-connect it to its ‘human features’, that in addition to formal logic utilizes persuasive argumentation and exploits rhetorical means.

### **Argumentation theory and ‘The New Rhetoric’**

Aberdein (2016) rejects the common thesis that mathematical reasoning is fundamentally different from everyday reasoning and that formal logic adequately models the practice of mathematical reasoning. Research in mathematical education uses argumentation theory to address aspects of mathematical argumentation other than formal logic, and for that purpose frequently uses Toulmin’s model that permits schematic analysis of formal proofs as well as of arguments classified as deductively invalid. Toulmin’s model has been shown to be an efficient framework to discuss local arguments as well as global argumentation structures (e.g. Knipping & Reid, 2013) and Inglis, Mejia-Ramos and Simpson (2007) claim that implementing Toulmin’s full model (including rebuttals and qualifiers) should be used for this purpose. However, Toulmin’s model has been criticized for not relating to the effect of the arguments on the audience, and for denigrating rhetoric in argumentation (Olbrechts-Tyteca, cited in Frank, 2004).

In 1958, Perelman and Olbrechts-Tyteca published ‘The New Rhetoric’ (PNR, translated in 1969), an argumentation theory based on the notion that argumentation aimed at justification of choices, decisions, and actions, is a rational activity complementing formal argument. PNR studies techniques used by an arguer to increase audience adherence to the arguer’s theses and conditions that allow argumentation to begin and develop. PNR asserts that reducing an argument to its formal aspects undermines the rhetoric features that support its meaning; it recognizes the distance between dialectic and rhetoric but creates an alignment between them. This complex view at times produced an inherent ambiguity in definitions of some concepts. However, PNR adds meaningful layers of analysis beyond the analysis of argument structure and type achieved by using Toulmin’s model.

PNR describes the ‘threads that make the cloth of the argument’: the starting points that establish a shared basis of agreement, the scope and organization of arguments, ways of creating presence to arguments, and different argumentation techniques. The audience plays a pivotal role in PNR since each ‘thread’, or aspect, is tied to what the arguer believes will deeply persuade the audience. This means that argumentation techniques should be adjusted to the audience’s frame of reference, its previous knowledge, experiences, expectations, opinions and norms. So arguers construct arguments that they consider persuading for a particular audiences or convincing by a ‘universal audience’ (an arguer construct consisting of all reasonable humans) (van Eemeren et al., 2014).

In our study, we wish to analyze rhetorical aspects of proof presentation, in a scenario of a lecturer presenting a mathematical proof to a class of students. We use PNR as a theoretical framework as it incorporates aspects of rhetoric, argumentation and lecturer-classroom relations. Elsewhere (Gabel and Dreyfus, 2017), we demonstrate an analysis of other PNR aspects: scope and organization of the argumentation, and presence of proof elements. In this paper we address a different aspect: establishing a shared basis of agreement with the audience.

### PNR's basis of agreement and its adaptation to proof teaching

According to PNR, argumentation can be successful if it advances from premises already accepted by the audience, i.e. the arguer established a shared basis of agreement with the audience. These premises are classified as follows: (1) *Premises relating to the real*: premises where the arguer claims recognition or acknowledgement of the universal audience. Those include: Facts, truths and presumptions. (2) *Premises relating to the preferable*: premises that have to do with the preferences of a particular audience. Those include: Values, value hierarchies and loci of preferable.

Facts and truths are statements already agreed to by the universal audience; they are considered to require no further justification. Truths stand for connections between facts. Presumptions are opinions or statements about what is the usual course of events which need not be proved, although adherence to them can be reinforced, and it is expected that at some point they will be confirmed. Values relate to the preference of one particular audience as opposed to another. They function as guidelines in making choices of the arguer (even though not all would accept them as good reasons). Values are normally arranged in value hierarchies, which are very important since different audiences may possess the same set of values arranged in different hierarchies. Values and value hierarchies generally remain implicit, but the arguer cannot simply ignore them. Loci of the preferable (aka commonplaces, Topoi) are premises used to justify values or hierarchies and express the preferences of a particular audience (e.g. quantity, quality, essence) (van Eemeren et al., 2014).

We have adapted PNR's classification of premises to the context of our study (analyzing proof presentation in class) as described in Table 1. We do not include in the table the loci of the preferable since they are highly abstract mental constructs which did not need adaptation.

		Adaptation to proof teaching
Premises relating to the real	Facts	Axioms, definitions, givens, previously consolidated symbols/results
	Truths	Lemmas, theorems, newly established symbols/results
	Presumptions	Statements or opinions about what previous knowledge to use, for example: mathematical techniques, proving methods, past theorems.
Premises relating to the preferable	Values	The preference or adaptability to a particular audience of a certain proving method or technique as opposed to another.
	Hierarchies of values	The hierarchies of values will affect audience preferences for choosing notation, proving method or mathematical technique.

**Table 1: Adapting PNR types of premises to a proof teaching context**

According to Perelman and Olbrechts-Tyteca, lack of agreement concerning the basis of agreement may occur at one or more of the following three levels:

- a) *Status of premises*: e.g. if the arguer advances something as a fact but the audience wants to see it proven or if the arguer assumes a value hierarchy not accepted by the audience;
- b) *Choice of premises*: e.g. if the arguer uses facts that the audience does not consider relevant to the argument or would have preferred not to see mentioned;
- c) *Verbal presentation of premises*: e.g. if the arguer is presenting certain facts (acknowledged as relevant by the audience) in words which have connotations unacceptable to the audience.

The ability of creating a shared basis of agreement with the audience is crucial to the success of argumentation. Arguers should therefore carefully consider the status they ascribe to premises, the selection of premises, and the wording of explicit premises (van Eemeren et al., 2014). Examine, for example, two possible values related to proof teaching: (1) Certainty: every argument in the proof should be proved formally or at least justified; (2) Pedagogy: parts of the proof should be left for the students. A lecturer may choose to leave parts of the proof as homework because her/his value hierarchy places (2) over (1). However, if the students have an opposite value hierarchy, this implies that the lecturer had a fallacy in the shared basis of agreement at the level of the status of his value hierarchy, which might consequently weaken students' persuasion.

## The study – description and methods

Our research concerns the notion of 'The flow of a proof' (Gabel and Dreyfus, 2017) which encapsulates various aspects of the proof presentation. The flow is an outcome of the choices made by the lecturer regarding presentation of: (i) the logical structure of the proof (arranging the proof of the theorem into claims, which are proved in a specific order); (ii) informal features and considerations of the proof and proving process (e.g. examples, intuitions), and (iii) mathematical and instructional contextual factors. One aim of the research was to analyze global and local aspects of the flow of the proof, in particular to examine rhetorical aspects of the proof presentation.

The research took place in a Number Theory course, given by the same lecturer to prospective mathematics teachers in two consecutive years. Each year, three lessons including the same suitable proofs (length, richness) were observed and audio-recorded. The three proofs were unrelated to each other. After each lesson students answered a questionnaire relating to cognitive and affective aspects; also, a reflective interview with the lecturer and individual interviews with students were conducted. The post-lesson interviews conducted with the lecturer in Year 1 were analyzed and interpreted, and a list of the lecturer's general considerations regarding proof teaching was produced. In this paper we relate to the second lesson in each year, in which the following theorem related to linear Diophantine equations  $ax+by=d$ ,  $x, y \in \mathbb{Z}$  was formulated and proved:

*Theorem:* The greatest common divisor (gcd) of two integers  $a, b$ , at least one of which is not 0, equals the smallest natural number of the form  $ma + nb$ , where  $m, n$  are integers:  $\gcd(a, b) = \min\{ma + nb > 0 : m, n \in \mathbb{Z}\}$ .

The full proof of this theorem requires the use of previously proven results. In the next section we present a partial analysis of the shared basis of agreement, demonstrating the different types of lecturer premises (in the PNR sense) reflected in the proof presentation, consider potential fallacies in these premises and demonstrate the lecturer's attempt to fix these fallacies.

## Examples of analysis of the basis of agreement

All post lesson interviews conducted with the lecturer in Year 1 were analyzed and interpreted as two sets of lecturer considerations (Gabel and Dreyfus, 2017). One of the sets contains general considerations for proof teaching. In the current paper we relate to three of these general considerations: (a) A proof should be mathematically complete and exact; (b) Some of the proof elements should be left for students to prove by themselves; and (c) Proof structure should be clear. One aspect of the clarity of proof structure was exhibited when the lecturer referred to the myth about Ariadne's thread: "I use... Ariadne's thread many times since mathematical proofs are built in such a way that you need to find the tip of the thread and just follow it..." We relate to these lecturer considerations as values that affect the lecturer's choice and status of premises.

Our examples stem from the last part of the proof as presented by the lecturer, and we will address lecturer premises as reflected in his arguments. In Year 1, just after proving that  $d$  is a divisor of  $a$ , leaving the (almost identical) proof that  $d$  is a divisor of  $b$  to the students, the lecturer said:

Lecturer: The same way we showed that  $d$  is a divisor of  $a$  it follows that  $d$  is a divisor of  $b$ , so  $d$  is a common divisor of  $a, b$ . Now, it can't be smaller than the gcd, yes? Because once I write the equation  $ax + by = d$  then...like we said in the beginning of the lesson, we said that this  $d$  must be divisible by  $\gcd(a, b)$  ... so it can't be smaller than  $\gcd(a, b)$  and that means it is equal to  $\gcd(a, b)$ .

Figure 1: Toulmin's scheme representation of 1st explanation

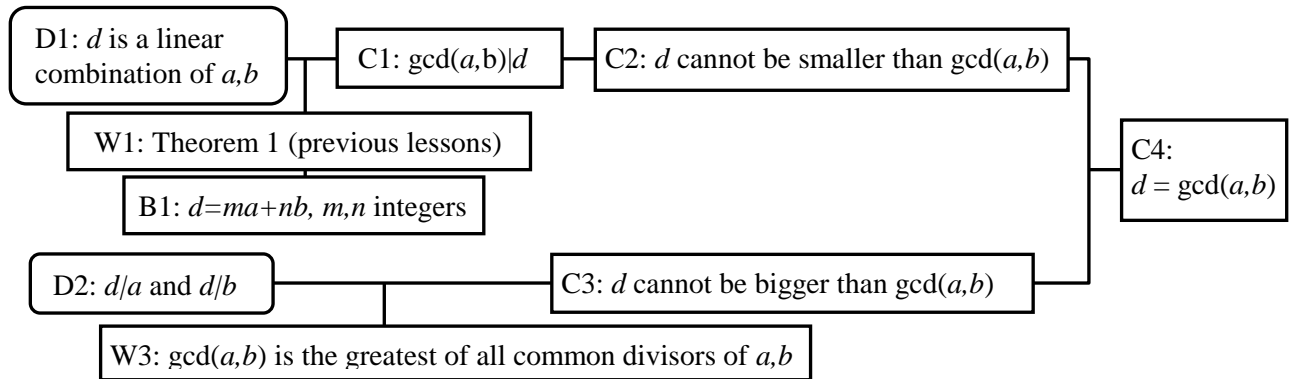

The argumentation in this excerpt is represented by the Toulmin's scheme in Figure 1. We suggest a possible interpretation of the lecturer's explicit and implicit premises reflected in this explanation. For the lecturer this argumentation requires very little justification (if any) and he presents it as a chain of facts (D1, C1, D2 and possibly C2) that does not need to be discussed, and whose connection results in the conclusion (C4) in a self-evident way. The lecturer implicit presumption is that in order to prove that  $d = \gcd(a, b)$  one needs to show two inequalities:  $(d \leq \gcd(a, b) \text{ and } d \geq \gcd(a, b)) \Rightarrow d = \gcd(a, b)$ ; he believes that this presumption does not need to be made explicit and that he and the students share this presumption. As for the values reflected in this explanation and their hierarchy, since the lecturer chose to leave some of the proof (that  $d/b$ ) to the students, in this case the pedagogical value of leaving some of the proof elements for students was placed above the value regarding proof completeness. In addition, we recognize another implicit value: for the lecturer the 'tip of Ariadne's thread' here is to realize that  $d$  is a common divisor of  $a, b$  from which the rest of the proof just unfolds.

However, the students had difficulties following this first explanation and asked the lecturer to repeat it. A possible reason for this difficulty is that the premises that the lecturer considered as facts were not considered as facts by the students and required further justification. For example, the students probably needed an explicit justification for the argument "if  $d$  is a common divisor of  $a, b$

then  $d \leq \gcd(a,b)$ ". Moreover, the lecturer's implicit presumption regarding the natural proving technique (the two inequalities) is not necessarily clear and natural to the students. In PNR language, there was a lack of agreement about the status and choice of the lecturer's premises, which caused a fallacy in establishing a shared basis of agreement. So, following the students' request, the lecturer instantly explained again the argument in Year 1 lesson as follows:

Lecturer: We said that  $d$ , as a minimal element of this set  $[\{ma + nb > 0 : m, n \in \mathbb{Z}\}]$ , is of the form  $a \cdot \text{integer} + b \cdot \text{integer}$ . Now the first thing I have shown today is that in such a situation, actually this is a result of theorem 1 that we have used before,... it follows that  $d$  must be divisible by  $\gcd(a,b)$ , yes? Once I can write a number as a linear combination of two numbers  $a, b$ , with integer multipliers  $m, n$ , this  $d$  must be divisible by  $\gcd(a,b)$ . On one hand it must be divisible by  $\gcd(a,b)$ ; on the other hand...it is a divisor of  $a, b$ . It can't be smaller than  $\gcd(a,b)$  so it can only be equal to it. Because  $\gcd(a,b)$  is the greatest common divisor, yes? And that finishes the proof...  $d$  is a common divisor of  $a, b$  that also has to be divisible by  $\gcd(a,b)$  so we conclude that  $d = \gcd(a,b)$ ...

**Figure 2: Toulmin's scheme representation of 2nd explanation**

The argumentation in this excerpt is represented by Toulmin's scheme in Figure 2. In the second explanation the lecturer added some justification (W1, B1, W3) to the conclusions C1, C2 and C3; we interpret they were not presented as facts but rather as truths, i.e. the lecturer changed the status of the premises to establish a stronger basis of agreement with the students. However, his presumption still remained implicit – a point which we will revisit shortly.

Before the lesson in Year 2 the lecturer was informed by the researcher about some student difficulties that were found in the post lesson students' questionnaires of Year 1; in particular, the questionnaires reflected that the last part of the proof, where combining the inequalities  $d \leq \gcd(a,b)$  and  $d \geq \gcd(a,b)$  leads to the equality  $d = \gcd(a,b)$  was not trivial to the students. For lack of space we will concentrate on demonstrating the change in the lecturer's presumptions and his value hierarchy between Years 1 and 2. The lecturer took the reported students' difficulty into account and during the lesson in Year 2, just before the last part of the proof he explained:

Lecturer: Here we are doing something similar to what we already had in the past, when we wanted to prove that two numbers are equal...

Student: We assume that they are unequal...

Lecturer: No, we should prove two inequalities, right? Or refute two inequalities, right? I remind you, we already used it: when we wanted to show that two numbers are equal then we need to show that it is impossible that  $a$  is smaller than  $b$  ... it is impossible that  $a$  is bigger than  $b$ , or in other words ... to show that  $a$  is not smaller than  $b$  is actually showing that  $a \geq b$ , and instead of showing that  $a$  is not bigger than  $b$  we'll show that  $a \leq b$ . If I want to show that  $a = b$ , I need to show that  $a \geq b$ , i.e. not smaller than  $b$ , and that  $a \leq b$ , meaning that  $a$  is not bigger than  $b$ . Once I will show these two inequalities I am done, I've shown that  $a = b$ .

Here, the lecturer consciously makes his presumption explicit to the students, justifies the choice of this presumption and makes it relevant. By explicating his presumption the lecturer also caused a change of value hierarchies: he enhanced the clarity of the proof structure, making it more explicit before going into the details of the proof. Indeed, the lecturer also explicitly declared:

Lecturer: It remains to prove the other inequality:  $\gcd(a,b) \geq d$ . In fact, I will show you that this... minimum of the set,  $d$ , is a divisor of  $a,b$ ... and this will end the story...

So before formally proving that  $d$  is a divisor of  $a,b$ , the lecturer spread out his proving plan, identifying “the tip of Ariadne’s thread” and explained exactly why this “will end the story”.

We conclude this short example by stressing that while Toulmin’s model enables the presentation and analysis of the argumentation structure, PNR complements it by relating to other argumentation qualities, such as the adaptability to the intended audience. The fallacies that have been mentioned in the example were related to the status and choice of premises.

## Concluding remarks

Weber and Mejia-Ramos (2014) demonstrated that mathematics students and mathematicians have different perceptions regarding students’ responsibilities when reading a mathematical proof: the students believe that reading a good proof is quite a passive process, one in which they are not expected to construct justifications, diagrams or sub-proofs by themselves, and they may simply follow each and every step. Mathematicians believe the opposite. This tension between the students’ and their teachers’ beliefs supports our interpretation regarding the different value hierarchies that the lecturer and the students have. But beyond the identification of the difference, we argue that PNR has the potential to explain the consequences of that difference on the effectiveness of argumentation; in other words, PNR provides a suitable framework to identify ways to increase argumentation effectiveness, for instance by referring to the shared basis of agreement.

Moreover, PNR relates to other rhetorical and dialectical aspects of argumentation. Some of these aspects (scope and organization and presence) have been studied in Gabel and Dreyfus (2017); others, namely argumentation techniques and the manner by which PNR complements the use of Toulmin’s scheme, need further study. One advantage of PNR is that because of its theoretical scope, all these aspects can be studied within a single unifying theoretical framework.

Although Perelman perceived PNR as a complement of formal logic and focused on disputes in which values play a part (van Eemeren et al., 2014), we argue that PNR can be adapted to be a productive theoretical framework in the context of proof teaching, particularly the flow of a proof: firstly, Perelman was much inspired by formal logic (mainly the work of Frege), and secondly, the

context of argumentation in the mathematics classroom resembles PNR's context of persuading an audience. Thus PNR is a comprehensive argumentation theory that can broaden and enrich researchers' perspectives regarding different aspects of mathematics classroom argumentation.

# **Fostering and investigating students' pathways to formal reasoning: A design research project on structural scaffolding for 9<sup>th</sup> graders**

Kerstin Hein and Susanne Prediger

TU Dortmund University, Germany

[kerstin.hein@math.tu-dortmund.de](mailto:kerstin.hein@math.tu-dortmund.de), [prediger@math.uni-dortmund.de](mailto:prediger@math.uni-dortmund.de)

*Major obstacles for students learning formal reasoning are the lack of transparency of the logical structure of formal deductions, their theoretical status, and their verbal representation. For fostering students' learning of formal reasoning, making explicit the logical structures and unpacking their verbal representations is therefore necessary. In the design research project presented, a teaching-learning arrangement of angle theorems was designed in which given if-then-statements were to be connected with formal deductions based on the design principle of structural scaffolding. A case study of a pair of 9<sup>th</sup> graders investigated students' pathways towards becoming aware of and using the logical structures and exemplifies the functioning of structural scaffolding.*

*Keywords: Formal proof, logical structure, verbal representation, structural scaffolding.*

## **Introduction**

Formal reasoning, the logical deduction of new theorems from other theorems, has been shown to be a huge challenge for many students at both secondary and tertiary level. Empirical research studies have identified different reasons for these difficulties (Harel & Sowder, 1998). The design research project presented here focuses on one major obstacle, namely understanding the logical structure of deductions and deductive theory development, which is rarely explicit in mathematics classrooms (Durand-Guerrier, Boero, Douek, Epp, & Tanguay, 2011). For this obstacle to be overcome, researchers have suggested that it is important to make the logical structures of deductions and their verbal representations explicit (Durand-Guerrier et al., 2011).

This design research study follows this general suggestion. It draws upon the design principle of structural scaffolding (following general ideas of scaffolding, cf. Lajoie, 2005). It pursues two main research questions: (1) *How can a teaching and learning arrangement be developed to make logical structures of deductive reasoning explicit?* (2) *Which typical pathways towards formal reasoning can be initiated by such a teaching-learning arrangement, and which obstacles appear along the pathways?* The first two sections present the theoretical background and the methodological framework. The design outcome (a teaching-learning arrangement based on structural scaffolding) and a case study of two students in 9<sup>th</sup> grade on their pathway is presented afterwards.

## **Theoretical background: Approaching logical structures by structural scaffolding**

Formal reasoning is crucial in mathematics, not only for *convincing one self and others of the truth* of theorems or for explaining connections, but mainly for *building* (at least locally) *deductive theories* (de Villiers, 1990). Even if, for example, students immediately are convinced of the truth of angle theorems, deducing them from each other encourages students to organize them in a logical and deductive sequence and give insights in mathematical evidence instead of empirical (cf. Fig. 1).

**Figure 1: Locally deductive theory of angle theorems**

*Missing learning opportunities for formal deductions.* In school mathematics, in contrast, most reasoning activities do not refer to formal deductive reasoning but to semantical reasoning where the epistemic value is prioritized over the validity of a statement (Duval, 1991). Formal deductions are presented mostly in a ready-made form (Harel & Sowder, 1998). This does not allow students access to awareness of how to compose an argumentation using logical structure. Although composing the deductions is only the last step of proving (Boero, 1999), it is still necessary to offer learning opportunities for this last step, e.g. by linearly ordering all elements and formulating their logical relations in written forms (Russek, 1998).

*Logical structure of formal deduction and everyday argumentations.* Everyday argumentations have often been described by the argumentative structure of data, warrant, and claim (Toulmin, 1958). While in everyday argumentation the warrant may be omitted and only made explicit when an opponent raises doubts (Rapanta, Garcia-Mila, & Gilabert, 2013), it is crucial in formal reasoning and has a theoretical rather than semantic status (Duval, 1991). That means that the existence of mathematical theorems and their statements, which are not characteristics of reality, are of relevance. Thus, the range of possible warrants must be made explicit in mathematics (Douek, 1999). Also, the status of preconditions in if-then-statements differ: in most everyday argumentations, if-then-statements are only formulated when the conditions are satisfied (Nunes, Schliemann, & Carraher, 1993, p. 130ff). In mathematics, in contrast, if-then-statements are hypothetical, so the validity of the preconditions always have to be checked before applying an if-then-statement as an argument.

*Making explicit logical structures for students.* Due to these differences, many researchers have suggested explicating the logical structures of formal reasoning in the learning process (Durand-Guerrier et al., 2011). Cho and Jonassen (2002) used Toulmin's (1958) argumentation scheme for this purpose for college students in non-mathematical contexts, and we will extend this approach for 9<sup>th</sup> graders in a geometrical context by including the check of preconditions.

*Structural scaffolding as a design principle.* Explicating alone is not enough. For students to become acquainted with the logical structure, and to produce it in their own deductions, this study draws on the design principle of scaffolding. Scaffolding is characterized as enabling learners to realize supported activities before they can conduct them independently (Wood, Bruner, & Ross, 1976). Initially only applied to one-to-one interaction for language learning, the idea of scaffolding has increasingly been elaborated into a design principle for materials and computer tools, whole-class contexts, for open geometrical proofs (Miyazaki, Fujita, & Jones, 2017), and other learning contents (e.g. Lajoie, 2005).

## Methodology of the design research study

*Design research as methodological framework.* Because the study has the dual aim of designing a teaching-learning arrangement (here: on the logical structure of formal reasoning with the design principle of scaffolding) and developing an empirically grounded local theory of students' learning

pathways, we chose the methodological framework of design research with a focus on learning processes (Gravemeijer & Cobb, 2006). The concrete model of Topic-Specific Didactical Design Research (cf. Prediger & Zwetzschler, 2013) relies on the iterative and intertwined interplay of four working areas: (a) specifying and structuring learning contents; (b) developing the design of the teaching-learning arrangement, (c) conducting and analyzing design experiments; and (d) (further) developing local theories on teaching and learning processes.

*Design experiments for data collection.* Design experiments are the methodological core of design research studies (Gravemeijer & Cobb, 2006). For this project, 3 design experiment cycles were conducted with 20 ninth and tenth graders (age 14-16 years) in total. The case study reported here stems from Cycle 3 in which design experiments in laboratory settings were conducted and videotaped with 5 pairs of students, comprising two sessions of 60 minutes each (in total about 600 minutes video material). The students were familiar with the geometrical topic of angle theorems. The empirical part of this paper focuses on the case study of two female students, Katja and Emilia, from grade 9 and the first author as design experiment leader (in the following called tutor).

*Methods for qualitative data analysis.* The transcript of the video was analyzed with respect to students' development of explicating elements of the logical structure (using the analytic scheme of data, warrant, claim, cf. Krummheuer, 1995) and to how students articulate relations between these elements (linguistic analysis, not presented here). This makes it possible to investigate the functioning of the scaffolding tool and typical pathways and obstacles.

## Design Outcome: Teaching-learning arrangement with structural scaffolding

*Mathematical topic.* Within the iterative design experiment cycles, a teaching-learning arrangement was developed for the mathematical topic of angle sets. This topic was chosen because the if-then-statements and the set of possible warrants are well limited in this field and locally organized (cf. Fig. 1).

*Structural scaffolding.* For structural scaffolding, we use *materialized argumentation structure forms* on paper as depicted in Fig. 2. In addition to Toulmin's (1958) argumentation structure, the materialized structure also makes explicit why the preconditions of the if-then-statements (named arguments) are satisfied. Every theorem that is already proven is offered as warrant for the next step of formal reasoning. Working with this materialized structural scaffold in each step allows the students to make explicit their often implicit ideas. In the following, the boxes (from above to below) are named data box, condition check box, argument box, and conclusion box.

*Learning trajectory for introducing the structural scaffold.* The intended learning trajectory starts by activating students' previous knowledge on angle sets in cases of determining angles for *concrete* constellations ("Find  $\beta$  if  $\alpha = 120^\circ$ ..."). When first asked to prove the *general* vertically opposite angle theorem, students' initial argumentative resources often include the critical feature, but are limited mostly by their semantic nature ("because

**Figure 2: Materialized argumentation structure forms as structural scaffolds**

supplementary angle”). Starting from these initial reasoning resources, the tutor introduces the structural scaffold by explaining the new practice of formal reasoning as making explicit *all* aspects *implicitly* contained in the students’ brief argumentation. The condition check box for checking if the precondition of the if-then-statement is satisfied had to be introduced after the first design experiment cycle in order to clarify the theoretical and hypothetical status of if-then-statements in mathematics. The structural scaffold serves different roles along the learning trajectory, (I) as a visualizer for the extended structure; (II) as a working tool for the students to check the completeness of their explicit reasoning; and (III) as a framework for writing down the proof. In our design experiment, after 120 minutes, the students write proofs with deductive chains of reasoning, even though they do not yet find deductive chains for more complex proofs on their own.

### Empirical insights into Katja’s and Emilia’s pathways to formal reasoning

Katja and Emilia start their learning pathway in the way described above. Figure 2 shows the product of the phase of jointly introducing the structural scaffold ending with Sequence 1.

#### Sequence 1: Reasoning determined by empiricism instead of validity of statements

When asked to prove that  $\alpha$  and  $\beta$  are equal, Emilia and Katja offer a typical initial, semantic three-word answer “vertically opposite angles” (unprinted Turn 339), assuming that classifying the type of relation between the two angles is enough. Becoming aware that they are supposed to prove the vertically opposite angle theorem by using arguments like the *argument of supplementary angles* (cf. Fig 2) and the *calculating argument* (“If there are angle measures, then it is possible to calculate with them like numbers.”), they start by naming the angles  $\gamma$  and  $\delta$  (Figure 3). Then they discuss the necessary conditions and conclusions.

**Figure 3: Marking angles as first step**

- 362 Emilia: [...] And now we could say actually that  $\alpha$  plus  $\gamma$  results in 180 degrees.
- 363 Tutor: Mmm.
- 364 Emilia: Also like here [*points to conclusion box of the last task with  $\alpha + 120^\circ = 180^\circ$* ]
- 365 Tutor: Yes.
- 366 Katja: Yes.
- 367 Emilia: And that, uh.
- 368 Katja:  $\gamma$  plus  $\beta$
- 369 Emilia: Yes, so actually this can be – Yes, precisely – But we have no concrete numbers [*points to the conclusion box previous task*] – and then we can go on – so, I don’t know, whether we can do this in such small steps, because we have no numbers at all, but then we could say,  $\alpha$  plus  $\gamma$  equals 120, umm, 180 degrees. And  $\beta$  plus  $\delta$  equals 120, umm, 180 degree
- 370 Tutor: Mmm.
- 371 Katja: And...
- 372 Emilia: And accordingly
- 373 Katja:  $\gamma$  plus  $\beta$  – plus  $\delta$  and then
- 374 Emilia: yes, okay, but actually, actually we need only one, don’t we? Then it is just unnecessary, this angle. [*points to the angle  $\delta$* ] – So I would say...

- 375 Katja: ... we have to – this with [6 sec break] yes,  $\alpha$  plus  $\gamma$  180 degree, then 180 degrees minus  $\beta$
- 376 Emilia: No, so I would easily write
- 377 Katja: [“unintelligible”]
- 378 Emilia:  $\alpha$  plus  $\gamma$  180 degree and  $\beta$  plus  $\gamma$  180 degree.
- 379 Tutor: Yes.
- 380 Emilia: And then, if, a system of equations could be created.

When asked to explain in more detail, the students offer details of steps of their calculation (“ $\alpha$  plus  $\gamma$  equals 120, umm, 180 degrees”, Turn 369), but do not explicate the warrants for these relations (here the argument of supplementary angles). In this way, they find out that they do not need the angle  $\delta$ . Interestingly, they formulate steps of action or calculation instead of general relations, and consequently, these steps are combined temporarily (“and then” in Turn 373) instead of logically.

## Sequence 2: Filling the argumentation structure form without verbalizing the connections

When filling in the materialized argumentation structure form (Fig. 2), the students discuss whether they need  $\delta$  and organize their process:

- 403 Emilia: Well then – eh, I would say – I know, I think, that here [points to the argument box], we first write that the supplementary-argument is our argument. Then we think which has to be there [hints to the condition-check box]
- 404 Katja: [writes “supplementary angle” in the argument box, 21 sec break] Yes, that here
- 405 Emilia: Ah, I wanted to write that
- 406 Katja: ... that we  $\gamma$  here
- 407 Emilia: Yes, that  $\alpha$  and  $\beta$  have the same supplementary angle.
- 408 Katja: [3 sec break] Where?
- 409 Emilia: Here [hints a finger at the condition check box]
- 410 Katja: [writes in the condition check box:  $\alpha$  and  $\beta$  have the same supplementary angle  $\gamma$ ] [...]
- 417 Emilia: Yes, okay. – Umm, then I would now write here, umm, -  $\alpha$  plus  $\gamma$  equals 120 degrees and  $\beta$  plus  $\gamma$  equal 120, umm, 180 degrees. Why do I always say 120? Yes,
- 418 Katja: [writes both equations in the conclusion box, cf. Fig .2]

The students succeed in filling in the argumentation structure form mostly without help from the tutor. In particular, they correctly identify all elements of the logical structure, first choosing the argument and then checking whether its precondition is satisfied (Turn 403). After filling in the form, they condense the proven theorem as a new argument to be used for further proofs (in non-printed Turns 452-471): “Argument of vertically opposite angles: If two lines cross each other, then the opposite angles are equal. (They are called vertically opposite angles.)”. This illustrates how the scaffold supports them to produce a complete argumentation and to understand the logical structure. However, it is remarkable that they still do not use any logical connectors to relate the different elements to each other. The language is rather deictic (“here”, “there” in Turns 403, 404, 409, 417), but the logical relation between the elements is not verbalized by the students. To give an expert model of how the connections could be expressed, the tutor finally intervenes as follows:

474 Tutor: [...] Also this condition of point of intersection was considered, so that we have two times two supplementary angles. Here as condition, and because we have supplementary angles, we could use the supplementary-argument that says that a pair of supplementary angles add up to 180 degrees. Therefore, it can be used for our supplementary angles and umm, here two times two were regarded, this means we have two times this equation with, umm, our angles. [...]

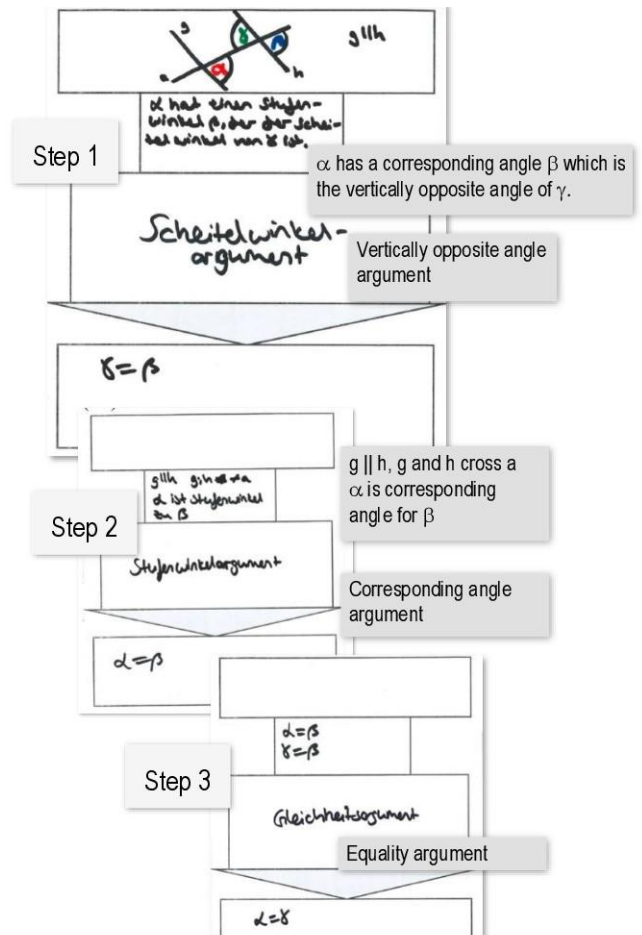

### Sequence 3: Mastering formal reasoning

**Figure 4: Alternate interior angle theorem**

After determining a specific alternate interior angle, the next task for Emilia and Katja is to prove the general alternate interior angle theorem (Fig. 4). For constructing their formal argumentation structure, the students are given the equality argument (If  $\delta = \mu$  and  $\mu = \pi$ , then  $\delta = \pi$ . (transitivity)) and the corresponding angle argument (which can only be derived from the parallel axiom and is hence left unproved for the students, cf. Fig. 1). Again, the students successfully construct a complete argumentation structure supported by the structural scaffold of the form. Based on an enriched sketch, they deduce the theorem in three steps (cf. Fig. 5): In Step 1, they use the vertically opposite angle for deriving that  $\gamma = \beta$ . In Step 2, they use the corresponding angle argument for deriving  $\alpha = \beta$ . For deriving that  $\alpha = \gamma$ , they use the equality argument and produce the last chain of reasoning in Step 3.

The written text produced by Katja for this last step shows what she has learned (cf. Fig 6). Katja's text provides at least situational evidence that she has grasped the logical structure of formal reasoning and can express some of the logical connections. In contrast to the beginning of the students' learning pathway, she makes explicit the warrant ("the equality argument says that") and the conditions of its application ("Now, we know that  $\gamma$  and  $\beta$  have the same measure and  $\alpha$  and  $\beta$ "). For expressing the logical connections, she adopts elements of a language offered by the tutor in Turn 747 ("the supplementary-argument that says"). She also expresses the deduction from the argument to the conclusion: "from this we can conclude". However, the order of aspects is still the order of discovery, not yet the strict order of formal reasoning as the conditions are again guaranteed after using the argument.

**Figure 5: Katja's and Emilia's three steps of formal proof for the alternate angle theorem**

Jetzt wissen wir, dass  $\gamma$  und  $\beta$  gleich groß sind und  $\alpha$  und  $\beta$ .  
 Das Gleichheitsargument besagt, dass wenn ein 1. Winkel genauso groß ist wie ein 2. und dieser genauso groß ist wie ein 3., dass der 1. und der 3. gleich groß sind. In dem Fall ist der 1.  $\gamma$ , der 2.  $\beta$  und der 3.  $\alpha$ .  
 Daraus können wir dann folgern, dass  $\gamma$  genauso groß ist wie  $\alpha$ .

"Now we know, that  $\gamma$  and  $\beta$  have the same measure and  $\alpha$  and  $\beta$ . The equality-argument says, that if the first angle has the same measure as a second and this has the same measure as a third, that the first and the third have the same measure. Here the first is  $\gamma$ , the second  $\beta$  and the third  $\alpha$ . From this we can conclude that  $\gamma$  has the same measure as  $\alpha$ ."

Figure 6: Katja's verbalization of the third step of reasoning

### Looking back to Sequence 1 – Sequence 3

In total, these three sequences from the students' learning process provide insights into the students' pathway from their everyday argumentative resources towards formal reasoning, their induction into mathematical proof as a cultural practice. The structural scaffold strongly supports comprehending of the logical structure, the designated Function (I). The students also capture the norm that the practice of formal reasoning is characterized by making explicit every element in the logical structure (every box must be filled, Function II). However, the scaffold alone does not sufficiently support the process of talking about the logical structures, as visible in Sequence 2. Hence, the structural scaffold had to be complemented by language scaffolds (in this case oral expert modelling offered by the tutor). The written product from Sequence 3, finally, shows that the students can adopt the language scaffolds for communicating about the formal deductions.

### Discussion and outlook

The case study of Katja and Emilia gives a first indication for the potential efficacy of the structural scaffolding. Other pairs of the 10 students in Design Experiment Cycle 3 also succeeded in mastering formal reasoning, supported by the scaffold. Filling the boxes serves as prompts for identifying every single aspect of the logical structure (data, warrant, and conclusion) and the satisfaction of preconditions of argumentations. The specific strength of the materialized structure form is that it not only makes the logical structure visible, but also permits students to complete the form in non-linear order. Based on this structural scaffold, the students' written texts are mostly produced in linear, deductive order. As with any provided format, it can be done non-generatively, passively, locally filling each box but not attending to what role the boxes play in formatting the reasoning. However, not only Katja and Emilia but also other students we observed benefited from the scaffolding as they learnt to distinguish between preconditions, if-then-statements and conclusions. The scaffold supported the students to express the relations between the elements of the logical structure verbally and to reflect amongst other things about the generality of the statements or which characteristics of the sketches are important. These features are crucial to increase awareness of formal reasoning.

Of course, the study still has methodological limitations which have to be overcome in later cycles or future research. Limitations concern the sample size (2 students presented, 10 in total) which is not yet representative. So far, the teaching-learning arrangement is focused on one specific topic, the angle theorems, which need to be extended to other topics in future research in order to gain evidence of the overall claim of efficacy. The most important limitation in view for the next cycle of the presented project concerns the language: we intend to identify the phrases and syntactic structures which appear to be necessary for students to realize the need to articulate the logical connections

between the elements in the argumentation. This will provide support for the students on the linguistic level as well as on the logical-structural level.

*The issue of students' misconceptions in mathematics and how to prevent and deal with them in teaching has been a major concern of mathematics educators since at least four decades. At the same time our knowledge about the processes of developing understanding and skills in proof and argumentation from early school years has increased. We argue, that there are connections between these two areas of studies important to make explicit for teachers. In this paper, we first elaborate the relation between the research on students' misconceptions and the ideas of developmental proof. Then we present the relevant results of an empirical study about how mathematics teachers in the field interpret this relation. Our conclusion is that there are important connections between these two research fields that are not always visible for teachers.*

**Keywords:** *Misconceptions, developmental proof, teacher education, MKT.*

## Background

Teachers' knowledge about students' misconceptions in mathematics and how to deal with them has been pointed out as an important part of teachers' mathematical knowledge for teaching (MKT) (e.g., Hill, Rowan & Ball, 2005). Knowledge about them has also been raised as an important part of educative curriculum materials and many of these provide information about common student misconceptions and suggestions on how to address them (Cengiz, Kline & Grant, 2011). At the same time a growing number of research articles have raised the importance of enhancing students' skills and understanding of proof and proving and research has shown that it is possible and beneficial to start to develop students' proof-related competences during early school grades (e.g. Hanna & De Villiers, 2009; Hemmi, Lepik & Viholainen, 2013). This knowledge can also be considered a part of MKT, and in line with knowledge of students' misconceptions close to what Shulman calls pedagogical content knowledge. Research shows that teachers who have strong knowledge in different areas of MKT are more able to create opportunities for extending student thinking (e.g. Hill et al. 2008). This is especially important to consider in teacher education and teacher professional development. Yet, the relationship between specific aspects of MKT still remains unclear (cf. Cengiz et al., 2011). This study contributes to the field by investigating the relation between two particular research areas, namely the knowledge about students' misconceptions on the one hand and the development of understanding of and skills connected to proof and proving. More specifically, we do not consider students' misconceptions in a deficit (cf. Jaworski, 2001) manner but investigate how we could use them to enhance students' understanding of proof and vice versa. The following questions are in the focus of this study:

- 1) What kind of connections can be found between the research field concerning students' misconceptions and the development of students' knowledge and skills with respect of proof?
- 2) How do teachers relate to students' misconceptions, proof and the relation between them?

First, we offer an analysis about the connections related to the first research question. Then, we briefly describe the methodology of the empirical study focusing on upper secondary school teachers' conceptions about these areas. Finally, we report the results of the empirical study and discuss them in the light of the connections found in the theoretical section.

## **Misconceptions in mathematics related to developmental proof**

Hanna and de Villiers (2008) introduced the idea of *developmental proof* as something that should grow in sophistication in action, perception and language as the learner matures towards more coherent conceptions. We have earlier concretized the idea of developmental proof by identifying in research literature and school curricula proof-related competences that could be developed through the school grades from 1 to 12 (Hemmi et al., 2013). These competences address besides the development of argumentation and proving, the meta-level knowledge about proof, such as the character of mathematical definitions, methods of proofs, logical and formal aspects that often remain invisible for students (cf. Hemmi, 2008) as well as investigations with validation of either students' own or others' reasoning and results. For a comprehensive description see Hemmi et al. (2013).

Research on misconceptions and how to prevent and deal with them has roots in cognitive research and constructivism. For example, some researchers claim that students find it difficult to give up their misconceptions as they have actively constructed them (e.g. Egodawatte, 2011). Further, research on misconceptions is often concentrated within a certain topic in mathematics or science. One of the earlier ideas about reasons for misconceptions is that of Fischbein (1994). He defines three basic components in mathematical practice: the formal, the algorithmic and the intuitive. According to Fischbein, the intuitive knowledge is often experienced as self-evident and may not be problematized or deeply justified in school mathematics and therefore may conflict with the mathematical, logically proved "truths". Scholars agree that the main function of proof in school is to offer explanations (e.g. Hanna & de Villiers, 2009). Yet, the explanations offered in early school years for operations of natural numbers do not always explain properties of operations when operating in other domains. For example, the concept of multiplication is often explained as repeated addition, in order to reveal connections between arithmetic operations. Yet, this explanation leads to an intuitive conception that multiplication always results to a bigger number than the one you multiply (cf. Fischbein, 1994). When students start to operate with rational numbers this intuitive belief could be made visible and be challenged by investigations, explanations and justifications developed by the classroom community. The transition from the domain of integers to the domain of rational numbers could offer a fruitful platform for developmental proof concerning some logical aspects of reasoning connected to universal statements' truth-values in different domains (see e.g. Durand-Guerrier, 2003). Hence, we argue that besides prevention of future misconceptions in mathematics, this kind of testing and challenging of intuitive rules could also develop students' understanding of proof in mathematics and the other way around.

Another example about misconceptions that can be connected to intuitive rules is "over generalizing", often involving improper use of analogical reasoning, for example in connection to ratio between area of a figure and volume of a figure (see, for example, Tirosh & Stavy, 1999;

Chick & Baker, 2005). These kinds of misconceptions also offer excellent possibilities for students' investigations and proofs where students could for example develop their understanding of differences between analogical and deductive reasoning. Indeed, new approaches to proof using students' investigations have been developed and tested in order to enhance students' skills and appreciation of proof as an important part of doing mathematics (e.g. Heinze & Reiss, 2004). These studies often advocate investigative approaches covering the whole process of proving, starting from the first experiments to generate an idea for a hypothesis up to the final step of writing down the complete proof. We think, that beside this, it is also beneficial to conduct continuously smaller investigations about truth-values of various statements, for example connected to algebraic laws. Scholars agree that several identified student misconceptions are due to students' difficulties in algebra. The idea of developmental proof has parallels with ideas about children's development from an understanding of arithmetic to algebra (cf. Hemmi et al., 2013). For example, the generality of reasoning is an important component in investigations and proving where the move from concrete and specific to general is needed when justifying the conjectures made on the basis of the observations of regularities.

Application of rules to situation where the rule is not valid is still another type of misconceptions found in the literature (e.g. Fischbein, 1994; Egodawatte, 2011). As an example consider the following typical misconception in simplifications of expressions (Egodawatte, 2011):

$$(1) (2 + x)/x = 2$$

$$(2) (12 \cdot 2x)/2 = 6x$$

The rule applied in the first example is valid for rational expressions with only multiplication in the numerator, but not with addition, while the rule applied in the second example is valid for rational expressions with addition in the numerator. Typical misconceptions also concern the use of the distributive law in situations where it is not valid (e.g. Fischbein, 1994). These kinds of misconception could be regularly used as an object for investigations in order to enhance students' understanding of treatment of algebraic expressions and derivation of rules. Explanation in mathematics often refers to making mathematical connections explicit. Kuchemann and Hoyles (2009) emphasize the importance of the mathematics instruction to move from a computational view of mathematics to a view that conceives mathematics as a field of intricately related structures in order to develop students' proving competences. Seeing connections and mathematical structures is also an important proof-related competence connected to developmental proof (Hemmi et al., 2013). Still another kind of misconception identified in the literature is connected to mathematical definitions. For example, several researchers present similar ideas about students who often operate as if all functions were linear (Tirosh & Stavy 1999). This is connected to development of understanding the role and character of definition in mathematics, also identified as an important aspect of developmental proof (Hemmi et al., 2013).

Scholars have also attempted to explain why some misconceptions are developed and how to deal with them to change them (e.g. Tirosh & Stavy, 1999). There are significant connections between the suggestions offered to deal with students' misconceptions and the developmental proof, for example, the understanding of counter example, critical thinking, and argumentation with peers. Several studies show that erroneous conceptions are so stable because they might be correct in some instances. Scholars state that teachers should encourage students to critically evaluate their solutions and develop a skeptical approach to their intuitive rules. Balacheff (2010) points out that proving is

the most visible part of validation and something that cannot be separated from the ongoing controlling activity involved in solving problems or achieving tasks. Scholars also advocate the use of common misunderstandings for planning of effective sequences of instruction by both using situations where the intuitive rule is valid and where it is not valid in order to create *cognitive conflict*. Creating cognitive conflict by using a counter example is not always fruitful if students do not understand the role and the logic of counter example in mathematics. Here the development of students' understanding of the role of counter example in mathematics is important and connected to developmental proof. Interestingly, the idea of creating cognitive conflict has also been used to change students' misconception concerning the use of specific examples in validation of mathematical statements and the promotion of students' feeling for the need of proof (Stylianides & Stylianides, 2009).

## The empirical study

In Finland, proof was an important part of upper secondary school mathematics in the 1970s during a period of 'New Math' reforms but since then its importance has decreased significantly. Yet, the Finnish steering document for the compulsory school curriculum (2004) addresses a number of proof-related topics (Hemmi et al., 2013) and although the word proof is not mentioned in upper secondary curriculum, in textbooks for the advanced course, proof and deductive reasoning is an important part of the contents (Bergwall & Hemmi, 2017). There are two programs in upper secondary school mathematics in Finland. The *basic course* is for students who study humanities and social sciences while the *advanced course* is for those students who want to study mathematics, science and computer sciences at the university.

The empirical study was conducted with Swedish speaking<sup>1</sup> upper secondary school (about the age of 16-19) mathematics teachers in Finland (Julin, 2016). The aim of the entire study was to investigate teachers' knowledge, experiences and views of students' misconceptions and the role of proof in mathematics and in teaching. A questionnaire comprised mostly closed statements and questions that were developed from items in literature. For example were teachers asked to judge how often they had experienced seven common misconceptions and how they usually reacted to them when encountered them in their teaching (see Figure 1). Concerning their reactions teachers could choose from five methods applied from Chick and Baker's (2005) study: counter example, re-explain the procedure, re-explain the concept, cognitive conflict, and probe student thinking. These methods were shortly described in the questionnaire. The items in the questionnaire also addressed proof in mathematics and in teaching and finally the relation between misconceptions and proof. As a complement to the quantitative part we also posed an open question: "Explain shortly why you use/do not use proof in your teaching", and finally there was a possibility for the teachers to freely write their own thoughts about these issues.

The electronic questionnaire was sent to all mathematics teachers working in the Swedish speaking upper secondary schools in Finland, in all 90, and of them 36 teachers responded to the questionnaire. Both the gender and age distribution were representative for the whole group and the responding teachers' teaching experience varied from 1 to 40 years. All teachers responding to the

---

<sup>1</sup> About 5 % of the Finnish population has Swedish as a mother tongue.

questionnaire were certificated mathematics teachers. The responses to the quantitative part of the study were analyzed using descriptive statistics and the open questions were analyzed inductively.

### Teachers' relation to misconceptions and proof

Most teachers (97 %) state they recognize the common misconceptions in their own teaching and all of them consider the knowledge about misconceptions relevant for their work. Almost 70 % of the teachers state that they know how to deal with these misconceptions.

**Figure 1: Methods used by teachers when encountering misconceptions**

Further, over one half of the teachers who state that they do not know how to deal with students' misconceptions had less than 10 years of teaching experience and 36 % of them wanted to learn more. The methods teachers would choose to deal with students' misconceptions varied depending on the character of them. The use of a counter example and cognitive conflict are related and were dominating among the methods that the teachers preferred (Figure 1). The least popular method was the probing students thinking. Yet, it seems to be usual for the teachers to use the analysis of the steps in the reasoning when sorting out the situation and then utilize the other methods. Some teachers suggested that a teacher should focus on common misconceptions already when presenting the theory of a new topic and explain why that is not true in order to create a cognitive conflict from the beginning.

One can let students work pairwise and judge the correctness of different solutions and ask them to justify their judgments. Surprisingly, students are insecure and experience these tasks as

difficult. I have tested this with both students taking the advanced course and students studying the basic course in mathematics. This is really instructive for both a teacher and students. (All of my examples were authentic student solutions.)

Most of the teachers stated that they used their knowledge about the common misconceptions when they designed their teaching and chose tasks. Yet, peer instructions (students discuss and argue about the correctness of different solutions) was utilized (sometimes /more often) only by 25 % of the teachers (Figure 2).

**Figure 2: Teachers' use of misconceptions**

Mathematics is a cumulative subject. Elementary school has a great responsibility. Unfortunately the textbooks I have seen are quite bad. Students cannot see the structure because of all details. Mathematics is not only using of Pythagorean theorem or calculation of percent that students do without understanding. It is a logical structure.

All the teachers consider proof as more or less important for mathematics as science and they present (sometimes or more often) proofs for students studying the advanced program in mathematics. They also agree that proof somehow contributes to the teaching of mathematics. Yet, only 2 teachers present proofs for students studying the basic program, one of them states that “proof gives often a greater broadness than ‘learning by heart’” and if students learn to prove the formulas then they also can modify them so that they can solve a broader spectrum of tasks. Another view of the role of proof in school mathematics is shown by a teacher who states: “Proofs are good and beautiful but in the upper secondary school reality teaching is far away from building teaching around proving”. About 30% of the teachers seldom let their students work with proof and proving by themselves. Concerning the teachers' views of the connections between students'

misconceptions and proof, most of them are not convinced that proof and proving would have a positive effect on students' misconceptions. Only 9 teachers agree with the statement "Proof and proving can help to change students' misconceptions" and 8 teachers agree with the statement "If students learned proving, their incorrect steps of reasoning would diminish."

## Concluding remarks

The paper focuses on the relation between research on students' misconceptions and developmental proof. The elaboration of the research literature on students' misconception from the perspective of proof reveals several important connections between the ideas and results of the two research fields. However, the empirical study shows that these connections are not clear for teachers. For example, we find it significant that the teachers in our study most often use counter examples or cognitive conflict that are closely related to developmental proof as a method for changing students' misconceptions but at the same time only about 25 % of them consider proof and proving as beneficial to prevent and change students' misconceptions. We also recognize different views of proof in school mathematics among the teachers that may have crucial consequences for students' possibilities to develop their understanding and skills in proof and proving and therefore also using students' misconceptions as a starting point for this and vice versa. The idea of developmental proof is probably not in focus in mathematics teacher education. Furthermore, it is possible that teacher educators focus on both students' misconception and proof but because of the different research traditions the connections and the possibilities of these connections between these areas may not become clear for student teachers. More studies are needed to investigate teachers' views of proof in relation to their views of these connections in the teaching of mathematics.

*There is a significant corpus of studies indicating that children even from the age of primary school are capable of providing convenient arguments and that the cultivation of this ability fosters learning significantly. Based on these assumptions, the present paper examines the forms of the arguments that students of primary and middle school use to support their answers. In particular, this study was divided in seven independent activities, where students of a fifth and an eighth grade class had to complete mathematical tasks and support with arguments how they concluded to their answers. We used the simplified Toulmin's argumentation scheme and subsequently, enriched our findings with the argumentation scheme perspective, in order to gain a better understanding of student's reasoning characteristics.*

*Keywords: Toulmin, argumentation, scheme.*

## Introduction

Basic aim of the new teaching methods, starting from the new curriculum in mathematics, which was published by the National Council of Teachers of Mathematics in 1989, is to reinforce reflective thinking and shift from 'learn mathematics' to 'do mathematics'. According to Dewey (1903), children learn effectively through inquiry-based processes, which require from students not only to solve mathematical activities, but also to express their thinking, state their opinion and finally, compare their statements with their classmates'. Thereupon, it can be stated that reasoning organises students' ideas, builds strong conceptual connections and fosters mathematical thinking (Dewey, 1903). Following these assumptions, the cultivation of proper language skills plays a significant role in this thinking process, as it allows students to express accurately their thoughts by forming arguments. Halliday (1993) uses the phrase 'interpersonal gateway' to refer to the power of language as interactive tool in the communication between students and teachers. Regarding our study, we adopted Toulmin's argumentation model in order to explore the reasoning ability of primary and secondary students. Toulmin's model was first used by Krummheuer (1995) in the field of teaching mathematics. According to the latter, claims, data and warrants are not predetermined, but are constructed through the process of classroom discourse and interaction. Toulmin's model can describe the structure of an argument by specifying its components, but it cannot characterize the quality of the particular argument. Therefore, at a second analytical level, we enhanced our analysis by using argumentation scheme theory, used as in Metaxas, Potari, & Zachariades, (2009).

## Theoretical background

According to Schwarz et al. (2003) constructing knowledge is the process of composing evidence in such a way, that the selected claim is supported by provided evidence and further supported related to other co-existing beliefs. Moreover, a plethora of studies have established that argumentation

plays a crucial role in the development of knowledge and scientific reasoning. The same holds in the field of education, either as a means to learn (argue to learn) or as a goal of instruction (learn to argue). Schwarz (2009) describes “learning to argue” as the acquisition of general skills such as justifying, challenging, counterchallenging, or conceding, whereas “arguing to learn” refers to the fulfillment of a certain goal through argumentation in a specific educational framework. In other words, the first path uses argumentation as a goal, while the second one as a tool that contributes to the learning process. In order to analyse students’ argumentation we employed the classical Toulmin’s model and subsequently, the recently developed, argumentation scheme approach.

### **Toulmin’s theory**

Argument structure has been used several times as a tool of analysing public discourse regarding mathematics and their teaching. A significant number of these analysis have been conducted by using Toulmin’s theory. Toulmin (1958) has claimed that the traditional formal logical analysis of arguments is not rich enough to include parts of common arguments such as qualified conclusions, response to other arguments and inferences. He proposed a model for the layout of arguments that consists of six basic parts, each of which plays a different role in an argument (Metaxas, Potari and Zachariades, 2016). The first one to apply Toulmin’s model in mathematics education was Krummheuer (1995). Since then, some researchers have focused on the analysis of mathematical arguments of students, including usage of proof in general (Yackel 2002), number skills (Evens & Houssart 2004), geometry (Pedemonte, 2007) and algebra (Pedemonte 2008). By studying the argument components a student is using when talking about a solution in mathematics, we could have some indication about his/her understanding and generally, his/her perception about mathematics.

### **Argumentation schemes**

Toulmin’s model describes the structure of an argument giving its components, but it does not reveal much about the quality of the particular argument. However, the content of the Warrant and the Backing in an argument should be considered in the evaluation process of an argument. For this reason, we combined Toulmin’s model with the tool of argumentation schemes to analyse the quality of the Warrant and the Backing. For example, a Warrant that is based on the authority of a source (teacher has said so...) is fundamentally different to a Warrant that is based on a mathematical relation or to an intuitive remark. Standard accounts of argumentation schemes describe them as the representation of different types of plausible arguments that, when successfully deployed, create presumptions in favor of their conclusions (Metaxas, Potari and Zachariades, 2016). Argumentation schemes have been assigned a role in the analytical reconstruction of an argument, as well as its evaluation. In reconstruction, these schemes can be used to identify and categorise certain patterns of reasoning, contributing to the identification of implicit claims of the arguer. Moreover, a set of critical questions are associated with each argumentation scheme to be used in the evaluation of arguments and their correspondence with each category (Walton, Reed & Macagno 2008). Another significant aspect of argumentation schemes is that the evaluation of the argument is directly associated to the dialogue as a whole, rather than evaluating it independently and isolated from the context that is being constructed. Consequently, every argument will be evaluated via the critical questions, in the context of the dialogue of which it is a part of. Thus, critical questions are a kind of evaluative points, providing a list of individually necessary

conditions for the success of particular schematic arguments. For instance, an argument can be characterized as weak if it fails to answer appropriate critical questions that have been or might be asked in a dialogue (Walton, 2006). In addition, an argumentation scheme could inform us about the quality of a warrant or a backing as a form of an argument (Metaxas, Potari and Zachariades, 2016).

### **The structure of the course**

The theoretical underpinnings for looking at the classroom discourse was the theory of symbolic interactionism. Individuals are seen to develop personal meanings as they participate in the ongoing negotiation of classroom norms (Cobb, 1999). The centrality given to the process of interpretation in interaction is one of its main principles (Blumer 1969). While individuals are interacting with each other, they have to interpret what the other one is doing or is about to do. Each person's actions are formed, in part, as he/she changes, abandons, retains, or revises his/her plans based on the others actions (Cobb, 1999). Moreover, the group discussions can provide participants with learning opportunities by turning their implicit supporting arguments into explicit. In addition, the objects of debate can result in a change of their status and engage them at a higher level of mathematical reasoning. The very act of argumentation could produce learning on the part of the arguer (Jermann and Dillenbourg, 2003). In our study, the materials used to trigger the discussion were tasks, which were based on topics that research and experience have highlighted as important.

### **Data analysis**

In order to study the ability of elementary students to reason in mathematics, we implemented a series of activities, where the students of a fifth and an eighth grade classroom in Greece were asked to solve mathematical exercises and in addition, to provide with written arguments why they believe their answers were correct. Having analyzed all the written answers following the methodology of previous studies (McNeill, 2011), we drew the conclusion that students of that age have the ability to form arguments in order to support their solutions. More specifically, 66% of the students who provided some kind of argumentation, used to some extent the simplified Toulmin's argumentation scheme, which is consisted of three parts; claim, data and warrant. Although not all answers had all three essential parts, they could be adjusted to Toulmin's pattern arguments. Toulmin's model allows students to reason in a completed way, which presents the hypothesis, the explanation and the solving process. Subsequently, the arguments that followed Toulmin's model were analyzed according to their structure following the analysis of other relevant studies (Evagorou and Osborne, 2013) that have taken place in the past and adopted the modified version of Toulmin's Argumentation Pattern (Erduran et al., 2004). Out of the 66% that is mentioned above, nearly half of the students (Table 1) included all three essential parts, that is they were able to state their opinion (claim), provide all the necessary support (data) and finally, connect them in a sufficient way (warrant). This completed structure is followed by the students who managed to include the claim and the data to their answers, but weren't able to provide effective warrant (33.4%). Finally, a little less than 20% wrote only their opinion, without justifying or explaining how the concluded to this claim. There is a similar pattern in secondary school students, where there is only a slight differentiation around 2-3% in the first two columns.

Reasoning forms of Toulmin's Model			
	Claim – Data - Warrant	Claim – Data	Claim
Primary school	47.6%	33.4%	19%
Secondary school	45.2%	36.2%	18.6%

**Table 1: Reasoning structure of Toulmin's Model**

The following table presents an example of each category, taken from an activity that students had to form the biggest decimal number by throwing a dice and placing the digit in a suitable place.

Claim only	<i>I have to place the numbers with greater value in tenths etc.</i>
Claim-Data	<i>If I get 6, I'll place it in tenths because 6 is the biggest number I can get. If I get 1, I'll place it in thousands because is the smallest number I can get.</i>
Claim-Data-Warrant	<i>In order to win the game I have to make the biggest number. I need to place the bigger numbers in the integer part and the smaller ones in the decimal part. So, the best thing I can do is to place the numbers from the biggest to the smallest.</i>

**Table 2: Excerpts from each category**

Having completed the primary data analysis, we studied the produced arguments using the argumentation scheme theory, which helped us gain insight regarding the quality of the argumentation used.

## Discussion

Having analyzed the data and in correlation with previous related studies, it can be clearly said that elementary students can form arguments in order to justify their mathematical thinking and that the most common way to state their reasoning is by using Toulmin's Argumentation Pattern (TAP). However, students of that age do not recognize the significant role of proof and therefore, they don't understand that justification of their thinking is essential. Even though they solved the exercises correctly and they presented the important data, they don't define clearly the connection between data and claim, which according to TAP is known as warrant. This deficiency must not be understood as lack of students' ability, as in many of their answers and especially when is asked by the teacher they expand their reasoning and include the semantic warrant. The obvious implication that follows the existence of a correct claim and a written data could be the reason the students don't regard as necessary to include a warrant in their answers. Consequently, this identification and evaluation of the missing premises or conclusions could be greatly enhanced by the employment of

the argumentation scheme theory (Walton, Reed & Macagno, 2008), where most of the arguments are considered forms of plausible reasoning that do not fit into the traditional deductive and inductive argument forms. In this case, a further analysis is needed in order to evaluate the content of the argument accurately. For example, the absence of the warrant or backing is due to people's belief that these are automatically entailed from the data given and there is no need for further justification. This deficient form of argumentation can be enriched and expanded in order for an argument to acquire the desirable structure. Likewise, short answers that were given by the students and were characterized by lack of structure, were in fact complete, if the essential parts that were considered obvious and were implied, are included so as to form a complete argument. Below there are given two examples of arguments that were at first deficient, but after expanding them, they transformed in complete arguments according to TAP. The first example is taken from an activity, where students had to form the biggest possible decimal number, using the digits that were given after rolling a dice six times.

*Student: I will win by putting the number to the correct places. For example, if I get number 1 I will place it in the thousandths.*

The above argument is considered short and deficient. However, it is clear that the student has understood the procedure in order to form the biggest number, but still prefers not to include all the essential information to his answer, as he believes that it is obvious. He argues by employing an argumentation scheme of illustration, which nevertheless remains without support. Nonetheless, after the teacher's claim, the student added the hidden parts in order to transform his deficient answer to a complete argument. We give a reconstruction of the argument:

*Student: I will win by putting the number to the correct places [claim]. I have to place the small numbers in the decimals' places (tenths, hundredths, thousandths) and the bigger ones in the integer part of the number (tens, hundreds, thousands), because decimals have smaller value than integers [warrant]. For example, if I get number 1 I will place it in the thousandths [claim], because number 1 is the smallest I can get and thousandths have the lower possible value compared to the other places [warrant].*

In analyzing student's elaboration of his argument, we can either consider the second argument as a continuation of the first one, in the sense of using the previous claim as the data of the second argument, or we could interpret the whole second syllogism as a backing of the first one. In any case, the scheme employed in the second argument is, again, a scheme from illustration but now connected to the previous scheme from established rule (I have to place ...integers). As a result, regarding the quality of the schemes employed, the student actually elaborates his reasoning by using an established rule, which again is supported by a scheme from illustration.

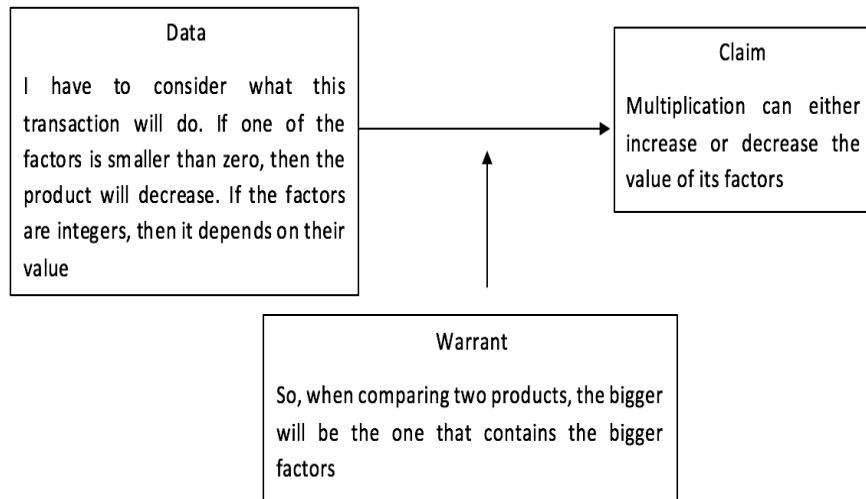

The second example is taken from an activity, where students were asked to estimate the product of a decimals' multiplication without making the transaction, by simply observing the factors.

*Student: I have to consider what the multiplication does; if it makes the number bigger or smaller.*

The above claim contains the perception that multiplication can either grow or reduce the value of its factors. Even though he misses many essential parts, if the claim is expanded, we can take an efficient answer. A reconstruction of the above statement could be the following:

*Student: Multiplication can either increase or decrease the value of its factors [claim], so I have to consider what this transaction will do. If one of the factors is smaller than zero, then the product will decrease. If the factors are integers, then it depends on their value [data]. So, when comparing two products, the bigger will be the one that contains the bigger factors [warrant].*

**Table 3 - Analysis of student's extended argument**

Again, taking into consideration the schemes employed, we could note the presence of a scheme from (positive) consequences (Walton, Reed & Macagno, 2008). The (implied) fact that in order to answer the posed question, we should consider the effect of the multiplication on the magnitude of the numbers, is a scheme from consequences. The explanation that follows is the elaboration of the scheme; the consequences in each case. The student explains in a more abstract (mathematical) way his reasoning, which is in a clear contrast to the previous excerpt (where the invocation of an illustration was employed).

Our thesis is that elementary students are capable of forming arguments and reasoning in mathematics, but one of the main characteristics of that age is the short way they express their arguments and therefore the absence of basic parts. The deficient character that defines most of the arguments can lead to the conclusion that all students reason according to TAP, but the structure is incomplete, as some parts are considered obvious and children believe are excessive. Additionally, another interesting point is the insignificant difference between the two grades, especially if considered that students from the seventh grade start using and structuring their first proofs. Nevertheless, by taking into account the types of the syllogisms employed, in the sense of argumentation schemes, we could shed a bit more light into the quality of arguments used. In the primary school case, students used mainly schemes from illustration and from consequences, which probably is due to the students' inadequate exposure to mathematical thinking or argumentation structuring in general. On the other hand, the eighth grade students employed more schemes from rules to cases, which accounts to their better understanding of the structure and function of a proof. As a result, although the Toulmin model is indicative of the structure of the arguments students use, it is not enough to discern the difference of the quality of their arguments. This could be easily overruled by using argumentation schemes. Finally, it should be noted that justification and correctness should be distinguished in the analysis of an argument. For example, a premise that is

based on an authoritative opinion or is justified by intuition or a meme could be turn out to be false. Consequently, representational tools as the argumentation schemes that could exhibit the implicit structures of arguments can enhance the reconstruction and comprehension of the syllogism. In further studies it would be interesting to examine ways that will cultivate the argumentative way of thinking and grow the ability to express completed arguments that contain all essential parts.

*Although the mathematical activity of proofs and refutations is widely recognised as significant in school mathematics, much remains under-explored about ways of facilitating such activity in the classroom. In this paper, we address this issue by focusing on task design in dynamic geometry environments. In particular, we formulate three principles for the task design and use these to develop classroom tasks. We analyse a task-based interview with a triad of upper secondary school students to show how the designed tasks stimulated their activity of proofs and refutations.*

*Keywords: Proof, refutation, counterexample, task design, dynamic geometry environment.*

## Introduction

The mathematical activity of proofs and refutations described by Lakatos (1976) is significant in school mathematics because it enables students to experience authentic mathematical practice (Lampert, 1992). Although several researchers have described student behaviour with Lakatos' terminology (Komatsu, 2016; Larsen & Zandieh, 2008), few studies have examined ways of purposefully introducing such activity into classrooms (Komatsu, Tsujiyama, Sakamaki, & Koike, 2014; Komatsu, 2017; Larsen & Zandieh, 2008). Given the importance of mathematical tasks for student learning (Kieran, Doorman, & Ohtani, 2015), this study aims at developing task design principles and actual tasks for realising proofs and refutations.

To achieve this purpose, we specifically focus on dynamic geometry environments (DGEs). Research has shown the capability of dynamic geometry software (DGS) for enhancing proof-related activities such as making conjectures and subsequently constructing proofs. In particular, some studies have shown how using DGS enabled students to discover the refutations of their conjectures and proofs and cope with these refutations (Healy & Hoyles, 2001; Olivero & Robutti, 2007). The successful use of DGS in previous research was accompanied by carefully-designed tasks (Hanna, 2000). Nevertheless, how the tasks were designed was often not clarified explicitly, and task design in DGEs remains understudied (Sinclair et al., 2016).

To address these issues, the study reported in this paper focuses on the following research question: What principles can underpin the design of DGE tasks that facilitate student activity of proofs and refutations?

## The meaning of proofs and refutations

Based on Lakatos (1976), we conceptualise the meaning of proofs and refutations as depicted in Figure 1. Students make conjectures (or are provided with statements), and then attempt to prove them. In this, they are confronted with refutations of the conjectures/statements or proofs, and refine them by addressing the refutations (Komatsu, 2016).

**Figure 1: The conceptualisation of proofs and refutations**

As there is insufficient space to explain Figure 1 fully, here we clarify only two points. First, we take the meaning of proof in a broad sense such that a deductive proof may be valid only for a subset of all cases considered in a conjecture and statement. Second, although the word *refutation* is sometimes used only for conjectures and statements, not for proofs, this study utilises *refutation* for conjectures/statements and for proofs. These two points are epistemologically consistent with Lakatos' view of mathematics. In *Proofs and Refutations* (Lakatos, 1976), he dealt with deductive proofs that were only partially valid. He also argued that proof was inextricably linked to refutations (Reid, Knipping, & Crosby, 2008) and coined the term *local counterexamples* to denote the refutations of proofs.

### Task design principles

To design tasks for fostering the student activity of proofs and refutations, we develop principles for the task design from three aspects. First, Hanna (1995) pointed out that Lakatos' (1976) story rested on the topic of polyhedra, where it was relatively easy to suggest counterexamples. This confirms that it is necessary to create tasks intentionally where counterexamples can be produced. Because it is the ambiguous meaning of polyhedra that made counterexamples possible in Lakatos' research, it is essential to develop tasks whose conditions are purposefully ambiguous so that counterexamples can be proposed. In fact, we previously demonstrated that specific tasks that include hidden conditions, namely *proof problems with diagrams*, are useful for introducing proofs and refutations into secondary school geometry (Komatsu, et al., 2014; Komatsu, 2017).

Second, research indicates that students encounter difficulties in producing proper counterexamples (Hoyles & Küchemann, 2002). Thus, it is important to prepare tools that foster student production of counterexamples. DGS could play the role of such tools in geometry education because the main advantage of DGS is that students can easily transform diagrams by dragging (Arzarello, Olivero, Paola, & Robutti, 2002) and thus the students have access to various diagrams. From research on dragging modalities and measuring modalities in DGEs (Arzarello et al., 2002; Olivero & Robutti, 2007), the following are relevant to refutations of conjectures and proofs: dragging test, validation measuring, and proof measuring.

Third, several studies have reported that when students encounter counterexamples, some of them refuse to accept the counterexamples and do not try to revise their conjectures (e.g. Balacheff, 1991). For resolving this problem, we capitalise on the potential of contradictions, because if contradictions are appropriately induced, confusion generated by the contradictions can be beneficial for learning (D'Mello, Lehman, Pekrun, & Graesser, 2014). To trigger contradictions, it is likely helpful to combine tasks intentionally (rather than use a single task) where students can recognise contradictions

between their solutions to tasks and their thinking in subsequent tasks (Hadas, Hershkowitz, & Schwarz, 2000; Prusak, Hershkowitz, & Schwarz, 2012).

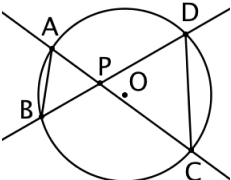

In summary, we formulate the following principles of task design for fostering the student activity of proofs and refutations: 1) Using tasks whose conditions are purposefully ambiguous and thus allow the occurrence of counterexamples; 2) Providing tools that enhance the production of counterexamples; and 3) Increasing students' recognition of contradictions that facilitates them to revise conjectures/statements and/or proofs.

## Methods

### Participants

This paper analyses a task-based interview in which a triad of students, Kakeru, Sakura, and Yuka (pseudonyms), voluntarily participated. They were 11th graders (aged 16–17 years old) in an upper secondary school in Japan. According to their mathematics teacher, their mathematical capabilities were above average. The first author conducted the interview. The DGE was GeoGebra. Because the students had no experience with DGS, four hours was devoted, prior to the interview, to teaching the students the basic functions (e.g. basic construction, dragging, and measuring) of the DGE. The students had learnt geometric proofs using the conditions for congruent triangles and those for similar triangles. They were familiar with the inscribed angle theorem, the inscribed quadrilateral theorem, and the alternate segment theorem, all of which are related to tasks used in the interview.

### Tasks

<p>Q1. (1) As shown in the diagram given, there are four points A, B, C, and D on circle O. Draw lines AC and BD, and let point P be the intersection point of the lines. What relationship holds between <math>\triangle PAB</math> and <math>\triangle PDC</math>? Write your conjecture. (2) Prove your conjecture.</p> <p>Q2. Construct the diagram shown in Q1 with DGS. Move points A, B, C, and D on circle O to examine the following questions. (1) Is your conjecture in Q1 always true? (2) Is your proof in Q1 always valid?</p>	
--	---

**Figure 2: Tasks used in the interview**

The tasks used in the interview are shown in Figure 2. We developed them according to the aforementioned design principles. Q1 is relevant to the first principle that involves ambiguous conditions. The condition of Q1 is vague because there is no reference to the locations of points A, B, C, and D in the problem sentences. If the locations are changed, refutations of the proof constructed in Q1 can be discovered, as shown below. The second principle corresponds to Q2, where students are invited to construct the given diagram with DGS and produce various diagrams by dragging. The third principle is related to the combination of Q1 and Q2. It is, of course, possible for Q1 to stipulate the use of DGS to produce various diagrams for making a conjecture before proving. However, we designed Q1 and Q2 in the way set out in Figure 2 because we expected that proof construction in Q1 could increase students' conviction in their conjecture and proof. This design could lead to students' recognition of a contradiction between their conviction and the subsequent refutations in Q2.

## Data collection and analysis

The three students were asked to solve task Q1 collaboratively with paper and pencil and task Q2 with DGS on a desktop computer. The task-based interview lasted for approximately 35 minutes in total. It was video-recorded and the audio transcribed. We used two cameras for the recording, one placed to video the students and the other placed to record the screen of the computer. The worksheets the students completed, and the DGS file the students made, were collected. We analysed these data by focusing on what type of diagram the students produced and how they dealt with the diagrams.

## Results

### Conjecture, proof, and types of diagrams the students produced

Immediately after student Kakeru read the problem sentences in Q1, Sakura conjectured “similar?”. The students then wrote the following proof on their worksheet:

In  $\triangle PAB$  and  $\triangle PDC$ ,

From the vertical angles,  $\angle APB = \angle DPC \dots (1)$

From arc BC, since inscribed angles are equal,  $\angle PAB = \angle PDC \dots (2)$

From (1) and (2), since two pairs of angles are equal,  $\triangle PAB \sim \triangle PDC$

After that, the students worked on Q2. As they worked, they produced and examined the six types of diagrams shown in Figure 3. In Figure 3a, triangle PAB (or likewise triangle PDC) is not constructed, while both triangles are not constructed in Figures 3b and 3c. Point P is located outside circle O in Figures 3d and 3e. In the type of diagram shown in Figure 3f, the students regarded points A and C (or likewise with points B and D) to be coincident and considered line AC (or likewise BD) to be a tangent to circle O.

**Figure 3: Types of diagrams the students produced**

In the following, we report the cases regarding Figures 3e and 3f because the students devoted more efforts to these types than to the other types.

### Case where point P is outside the circle

At the beginning of Q2, the students produced the type shown in Figure 3e:

- |     |         |   |
|-----|---------|---|
| 116 | Kakeru: | Is the conjecture in Q1, similarity, always true? [Reading the problem sentence.] |
| 117 | Sakura: | Not similar.  |
| 118 | Yuka:   | In this case, ... impossible.   |
| 119 | Kakeru: | The intersection point is outside the circle.                                     |

Here, Sakura and Yuna recognised a contradiction because although they proved their conjecture in Q1, they considered the type of Figure 3e to be a counterexample to their conjecture (lines 117 and 118). Kakeru then responded to their judgement:

- 132 Kakeru: We can say that they are similar.  
 133 Sakura: Why? We can't say that.  
 134 Kakeru: Because.  
 135 Sakura: Wait. Because.  
 138 Kakeru: PAB and PDC. These are similar. This and this [angle P] are common and equal. Then, because [quadrilateral ABDC is] a quadrilateral that is inscribed to the circle.  
 139 Sakura: That one.  
 140 Kakeru: This [angle PAB] and this [angle PDC] are equal.

A dispute between the students can be seen in this dialogue, where Kakeru argued that their conjecture was still true (line 132), whereas Sakura objected to his argument (lines 133 and 135). To respond to Sakura's objection, particularly for showing the congruence of angles PAB and PDC, Kakeru proposed using the inscribed quadrilateral theorem (lines 138 and 140): an interior angle is equivalent to the exterior angle of the opposite angle. Sakura agreed with his thinking (line 139), and, thus, they were able to resolve the dispute by proving the similarity of the triangles in the type of Figure 3e.

### Case where a line is a tangent to the circle

After producing the diagram type shown in Figure 3e, the students examined the type shown in Figure 3f (note that, strictly speaking, this type is different from the original problem where line AC cannot be drawn if points A and C coincide.) When encountering this type, Kakeru was convinced that their conjecture would be still true, and proposed using the alternate segment theorem to prove the conjecture. Nevertheless, when he started explaining his idea to Sakura and Yuka, he had a doubt as to why line AP can be considered as a tangent. The students struggled to resolve this doubt. During their struggle, as the students mentioned only once that the type of Figure 3f might be a counterexample to their conjecture, they consistently anticipated that their conjecture would be true in this type. Eventually, they judged that line AP was the tangent by measuring the degree of angle PAO and finding that it was almost 90 degrees. The subsequent student interaction was as follows:

- 357 Kakeru: If we consider this as a tangent, we can use the theorem about the angle formed by a tangent and a chord.  
 358 Sakura: I see.  
 359 Kakeru: We can show the similarity.  
 360 Sakura: This (angle DCP) and this (angle PBA) and P.

This dialogue shows that the students were able to prove their conjecture in the type of Figure 3f with the alternate segment theorem.

### Examination of the initial proof

The students concluded their activity without considering Q2(2), so the interviewer questioned them as follows: "Please read again the sentences in Q2 carefully. When you say it does not hold, do you mean your conjecture is false, or your proof is invalid?" When addressing this question, the students noticed that the reasons in their initial proof were not applicable to the diagrams that they produced.

In other words, they regarded these diagrams as local counterexamples to their proof in the sense of Lakatos' (1976) terminology. For example, the following is their discussion about Figure 3e:

- 456 Sakura: We wrote, "From arc BC, since inscribed angles are equal,  $\angle PAB = \angle PDC$ ".  
 457 Kakeru: PAB and PDC. This [the initial proof] is for this case [shown in Figure 2].  
 458 Sakura: This [the last line in the proof] is valid, but the sentences [the second and third lines in the proof] are not valid, right?  
 461 Kakeru: This [the initial proof] is only for this [Figure 2].  
 462 Yuka: If so, this proof ...  
 463 Sakura: Is not always valid, right?

After that, the students pointed out that it was sufficient to revise the reasons in their initial proof by replacing the equality of vertical angles and the inscribed angle theorem with the identity of the angles and the inscribed quadrilateral theorem, respectively. They also examined and revised the initial proof in the type of Figure 3f in a similar way, with the alternate segment theorem.

## Discussion and conclusion

The students in the interview were able to engage in mathematical activity of proofs and refutations depicted in Figure 1. After making and proving a conjecture, they produced diagrams to scrutinise whether their conjecture was always true. Although they initially judged the type of diagram in Figure 3e to be a counterexample to their conjecture, they modified their judgement by proving that their conjecture was still true in this type. This proof was constructed without looking back at their initial proof and revising it. However, after the interviewer's intervention asking them to consider Q2(2), the students recognised that their initial proof was not applicable to the types of diagrams in Figures 3e and 3f, and revised the proof for these types.

The three design principles and the tasks developed based on the principles were generally helpful for fostering the students' activity. Based on the first principle, we used the proof problem whose condition regarding the locations of points A, B, C, and D is ambiguous (Figure 2). This task enabled the students to produce the six types of diagrams that had the potential to refute their conjecture and proof (Figure 3).

With regard to the second principle, DGS in general and its dragging function in particular (Arzarello et al., 2002), were highly useful for producing such a variety of diagrams. In our earlier research, many students in a lower secondary school encountered difficulties in drawing diagrams that refuted their proofs in paper-and-pencil environments (Komatsu, Ishikawa, & Narazaki, 2016). Although the tasks used in that study were more difficult than those in this study, without DGS it would likely be challenging for the three students in this study to produce various diagrams different from Figure 2.

The combination of Q1 and Q2 based on the third principle played a role in stimulating the subsequent students' activity. In the case where point P was outside circle O, Sakura and Yuka felt a contradiction between the truth of their conjecture that was proved in Q1 and the refutation in Q2 where they judged the type of Figure 3e to be a counterexample to their conjecture. This contradiction triggered the dispute with Kakeru, where Sakura and Yuka's judgement was revised through Kakeru's proof showing that their conjecture was still true. In the subsequent case where a line was a tangent to circle O (Figure 3f), the students did not seem to perceive such a contradiction. This was likely related to the students' earlier experience, where they could show that the type of Figure 3e, which was initially

regarded as a counterexample, did not refute their conjecture. This experience would constitute a source of their conviction in the truth of their conjecture as regards the type of Figure 3f. If the students encountered this type prior to the type of Figure 3e, they would think that it might refute their conjecture, and would perceive a contradiction between their conjecture and the refutation.

This study has limitations as it is based on a case with one set of tasks. It is necessary to develop other tasks based on the design principles of this study and conduct further empirical studies, including studies in real classroom settings, to inspect the values of the principles and tasks. Another interesting future issue is to examine whether the design principles of this study are applicable to content areas other than geometry (for example, number theory). The design principles are not conceptually restricted to geometry education; the ‘tools’ mentioned in the second design principle are not only DGS tools. This issue is worth addressing in order to extend the opportunity to introduce proofs and refutations from geometry into other topics in the mathematics curriculum.

*The Hungarian curriculum for mathematics teachers' training specializes in a problem-solving Seminar aimed at teaching heuristic strategies. This fact motivated our research focusing on problem-solving competency of teacher trainees. In this study we deal with some aspects of inductive reasoning. We summarize the results of a diagnostic survey. We chose a closed problem which could be solved through inductive reasoning, and analyzed problem solving process of 94 students. Our primary interest was how students apply general phases of inductive reasoning, if they use it at all; that is, how they conclude general statements after pattern recognition, and whether they close it deductively or not.*

**Keywords:** Problem solving, inductive reasoning, proof and proving, rational errors.

## Introduction

In the midst of a long-term discussion on the role of metacognition and teaching heuristic strategies in order to enhance mathematical problem solving skills (Schoenfeld, 1985; Cai, 2010), the new Hungarian curriculum for mathematics teachers' training<sup>1</sup> explicitly specializes such a course. We think that there is no final rule concerning this polemics; moreover there is no comprehensive research focused on this student group in Hungary in this respect. One of the antecedent studies, the PhD dissertation (Pintér, 2012) focused solely on primary teacher trainees. Motivated by these facts we have begun a research to map the status quo in Hungary, with the aim to give didactical consequences and finding ways of teaching heuristic strategies, general problem solving skills effectively.

According to Polya (1954), heuristic reasoning is based on induction or analogy. In this study we focus on inductive reasoning process only. Csapo (1997) supports the proposition that inductive reasoning and skills of proof develop during broad age range (Grade 1-11). We therefore assume that problem solving skills, especially proper utilization of inductive reasoning strategy develop after entering higher education, and should be subject to development.

## Inductive reasoning and inductive problem-solving strategy

The word “induction” means a scientific procedure starting from experience. In inductive reasoning, one makes a series of observations and infers a new claim based on them. The mathematics education offers the possibility of learning the way of inductive reasoning beside the deductive one. Within the process of inductive reasoning Polya (1954) distinguishes stages such as observation of particular cases, formulating a conjecture (generalization), testing the conjecture with other particular cases. Haverty, Koedinger, Klahr, & Alibali (2000) identify the “function finding task” as the “representative of inductive reasoning” and use this term in a narrower sense as we use it, thinking

---

<sup>1</sup> This curriculum was introduced in 2013.

only on open problems and determine three basic inductive activity such as data gathering, pattern finding and hypothesis generation. Yeo and Yeap (2009) make the difference between inductive observation and inductive reasoning clearer. If students observe a pattern when specialising, the pattern is only a conjecture and they call it ‘inductive observation’. But if students use the underlying mathematical structure to argue that the observed pattern will always continue, this can be called ‘inductive reasoning’. Motivated by these approaches we describe inductive reasoning with five phases. (1) Observation of particular cases including looking for possible pattern as well. (2) Following the observed pattern, i.e. applying it for other cases. It often happens without formulation of a general statement. (3) Formulating a general conjecture. (4) Testing it by other particular cases. The result of the inductive reasoning is a general statement, but the mathematical problem solving process requires its deductive closure (5). The form of deductive closure could be either a rigorous proof or justification using the underlying mathematical structure (Mason, Burton, & Stacey, 2010). Moreover, Rivera (2013) uses the term of *empirical structural argument*, as a type of justification. Empirical structural argument means that one uses the steps of a logical deductive proof with concrete numbers or objects instead of variables. This process is closely related to the phenomenon of *generic example* (Stylianides, 2009) and *transformational proof-scheme* (Harel & Sowder, 2007). Thus, we look not only for the clues of the formal proof but the clues of empirical structural argument too while investigating Phase 5.

Haverty et al. (2000) argue, in accordance with other studies, that the detection of patterns is crucial to inductive reasoning. In patterning activity there is a difference between near generalization, a description of a pattern allowing one to determine the next term in a sequence, and far generalization, the construction of a general rule or a far stage in the pattern (Rivera, 2013). Solving the problem we investigated in this research requires mainly the near generalization activity; the formulation of a general rule could be useful, but is not necessary.

We identified in many cases that a mental manipulation process led to the inductive observations. The same phenomenon was detected by Simon (1996) who defined the concept of transformational reasoning, which is rather a dynamic process. Transformational reasoning visualizes the transformation of a mathematical situation and the results of that transformation. The conjecture is drawn from the result of the mental manipulation.

Besides inductive strategy, some other strategies may work for many closed mathematical problems. As Ben-Zeev (1996) pointed out, the schema-based thinking could be a useful way for organizing mathematical experiences. Using a schema – the knowledge structure for a particular class of concepts – in a proper way can predict the solution of the problem. However, schematic reasoning often lead to rational errors when applied rigidly or without understanding the context. The term rational error “refers to process where student first induces an incorrect rule and then proceeds to follow it “correctly” in a logical consistent manner” (Ben-Zeev, 1996, p. 65).

In this current study our main focus is on the way of problem solving of our teacher trainees with special interest in inductive reasoning. Thus, we have formulated the following research questions.

- Q1 Whether they use inductive arguments during the problem solving process or not?
- Q2 If not, what are the frequent types of their reasoning?
- Q3 What are the characteristics and the typical errors of their inductive reasoning process?

In order to answer these questions we constructed a problem which may be solved in different ways, among others using inductive strategy.

### The problem

In Figure 1  $AC_1 = C_1B_1 = B_1C_2 = C_2B_2 = B_2C_3 = C_3B_3$ .

1. If  $\alpha = 15^\circ$ , find  $\beta$ .
2. How many isosceles triangles can be drawn following the algorithm presented in the figure?
3. For some  $\alpha$ , we can draw exactly 9 isosceles triangles. Find  $\alpha$ .

Figure 1: The initial problem

The first question requires only minimal geometrical knowledge; moreover, the completion is the only cognitive operation needed, where by completion we mean finishing arithmetic operations in this context. The second question tests whether the student could follow the algorithm given by the figure. Our hypothesis was that the third question should be a mathematical problem for our students. Since the solution is completely determined by the underlying geometrical structure, this problem is suitable for examination Phases 1-5 of inductive reasoning.

A possible strategy is based on two steps. (1) The  $n^{\text{th}}$  isosceles triangle has angles with measure  $n\alpha$  on its base. (2) If we can draw the  $9^{\text{th}}$  triangle, then  $9\alpha < 90^\circ$ ; moreover, we cannot draw the  $10^{\text{th}}$  triangle, thus  $10\alpha \geq 90^\circ$ . It means  $9^\circ \leq \alpha < 10^\circ$ .

Our primary interest was in Step (1). If the student uses this general statement, how he or she concludes it. This “general approach”, i.e. when we use a general  $n$  in the solution instead of a concrete number of triangles, may appear in all parts of the solution; however it is not necessary for this particular problem. The reason is that only near generalization is involved here, i.e. direct methods (drawing, counting, and determining all the angles) could be effective (Rivera, 2013).

We highlight here only one more question: how students deal with the last possible triangle? We briefly refer to this question as “condition for halt”.

### Dimensions and methodology of the research

In academic year 2015/16 we investigated the solution of the problem described above with involvement of 94 students, including 49 prospective primary school teachers and 45 prospective secondary and upper secondary school Mathematics teachers. Solving of the problem does not require advanced mathematical knowledge and skills. Thus, we do not distinguish between these two groups in our research. The base group consists of 83 students (S01-S83 in the transcripts). In this group we investigated students’ written elaborations. The interview with 11 other students completed the frame of this research (S84-S94). During the interviews we followed students’ activities and made sound records. Students were asked to say out loud what they are thinking of when solving the problem. We corrected numerical errors immediately; otherwise we did not put guiding questions.

## Results: Students' activity during problem solving

### Overview

Analysis of students' performance handling the third question represents the overall problem solving process well. We identified two classes of solutions (Figure 2). *Concrete solution class* means that student deals with 9 triangles only and sticks to the text verbatim. Because the third question is a near generalization of the previous one, this plan is acceptable. By *general solution class* we mean, that solution works for arbitrary number of triangles. Some students used more than one strategy. 18 students didn't show up any strategy, 5 of them ignored the problem, and 13 students could only compute the angle of the 5<sup>th</sup> triangle.

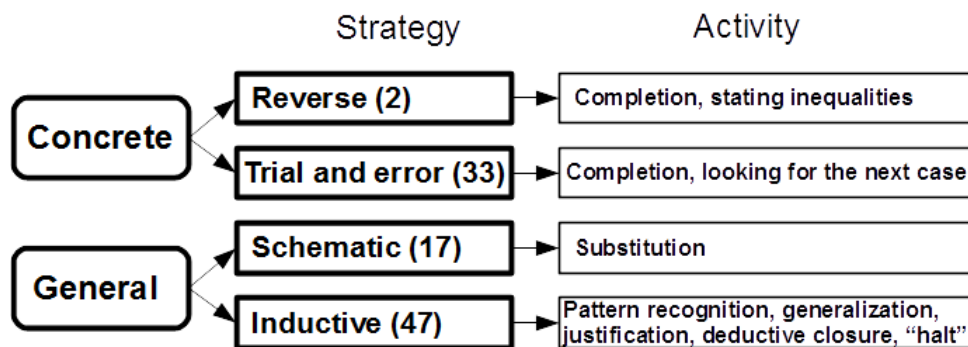

Figure 2: Strategies and activities with number of students following the particular strategy

### Reverse strategy

By reverse strategy we mean here that student's starting point is the final configuration with 9 triangles. This is a successful approach, where the student investigates the figure with 9 and 10 isosceles triangles and computes all the necessary angles directly, with or without showing signs of pattern recognition. We encounter this approach in 2 interviews, but nobody completed the third question using this strategy in the base group.

### Trial and error approach

Trial and error strategy is characterized by repeated, varied attempts which can be continued until success. Although this approach appeared 33 times, in most cases it played certain role in the inductive reasoning. 10 students applying this strategy did not show inductive or any other strategies; however, in 4 cases the activity was controlled with the (unproven) hypothesis that  $n(\alpha)$  is a decreasing function, where  $n$  is the number of isosceles triangles. One student in the interviewed group followed this pattern. Her view demonstrates that trial and error could be a rational activity even for this problem. After reading the text, her first and immediate reaction was applying trial and error method. After two trials with angle measure 10 and 5 the interviewer interrupted her:

Interviewer: Do you think that the solution is an integer?

S86: Certainly.

Interviewer: Why?

S86: I don't know... It is a nice problem and the solution should be a 'nice' integer.

Interviewer: [He gave a hint that  $\alpha \in \mathbb{R}$ .] In what cases is trial and error effective?

S86: When we have small number of cases to check. [She gave up.]

The transcript points out the role of student's belief in the problem solving process (Schoenfeld, 1985). Theoretically she knows that her effort is hopeless, but her belief in 'nice' solution overwrites this knowledge. In this context the false trial and error strategy is a rational error here in the sense of Ben-Zeev (1996), because if  $\alpha$  is an integer then we have finite number of integers to check. We detected 24 students with belief that the solution is an integer but in some cases with sign of uncertainty, e.g. "If we reject the condition that  $\alpha$  is an integer, then we have infinite possibilities" (S37).

### Schematic reasoning, false scheme

Schematic reasoning is the process of reasoning by which new information is interpreted according to a particular schema. In our problem the number of isosceles triangles is  $n(\alpha) = \left\lceil \frac{90}{\alpha} \right\rceil - 1$ , where  $\alpha$  is the given angle. This function, to be more precise, some approximate idea of  $n(\alpha)$  appeared in students' responses. First of all,  $n(\alpha)$  is a decreasing function, and 15 students referred to this property properly or erroneously (i.e. in strict form) without proof or explanation. The following transcript demonstrates the typical usage of this observation. Previously this student settled that for  $\alpha = 9^\circ$  there are 9 triangles. "If  $\alpha < 9^\circ$ , then the number of isosceles triangles is more than 9" (S10). We presume that the transformation reasoning (Simon, 1996) is behind this recognition. Some students showed explicit evidence of transformational reasoning. We encountered sentences like the following transcript 5 times in the base group. "If we decrease the angle, then we get more triangles" (S03). Students' observations are the result of the mental transformation of the angle.

In some cases it invoked the scheme of inverse proportionality or the misconception of *strictly* decreasing  $n(\alpha)$  function. Two false solutions with inverse proportionality scheme appeared in our experiment and caused a rational error. Two other students referred to inverse proportionality, but later revised the idea.

Other false scheme was the direct proportionality scheme. Perhaps the following interpretation of the problem invokes it. "In case of  $15^\circ$  we have 5 triangles, how much is the angle if we have 9 triangles?" This is a common pattern in elementary word problems. Transcriptions of data demonstrated in Figure 3 strengthen this presumption. Data from the second question is not necessary to answer the third question, but students who applied the direct proportionality scheme connected data in this way. S13 misprinted the angle and used 30 instead of 15. S36 revised her outcome. S08 finds  $x$  by the 'proper' way:  $5x = 9 \cdot 15$ . He just began the division (the tick between digits 3 and 5 indicates this), but presumably rejects the result which he found too big and finishes the calculation "forcing" a more reasonable result. Direct proportionality appeared 5 times, but 1 student revised this solution.

Figure 3: Direct proportionality (left: S13, center: S36, right: S08)

### Looking for a general solution using inductive strategy

We consider that the inductive strategy appears if a student reaches at least the first phase of the inductive reasoning process i.e. at least observes particular cases and looks for a possible pattern. Half of the students in this research (47 people from 94) used or tried to use this problem solving strategy. (Some of them used other strategies too.) Eight students stopped at the first stage because of the possible lack of near generalization ability. In the second phase (near generalization) the others determined the 9<sup>th</sup> and the 10<sup>th</sup> angle in the sequence in a way that they skipped some members and tried to transfer the “condition for halt” observed before. In our problem we didn’t ask to formulate a general statement; however 11 students made it (far generalization, Phase 3). The statements were expressed either by symbols or by words, like S85 told “Thus the length of one step is equal to the opener.” [The difference between the base angles in two consecutive triangles is equal to the given angle.]<sup>2</sup>

We wondered whether the students feel the need of testing their conjecture by other particular cases or not (Phase 4). The following transcript represents this phenomenon well. After calculating  $\alpha$ ,  $2\alpha$ , and  $3\alpha$  S88 said: “I’m sure the result will be something similar.  $\beta$  equals probably  $5\alpha$ , but I will compute it.” 13 solutions contained test of the near/far generalized conjecture.

Concerning Phase 5 (deductive closure) we confronted with the dilemma of “proving or not”. The near generalization feature of the problem probably caused the fact that no one has felt the necessity of proving of the observed and applied conjecture. The following transcript represents a typical attitude during the interviews:

Interviewer: Why are you sure that the 9<sup>th</sup> angle equals  $9\alpha$ ?”

S93: Because it was clearly visible, and I felt that it will work always in the same way.

The clue of empirical structural argument (Figure 4) appeared only in 5 works. Previously S88 determined the 5<sup>th</sup> angle without any skipping, after that she skipped to the 9<sup>th</sup> angle directly.

Here the recursive counting procedure confirms that the measure of the angle increases by  $\alpha$ .

Figure 4: Empirical structural argument of S88

Four students were able to make a correct deductive closure of the inductive reasoning by mathematical induction proof after the interviewer asked them to prove their conjecture. One of them said “I can prove if you wish.” (S93)

<sup>2</sup> Rephrased by the authors

### Typical error during inductive reasoning: spurious abstraction from irrelevant feature

Solving the first and second problem, students have some previous experience in the third problem. In 18 solutions we found that they abstracted a false rule from a previous experience, what is more, from one particular case. We highlighted only a few examples here. In the third part of the problem 2 students used the same difference (i.e. 15) for the arithmetic sequence of base angles as in the first part of the problem. In 2 cases the starting point was that the measure of base angles of the last possible triangle always equals  $75^\circ$ . The most frequent spurious abstraction concerns the “condition for halt” (12 students). In Figure 1  $\angle AC_3B_3 = 90^\circ$  causes the halt. Generally this condition is  $\angle AC_nB_n \leq 90^\circ$  (for the smallest  $n$ ), but these students kept the equality instead of inequality. The following transcript is a typical answer to the third question: “ $90/10 = 9$ , because in this way the tenth triangle would have two right angles” (S16).

### Findings and interpretation of results

The students involved in this research dealt with the presented problem in many different ways, and we detected many different solution strategies. Thus, we conclude that the chosen problem was an appropriate instrument to answer our research question in particular and to make some conclusions in general. We have summarized our findings for research questions as follows.

- Q1 50% of the students used inductive arguments during their problem solving process.
- Q2 In the other cases the most frequent type of their reasoning was trial and error strategy. Other strategies appeared, namely schematic, and reverse as well. Furthermore, we found that lot of students (19% in this research) did not go beyond the computational activity; they did not have any other idea. Yeo and Yeap (2009) describe the same phenomenon for weaker students.
- Q3 We found an uncertainty in inductive reasoning: students formulated conjecture from a few particular cases; moreover, they did not confirm it and 95% of students did not make any form of deductive justification. They often abstracted a false rule from a previous experience, what is more, from one particular case. Students relied on their intuitions without doubt; and this behavior calls for rigid schemes. They often mixed or changed these strategies without any result.

Possible explanations of these findings are complex. First of all, our students are not familiar with heuristic strategies, especially with strategy for determining patterns. The recognized pattern which described the relation between the angles and the number of triangles was a plausible one in their mind instead of a definite pattern in situation with well-defined mathematical structure. Moreover, the common misconception appears in the interviews that particular examples prove a general statement. With respect to the function concept we conclude that it is not deep enough, students have difficulty with step function. In many cases our students had in mind natural numbers instead of real numbers, as possible values of an angle, which suggests that their number concept is very simple and/or their belief in “nice whole number” solution is very strong.

*The aim of this paper is to understand how a proposed set of design principles regarding tasks and teacher actions provide students with opportunities to justify. We see justification as a reasoning process that relies on mathematical concepts, properties, procedures, ideas, and, in some situations, particular cases. The teaching intervention, part of a design-based research, is carried out in a grade 7 class of an experienced teacher in nine lessons about linear equations. Data is gathered by classroom observations (video and audio recorded) and a researcher logbook. Data analysis takes into account a set of design principles and a framework regarding students' justifications. The results show that paths of teacher's actions that rely on the design principles enable students to present rather complete justifications based on logical coherence and on mathematical aspects of the situation.*

**Keywords:** Reasoning skills, teaching practices, teacher-student interaction.

## Introduction

Developing students' mathematical reasoning is an important aim of teaching and learning mathematics. Students' engagement in reasoning processes allows them to move from using procedures with little or no understanding towards envisioning mathematics as a logical, interrelated, and coherent subject. We consider reasoning as making justified inferences (Brousseau & Gibel, 2005), using processes as formulating questions and solving strategies, formulating and testing generalizations and other conjectures, and justifying them. In this paper, we focus on justification as a central reasoning process. Enhancing students' mathematical reasoning in the classroom requires the set-up of challenging learning environments that go much beyond proposing students to solve exercises using well-known procedures. In order to better understand how teachers may foster students' mathematical reasoning, we conduct a design-based research (Cobb, Jackson, & Dunlap, 2016) that relies on whole class mathematical discussions triggered by exploratory tasks as privileged moments to promote students' mathematical reasoning. In this paper, we aim to understand how a set of design principles regarding tasks and teacher actions that focus on justification might promote students' justifications during whole class discussions.

## Students' justifications

In the classroom, justifying, particularly justifying conjectures and generalizations, is a reasoning process that rarely emerges spontaneously. Often, students accept conclusions such as conjectures and generalizations without feeling the need to test or justify those (Henriques, 2010). In many situations, students focus mostly on what is familiar or on ideas that they superficially recall, paying little or no attention to the mathematical properties or concepts implicated (Lithner, 2000, 2008). However, justifying is a reasoning process central to mathematics learning, as it allows students to connect mathematical ideas, concepts, and objects, to present arguments to support statements and conjectures, to solve problems and to develop new mathematical ideas (Brodie, 2010). We consider

justifying as a reasoning process and as the way to prove statements by relying on concepts, properties, procedures, and mathematical ideas and, in some situations, on particular examples.

Justifications in the classroom can occur at different levels regarding formality and complexity. Brousseau and Gibel (2005) propose three different levels regarding the formality of a justification: Level A – Justification that is not formally presented, but that might be associated with the student's actions as a model of his/her action; Level B – A formal but incomplete justification with inferences based only implicitly in elements of the situation or on what is considered to be shared knowledge; Level C – A formal justification based on a sequence of related inferences, with explicit reference to the situation or to what is considered to be shared knowledge. The concept of formal justification referred in these three levels is not necessarily the same as a formal justification in mathematics related to a mathematical proof, but rather to what is considered to be formal in a specific situation, namely accordingly to the grade level and the knowledge of students. However, as students advance through their schooling, formal justifications should be increasingly more formal from a mathematical standpoint, being sometimes equivalent to proofs or to significant parts of proofs. Drawing upon the classifications of Lannin (2005) and Carraher, Martinez and Schliemann (2008), it is possible to consider six levels of complexity: Level 0 – no justification, when the answers do not include a justification; Level 1 – Appeal to external authority, when the justification refers to other individual or reference material; Level 2 – Empirical evidence, when the justification is based in particular examples; Level 3 – Logical coherence, when justification is based on logic; Level 4 – Generic example, when the justification is deductive, but stated in relation to a particular situation; Level 5 – Deductive justification, when the validity of the justification is based on a deductive argument that is independent from the particular cases or examples. At all these levels, a justification presented by a student may be correct, partially correct, or incorrect. Thus, it is important that the students understand what validates a justification and reject justifications based on authority, perception and common sense (Lannin, Ellis, & Elliot, 2011).

## **Tasks and teacher actions to enhance justification**

Students learn to reason by “reasoning and by analyzing the achieved reasoning processes” (Ponte & Sousa, 2010, p. 32). Therefore, to enhance justification processes it is necessary to provide situations in which students have the possibility to justify their answers. As such, in mathematics teaching and learning, and particularly to enhance students' mathematical reasoning, a central aspect is the design of suitable tasks. It is important to understand the nature of those tasks, the ways students engage in them, and the interactions that may emerge (Brodie, 2010).

Several studies refer that problem solving and exploratory tasks have potential to develop students' mathematical reasoning (e.g., Francisco & Maher, 2011; Henriques, 2010). However, it is not necessary or even appropriate that all tasks involve questions at a high challenging level (Brodie, 2010). Such challenge may be infeasible due to time constraints and may lead to students' demotivation and loss of interest. Moreover, while designing a task, its structure and level of challenge should be considered according to the students to whom it is going to be proposed. In addition, we note that, just by themselves, exploratory tasks and problems, are not sufficient to foster students' mathematical reasoning. Teacher actions emerge as equally central to provide situations that promote students' mathematical reasoning. Regarding teacher actions to enhance

justifications, Bell (2011) highlights that the teacher should help students to make sense of justifications, ask for alternative justifications, emphasize what validates a justification, and focus on the explanation of “why”. Also, it is important that the teacher encourages the students to share their ideas and various versions of their reasoning, seeking to consider students’ incorrect or partial contributions and to broaden their valid contributions (Brodie, 2010).

## **Methodology: Design, participants, data analysis**

This paper originates from a broader research study that aims to develop a local theory about enhancing students’ mathematical reasoning in the classroom, following a design-based research (Cobb et al., 2016). In order to do so, we established several design principles (Cobb et al., 2016), i.e., heuristics that structure the intervention, based on the research literature and on a previous cycle of experimentation focusing on tasks and teacher actions to enhance students’ mathematical reasoning. Four of these principles specifically focus on justification. One principle refers to task design and states that tasks must include questions that ask for a justification of answers or of solving processes. The other three principles concern teacher actions and indicate that the teacher must promote situations that prompt students to (a) justify and present alternative justifications; (b) identify valid and invalid justifications, indicating why; and (c) share ideas, namely by accepting and valuing incorrect or partial contributions, deconstructing, supplementing, or clarifying them.

This is the third cycle of design, after a first cycle that took place in lessons about sequences and a second cycle in lessons about linear equations. This third cycle took place in a public school in a grade 7 class with 27 students (12-13 years old), throughout nine lessons about linear equations. A detailed plan of each lesson was prepared considering tasks specifically designed to promote students’ mathematical reasoning and considering possible teacher actions. Each lesson plan was proposed by the first author and discussed in detail with the teacher, who made all the amendments and adjustments that she felt necessary considering the class characteristics and the available resources. The participating teacher was selected because of her experience and her availability to consider changes on her practice. All participants in this study are volunteers, provided an informed consent, and their names are fictitious.

Data analysis is centered on the design principles regarding tasks and teacher’s actions and also on students’ justifications. The episode that we present is from lesson eight that aimed to lead students to be able to relate equations and functions. This lesson was directly observed and video and audio recorded and notes were made in a researcher’s logbook.

## **An episode about equations**

### **Task and context**

The episode presented in this paper focuses on the first part of the task proposed in lesson eight of the nine lessons that constitute the linear equations unit. This segment of the task (Figure 1) aims to lead students to establish a procedure to figure out the intersection point of two functions. Earlier in the school year, the students learned about algebraic and geometric representations of linear functions, with no participation from the researchers.

Frances received a plant as a gift and she registered its growth. Simon thought it was a really nice idea and, on the same day, bought a plant and also registered its growth. The functions that follow represent the height of both plants on their first days with the students:

$$\text{Frances' plant: } f(x) = 0.4x$$

$$\text{Simon's plant: } s(x) = 0.2x + 2.2$$

1. Represent graphically the functions  $f$  and  $s$ .
2. Based on the previous representations, indicate on which day the plants have the same height.
3. Consider the comment: "Graphs are not necessary to know on which day the plants have the same height. Knowing the functions that represent the height of each plant is enough to find out when they are equal". What would be the other approach to figure out the day when the plants have the same height? Justify your answer.

**Figure 1: Proposed task about functions and equations**

In the first two questions of this task, the students can support their answers by using GeoGebra app, as this particular school has iPads available by request. This was not the first time that the students used either the tablets or GeoGebra. Taking into account the design principle regarding task design, question 3 asks for a justification.

### Justifying based on knowledge about functions

At the beginning of the lesson, the teacher asks a student to read the questions to the class and clarifies the aims of the task and the tools to use. Then, students work autonomously, in pairs, for a couple of minutes. After inserting the algebraic expressions of the functions in GeoGebra, some of them state that the plants have the same height on the 11<sup>th</sup> day. The teacher begins the whole class discussion by asking for a justification to that answer:

Teacher: How do you know that it is on the 11<sup>th</sup> day? (Several students raise their hands in order to answer.) Isa.

Isa: Because, if we check, both straight lines intersect in 11.

The teacher's invitation to justify (principle (a)) led Isa to justify her answer to question 2 based on her previous knowledge about functions. This justification is incomplete regarding referencing "in 11", however, it refers to elements of the situation, namely, the graph representations of both functions and the intersection point. Thus, Isa presents a generic justification regarding the available data (level 4 justification).

Aiming to complete Isa's answer (principle (c)), the teacher revoices this student's answer leading to a more accurate justification:

Teacher: In 11...

Isa: In point 11.

Teacher: In point 11?

Gabriel: Abscissa.

Teacher: In the point with abscissa 11.

By referring to parts of students' answers, the teacher implicitly identifies what is invalidating the justification (principle (b)), and based on the students' answers, the teacher highlights what completes the justification (principles (b) and (c)).

After validating Isa's answer, the teacher decides to go further on justifying, asking for another justification (principle (a)):

Teacher: Why am I looking at the intersection in  $x$ -axis . . . For the value in  $x$ -axis?

Isa: Because  $x$ [-axis] is the axis of objects...

Teacher: Yes... And how do I know if I am looking for an object or looking for an image?

Isa's justification relies on mathematical concepts (level 3 justification), however, her statement is not sufficient to provide a justification in this specific situation as it does not relate to the context of the problem. Once again, the teacher validates a partial contribution from Isa and encourages the students to complete that contribution (principles (b) and (c)). Another student tries to justify, but he does not add any information to what Isa has already said. Then, Gabriel participates in the discussion:

Gabriel: I think it is because the height is in... In... I just forgot the name.

Teacher: The axis...

Gabriel: The ordinate, the ordinate axis, and the days are in the abscissa [axis].

At this point of the discussion, Gabriel adds some relevant information to the justification, by relating objects and images of these functions to the context of the situation (level 4 justification). Despite this relevant relation, the required justification is still incomplete, and so the teacher continues on encouraging students to justify (principle (c)):

Teacher: And how do I know that days, in this particular case, are objects and heights are images?

Gabriel: Because there is... I forgot it...

Leonardo: Why it is that way, isn't it? Let me reason the other way around... If the height would be there [in  $x$ -axis]...

As the students struggle to address the teacher's question without being able to justify (level 0 justification), the teacher gives some more information in order to complete the justification (principle (c)):

Teacher: What do the functions  $s$  and  $f$  represent?

Several students: Height.

Teacher: Plant's height, right? Depending on what?

Several students: Time.

Teacher: The time that elapses, in days. OK, very well.

This information provided by the teacher leads the students to easily identify dependent and independent variables, thus completing the required justification (level 4 justification).

Both this and the previous justifications in this segment rely on students' prior knowledge about functions and emerge during the whole class discussion supported by the teacher's actions based on the defined design principles.

### Justifying based on knowledge about equations

Right after discussing question 2, the teacher introduces question 3. At this point, a student immediately proposes a strategy to solve this question. This leads the students to engage in a new segment of whole class discussion, without having time to work autonomously on this question:

Teacher: Now, pay attention to question 3, because... (Santiago raises his hand). Tell me.

Santiago: So teacher, we have that thing that was G.C.D. (M.D.C. in Portuguese), I believe it was... Multiple (regarding the M in M.D.C.)...

As the teacher allows Santiago to intervene, he brings to the discussion a strategy based on a mathematical concept that was not expected in this situation. Despite seeming a senseless idea, the teacher lets him go on with his explanation (principle (c)):

Teacher: Greatest common divisor?

Santiago: Yes, something like that. Can't we use it to answer to when do they intersect? . . . I can't recall it, but wasn't there something in common? Doing each number and then...

By allowing Santiago to justify it is possible to understand that, despite incorrect, the student's justification relies on an idea with some logical coherence (level 3 justification). Thus, both in G.C.D. and in intersecting functions one is trying to find "something in common", as he refers. At this point, the teacher poses more questions in order to deconstruct the misconceptions about G.C.D. which leads the other students to identify Santiago's strategy as not fitting to this situation.

After clarifying that, Clara presents her strategy:

Clara: We can use an equation (referring to  $0.4x=0.2x+2.2$ ), and the number that we get is the day they have [the same height].

...

Teacher: What are you expecting as a solution of this equation?

Several students: 11.

Teacher: 11. So, confirm that.

Evoking the information obtained in the previous questions, the teacher supports Clara's strategy to solve this equation and, by asking to confirm the result, she prompts the students to justify (principle (a)) that 11 is the solution of the mentioned equation. Students do this in autonomous work, and then Daniel intervenes:

Daniel: Teacher, it isn't.

Teacher: It isn't? So, solve the equation over there (on the board).

As Daniel solves the equation on the board, the teacher realizes that he has just missed an  $x$  in one of the steps and, by following his solving process (principles (b) and (c)), the justification based on procedures is properly achieved (level 4 justification).

In this segment of the discussion, justifications, either valid or invalid, are based on knowledge about mathematical concepts. These justifications emerge when teacher's actions rely mostly on

encouraging students to share ideas and completing those ideas.

## Conclusion

All the situations in the episode that we analyze were prompted by the proposed task. This task, focused on making sense of the relationships between equations and functions, provides an opportunity for students to develop a procedure to find where two functions intersect. This underscores the idea that collective activity in whole class discussions enable students to share, debate and clarify their reasoning and, in particular, their justifications (Galbraith, 1995).

This study shows that, if particular teacher action paths that rely on the design principles are followed, justifications are likely to emerge in whole class discussions. In this episode, when the principle regarding asking for a justification is enacted, the students present justifications. These justifications are based on previous knowledge about mathematical concepts or ideas or on known mathematical procedures. Thus, those are justifications based on logic or deductive justifications stated in relation to a particular situation. However, these justifications are often incomplete and sometimes incorrect, and, as it has been seen in previous research (Galbraith, 1995), the use of available information about a certain mathematical concept or idea is not always adequate given the definitions or assumptions of the task. When the justification is incomplete, the teacher tends to encourage the students to complete the justification, validating or invalidating their statements only implicitly. Depending on her appraisal of the support that the students need to mobilize their knowledge, the teacher provides them with more or less information. By relying on these principles, the complete justification emerges from the whole class discussion. When an invalid justification is at stake, and according to the defined principles, the teacher values students' contributions and keeps on encouraging them to present their ideas, leading them to present justifications based on logical coherence or on mathematical procedures. In these situations, where a student's justification is incorrect, teacher's actions strive either to abandon that justification and to focus on an alternative justification or, if possible, to adjust it to its correctness.

In this particular episode, students' justifications, despite sometimes incomplete or invalid, tend to be reasonably formal as they are based on mathematical aspects of the situation. Also, in the context of a whole class mathematical discussion based on the design principles, those justifications emerge often as justifications in a logical coherence level and, as students continue to add information, those justifications became generic example justifications. As this episode illustrates, in order to provide students with opportunities to move in-between levels of justification, it is not enough to ask students to justify and validate their justifications, but also to accept and value partial and incorrect justifications. Thus, the presented paths are likely to provide promising environments to develop students' justifying abilities, hence to be better prepared to deal with mathematical proof later in their schooling.

# A reference for studying the teaching of logic

Zoé Mesnil

Université Paris Est Créteil, Laboratoire de Didactique André Revuz, France; [zoe.mesnil@u-pec.fr](mailto:zoe.mesnil@u-pec.fr)

*This paper presents a work developed in my thesis on the teaching of logic in high school in France. The current official instructions specify that teachers don't have to make a mathematical logic course, but have to help their students develop a relevant use of some notions of logic as tools. Therefore, I point out in this paper that in order to take this constraint into account in the study of didactic transposition process, it is relevant to describe it from a reference knowledge for logic, but that such knowledge has never been established by the mathematics community. In order to offer such a reference, I base myself on a double epistemological and didactical study in which I favor the links between logic and language. I will also explain the choices made for this reference and its use as a methodological tool through the example of quantifiers.*

*Keywords: Logic, teaching, didactic transposition, quantifiers.*

## Introduction

In France, mathematics syllabuses for high school (students between 15 and 18) mention explicit goals concerning certain notions of logic. For example, they recommend that “students [be] trained on examples to wisely use the universal and existential quantifiers (the symbols  $\forall$ ,  $\exists$  are not required) and to identify the implicit quantifications in some propositions, particularly in conditional propositions”. These current recommendations come after twenty years during which the logic was excluded from syllabuses. This exclusion itself is a reaction to the too abstract and formal aspect of modern mathematics (taught in France between 1969 and 1981) for which mathematical logic and set theory were basic elements. They strongly highlight the logical notions as tools and even show distrust against their feature as objects. This distrust can be interpreted as a resistant mark of turning down modern mathematics. The syllabuses specify that “the concepts and methods of the mathematical logic should not be subject of specific courses but must naturally take place in all chapters of the syllabus”. I described more precisely the characteristics of the conditions and constraints due to these official instructions in a contribution to CERME 8 (Mesnil, 2013): teaching goals are ill-defined and subjected to strong constraints. Moreover, mathematics teachers do not share a common reference for interpreting these syllabuses. Indeed, mathematical logic is not part of the domains necessarily studied by a mathematics student, bringing a diversity of teachers' knowledge, that is usually not filled during their training in which teaching of logic is often only superficially and quickly addressed.

In this contribution, I would like to pursue this issue of a reference for the teaching of logic. In my thesis, I studied the teaching of logic in high school as the result of a didactic transposition process, and I'll explain first why the nature of mathematicians' logical knowledge requires thinking this transposition not from a *mathematical knowledge* like mathematical logic, but from a *reference knowledge*, nonexistent for the moment in the mathematical community (Mesnil, 2014). Secondly, I will justify the choice I made then to construct a methodological tool to conduct the analysis of syllabuses and textbooks. This tool is a *reference* in which the notions of logic are presented from three points of view that root them deeply in mathematics, in mathematical activity, and in the

classroom. I will conclude by illustrating the choices I made for this *reference*, and its use through the example of quantifiers.

### **The need for a *reference***

During the didactic transposition process (Chevallard, 1985), a mathematical object is identified in a body of knowledge (in French, *savoir savant*), and a first succession of adaptations will make it able to become an object of teaching in a particular institution. It is then identified by mathematics teachers in the knowledge to be taught (in French, *savoir à enseigner*) and is subjected to a second succession of adaptations to become a taught object.

But except in some university courses, teaching logic does not mean teaching mathematical logic, but the logic at work in mathematical activity, which supports mathematicians' expression and reasoning. We can consider that mathematicians have a logical knowledge, which may be the subject of a didactic transposition process, but this knowledge is more visible in practices than in treaties. Mathematical logic can be perceived as a description of the principles of this logic. It was then explicitly taught during the time of modern mathematics, in France and elsewhere, but these experiments showed that this teaching, conducted formally and isolated, did not help pupils to express themselves and to reason (Adda, 1988). Several researchers in mathematics education now agree that such teaching should be explicitly linked together with mathematical activity in which the logic is omnipresent (see for example Epp, 2003; Durand-Guerrier, 2005). However, there are few research studies on the effect of teaching logic on reasoning and expression capacities, which is still an open issue.

Thus, to take into account this particular nature of the logical knowledge and its connection to mathematics, and to appropriately study the didactic transposition process of this knowledge, I propose to describe this transposition not from a mathematical knowledge, but from a reference knowledge. I take this notion from Rogalski and Samurçay (1994) who thus characterize a knowledge produced by practices, but decontextualized from situations where knowledge is apparent into action. These authors state that it is necessary that this reference knowledge can "be expressed with its concepts, its methods, its systems of representation and its language" (*ibid*, p. 46). However, concerning notions of logic, such a reference knowledge does not appear in that there is no corpus collecting the logical knowledge necessary to mathematical activity and about which everyone agree the choices of concepts which are featured and of their representation.

I then conducted a study to answer the following research question: what kind of reference knowledge would be epistemologically and didactically relevant to the logic teaching? This study allowed me to construct a *reference*, which I then used to analyze the knowledge to be taught in high school in France. I call this analysis tool *the reference*, and not reference knowledge, because the production of a knowledge falls under a long and collective process.

### **The importance of language for reasoning, and its links with logic**

The study of various logical systems across the ages allowed me to identify invariants and differences in the role assigned to logic and in the ways that are given to it to fulfil it. The study of didactic studies shows how issues relating to the teaching of logic meet the concerns and choices of these logicians.

All these logical systems are built from a work on language. The concept of proposition is primordial in them all. Aristotle describes it in terms of subject-copula-predicate, and it was not until Frege at the end of the XIX<sup>e</sup> century that this analysis was to be replaced by an analysis in terms of function and argument allowing two things essential for mathematical language: on one hand to consider predicates with several arguments, on the other hand to pull out the act of quantification from the proposition by making it expressed by quantifiers which act on variables. Predicate logic that is then born is able to model mathematical propositions. From a didactic perspective, several research studies have shown many examples of situations in which the predicate logic is a relevant reference for didactic analysis which allows to highlight the importance of issues on quantification (Durand-Guerrier, 2005).

The current language of mathematicians is inspired by Frege's formalism, but it isn't a strict use of a formal language. Focusing particularly on problems of language in mathematics teaching, Laborde (1982) showed that there is a particular use of language in mathematics, due to the interaction of the two codes of symbolic writing and natural language. This interaction allows mathematicians to use reformulations useful for conceptualization. Teachers are familiar with the particular features of mathematicians' language, but they can cause difficulties for students who "discover together the concepts and the way we talk about them" (Hache, 2015, p.28).

The common goal of the studied logical systems is to ensure the validity of reasoning, with a preliminary work on language. But for the authors of *The Logic of Port Royal*<sup>1</sup>, logic above all needs to be trained and the formalization of reasoning is seen as an obstacle to the use of intuition, whereas for Leibniz and Frege on the contrary, logic must provide a system of signs in which reasoning can be expressed, and this formal expression guaranteeing its infallibility. Gandit (2004) denounces the excessive place taken by the formal aspect in the beginning of proof learning. But being careful about formalization at the time of the discovery of deductive reasoning does not mean that it cannot subsequently help those who begins to have a good practice of it. Thus, in higher education, Selden and Selden (1995) suggest presenting theorems and definitions in an informal formulation, which allows intuitive understanding, and in a formal language, which allows linking structure of the statements and structure of its proof.

### **Organization of the reference**

In the *reference* I proposed, I decided to give a broad place to language. Entering into logic by the language is consistent with the epistemological study, granting it an important place is consistent with didactic studies. Of course, in the same way as it is done in the studied logic systems, especially in a didactic perspective, the study of notions of logic as components of mathematical language has to be articulated with their use in reasoning.

Finally, these epistemological and didactic studies led me to propose a *reference* in which the presentation of logical concepts combines three approaches:

---

<sup>1</sup> Name of a famous french treatise, which original title is « La logique ou l'art de penser », written in 1662 by A. Arnauld and P. Nicole, who were very influenced by Descarte's method.

- The mathematical logic. It is a recent branch of mathematics that can be considered as a result of what has been sought by different logical systems creators since Greek antiquity. Mathematical logic seems so particularly suitable as a formal reference to describe the logic at work in mathematics.
- The study of the language practices of mathematicians. In this way, the presentation of the logical concepts is rooted in mathematical activity taking into account how they are expressed in mathematical discourse, using predicate logic to uncover some complex and sometimes ambiguous formulations that are yet a part of the language practices of mathematicians, widely imported in the mathematics classroom.
- The research in mathematics education. In this way, the presentation of the logical concepts is rooted in mathematics classroom, taking into account the difficulties that the complexity of these notions can bring for students.

In this *reference*, the components of mathematical language are shown, beginning with the primordial notions of proposition and variable. Then for the connectives AND and OR, implication, negation, quantifiers, I have consistently adopted the three approaches mentioned<sup>2</sup>. Although the focus is on the language, reasoning is of course not absent from the *reference*. A difficulty for pupils and students is to distinguish, in a text of a proof, mathematical propositions concerning mathematical objects, and parts of the text which allow to follow the progression of reasoning, such as variable introductions, or justification of an inference. The confusion between implication and deduction falls under this type of difficulty.

### **The example of quantifiers in the *reference***

As announced, the *reference* contains first a presentation of logical concepts from mathematical logic. Predicate logic uses two quantifiers: applied to a variable  $x$ , and from a proposition  $P$ , the universal quantifier allows to obtain the proposition  $\forall x P$ , and the existential quantifier allows to obtain the proposition  $\exists x P$  (description of the syntactic aspect of the quantifiers: they operate on a variable and a proposition to build a new proposition).

Let  $E$  be a set in which the variable  $x$  can take values. The proposition  $\forall x P[x]$  is true<sup>3</sup> when for any element  $a$  of  $E$ , the proposition  $P[a]$  is true. The proposition  $\exists x P[x]$  is true when there is at least one element  $a$  of  $E$  such that  $P[a]$  is true (description of the semantic aspect of quantifiers: truth conditions of a quantified proposition). Quantifiers have an important effect on the variables: a variable that is in the scope of a quantifier is a dummy variable in the quantified proposition, and this proposition does not give information on the object designated by the variable, but on the set in which it can take its values.

Some important results on quantified propositions may be established by a semantic way, using the sense, as well known equivalence between  $\text{NOT}(\forall x P[x])$  and  $\exists x \text{NOT}(P[x])$ , or the fact that if  $\exists y$

---

<sup>2</sup> For each of these themes I have summarized the mathematical content, the language related issues, and research findings on student difficulties.

<sup>3</sup> This semantic characterization can be described as “naïve” because I do not strictly define what “being true” means. But of course, this characterization may be more rigorous with the notion of satisfaction of a formula in a model introduced by A. Tarski.

$\forall x P[x,y]$  is true, then  $\forall x \exists y P[x,y]$  is true. These results are then used in syntactic manipulations, independent of the sense, in the same way we manipulate algebraic equalities.

In mathematical language, the quantifiers are a way to express the quantification, but there are many others. We can see this through some examples of mathematical propositions<sup>4</sup>:

- 1) Le carré d'un nombre réel est positif (The square of a real number is positive)
- 2) Le carré d'un nombre réel est toujours positif (The square of a real number is always positive)
- 3) Tous les réels ont un carré positif (The square of any real number is positive)
- 4) Tout réel  $x$  est tel que  $x^2$  est positif (Any real number  $x$  is so that  $x^2$  is positive)
- 5) Pour tout réel  $x$ ,  $x^2$  est un réel positif (For all real number  $x$ ,  $x^2$  is a positive real number)
- 6)  $\forall x \in \mathbb{R}, x^2 \geq 0$

They are several formulations of the same property, but universal quantification is expressed very differently. In proposition (1), quantification is implicit, implied by the word *un* (translated with *a*). We frequently use the indefinite article *un* to mark a universal quantification, in everyday language as in mathematics. But *un* is also sometimes used to mark an existential quantification, which is obviously confusing! Sometimes, the two usages coexist in the same proposition, such as in “un réel positif possède une racine carrée” (“any positive real number has a square root”, in English, the first *un* is rather translated with *any* and the second *une* is rather translated with *a*, and there is no confusion). In proposition (2), the adverb *toujours* (always) is used to explicitly mark this universal quantification, as the word *tous* (any) in proposition (3). Propositions (4) to (6) are distinct from the first by the use of a variable. Furthermore, one can identify in each of these propositions an expression which express the quantification (here universal quantification) and which has the property that it can be separated from the proposition “ $x^2$  is positive” (or equivalent formulation). Such expression works as quantifiers of mathematical logic, and I therefore also calls them *quantifier*.

Finally, we saw that in the language practices of mathematicians, quantification can be implicit or explicit, and in the second case, possibly marked by a quantifier which is an expression observing syntactic rules of use. Propositions (4) and (5) may seem closer to propositions (1) to (3) as they are formulated “with words” contrary to the proposition (6) which only uses mathematical symbols, and that may seems much more formal. I would like to stress that such a vision hide formalization still existing in these propositions, in the sense of a shaping according to certain rules, even if that formalization is not accompanied by a symbolization.

I will conclude by mentioning some of the difficulties of high school students or senior students in related to the use of quantifiers. First, the implicit quantifications are not always perceived by students. The case of the universal quantification associated with the implications and the formulation *if ... then ...* is highlighted for a long time (Durand-Guerrier, 1999). Quantification is often encapsulated in stiffened structures (for example, “ $u_n$  is as big as we want by taking  $n$  big enough”) that the expert mathematician knows how to reformulate by explaining the quantifications, but these reformulations in more formal language tend to disappear from the language used in high school, and

---

<sup>4</sup> I give the examples in French first because I will explain some difficulties linked to the word *un* which is used in this language in different meanings, and which is translated in English with *one*, with *a*, with *the*... Commentaries following the examples refer to the French expression.

are a source of difficulty when students meet them in higher education. Another difficulty concerns the failure to take the order of quantifiers into account when there is an alternation. We know that students have rather an interpretation *for all... there exists...* even though they are facing a proposition *there exists... for all...* (Dubinsky & Yiparaki, 2000). Furthermore, Chellougui (2004) showed student difficulties with the use of an existential proposition. In a proof text, there is generally a confusion between the affirmation of the existence of an element checking a property, and the act which consist to consider it and give it a name. Likewise, mathematicians do not get trapped by the “dependence rule” in the statements *for all... there exists...* and identify easily this error in a student production. However, they do not necessarily explain this error to the students by linking it to formal rules of manipulation of variables and quantifiers (Durand-Guerrier & Arsac, 2005).

### **Examples of the treatment of quantifiers in school textbooks**

The *reference* I have developed allows an analysis of resources available to teachers highlighting sensitive issues that need to be paid attention to. I will then conclude with an analysis of two extracts from school textbooks.

The reintroduction of logical concepts in the syllabuses had an effect on the textbooks: those published in 2010 for the first class of high-school (15 years old students) all contained passages identified as speaking of these concepts. Nine textbooks out of ten have chosen to dedicate a few pages (between one page and nine pages) to notions of logic, usually located at the beginning or at the end of the textbook (only one textbook does it in a disseminated way). Moreover, they all contain exercises with a stamp “logic” (from ten to fifty-four exercises in the studied textbooks).

In the eight textbooks that deal with quantifiers, the letters are introduced by examples. Seven of the eight textbooks give only examples of true quantified proposition, and this choice eliminate the syntactic aspect of quantifiers: quantifiers are used only to affirm something, there isn’t the idea of a proposition built with a quantifier that one could wonder whether it is true or false.

The textbook *Indice* gives the example of the proposition “le carré d’un réel est positif” (“the square of a real number is positive”) and states that “cette proposition est vraie quel que soit le nombre réel” (“this statement is true for all real numbers”). The authors of this textbook probably want to emphasize on the various possible meanings of the word *un*, but do not offer at the same time an example of the meaning as existential quantification. Moreover, to know that the meaning of *un* in this proposition is a universal quantification, it is necessary... to know that the universal proposition is true! Mathematical knowledge is therefore needed to decide between the two possible meanings of the word *un*, which calls for caution when using this word in a context where student knowledge is potentially fragile. Let’s go back now on the comment “this statement is true for all real numbers”. It makes no sense to say that the proposition “the square of a real number is positive”, which is equivalent to “for all real  $x$ , the square of  $x$  is positive” is true for all real numbers, since the variable  $x$  is dummy in this proposition. The proposition referred to in this commentary is not the quantified one, but the not quantified proposition “the square of  $x$  is positive”. Finally, there is a confusion between the use of “quel que soit” (“for all”) to simply mark the universal quantification, and its use to assure that this universal proposition is true.

Now let’s look at an example of exercise, taken from the textbook *Repères*, but it is an exercise that is found in many textbooks. Students must “complete the sentences (for example “... real number

$x \dots f(x) > 0$ ”) using either *for all... we have...* or *there exists... such that...*” from the graphical representation of the function  $f$ . Note first that the application is not explicitly to complete so that sentences are true! Furthermore, the instruction “complete using either... or...” suggests that each time only one of the both quantifiers is correct. Yet, when the proposition “for all  $x$   $P[x]$ ” is true, the proposition “there exists  $x$  such that  $P[x]$ ” is also true, so when it is possible to complete with the universal quantifier, it is also possible to complete with the existential quantifier. In everyday language, we respect the principle of maximum information, according to which we give to our interlocutor all information in our possession. So, if I say “on my holidays, it rained some days”, I say in the same time that it did not rain every day. The practice of this principle leads us in this exercise to complete naturally with the universal quantifier when possible. However, the notion of truth of a proposition will be contradicted by saying that using the existential quantifier is a mistake, because in mathematics, when the proposition “for all  $x$   $P[x]$ ” is true, it is not “more true” than the proposition “there exists  $x$  such that  $P[x]$ ”. Some students, however, adopt this position, and we can doubt position of the authors of the teacher’s textbook who offers as a correction only the universal quantifier when it is possible.

## Conclusion

I presented in this paper a methodological tool, a *reference* to study the teaching of logic. It is of course to be completed, to be improved, both from an epistemological and from a didactic point of view. Important work remains in particular on the concept of proposition, generally not made explicit in teaching, and on the notion of variable (didactic of algebra is very concerned about the status of the letters, but it seems to me that a logical point of view on the concept of variable, such as taking in Epp, 2011, or as I suggested in Mesnil, 2014, is more unusual), especially to identify students difficulties with these concepts that can be related to their epistemological complexity, or their use in the classroom.

Moreover, I have used for the moment this *reference* to analyze the syllabuses and textbooks, and a training for teachers who offers a similar approach of notions of logic. But it could also be used to study the practices of teachers, students’ activity and conceptions. It would be particularly interesting to compare the effect of knowledge in mathematical logic that teachers have or have not.

# Revisiting Odysseus' proving journeys to proof: The 'convergent-bounded' question

Andreas Moutsios-Rentzos<sup>1</sup> and Faidra Kalouzoumi-Paizi<sup>2</sup>

<sup>1</sup> University of the Aegean, Greece; [amoutsiosrentzos@aegean.gr](mailto:amoutsiosrentzos@aegean.gr)

<sup>2</sup>KJPTTh, Kinder- und Jugendwohnheim Leppermühle, Germany; [faidra.kp@gmail.com](mailto:faidra.kp@gmail.com)

*In this paper, we investigate the cognitive and affective task-specific experiences of Odysseus, a mathematics undergraduate, as he attempts to answer to an exam-type proving question: the convergent-bounded question. The concurrent investigation of Odysseus proving strategies and his basic emotions appears to help in gaining deeper understanding about his proving experience.*

*Keywords: Proof, proving strategies, emotions, examinations, thinking styles.*

## Cognitive and affective aspects of proving

The notion of proof lies at the heart of modern mathematics (Thurston, 1994) and of mathematics education research (Furinghetti & Morselli, 2009; Reid & Knipping, 2010). In this paper, we focus on the cognitive and affective task-specific proving experiences (drawing upon Moutsios-Rentzos, 2015). Researchers have identified different proving strategies that the students employ when facing with a proving task (Weber, 2005), while others have investigated the type of the argument utilised in a proof (Inglis & Mejia-Ramos, 2008). Considering the affective aspects of proving, famous mathematicians stress the pleasure that a proof brings (for example, G. H. Hardy; Hoffman, 1998), which is in contrast with the reality as pictured by mathematics undergraduates (Rodd, 2002) and with the gloomy in-class mathematics experience, with 16-year old students reporting that “I hate mathematics and I would rather die” (Brown, Brown & Bibby, 2008, p. 10).

Emotions “give information about progress, or ability to progress, relative to goal states and anti-goal states” (Skemp, 1979, p. 18) set by an individual. The pleasure that derives from our dealing with a task is linked with our concentrating our cognitive efforts to solve it (Changeux & Connes, 1998). It is argued that research should attempt to co-consider cognitive and affective aspects of a proving experience (Furinghetti & Morselli, 2009). Moreover, we draw upon the idea that a theory may act as a meaningful attractor (Moutsios-Rentzos, 2015) of the different methodological-theoretical perspectives investigating a phenomenon. Furthermore, since the assessment process is strongly linked with the learning outcome of any educational system (Boud & Falchikov, 2007), we focused on the exam-type proving questions that all mathematics undergraduates undertake. Considering that being successful in exams is a highly goal-oriented activity, we adopt a theory developed for such experiences which also addresses both cognitive and affective aspects: Skemp's (1979) theory of social survival and internal consistency. Consequently, we address the question: *What are the affective and cognitive task-specific experiences of a mathematics undergraduate as he attempts to produce an exam-acceptable answers in an exam-type proving question?*

## Theoretical – methodological approach

Skemp (1979) theorised that the learners survive both socially and internally. They survive socially by meeting the socially accepted, (usually externally) set criteria of a task (for example, exams), whilst they survive internally in the sense of achieving consistency within their internal reality (for

example, by satisfying their inner need for being creative or for identifying and following the rules), which crucially includes both cognitive and affective aspects. Hence, considering that producing exam-acceptable answers is essentially a goal-oriented activity, Skemp's theory is employed to give meaning to both aspects of the investigated phenomenon: proving strategies and basic emotions.

The students' proving strategies refer to the students' answering a proving question, rather than reflecting upon an answer. The A-B- $\Delta$  proving strategy classification scheme (Moutsios-Rentzos, 2009) was utilised to identify the students' qualitatively different proving strategies when they deal with exam-type questions. At the crux of the scheme lies the potential tension between proving to oneself and proving to others (respectively, ascertaining and persuading; Harel & Sowder, 1998). The scheme has been developed explicitly for exam-type proving questions (see Moutsios-Rentzos & Simpson, 2011), corresponding to well-known classifications, such as Weber's (2005) syntactic–semantic–procedural proof constructions, or the deep–surface–achieving/strategic approaches (Zhang, Sternberg & Rayner, 2012). Five strategies are identified organised in three types. In the  $\alpha$ -type strategies (A &  $\Delta_A$ ), the students demonstrate a need to first investigate whether the given statement makes sense. Once an ascertaining argument has been chosen, a persuading argument is employed, thus potentially separating ascertaining from persuading. In an A (alpha) strategy, the ascertaining argument is appropriately 'mathematised' to serve as a persuading argument, whereas in a  $\Delta_A$  (delta-alpha) strategy persuading appears to constitute a completely new process. In the  $\beta$ -type (B &  $\Delta_B$ ), the students immediately commence the persuading process, without pondering whether the given statement is meaningful to them or not. In a B (beta) strategy, the students attempt to recall either the proof of the statement or a proof that may serve as a template for proving the given statement, whilst in a  $\Delta_B$  (delta-beta) strategy, the students concentrate their efforts on producing symbolic mathematical expressions to construct an exam acceptable proof. Finally, in a  $\delta$ -type ( $\Delta_\Delta$ ; delta-delta), the focus is on producing a proof that would get the maximum grade in exams, through symbolic mathematical expressions based on a variety of means (including, theorems, images and examples). The students may investigate whether the given statement makes sense, but only for their facilitating their mathematical expressions producing pursuit.

In this study, emotions refer to a state of alertness that mobilises the human body with respect to a stimulus, including psychological and neurophysiological effects (Oatley & Jenkins, 1996). These emotions are clearly differentiated from the mentally processed, socially situated, affective reactions towards a proving situation (Hannula, 2012). Ekman identifies seven evolutionally derived basic emotions that are universally manifested in the humans' facial expressions (Ekman & Friesen, 1978): sadness, anger, contempt, fear, happiness, disgust, surprise. Thus, we attempt to map the reflexive affective exam-type proving experiences. Certain combinations of micro-movements of the facial muscles are linked with specific basic emotions as described in the 'Emotional Facial Action Coding System' (EMFACS; Ekman, Irwin & Rosenberg, 1994). Considering emotions and conviction, a positive affective state is linked with more superficial and/or authority-based judgements, whilst a negative/neutral affective state is linked with more thorough judgements, reducing the effect of authority (Oatley & Jenkins, 1996). Nevertheless, these studies mainly refer to judgements, rather than to multifaceted mental productions such as proof.

Overall, in this study, we discuss the proving cognitive and affective experiences of a mathematics undergraduate, Odysseus, as he deals with the exam-type proving question "Let a sequence  $(a_n) \in \mathbb{R}$ ,

$n \in \mathbb{N}$ . Prove that if  $(a_n)$  is convergent, then  $(a_n)$  is bounded” (‘convergent-bounded’). In Moutsios-Rentzos (2009), it was posited that the students’ general thinking preferences reveal aspects of their inner realities, thus affecting their initial strategy choices. Their back-up strategy choices indicate that the ineffectiveness of the initial attack lead them to re-evaluate the given situation and to choose a strategy that more appropriately fits with this new experience of the situation. In Moutsios-Rentzos and Kalozoumi-Paizi (2014), a small part of those data (of Odysseus) was subjected to additional analyses to illustrate the advantages of the synchronous mapping of cognitive and affective experiences as he dealt with six proving questions. In this study, we concentrate on only one task that Odysseus dealt with to elaborate on his affective-cognitive task-specific experiences.

### **Odysseus proving experience of the ‘convergent-bounded’ question**

Odysseus’ proving strategies were identified through video-recorded clinical interviews (in the sense of Ginsburg, 1981), in which he was asked to produce an exam-appropriate proof and to think aloud during that process. Since the focus was on the choice of means, Odysseus would be provided with any mathematical information (including definitions, figures) he would need (in line with Weber, 2001). During the think aloud process, his emotions were identified through the video-taped proof productions by an EMFACS trained and certified researcher. Following Ekman, all the emotions and emotional blends (more than one emotion in a single instance) were interpreted within the context they occurred. Finally, the Odysseus’ perceived internal and external reality is reported (by identifying his mathematics attainment, thinking dispositions and understanding of exam-acceptable answer) to gain deeper understanding of the findings.

### **Odysseus’ experienced realities: thinking styles and exam views**

Odysseus was an above average attaining, 2<sup>nd</sup>-year student, attending a 4-year BSc-equivalent degree in Mathematics in a Greek University. Considering Odysseus’ broader experienced internal or social realities, his thinking styles profile (i.e. his broad thinking dispositions; Sternberg, 1999) was identified as ‘ground breaking’ (expected to prefer creative, original and non-prioritised thinking; Moutsios-Rentzos, 2015). Considering his views about exams and exam-acceptable answers, Odysseus concentrated mainly on the peripheral aspects of their answer: the *amount of information*, the *language* used, the *structure* of the solution, and the *aesthetics* of the presented proof. Considering ‘amount of information’, he wondered: “*Hmm ... this is one of my greatest problems when I write down a solution ... should I ... Do I have to prove this? [...] and when I know something and it doesn’t have a name whether I should describe it ...*”. Considering ‘language’ and ‘structure’, Odysseus noted that an exam-type proof should be axiomatically based, written symbolically in a linear form, since a proof presented this way was considered to affect positively his grade. Furthermore, he was particularly concerned about the ‘aesthetics’ of the presented proof, stressing: “*Presentation is very important ... that is why I use draft first [...] If I had more time, I would spend 10 or 15 minutes on figuring out how exactly I would present it*”.

### **Odysseus’ Alpha (A) proving strategy to the convergent-bounded question**

In the following excerpt, Odysseus employs an Alpha strategy to deal with the ‘convergent-bounded’ question. He reads the question and then he tries to produce a ‘draft’ solution. Odysseus tries to ‘reconstruct’ the definition, ‘giving meaning’ (Pinto, 1998) to his concept image.

- Odysseus: I'll 'create' it ... I usually don't remember the formulas ... I 'create' them ... but ...
- Researcher: Do you want me to tell you the definition?
- Odysseus: Err ... in exams, if this [the interview] is a simulation [of exams] ... I would not remember it [the definition] ... I would try to 'create' it ...

Moreover, Odysseus draws upon his concept image to generate hypotheses and to validate these hypotheses. He conceptualises convergence as something 'constraining', evident both in his verbal and non-verbal communication, which suggests the meaningful interplay between concept image and concept definition (typical of an Alpha strategy).

- Odysseus: ... well these  $\varepsilon$  and  $n_0$  must have a relationship ... for every  $\varepsilon$  I should be able to find a  $n_0$  ... not the way I have put it ... [many gestures].
- Researcher: Do you say that based on your memory? Or ...?
- Odysseus: No! I don't say that based on my memory, I say it 'logically' ... I mean ... I say for every  $n > n_0$  there exists  $\varepsilon > 0$  so that  $|a_n - a_{n_0}| < \varepsilon$  ... this is what I have written ... [He makes gestures as he talks that 'show' what he talks about.] ... But this should be true for everything ... the  $\varepsilon$  ... there is a an infinite number of  $\varepsilon$  that are suitable ... this is true ... therefore I need something more 'constraining' ... therefore this [the writings] does not describe convergence, because convergence is something that is constraining ... it converges [gestures] to a specific number...

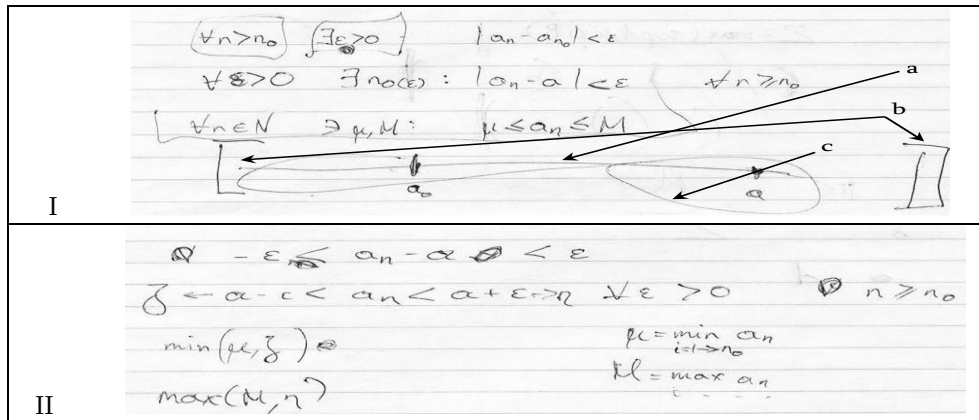

Furthermore, Odysseus' images are not pictorial, but 'fuzzy' and he likes to call them 'thoughts'.

- Researcher: Do you have a specific 'image' in your mind?
- Odysseus: No, I don't have it as a picture. I have it as ... I would call it 'thought'...

Once Odysseus is satisfied with the definitions of the mathematical notions included in the statement he is asked to prove, he focuses on proving it (see Figure 1, definition). For Odysseus, it is crucial that the statement that he wants to prove is what he terms as 'logical'; that it *makes sense*. He *needs* to be convinced that the statement makes sense, before he tries "to solve it".

- Odysseus: Convergent ... belongs to  $\mathbb{R}$  ... ok ... it begins from an  $a_0$  and it goes to something else [Gestures] ... therefore ... logically ... if it is let's say in a straight line ... it would be from here ... here there would be something that 'blocks' it ... unless it goes up and down ... but since it converges somewhere it will reach somewhere that ... it might follow a different route that might go like this or like that ... I don't mind ... it will reach here ... the route has an end ... and therefore ... it is 'logical' that it is bounded ... and so we will try to solve it.

In this process, Odysseus draws upon his concept image, which is evident from his gestures and figures: the straight line ('a', Figure 1) that denotes the real numbers and the boundaries he draws (on the left and right of this line; 'b', Figure 1); the curved lines ('c', Figure 1) denote the potential 'routes' the sequence might follow from ' $a_0$ ' (the first term of  $a_n$ ) to 'a' (the limit of  $a_n$ ).

**Figure 1: Odysseus' 'draft' definition (I) and answer (II)**

Odysseus builds on the above to 'solve' the question. He looks at the definition of the convergent sequence, expands the inequality using the property of the absolute value, reaches a double inequality and stops to explain his rationale:

Odysseus: [...] Until  $n_0$  it is a finite set ... so it would have to be a finite segment [He shows it on the curved lines] ... from  $\lambda$  to  $\kappa$  [gestures] ... and after that [ $n_0$ ] we have shown that they are all under  $a+\varepsilon$  for every  $\varepsilon$  I have chosen, right? ... so we have a big boundary that reaches to  $n_0$  and after that all will be bounded somewhere else ... they could be here [he shows segments with his hands] ... or there ... or inside ... so let this be  $\eta$  and this be  $\zeta$  [Figure 1] and we will have that the minimum ... it's not still a proof... we will have that the minimum of  $\mu$  and  $\zeta$  ... no value will be below this [minimum] ... where  $\mu$  is the minimum of  $a_i$ ,  $i$  from 1 to  $n_0$  ... and  $M$  is the maximum of  $a_i$  ... from these two [ $\mu$  and  $\zeta$ ] it will be the minimum value ... it cannot be less than this... similarly for the maximum ... now what I have to do is to write this mathematically, but *for me it is already finished*...

Odysseus' argument convinced him of the 'truth' of the statement he is asked to prove. As he presents his argument, Odysseus draws upon his concept image using gestures to generate and validate his argument. For example, for validation, Odysseus is certain of the validity of this 'proof': for him "it's already finished". His certainty appears to derive from his image manipulation and his gestures: at first, he notes that his argument "is not still a proof", but subsequently he claims that "it cannot be less than this". At the same time, he acknowledges that this argument cannot be *presented* as a proof and that he needs "*to write this mathematically*". His mathematised argument is close to the original argument and though the ascertaining argument draws upon his concept image, his mathematised argument is a 'translation' to a mathematically 'acceptable' language.

Finally, it is noted that, Odysseus' 'formal' proof was carefully structured like a textbook proof based in axioms and definitions (unlike the less linear, based on image manipulation 'draft' proof).

## Emotions in proving according to EMFACS

Time	Emotions (EMFACS; Ekman et al, 1994)	Excerpt	Answering phase
<b>'Draft' answer</b>			
12:59:84	Sadness	Researcher: So would you like to give it a couple of tries first and then ... Odysseus: Yes	Definition construction
14:27:00	Sadness-Anger	Odysseus: But this should be true for everything ... the $\varepsilon$ ...	
14:27:60	Sadness-Contempt		
14:56:64	Fear	Researcher: Do you have a specific 'image' in your mind?	
14:56:80	Happy -Fear	Odysseus: No, I don't have it as a picture. I have it as ... I would call it 'thought'...	
14:57:16	Happy		'Truth' investigation
17:11:03	Happy	Odysseus: and therefore ... it is 'logical' that it is bounded ... and so we will try to solve it	
21:54:24	Sadness-Anger	Odysseus: more or less I am done [...] How much time do I have left?	
<b>'Formal' answer</b>			
36:50:80	Sadness-Anger	Odysseus: How much time do I have left?	Beginning
37:04:88	Contempt	Odysseus: ...and in exams there are many similar problems [such as time constraints]	
39:22:72	Contempt-Anger	Odysseus: I'll write it in a different way ... it is not essentially different	Writing-up
44:03:24	Contempt-Anger	Odysseus: I'll write it down differently [instead of writing down two more lemmas]	
44:29:20	Happy-Contempt	Odysseus: In mathematics if you can avoid too many variables it is better, because ... in the end you get lost...	
45:09:96	Contempt-Sadness	Odysseus: Because I consider it [a theorem] as given... it might be silly of me, but ..	

**Figure 2: Odysseus, emotional journey to proving the 'convergent-bounded' task**

The results of the EMFACS analysis are outlined in Figure 2 along with the corresponding excerpt and answering phase. Odysseus' positive emotions are few, mainly linked with his mathematical ideas: when he describes them as 'thoughts' or when they make sense. His negative emotions or emotional blends are predominantly linked with his attempting to meet the requirements of an exam situation: time constraints, appearance, amount of information included in the formal answer. In line with the rationale of differentiating amongst different proving strategies, Odysseus' emotions can be differentiated between *internally referenced* (linked with his inner reality; Skemp, 1979) or *externally referenced* (linked with the perceived by Odysseus social reality of the given situation, including the exam-status of the given questions). For example, Odysseus in his 'draft answer' manifested an internally referenced 'happiness' emotion (17 min) when convinced of the truth of the statement (ascertaining): "It makes sense to me that it is bounded and so I'll try [to prove] it". In contrast, in the end of his 'draft answer', when he completed the persuading process, he expressed an externally referenced sadness-anger blend (21 min), because the moment he realised that "more or less I am done", he almost immediately wondered "How much time do I have left?". His emotional clash is in line with his cognitive clash due to his tendency for choosing more  $\alpha$ -type strategies (potentially differentiating ascertaining from persuading), linked with his ground breaking thinking styles profile (Moutsios-Rentzos, 2009).

## Concluding remarks

In this study, we investigated the proving strategy and the emotions of a mathematics undergraduate, Odysseus, as he dealt with an exam-type question. Skemp's theory of internal consistency and social survival helped in gaining deeper understanding of the concurrent phenomena. A complex proving reality was revealed, diversely affecting Odysseus' experiencing a need for constructing a proof (Zaslavsky, Nickerson, Stylianides, Kidron & Winicki-Landman, 2012). His negative emotions were linked with the externally experienced communication of the answer, whereas his positive emotions were linked with the internally referenced success in finding a proving argument. Emotions are *non-verbal, facially expressed reflexes*, indicating Odysseus' emotionally interiorising of his previous proving experiences. The presented approach complements existing studies based on language and/or introspection (Furinghetti & Morselli, 2009), by revealing the students' real-time emotional states. It is stressed that the identified emotions are affected by the thinking aloud protocol and, thus, a current project is focussed on identifying the students' emotions as they prove without thinking aloud and on their evaluating written proofs. Overall, the proposed line of research may help in designing pedagogies reinforcing the positive affective aspects of proving, thus promoting the students' deeper engagement with proving, which is expected to facilitate their developing a fully-fledged internal need for proof.

# Play and pre-proving in the primary classroom

Maria Pericleous<sup>1</sup> and David Pratt<sup>2</sup>

<sup>1</sup>UCL Institute of Education, United Kingdom; [mariapericleous19@gmail.com](mailto:mariapericleous19@gmail.com)

*This report focuses on a research study the aim of which is to investigate the activity of proving as constituted in a Cypriot classroom for 12-year-old students. By drawing on Cultural Historical Activity Theory, this study explores the way the teacher is working with the students to foreground mathematical argumentation. Analyses of video-recorded whole class discussions show how explaining and exploring provide a key pathway for the development of proving. We refer to these developments as pre-proving. However, inherent contradictions within explaining and exploring hinder the constitution of proving in the classroom.*

*Keywords: Proof, exploration, explanation, play, CHAT*

## Introduction

It is now acknowledged that proof and proving should become part of students' experiences throughout their schooling (Hanna, 2000, Yackel and Hanna, 2003, Stylianides, 2007). However, secondary school students as well as undergraduate students face difficulties when giving formal mathematical arguments. At the same time, research that shows how upper primary school students approach and construct proofs is still limited (Stylianou et al, 2009). It is also argued that argumentation, explanation and justification provide a foundation for further work on developing deductive reasoning and the transition to a more formal mathematical study in which proof and proving are central (Yackel and Hanna, 2003). But what is meant by proof and proving? Mathematical argumentation is a discursive activity based on reasoning that supports or disproves an assertion and includes the exploration process, the formulation of hypotheses and conjectures, explaining and justifying the steps towards the outcome and the proof of the statement. Thus, proof is at the core of mathematical argumentation, as a justification, an explanation and a valid argument.

Research has responded to the need to conceptualize proof and proving in such a way that it can be applied not only to older students but also to those in elementary school (Stylianides, 2007). The challenge remains however to understand how proof and proving is shaped by the practices in the mathematics classroom. This is in accordance with Herbst and Balacheff (2009), who argue that the focus should not only be on proof as the culminating stage of mathematical activity, but also on the proving process and how this is shaped by the classroom environment. Thus, in understanding how proving is constituted in the classroom, a wider network of ideas is required as these ideas no doubt have an impact on how proof in the narrow sense is constituted.

To address this issue, we refer to pre-proving, that aspect of mathematical reasoning that might nurture proving. What are the roots of proving? Given that proof is both a justification and an explanation, it can be argued that emphasis should be placed in these two aspects of mathematical reasoning. In considering those functions of proof that are considered important for school mathematics (Hanna, 2000), evidence has been reported that the establishment of sociomathematical norms (Yackel and Cobb, 1996) for explanation and justification (Yackel and Hanna, 2003) might foster deductive reasoning in the classroom. That is, describing, conveying and exchanging ideas through the act of communication, explaining and justifying statements influences

the appearance of proof and the transition from unsophisticated empirical arguments to the level of sophistication that might be expected at the tertiary level. It is through exploration and investigation that all these elements surface and develop in the process of proving. Thus, when discussing the roots of proving, exploration, which activates intuition and encourages thinking, constitutes another notion that should be taken into consideration. Thus, pre-proving refers to those elements that direct mathematical reasoning towards the ultimate goal of formal proving; that is exploration, explanation, justification and communication. In the social environment of the classroom, where hypothesizing, explaining and justifying conjectures is encouraged, the tools and tasks used, the rules of the classroom, the way the students work together, the way the teacher negotiates meanings and other external factors all interact, interrelate and influence each other in forming classroom activity. The purpose of this study is to explore pre-proving and proving in the elementary mathematics classroom and the way the structuring resources of the classroom's setting shape this process.

### **CHAT based theoretical constructs**

As this study is exploring the various forces that impact on the activity of proving, Cultural Historical Activity Theory (CHAT) is being employed as a descriptive and analytical tool alongside collaborative task design (a means of gaining access to the teacher's objectives), to capture the interaction of different levels, such as the actions of teachers, students and the wider field as evidenced in curricula and research documentation. The analysis and discussion in this paper draws upon the following CHAT perspectives: (i) the object of the activity and (ii) the notion of contradictions. Initially, the unit of analysis in CHAT is an activity, a "coherent, stable, relatively long term endeavor directed to an articulated or identifiable goal or object" (Rochelle, 1998, pp.84). The object of a collective activity is something that is constantly in transition and under construction, has both a material entity and is socially constructed and its formation and transformation depends on the motivation and actions of the subject indicating that it proves challenging to define it. Among the basic principles of CHAT is the notion of contradictions. Contradictions are imbalances, ruptures and problems that occur within and between components of the activity system, between different developmental phases of a single activity, or between different activities. These systemic tensions lead to four levels of contradictions (Engeström, 1987). This conceptualization, should be differentiated from mere problems or disorienting dilemmas from the subject-only perspective as they are more deeply rooted in a sociohistorical context (Engeström, 2001). Contradictions are important because they may lead to transformations and expansions of the system and thus become tools for supporting motivation and learning. This paper focuses on a primary contradiction on the teacher's object. The primary contradiction can be identified by focusing on any of the elements of the activity system (subject, tools, object, rules, community, division of labor). For instance, within the mathematics classroom, the clash between the teacher's goal of teaching a specific content of the mathematics curriculum and her need to continually manage student behavior and maintain focus, leads to a primary contradiction within the system's subject (the teacher).

## Data collection and analysis

This study was conducted in a year 6 classroom in a primary school in Cyprus. Apart from the researcher, the participants were the teacher, a Deputy Principal at the school who endorses the integration of technology in teaching mathematics, and 22 students (11-12 years old) of mixed abilities. Even though using computers was part of the classroom's routine, the students were not familiar with dynamic geometry environments, DGEs. The data collection process as relevant to this paper included video data from the classroom observations and field notes. The content of the curriculum covered during the classroom observations was the area of triangles, and the circumference and the area of circle. The overall process of analysis of the collected data was one of progressive focusing. According to Stake (1981, pp.1), progressive focusing is “accomplished in multiple stages: first observation of the site, then further inquiry, beginning to focus on relevant issues, and then seeking to explain”. The systematization of the data led to the evolution of two broad activities: (i) the activity of exploration including the exploration of mathematical situations, exploration for supporting mathematical connections and exploration of the DGE and (ii) the activity of explanation which focuses on clarifying aspects of one's mathematical thinking to others, and sometimes justifying for them the validity of a statement. These activities were then interpreted through the lens of CHAT, by generating the activity systems of both exploration and explanation. Achieving this also made possible the identification of tensions.

There is insufficient scope in this short paper to consider in detail these various levels and so this specific study focuses on illustrative episodes, which were generated during classroom discussion, to show one aspect of how the teacher was working with the students to foreground mathematical argumentation. To elaborate more, while the teacher was endeavoring to provide opportunities for exploration and investigation, it was observed that the teacher would sometimes interrupt this exploration. This interruption was often followed by the teacher either translating students' exploration as playing and/or was providing the step that needed to be followed. This paper focuses on the teacher using the word ‘play’ as part of the activity of exploration. The relevance of this emphasis of the paper lies in the connection that exists between exploration and play. That is, analyzing ‘play’ provides important information in portraying the activity of exploration and identifying the way this might influence the activity of explanation, and thus, shed light on how proving is constituted in the classroom.

## Results

This section provides a chronological overview of the protocols that illustrate the teacher intervening in the classroom by using the word ‘play’.

### Protocol 1

On the first lesson related with the area of triangles, the students are expected to say the area of rectangles presented on the interactive whiteboard and make explicit the way they worked towards the answer.

Teacher: 12 again ... but why are your playing? We are not doing something on the computers now. Stop.

In this protocol, the teacher is relating exploration of DGE with ‘play’. That is, exploration was interpreted by the teacher as ‘playing’ instead of learning.

### **Protocol 2**

After demonstrating on the interactive whiteboard how to construct a rectangle in which the triangle is inscribed, the students worked in pairs and constructed rectangles on a DGE. When they finished, the teacher asked:

Teacher: Now that you constructed the rectangles, can they help you to find the area of the triangles?

Students: Yes.

Teacher: What is the area of triangle PRS?

Student1: 3.

At this point, the teacher interrupted the classroom discussion as she was concerned with a student ‘playing’ with the computers.

Teacher: Student2 you are still talking. You are playing all the time and I will move you from the computers.

In this protocol, the teacher is relating exploration of DGE with ‘play’. That is, exploration was interpreted by the teacher as ‘playing’ instead of learning.

### **Protocol 3**

On the third lesson, after revising the mathematical formula for the area of triangles, the students would construct triangles with specific areas on the DGE. Before the teacher demonstrated to the class the steps followed so as to construct a triangle on the DGE, she said:

Teacher: Now we will go back to the DGE to play with its features. I will give you instructions and you will construct ... to see how it operates and then we will move on to a game where you will play in pairs on the computers online.

In this protocol, the teacher relates both exploration of the DGE, and playing a game on the computer with ‘play’, something encouraging and constructive.

### **Protocol 4**

On the first lesson related with circle, after defining circle, the class moved to the computers. Before engaging in tasks so as to explore mathematical relationships related with circle, the teacher introduced the class to a new DGE. Eventually, the teacher, referring to a circle presented on the DGE made the following comment:

Teacher: I can make it bigger or smaller. Look what we will do next. We will play later. Construct a circle and move it. Click on the center. Did you all do it? Nice. Stop.

This protocol focuses on the teacher relating exploration of DGE to ‘play’, something that has a positive value.

### Protocol 5

On the second lesson, after revising the definition of a circle, the teacher asked the students to tell her the mathematical relationships explored the day before. At this point, several students could not give an answer. The following comment comprises the teacher's interpretation of the hesitation these students had in participating in the classroom discussion:

Teacher: You shouldn't only play but concentrate and listen in the classroom.

In this protocol, the teacher is relating exploration of DGE with 'play'. That is, exploration was interpreted by the teacher as 'playing' instead of learning.

### Protocol 6

In the following part of the lesson, the class engaged in discussing ways in calculating the area of circle. Among the students' ideas was to count the squares inside a circle. However, it was concluded that this could prove difficult to achieve. Other students hypothesized that the area might be equal to circumference times radius. Others said that the area could be equal to circumference times diameter. The teacher encouraged them to investigate and test these hypotheses while exploring a task on a DGE, by making the following comment:

Teacher: I will leave you for a while to play.

In this protocol, the teacher is relating exploration of DGE with 'play'. That is, exploration is translated as something encouraging and constructive.

### Protocol 7

During the third lesson that followed the exploration of the mathematical formulas of the circumference and area of circle, the teacher asked the students to find the radius and area of a circle with a given circumference.

Student1: But how?

Student2: I do not understand.

At this point, the teacher interpreted the queries the students had as a result of 'playing' with the computers.

Teacher: We came up to some conclusions. We have been working on the computers for two days now. We should not only play but also find ...

Through classroom discussion, the students were able to use the mathematical formula, separate the variables, use division and find the radius and area of a circle with a given circumference.

In this protocol, the teacher is relating exploration of DGE with 'play'. That is, exploration was interpreted by the teacher as 'playing' instead of learning.

### Discussion

Analysis of the above protocols indicates that the word 'play' as used by the teacher has differing connotations. This leads to the emergence of two contrasting values, play/learn.

Initially, one value the word ‘play’ entailed was related with the teacher interpreting exploration as ‘playing’ instead of learning. That is, while the teacher would encourage the students to explore an activity in order to reach some conclusions, she would also make a negative comment about this exploration as something that had no didactical value. In protocols 1 and 2, the teacher is relating exploration of DGE that preceded the classroom discussion with ‘play’. That is, exploration was interpreted by the teacher as ‘playing’ *instead* of learning, though, in protocol 2, the student was still exploring the DGE, so as to construct the triangle. In protocol 5, the teacher translated the fact that some students could not really summarize the work which was done previously as ‘play’ instead of learning. Furthermore, in protocol 7, the teacher is relating the exploration of DGE (as in protocol 6 which is described subsequently) with ‘play’, something that has no didactical value. What is striking is the fact that the teacher is referring to the DGE tasks that were designed in collaboration with the researcher in such a way that could initiate the formation of hypotheses and mathematical argumentation. This intervention was followed by the teacher guiding the classroom discussion.

The word ‘play’ had an opposite value when used by the teacher to refer in a general way to the exploration of the activity. In protocols 3 and 4, exploring the features of the DGE and working in pairs for the construction of triangles, and investigation of mathematical relationships accordingly, is translated as something encouraging and constructive. What should be noted though for protocol 4, is that it appears that exploring the environment by following the teacher’s instructions has more value than the students exploring the environment themselves, which is called ‘play’. In protocol 3, the teacher announces that the students will have the opportunity to play a game on the computer. In this protocol, the word play is used with its authentic meaning, even though, from an educational and didactical perspective, it can be considered as a form of reflection, evaluation and further understanding. In protocol 6, the teacher is encouraging investigation and exploration of a mathematical situation that would lead to explanation and justification.

The ‘play’ dichotomy relates to the notion of the play paradox (Hoyles and Noss, 1992) and the notion of the planning paradox (Ainley et al, 2006). Hoyles and Noss (1992) introduce the notion of the play paradox to describe the multiplicity of paths that are available to students when using a tool in an exploration related with a mathematical task. That is, the students, through their exploration, might not encounter the mathematical ideas that were perceived as the objectives set by the teacher or the curriculum materials. Thus, the teacher may decide to close down an exploration opportunity as she may interpret students’ exploration as shifting away from her own objectives. In a similar way, Ainley et al. (2006) call the conflict that may occur in the daily mathematical classrooms, due to contextualize tasks as the planning paradox. This tension may also be related to the notion of ownership as perceived by Papert (1993) in his formulation of Constructionism. That is, while the students are provided with the necessary tools to participate and to take ownership of the learning process, the teacher is at the same time attempting to avoid facing these paradoxes.

Considering the dichotomy related with the word ‘play’ through the CHAT constructs, this tension is a manifestation of a primary contradiction. The primary contradiction that emerges is inherent in the component related with the object of the activity system. In the activity of exploring as part of pre-proving, the object for the teacher is related with exploring triangles and circles. At a first glance, this object seems to be clear and distinct. However, this object is multifaceted. To be more precise, the object for the teacher is related with the investigation of situations that lead to

conclusions related with the aforementioned parts of the mathematics curriculum. The teacher on one hand understands the importance of providing enjoyable exploring opportunities that keep students' motivation and interest to engage with the problem. As a result, the teacher provides opportunities that can be approached by the students in their own way. On the other hand, students, through the exploration of these opportunities are expected to reach those conclusions regarding triangles and circles as pre-determined by the teacher. The two poles of the object lead to a constant struggle in the teacher's everyday practice. The teacher, due to this multifaceted object, is faced with the play/learn dichotomy and thus the play and the planning paradoxes. That is, students' free exploration may lead to paths other than those expected by the teacher. This initially shows that the students share the teacher's object. Thus, the object related with exploring is being reached. However, if the exploration moves away from the teacher's motive, the teacher will inevitably close down the exploration opportunity and guide the students towards the exploration that leads to the conclusions that satisfy her. Time management and the pressure of the coverage of the curriculum further highlight this tension. Inevitably, even though closing down the exploration is necessary, the object will not be met because of this contradiction.

Manifestation of this contradiction leads to a clash between the activity of exploration and explanation and, subsequently, with the way pre-proving activity occurs in the classroom. It has been illustrated that pre-proving activity is closely connected with exploration and explanation. That is, those aspects of reasoning that appear to have the qualities of proving, even though they may not be proving in themselves, entail exploration and explanation that provide a point of reference for proof production. Correspondingly, the object of developing proving in the classroom is related with these notions. The object of the central system of pre-proving activity is related with exploration that leads to explaining and justifying for a specific part of the mathematics curriculum. However, closing down the exploration has an impact on how explanation and justification are established in the classroom. Furthermore, closing down an exploration opportunity may have a negative impact on the students' ability to approach the construction of a proof. Referring to exploration as 'play' may also have a negative impact on students' confidence in relying on their intuitions when exploring a situation.

## **Concluding remarks**

The aim of this paper was to shed some light on the area related with the activity of proving as constituted in the naturalistic setting of the mathematics primary school classroom. The elements that drive pre-proving activity and influence the way proving may be established in the classroom have been identified. That is, in mathematical argumentation, pre-proving is coming out of reasoning through exploring, explaining and justifying and can lead to proving. This paper reports on a teacher whose object is related with exploration that leads to explaining and justifying. However, this object is being conflicted as while a play-like exploration can facilitate learning, this can prove quite challenging for the teacher, as she wishes to maintain focus and is worried that exploring detracts from that focus. The contradiction between emphasizing exploring and maintaining focus is one of the tensions which make the constitution of pre-proving in the classroom inherently complex. However, this does not tell the whole story. Exploring opportunities that were closed down were exploited so as to negotiate and establish socio-mathematical norms in the classroom. As these norms are related with the very nature, functions and characteristics of

proof and proving, they can lead to explaining and justifying. Consequently, their establishment strengthens the activity of explanation and thus, the activity of proving.

# Proof-based teaching as a basis for understanding why

David Reid and Estela Vallejo Vargas

University of Bremen, Germany; [dreid@uni-bremen.de](mailto:dreid@uni-bremen.de), [vallejo@uni-bremen.de](mailto:vallejo@uni-bremen.de)

*The importance of proofs as a way to gain understanding has been observed many times. In this paper we show the result of two different experiences with division of natural numbers. The first comes from children in grade 3 who have learned about division and divisibility through what we call proof-based teaching (PBT), and the second comes from students who just finished their school studies and intend to become preservice primary teachers. Our main aim is to point out how different school experiences might lead to different (divergent) ways of gaining insight into the relationship between the divisor and the remainder. We particularly focus on describing some elements we identified in the third graders' instruction that might have allowed them to articulate their own understandings.*

*Keywords: Arithmetic, elementary school mathematics, number concepts, proof.*

## Proofs as a way to gain understanding

The goal of proof-based teaching is that students gain understanding through proving. Hence, it is based on past work on the role of proof as a means to understand or explain.

In mathematics education, explanation and understanding go together. The goal is understanding, so any explanation offered is aimed at having someone understand *why* a mathematical claim is true. This implies that a proof, to be useful in the classroom, should embody explanation. It should show not only that a result is true, but also *why* it is true. It should be concerned not only with its conclusion, but also with its main ideas, its overall structure, and its relationship to other mathematical fields and concepts (De Villiers, 2004; Hanna, 1990, 2000) (Hanna, 2016, p. 2).

Hanna (2016) discusses a number of different views of what makes a proof explanatory, but for our purposes, one aspect of these views is important. Explanatory proofs make reference to what we call a key notion, but which is also called a “characterizing property” or “salient feature”. “An explanatory proof makes reference to a characterizing property of an entity or structure mentioned” (Steiner, 1978, p. 143). “A proof can be explanatory only if ‘some feature of the result is salient’ and the proof builds upon that salient feature (Lange, 2014, p. 489, cited in Hanna, 2016, p. 4).

Elsewhere (Vallejo & Ordoñez, 2015; Reid, 2011) we have suggested that proof-based teaching (PBT), in which students learn mathematics through explanatory proving that builds on a shared body of knowledge, offers an opportunity for the development of relational understanding.

In the following we first elaborate on the elements of proof-based teaching based on our experience of a 3-year design research with third graders. We then show examples of the understandings of division of the third graders after a short unit of proof-based teaching instruction. Finally, we contrast these understandings with those of students who have completed secondary school and are about to begin university studies and draw some conclusions for teacher education.

## Proof-based teaching

Reid (2011) proposed proof-based teaching as “a way to develop understanding of mathematical concepts” (p. 28), and Vallejo has elaborated this idea in a 3-year design research intervention with third graders, the main goal of which was constructing division and divisibility knowledge.

The first intervention took place in 2013 in a Peruvian public school. This intervention was framed in the context of a master thesis (Ordoñez 2014) for which Vallejo was the supervisor. The second intervention took place in 2014 with a different group of third graders in the same public school. It addressed weaknesses identified in the first intervention through observing the difficulties students encountered in the lessons. We will report on the third intervention in the next section.

In the three interventions Vallejo taught all the sessions as a guest teacher in the classroom of another teacher. Written classwork assignments and quizzes were collected which helped the researchers to assess the students’ progress in their knowledge construction. All the sessions were videotaped, and significant parts of the first and third interventions were transcribed. In all three cases, the students had no prior knowledge of these topics at the time the interventions began as the goal was to see knowledge being constructed.

## Elements of proof based teaching

Through this research several elements of proof-based teaching have been identified as important: a ‘toolbox’ of shared knowledge, an expectation for explanation, and deductive explaining.

### The toolbox

In order to prove students must share a common set of accepted principles. A ‘toolbox’ of such principles is an essential feature of PBT and this also reflects the practice of professional mathematicians. We adopt the term “toolbox” from Netz (1999) who uses the term to describe the set of theorems and assumptions that are used in classical Greek proofs without explicitly referring to them. Thurston, (1995) describes the same phenomenon in contemporary mathematical practice:

Within any field, there are certain theorems and certain techniques that are generally known and generally accepted. When you write a paper, you refer to these without proof. ... Many of the things that are generally known are things for which there may be no known written source. As long as people in the field are comfortable that the idea works, it doesn’t need to have a formal written source. (p. 33)

In the interventions, Vallejo assessed prior knowledge through an individual diagnostic test, but more importantly, she established through a class discussion three “key notions” related to division and divisibility. These provided “a framework of established knowledge from which to prove” (Vallejo & Ordoñez, 2015, p. 231). The three key notions are:

Fair distribution: Distributions must give the same number of objects to each person.

Maximum distribution: The maximum number of objects possible must be distributed.

Whole distribution: Each person must receive a whole number of objects.

These key notions were the basis for the proof-based teaching of division and divisibility employing a mixture of written (individual and groups) tasks and class discussion.

## An expectation for explanation

From the very beginning, Vallejo's students were accustomed to being asked 'why?' for every conclusion they made or in general for every answer they gave based on the "key notions". "In the course of the sessions students also gave incorrect answers. Occasions of this type were exploited to promote discussion and justification by students since they were the ones who corrected the answers" (Ordoñez 2014, p. 334). She established in this way "an expectation that answers should be justified within this framework" (Vallejo & Ordoñez 2015, p. 231). It became part of the didactic contract (Brousseau, 1997) established in the classroom. In the context of proof-based teaching this is what we call an expectation for explanation.

## Deductive explanations

As part of the common 'toolbox' the whole class also shared an understanding of conjecture and justification, explained and modelled by the teacher, which was in tune with the meaning of proof given in A. Stylianides (2007). As part of the didactic contract the students knew that they could make as many conjectures as they wanted. The teacher wrote the students' conjectures at the blackboard to be analyzed by the whole class. But they were constantly reminded that in order for their conjectures to be upgraded to 'mathematical truths', they should provide strong support in the form of deductive arguments that were evaluated by the teacher.

## Third graders' understandings of division

We report here some results from the third cycle of the research design we discussed above. This intervention took place in a public school in Peru, in 2015, with a group of 21 third graders (7-8 years old). The intervention consisted of 23 sessions, each of them made of around 90 minutes. It was session 3 when these third graders discovered the relation between remainders and divisors and explained the relation using the key notions through a whole class discussion.

At the end of the intervention (session 23), the third graders were given a final test, including two items related to remainders:

Is it true that in a division by 4 we can have a remainder of 6? ☐ Yes ☐ No Justify your answer.

In a whole, fair and maximum distribution among 5 people, how many objects may be left over at most? Why can no more objects be left over? Justify your answer.

These two items were number 8 and 9 on a test with 11 items. We report here on the children's responses to these two items, which are summarized in Table 1.

	First Item	Second Item
Correct answer with explanation	9 (43%)	12 (57%)
Correct answer with unclear explanation	2 (10%)	2 (10%)
Correct answer with no explanation	1 (5%)	1 (5%)
Incorrect answer	1 (5%)	3 (14%)
No response or question misunderstood.	8 (38%)	3 (14%)

**Table 1: Summary of results from the third graders' test**

Of the 21 children, 12 (57%) answered the first question correctly and 15 (71%) answered the second question correctly. Most of those who answered the second question correctly were also able to give an explanation. Their answers are based on a relational understanding of division, bringing together knowledge of the key notions they learned and experience with explanatory proving in this context.

For example, Bruno answered the first question “No. Because if we divide by 4 the remainder is at most 3, and 6 is more than 3”. This shows that he understands why the answer is no, and can explain by making reference to specific knowledge about division by 4, and implicitly to a general rule concerning the maximum remainder possible. Some children who answered the first item correctly (2 of the 12) provided a similar explanation, although their knowledge of the possible remainders when dividing by 4 was faulty. For example, Eduardo wrote “No, because in a division by 4 the only remainders are 1, 2, 3”. Eduardo omits one possible remainder, but his explanation is still appropriate, as he points out that 6 is not among the possible remainders in a division by 4.

On the second item, Max answered “Question 1: 4 can be left; Question 2: because I can keep distributing (objects)”. His answer shows his understanding of why the remainder cannot be more than 4 when distributing objects among 5 people. Although he does not refer to the condition by name (maximum distribution), he uses a condition that makes reference to it (“because I can keep distributing objects”) as the question makes reference to cases in which the maximum number of objects has not yet been distributed. Max’s answer is an example of the kinds of arguments they were able to produce.

Similarly, Renato’s answer “There can be at most 1, 2, 3 and 4 left over. More objects can’t be left over because it wouldn’t be (a) maximum (distribution)”, shows he understands why the maximum value for the remainder in a division by 5 is 4. He is actually the only student who makes explicit reference to this condition by its name in his written work. Even though Renato’s answer is incomplete (he doesn’t consider the remainder zero) his explanation is correct. The use of this common toolbox was consistent in this intervention.

From the very beginning Vallejo invited the students to share their ideas orally, and they seemed to feel comfortable to communicate in this way. However, some students had troubles with their writing skills while communicating their ideas individually, though they could still share well-thought ideas orally. Hence, after the final test Vallejo decided to interview some of the students who had performed well in whole class discussions, but not so well on the written tasks. These semi-structured interviews revealed that some students who had not given explanations had not understood the questions being asked. For example, Piero had answered the first test item by giving an example of a division by 4 that does not result in a remainder of 6. He did not understand that the question refers to dividing by 4 in general. When Vallejo asked the same question in the interview, he answered “No, because if there would be 6 left over, it would be 6 divided by 4, and I must continue distributing (objects)”. Like Piero, most of the students who gave an answer classified as “Question misunderstood” showed in the interview that they had not understood the question in the first item. However, when the question was clarified and they were given time to reflect, most were able to provide reasons.

We feel that the explanations given by the third graders demonstrate a relational understanding of divisibility, which arose through the proof-based teaching they experienced. We have not (for practical and ethical reasons) attempted to make a comparison with a matched group of third graders taught about divisibility in another way. Instead, in the next section we compare their understandings with those of students at the end of secondary schooling, who have had many other opportunities to develop their understandings of division.

## University students' understandings of division

We analyze here the answers given on a diagnostic test given at the beginning of university studies to 148 students enrolled in primary level teacher education. These students were enrolled at a private university and had received a government scholarship to support their teacher education. Hence, they can be assumed to be among the best students enrolling in primary level teacher education. Around 65% of these students came from the capital city, Lima, where the university is located, and the other 35% came from the other parts of Peru. The test was given prior to any instruction at the university, which means that it assessed only the understanding the students retained from their school experience.

The students were asked the following question: "In a division of natural numbers with the divisor equal to 3, what are all the possible values the remainder can take? Why?" To ensure that the terminology used in the question was understood, the question was accompanied by the diagram shown (which is a translation of the real one) in Figure 1.

**Remember that in every division:**

Dividend	Divisor
(Remainder)	Quotient

**Figure 1: Reminder included with the question**

The task presented to these students is not exactly the same as presented to the third graders. This reflects the background knowledge of these two different groups. In the case of the prospective teachers, they were not familiar with the language fair, whole and maximum distributions and the third graders were not introduced to the terms dividend, divisor, or quotient. Despite that, one can see that both tasks ask for the same knowledge about the divisor and remainder relationship.

Table 2 summarizes the results from the pre-service teachers.

	Correct answer	Partially correct	Incorrect answer	No response
With explanation	9 (6%)	1 (1%)		
Reference to a general rule	25 (17%)	11 (7%)		
Without explanation	21 (14%)	13 (9%)	38 (26%)	30 (20%)

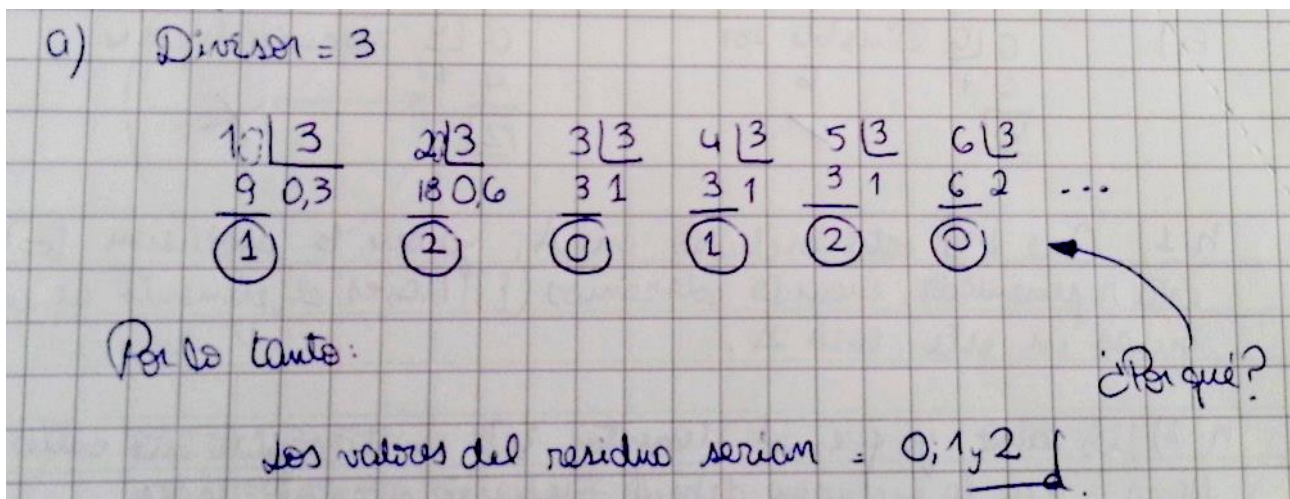

**Table 2: Summary of results from the pre-service teachers' diagnostic test**

A correct answer was given by 55 (37%) of the pre-service teachers. But of these only 9 gave explanations that show they understood the reason why the remainder must be 0, 1 or 2. For

example, Elizabeth wrote “It can only take values less than 3, in this case they would be (0, 1, 2)  $x < 3$ , because a number multiplied by 3 cannot be less than this. (x: Remainder)”.

Among those giving a correct answer the most common way to answer the question “Why?” was by reference to a rule such as “the maximum remainder is one less than the divisor’s value” or “the remainder is always less than the divisor”. These answers may reflect understanding, but the rule may have been memorized without understanding. The remaining 21 responses include no explanation, an unclear response, or empirical evidence as “explanation”. Figure 2 shows a response of this last kind. Note that the divisions are of small numbers, but were done using a standard algorithm. In the first two cases, the dividends 1 and 2 were treated as if they were 10 and 20 for the purpose of determining the remainder, although the first decimal place of the quotient is worked out as if 1 and 2 are being divided. The pre-service teacher writes “Por lo tanto:” [Therefore] suggesting she feels that her six examples are sufficient to explain her answer. She also wrote “¿Por qué?” [Why?] with an arrow pointed to her examples, which is consistent if she believes these examples answer the question. It seems she was not able to provide a mathematical explanation.

**Figure 2: A pre-service teacher’s response, showing a correct answer without an explanation**

Another 25 (17%) pre-service teachers gave partially correct answers (listing two of the three remainders, or listing 0 and 3 as distinct possibilities resulting in four remainders), 38 (26%) gave incorrect answers and 30 (20%) gave no answer. Overall, the responses of the pre-service teachers show an instrumental understanding (in the sense of Skemp, 1987) of division and limited number sense. Only 46 could give an explanation or cite a general rule and most used procedural approaches to determine the possible remainders in spite of the small numbers involved.

## Conclusions

We do not claim that this comparison replaces an experimental design with a control group, but this was not a goal of our design based research in any case. Nevertheless, it does offer some food for thought. One might expect that adults at the conclusion of more than a decade of schooling would have had many opportunities to develop concepts related to division, a basic operation in arithmetic and one that is basic to understanding of rational numbers and algebra. Why compare them with children who have had only twenty-three lessons on the topic? What we wish to compare are the

two different school experiences with division of natural numbers these two groups have had. Most of the preservice teachers can be assumed to have had a typical school experience in mathematics. That the third graders have a better understanding of division we feel reflects the non-traditional learning context they experienced, that allowed them to make sense of division. We strongly believe that proof-based teaching was important in their achievement of this understanding, but further research is needed to confirm this.

However, this comparison also raises an important question for teacher education. If, at the conclusion of secondary school, future primary school teachers do not understand basic concepts related to division, will they be able to guide children in the development of these concepts? If they are to develop these concepts as part of their teacher education, how can this best be done? Clearly the approaches taken in their schooling were unsuccessful. Our current research focusses on such pre-service teachers, and explore whether a proof-based teaching intervention at the university level can allow adults with instrumental understandings to develop relational understandings.

# Mathematical reasoning in the written argumentation of primary students

Silke Ruwisch

Leuphana University Lüneburg, Germany

[ruwisch@uni.leuphana.de](mailto:ruwisch@uni.leuphana.de)

*In Germany, there is increasing interest in language competences in mathematics lessons. Based on national curriculum standards, argumentation should also be strengthened in primary school mathematics classes (KMK, 2005). The reported interdisciplinary (linguistics and mathematics education) study on reasoning presents a model to rate arithmetic reasoning competences at primary level, in which mathematical reasoning and its linguistic realization are separately coded. In a pilot study, 243 third, fourth, and sixth grade students solved a number of arithmetic reasoning tasks. The results support a one-dimensional scale for the model of reasoning; its components identify differentiated requirements, which are formulated concretely in the coding guidelines and may point to didactical potential for language support in mathematical reasoning itself, as well as in mathematics lessons at primary level.*

*Keywords: Reasoning, written argumentation, primary school.*

## Reasoning in early mathematics learning

Early mathematical argumentation can be divided into four steps: detecting mathematical regularities, describing them, asking questions about them and giving reasons for their validity (Bezold & Ladel, 2014; Meyer, 2010; Bezold, 2009; Wittmann & Müller, 1990). The content base for argumentation is achieved by description of the detected structures or by reference to common knowledge (Krummheuer, 2000); reasoning is then needed to verify the described regularities as true (Toulmin, 2003/1958; Schwarzkopf, 1999).

The didactical value of reasoning in mathematics learning lies in gaining deeper insights into mathematical structures, so developing one's mathematical knowledge. In this sense, reasoning leads to questions about mathematical statements to ensure their correctness and to develop new mathematical connections (Steinbring, 2005). Two intertwined processes can be distinguished: one's own understanding and the process of sharing this understanding with others. In most cases, these processes don't occur separately, but are the response to cognitive-social needs (Harel & Sowder, 2007; Hersh, 1993). It follows that, in its epistemic function, mathematical reasoning may be monologic in leading to deeper individual understanding; in its communicative function, where mathematical structures are explained and justified, it is dialogic and dependent on other people (Neumann, Beier & Ruwisch, 2014; Ruwisch & Neumann, 2014).

In primary classrooms, mathematical reasoning usually occurs in the form of oral communication between pupils and in interactions with the teacher. These communicative processes have been widely studied. From an epistemological perspective, the emergence of shared knowledge and its structures has been described (e.g. Steinbring, 2005) while a more interactionist perspective traces the type and structure of argumentation in classroom interactions (e.g. Krummheuer, 2015).

Mathematical reasoning in this sense must be distinguished from reasoning in language classes, especially at primary level. While both are seen as concepts that develop out of situated everyday (“vernacular”) speech (Elbow, 2012), reasoning in language learning focuses much more on self-evident facts and personal meanings than on provable structures in special content areas. It follows that argumentation in language learning leads to more addressee-oriented cognitivization (Krelle, 2007), as reasoning of this kind is much more about persuasion than proving. Nevertheless, typical linguistic forms of reasoning are learned in these everyday situations, and students must learn how to use these in different content areas (e.g. Wellington & Osborne, 2001; Lemke, 1990). So, in combining mathematical and linguistic views of early reasoning, we can hope to gain a broader and deeper understanding of early reasoning.

While most age-related studies of primary students focus on oral communication, experts in language learning emphasise writing as an important instrument for deepening individual understanding (Becker-Mrotzek & Schindler, 2007; Pugalee, 2005; Galbraith, 1999; see also Wellington & Osborne, 2001; Morgan, 1998; Miller, 1991). Although primary school children are not yet expert in writing, fourth-graders are capable of constructing expository texts with a relevant number of causes in elaborating a topic (Hayes, 2012; Krelle, 2007). It may therefore be fruitful to look at their written argumentations, and especially at how they offer reasons for mathematical regularities (Ruwich & Neumann, 2014; Fetzer, 2007).

## Modelling written mathematical reasoning

To investigate children’s written reasoning, we developed a theoretical model that combines mathematical and linguistic aspects of reasoning (Ruwich & Neumann, 2014; Neumann, Beier & Ruwich, 2014).

### Arithmetic reasoning tasks

Following the four steps of argumentation in primary mathematics (see above), we decided to give the children an already structured situation (see Figure 1), which explicitly requires detection, transfer and description before offering reasons for the validity of their suggestion.

<p>a) <math>18 + 10 = \underline{\quad}</math>   b) <math>36 + 20 = \underline{\quad}</math>   c) <math>52 + 40 = \underline{\quad}</math>   d) <math>87 + 30 = \underline{\quad}</math>  <math>8 + 20 = \underline{\quad}</math>   <math>26 + 30 = \underline{\quad}</math>   <math>42 + 50 = \underline{\quad}</math>   <math>77 + 40 = \underline{\quad}</math></p> <p>Erfinde zwei weitere Päckchen, die zu den anderen passen.</p> <p>e) <math>\underline{\quad} + \underline{\quad} = \underline{\quad}</math>   f) <math>\underline{\quad} + \underline{\quad} = \underline{\quad}</math>  <math>\underline{\quad} + \underline{\quad} = \underline{\quad}</math>   <math>\underline{\quad} + \underline{\quad} = \underline{\quad}</math></p> <p>Vergleiche die Aufgaben im Päckchen. **Figure 1: Complex addition task (CA) as a sample item**  
**(left: original version; right: English translation)**

For the purposes of this study, four different arithmetic tasks were designed. Although differing in complexity of regularities, all of these tasks focused on detection and reasoning and were easy to compute. Format ZF involved three number sequences to be continued: +9, +7, and +2n. Format EA asked the children to continue a given additive structure by increasing all three summands by one so that the sum increases by three. In solving formats CA and CM, the children had to identify two

structures at the same time. To answer the complex addition task in Figure 1, the children had to find two tasks with the same sum. At the same time, they had to take into account that the summands must be changed by 10 in opposite directions. The multiplication tasks (CM) showed a constant difference in the product caused by the difference between the multipliers while the multiplicands remained constant.

### Sample

The data include 477 justifications written by 243 students. In total, 41 third-graders (♀21; ♂20), 96 fourth-graders (♀43; ♂53) and 106 sixth-graders (♀52; ♂54) worked out two of the four arithmetic reasoning tasks.

### Data analysis: Theoretical model of rating scales

The separate evaluation of mathematical and linguistic aspects of reasoning is fundamental to our model, which we assume allows differentiated exploration of the sub-skills of reasoning. We also wish to check whether experts in either domain (mathematics teachers and German language teachers) differ in their evaluations. As our tasks demanded both computing and continuation of a given structure (see Figure 1), competencies involving detection of a mathematical structure are distinguished from ability to offer reasons for its validity. Students' writings are rated by one detection scale and two reasoning scales (see Table 1).

*Mathematical detections:* Children were required to compute the arithmetic tasks on the sheet to identify the underlying structure and transfer it to two further packages of tasks. This process might be realised fully or only partly; sometimes, only irrelevant aspects were used to create new tasks. If the structure is transferred fully, the results of the given tasks are also correct, and three levels of this rating scale therefore seemed sufficient. This scale will not be discussed in the following application of the model, as it provides little information about reasoning skills.

Mathematical detections	Mathematical aspects of reasoning	Linguistic aspects of reasoning
irrelevant aspects as regularities	regularities (partially) described	indicators without reason-effect structure
.....	rudimentary reasoning	reason-effect structure
regularities partly transferred	reasoning through examples	explicit linguistic reference to the task
.....	partially generalized reasoning	completeness and consistency
regularities totally transferred	generalization/ formal reasoning	use of math. terminology/ decontextualization

**Table 1: Rating-scales to evaluate written mathematical reasoning**

*Mathematical aspects of reasoning:* Mathematical reasoning must be based on a description of mathematical elements. If only some regularities are described without giving reasons, this is coded as level 1. If rudimentary reasoning is given in addition to a description, the work is coded as level 2. To be rated as level 3 to 5, all relevant aspects must feature in the argumentation. If this is done

by use of examples, the work is rated as level 3; if already partly generalized, it is rated as level 4; and if it is totally general or constitutes a formal proof, it is rated as level 5.

*Linguistic aspects of reasoning:* Realisation of a mathematical argument by written language is also rated in terms of five levels, defined in terms of use of connectors and identifiable coherence of the text. If explicit linguistic indicators are used without any structured reasoning, the text is classified as level 1. If the text shows a reason-effect structure, it is coded as at least level 2. If explicit linguistic reference to the tasks is also included, the text is classified as level 3. A level 4 text shows consistent and complete argumentation. To achieve level 5, there must also be use of mathematical terminology for identifiable decontextualization.

### Process of coding

Each written argumentation was assessed by at least four raters; while preservice mathematics teachers concentrated on the mathematical scales, German language teachers rated the linguistic aspects. There was 62% absolute agreement in the judgments across all tasks and scales. Deviations of more than one stage occurred in 8% of cases—mainly for linguistic ratings, which were reported as more difficult. Coding quality could be seen to increase during the course of the project. Although there were acceptable internal consistencies across all tasks (Cronbach's  $\alpha = .80$ ), these values increase if only ZF ( $\alpha = .82$ ) and EA ( $\alpha = .84$ ) (which were used later in the project) are considered.

By excluding the multiplication task for the following overall scaling, an acceptable average internal consistency of individual scales was achieved for the remaining tasks ( $\alpha = .86$  for mathematical detections,  $\alpha = .81$  for mathematical aspects of reasoning and  $\alpha = .71$  for the linguistic aspects of reasoning).

### First results

Given the number of raters and in the interests of acceptable inter-rater-consistency ( $\alpha > .70$ ), the following results are based on the means of ratings.

### Overall scale

The IRT scale for the three tasks and all texts shows a common scale across all components (see Table 2). As items also conform to the model (WMNSQ .85-1.09), early mathematical reasoning in arithmetic as measured by the three tasks and ratings on our scales can probably be described as a one-dimensional construct. Looking at the three scales, it becomes clear that, as expected, it is easier to detect and transfer mathematical structures than to give reasons for their validity (negative deviation from zero). Comparing the two reasoning scales, it seems easier to realise mathematical aspects of reasoning than to find an appropriate linguistic structure. At the same time, the most stable dimension is *mathematical detections*, with a maximum difference of .783 as compared to 1.446 for the *linguistic aspects of reasoning* and 1.516 for the *mathematical aspects of reasoning*.

Comparing the three tasks, it seems that complex addition is the most difficult to transfer; simple addition and number sequences show almost no difference. The justifications show that it was easiest to realise both mathematical and linguistic aspects of reasoning in the number sequence tasks, followed by complex addition and then simple addition. Granted these differences, all tasks can be characterised as suitable for capturing mathematical reasoning in arithmetic.

Item	Mathematical detections		Mathematical aspects of reasoning		Linguistic aspects of reasoning	
	Estimate	WMNSQ	Estimate	WMNSQ	Estimate	WMNSQ
(ZF) number sequences	-1.556	1.02	-0.459	1.06	0.124	0.85
(EA) simple addition	-1.628	1.09	1.057	1.09	1.570	0.93
(CA) complex addition	-0.845	0.98	0.506	0.92	1.230	0.97

**Table 2: Item parameters (estimated) for IRT scaling**

### Student performance

Performance of the total sample is distributed normally to slightly right-shifted. On the raw scores level, 21.2% are one standard deviation above the mean; 9.6% are one standard deviation below; 6.2% are two standard deviations above; and 4.2% are two standard deviations below.

To facilitate comparison of the three groups of students, all scores were transposed to a scale with mean 100 and standard deviation 20. Figure 2 shows almost the same mean performance across third-graders ( $M = 102$ ,  $SD = 29$ ), fourth-graders ( $M = 98$ ,  $SD = 19$ ) and sixth-graders ( $M = 101$ ,  $SD = 17$ ).

Unexpectedly, reasoning competences seem not to increase over time. Interpreting the differences in standard deviations across the three groups, it seems that third-graders differ more within their group than fourth-graders, and both differ more than sixth-graders, suggesting homogenization during schooling. However, the relatively limited data and lack of comparative data means that any general conclusions remain speculative.

**Figure 2: Student performance by grade**

### Discussion of the model by application to examples

Five examples are presented here for deeper discussion of the model's adequacy (see Table 2). As it might prove difficult to discuss the argumentations only in the translated version, the original sentences are included on the left.

*Mathematical aspects of reasoning:* The child in example 1 has recognized that “something” is the same and “something” has changed. However, as he/she does not refer to any connection between the tasks or mention that the results are the same, this answer was coded as level 1. Examples 2 and 4 were coded as level 2; in example 2, it is clear that the child focused on only one of the two

relevant aspects. It is arguable whether child 4's argumentation is complete; as it is confined to one example in the task, it might be evaluated as level 3. In our opinion, the change of the summands in opposite directions is only implicit in "that's always 10 less". Answer 5 shows both connections clearly. Furthermore, the child is able to conclude (using an example) that the results must be the same, and so it is clearly to be coded as level 3. As child 3 is doing almost the same but also exhibits some generalization in using "always", we coded this as level 4.

1) es sind immer die gleichen Aufgaben nur umgedreht weil wenn man es rechnet merkt man das.	The tasks are all the same but vice versa because if you calculate, you'll realize it.
2) Es sind immer 10 mehr und 10 weniger.	It's always 10 more and 10 less.
3) Dass es die gleichen Ergebnisse sind, kommt davon, weil bei der einen Aufgabe immer 10 weniger sind als bei der anderen. Aber bei der Aufgabe wo 10 weniger sind, ist die Zahl die noch dazu gerechnet wird wiederum 10 größer als die über ihr.	The results are the same because in one task it's always 10 less than in the other one. But in the task that has 10 less, the number to be added is 10 bigger than the one above.
4) Das es immer 10 weniger sind. Zum beispiel $18+10=28$ aber wenn man 10 weg nimmt und in der mitte 10 dazu nimmt z.b. $8+20=28$ und dann kommt das gleiche ergebnis wie bei der 1. Aufgabe	That's always 10 less. For example, $18+10 = 28$ . But if you take away 10 and put 10 in the middle—for example, $8+20 = 28$ —then you'll get the same result as in the first task.
5) mir fällt auf das immer die Ersten 2 Ergebnisse gleich sind. Die Ersten zwei Ergebnisse sind gleich weil die bei zum beispiel a) $18+10=28$ und dann haben die bei $8+20$ einfach 18, 10 weniger 8, und bei 10 zehn mehr, $10-10$ ist 0, also bleibt das so	I notice that the first two results are always the same. The first two results are the same, because, for example a) $18+10 = 28$ , and then at $8+20$ it's simply 18, 10 less 8, and at 10 ten more, $10-10$ is zero, so it remains the same.

**Table 3: Examples of written argumentation for the arithmetic sample item**  
(left: original version; right: English translation)

*Linguistic aspects of reasoning:* Example 1 is coded as level 2 because as well as the comparative connector "because", a link between the sentences is also given. As example 2 includes only the indicator "always", without any link, it is coded as level 1. Examples 3 and 4 are coded as level 4 because there is a clear reasoning structure as well as a link to the tasks. As the argumentation in example 5 is ambiguous, and the language used is imprecise, it is coded as level 3.

## Conclusion

The model was again presented for discussion here to improve its didactical value in evaluating the written reasoning of fourth-graders. Although our descriptions in the coding book have continued to improve over time, there are still deviations of more than one level between raters. While we wish of course to develop the model for its psychometric interest, the levels should also help teachers to evaluate written reasoning.

Although these tasks provide a good deal of information about children's written reasoning, we have to be aware that because they focus on products collected in a test situation, the argumentation was necessarily ad hoc. As requests of this type are not part of students' normal mathematics lessons, and they do not have time to restructure their texts, neither the requisite procedural knowledge for writing nor situated mathematical argumentation can be grasped in this way. It follows that competence in mathematical reasoning—even in written form—may be higher than is indicated by the results to date.

# An expanded theoretical perspective for proof construction and its teaching

John Selden<sup>1</sup> and Annie Selden<sup>1</sup>

<sup>1</sup>New Mexico State University, Department of Mathematical Sciences, New Mexico, Las Cruces, U.S.A.; [jselden@nmsu.edu](mailto:jselden@nmsu.edu), [aselden@nmsu.edu](mailto:aselden@nmsu.edu)

*This paper presents a theoretical perspective for understanding and teaching university students' proof construction. It includes features of proof texts with which students may be unfamiliar. It considers psychological aspects of proving such as behavioral schemas, automaticity, working memory, consciousness, cognitive feelings, and local memory. We discuss proving actions, such as the construction of proof frameworks that could be automated, thereby reducing the burden on working memory and enabling university students to devote more resources to the truly hard parts of proofs.*

**Keywords:** Proof construction, behavioral schemas, automaticity, consciousness, feelings.

## Introduction

We report an expanded theoretical perspective to better notice, understand, and alleviate difficulties of university students' proof construction including: features of proof texts, types of proofs, situation-action links, behavioral schemas, automaticity, non-emotional cognitive feelings, and local memory. Most difficulties were observed and documented during a 10-year teaching experiment—a proof construction course. Our explanations call on the psychological as well as the education literatures. Local memory (Section 4.10) arose from observing our own proving experiences.

## Features of proof texts

The proving process involves many more actions (both physical and mental) than appear in the final proof text (e.g., Mamona-Downs & Downs, 2009; Selden & Selden, 2016). Indeed, researchers have distinguished argumentation from proof, noting that an informal line of reasoning may “justify” a theorem to the prover’s satisfaction, but this often differs from the corresponding final proof text written to the standards of the mathematical community (e.g., Pedemonte, 2007).

## The genre of proofs

Students sometimes find the manner in which proofs are written perplexing, as it is often at variance with other genres of writing. We have identified some significant features that generally occur in proof texts: (1) Proofs are not reports of the proving process. (2) Proofs contain little redundancy. (3) Symbols are (generally) introduced in one-to-one correspondence with mathematical objects. (4) Proofs contain only minimal explanations of inferences, that is, warrants are often left implicit. (5) Proofs contain only very short overviews or advance organizers. (6) Entire definitions, available outside the proof, are not quoted in proofs. (7) Proofs are “logically concrete” in the sense that quantifiers, especially universal quantifiers, are avoided where possible. (Selden & Selden, 2013a).

## Structures of proofs

A proof can be divided into a formal-rhetorical part and a problem-centered part. The *formal-rhetorical* part is the part that depends only on unpacking the logical structure of the statement of

the theorem, associated definitions, and earlier results. In general, this part *does not* depend on a deep understanding of the concepts or genuine problem solving in the sense of Schoenfeld (1985, p. 74). We call the remaining part of a proof the *problem-centered* part. It *does* depend on problem solving, intuition, heuristics, and understanding the concepts involved (Selden & Selden, 2011).

### Proof frameworks

A feature that can help write the formal-rhetorical part of a proof is what we call a *proof framework*, of which there are several kinds, and in most cases, both a *first-* and a *second-level* framework. For example, given a theorem of the form “For all real numbers  $x$ , if  $P(x)$  then  $Q(x)$ ”, a first-level proof framework would be “Let  $x$  be a real number. Suppose  $P(x)$ . ... Therefore,  $Q(x)$ ,” with the remainder of the proof ultimately replacing the ellipsis. A second-level framework can often be obtained by “unpacking” the meaning of  $Q(x)$  and putting the second-level framework between the lines already written for the first-level framework. Thus, the proof would “grow” from both ends toward the middle, instead of being written from the top down.

### Operable interpretations

Another feature that can help write the formal-rhetorical part of a proof is converting definitions and previously proved results into *operable interpretations*. These interpretations are similar to Bills and Tall’s (1998) idea of operable definitions. For example, given a function  $f: X \rightarrow Y$  and  $A \subseteq Y$ , one defines  $f^{-1}(A) = \{x \in X \mid f(x) \in A\}$ . An operable interpretation would say, “If you have  $b \in f^{-1}(A)$ , then you can write  $f(b) \in A$  and vice versa.” One might think translation into an operable form would be unnecessary or easy especially because the symbols in  $\{x \in X \mid f(x) \in A\}$  can be translated into words in a one-to-one way. But for some students this requires practice.

## Dimensions of potential proof construction difficulty

### The need for previous results—proof types: 0, 1, 2, 3

We have classified theorems of increasing difficulty to refine our inquiry-based “proof course” notes (Selden & Selden, 2013b). *Type 0* often follows immediately from definitions. *Type 1* may need a result in the notes. *Type 2* needs a lemma, not in the notes, but relatively easily to discern, formulate, and prove. For *Type 3*, at least one of discern, formulate and prove should be difficult. A sample *Type 3* theorem is: *A commutative semigroup  $S$  with no proper ideals is a group*, when provided only the definitions of semigroup and ideal. One needs to observe that, for  $a \in S$ ,  $aS$  is an ideal, so  $aS = S$ . This implies equations of the form  $ax = b$  are solvable for any  $b \in S$ . Using some clever instantiations of this equation, one can obtain an identity and inverses, and conclude  $S$  is a group.

### The need for unguided exploration

In constructing some proofs, one may reach a point where there is no “natural” way forward. In what we call *unguided exploration*, one may need to find, or define, an object and prove something about it, with no idea of its usefulness, that is, one may need to “explore” the situation. For example, in proving the above semigroup theorem, this can happen three times. First, one notes  $aS$  is an ideal and thus  $aS = S$ . Then one sees equations of the form  $ax = b$  are solvable for any  $b \in S$ . Such exploration may require self-efficacy (Bandura, 1994), which can be encouraged by arranging early student successes.

## The need to unpack the logical structure of a theorem statement

An *informal statement* is one that departs from the usual use of predicate and propositional calculus or fails to specify variables. For example, *Differentiable functions are continuous*, is informal because a universal quantifier and a variable are omitted, and because it departs from the usual “if-then” form of the conditional. Such statements are commonplace in everyday mathematics. They are not ambiguous or ill-formed because widely understood, but rarely articulated, conventions permit their precise interpretation by mathematicians and less reliably by students. An informally stated theorem can be memorable and easily brought to mind, but it may be difficult to unpack and prove (Selden & Selden, 1995).

## Psychological aspects of the proving process

We view proof construction as a sequence of actions that can be physical (e.g., writing a line of the proof or drawing a sketch) or mental (e.g., changing one’s focus from the hypothesis to the conclusion or trying to recall a theorem). The sequence of actions that eventually leads to a proof is usually considerably longer than the final proof text and is often not constructed from the top down.

### Situations and actions

When considering proving, we use the term, *action*, broadly as a response to a situation in a partly completed proof. We include not only physical actions, but also mental actions. The latter can include trying to recall something or bringing up a feeling, such as a feeling of caution or of self-efficacy (Selden & Selden, 2014). In addition, we include “meta-actions” meant to alter one’s own thinking, such as changing focus to another part of a developing proof construction.

### Situation-action links, automaticity, and behavioral schemas

If, during several proof constructions in the past, similar situations have corresponded to similar reasoning leading to similar actions, then, just as in classical associative learning (Machamer, 2009), a *link* may be learned between them, so that another similar situation evokes the corresponding action in future proof constructions without the need for the earlier intermediate reasoning. Using such *situation-action links* strengthens them, and after sufficient experience/practice, they can become overlearned and automated. We call automated situation-action links *behavioral schemas*.

### Features of automaticity

In general, it is known that a person executing an automated action tends to: (1) be unaware of any needed mental process; (2) be unaware of intentionally initiating the action; (3) execute the action while putting little load on working memory; and (4) find it difficult to stop or alter the action (Bargh, 1994). However, not necessarily all four of these tendencies occur in every situation.

Forming behavioral schemas converts S2 cognition, which is slow, conscious, effortful, evolutionarily recent, and calls on considerable working memory, into S1 cognition, which is fast, unconscious, automatic, effortless, evolutionarily ancient, and places little burden on working memory (Stanovich & West, 2000). This conversion into S1 cognition conserves working memory resources.

## Behavioral schemas as a kind of knowledge

We view behavioral schemas as belonging to a person's knowledge base. They can be considered as partly conceptual knowledge (recognizing and interpreting the situation) and partly procedural knowledge (doing the action), and as related to Mason and Spence's (1999) idea of "knowing-to-act in the moment". We suggest that, in using a situation-action link, or a behavioral schema, almost always both the situation and the action (or its result) will be at least partly conscious.

Here is an example of a behavioral schema that can conserve resources. One might be starting to prove a statement having a conclusion of the form  $p$  or  $q$ . This would be the situation. If one had encountered this situation a number of times before, one might readily write into the proof "Assume *not*  $p$ " and prove  $q$  or vice versa. While this action can be warranted by logic (if *not*  $p$  then  $q$ , is logically to,  $p$  or  $q$ ), there would no longer be a need to bring the warrant to mind.

## The genesis and enactment of behavioral schemas

The action produced by the enactment of a behavioral schema might be simple. It might also be compound, such as a procedure consisting of several smaller actions, each produced by the enactment of its own behavioral schema that was "triggered" by the action of the preceding schema in the procedure. We have developed a six-point theoretical sketch of the genesis and enactment of behavioral schemas (Selden, McKee, & Selden, 2010, pp. 205-206). Very briefly, here are the six points: 1) Within very broad contextual considerations, behavioral schemas are immediately available. 2) Simple behavioral schemas operate outside of consciousness. One is not aware of doing anything immediately prior to the resulting action – one just does it. 3) Behavioral schemas tend to produce immediate action, which may lead to subsequent action. One becomes conscious of the action resulting from a behavioral schema as it occurs or immediately after it occurs. 4) Behavioral schemas were once actions arising from situations through warrants that no longer need to be brought to mind. Behavioral schemas cannot be "chained together" and act outside of consciousness, as if they were one schema. 5) An action due to a behavioral schema depends on conscious input, at least in large part. In general, a stimulus need not become conscious to influence a person's actions, but such influence is normally not precise enough for doing mathematics. 6) Behavioral schemas are acquired (learned) through (possibly tacit) practice. That is, to acquire a beneficial schema a person should actually carry out the appropriate action correctly a number of times – not just understand its appropriateness. Changing a detrimental behavioral schema requires similar, perhaps longer, practice.

## Implicit learning of behavioral schemas

It appears that the process of learning a behavioral schema can be implicit, although the situation and the action are in part conscious. That is, a person can acquire a behavioral schema without being aware that it is happening. Indeed, such unintentional, or implicit, learning happens frequently and has been studied by psychologists and neuroscientists (e.g., Cleeremans, 1993). In the case of proof construction, we suggest that with the experience of proving a considerable number of theorems in which similar situations occur, an individual might implicitly acquire a number of relevant beneficial behavioral schemas. As a result, he or she might simply not have to think quite so deeply as before about certain portions of the proving process, and might, as a consequence of having more working memory available, take fewer "wrong turns".

### Detrimental behavioral schema

Many teachers can recall having a student write  $\sqrt{a^2 + b^2} = a + b$ , giving a counterexample, and then having the student make the same error somewhat later, perhaps in a different context. Rather than being a misconception (i.e., believing something that is false), this may well be the result of an implicitly learned detrimental behavioral schema. If so, the student would not have been thinking very deeply about this calculation when writing it. Furthermore, having previously understood the counterexample would also have little effect in the moment. It seems that to weaken/remove this particular detrimental schema, the triggering situation of the form  $\sqrt{a^2 + b^2}$  should occur a number of times when the student can be prevented from automatically writing “ $= a + b$ ” in response.

### Feelings and proof construction

The word “feeling” is used in a variety of ways in the literature so we first indicate how we use it. Often feelings and emotions are used more or less interchangeably, perhaps because both appear to be conscious reports of unconscious mental states, and each can, but need not, engender the other. We will follow Damasio (2003) in separating feelings from emotions because emotions are expressed by observable physical characteristics, such as temperature, facial expression, blood pressure, pulse rate, perspiration, and so forth, while feelings are not.

Feelings, such as a feeling of knowing, can play a considerable role in proof construction (Selden, McKee, & Selden, 2010). For example, one might experience a feeling of knowing that one has seen a theorem useful for constructing a proof, but not be able to bring it to mind at the moment. Such feelings of knowing can guide cognitive actions because they can influence whether one continues a search or aborts it (Clore, 1992, p. 151). We call such feelings *non-emotional cognitive feelings*.

For the nature of feelings, we will follow Mangan (2001), who has drawn somewhat on William James (1890). Feelings seem to be summative in nature and to pervade one’s whole field of consciousness at any particular moment. Non-emotional cognitive feelings, different from a feeling of knowing, are: a feeling of familiarity and a feeling of rightness. Rightness is “the core feeling of positive evaluation, of coherence, of meaningfulness, of knowledge”. (Mangan, 2001). About such feelings, Mangan (2001) has written that “people are often unable to identify the precise phenomenological basis for their judgments, even though they can make these judgments with consistency and, often, with conviction.” Finally, we conjecture that feelings may eventually be found to play a larger role in proof construction than indicated above, because they provide a direct link between the conscious mind and the structures and possible actions of the unconscious mind.

### The roles of affect and self-efficacy

In order to prove harder theorems--ones with a substantial problem-centered part--students need to persist in their efforts, and such persistence is facilitated by a sense of self-efficacy. According to Bandura (1995), self-efficacy is “a person’s belief in his or her ability to succeed in a particular situation”. Of developing a sense of self-efficacy, Bandura (1994) stated that “The most effective way of developing a strong sense of self-efficacy is through mastery experiences,” that performing a task successfully strengthens one’s sense of self-efficacy. Also, according to Bandura, “Seeing people similar to oneself succeed by sustained effort raises observers’ beliefs that they too possess the capabilities to master comparable activities to succeed.”

Bandura's ideas "ring true" with our past experiences as mathematicians teaching courses by the Moore Method (Mahavier, 1999). Such courses are taught from a brief set of notes consisting of definitions, requests for examples, and statements of major results, together with lesser results needed to prove them, but no proofs. The students provide the proofs and present them in class.

### **The development and uses of local memory**

Some may think that proof construction consists mainly of conscious thought (i.e., as communication with oneself or others using speech, vision, etc., or their inner versions, as suggested by Sfard, 2010). However, we take a somewhat different view. In constructing a proof of some complexity, often much more relevant information can be activated than can be held in one's short-term working memory (ST-WM). When such information is lost from consciousness, it may not return to its original state, but rather to a state of partial activation. Nonetheless, conscious thought can sometimes influence the activation of related information in long-term memory (LTM), that is, help bring something to mind. Ericsson and Kintsch (1995) stated that "reliance on acquired memory skills will enable individuals [experts] to use LTM as an efficient extension of ST-WM in particular domains and activities after sufficient practice and training." We speculate that mathematicians can do this when conducting their own research. We have observed of ourselves, when attempting an intricate complex proof, that a considerable amount of information is generated, but cannot all be kept in mind; however, it is easily recalled. We refer to such partially activated information as *local memory* -- it is available as long as we are seriously engaged with the proof. It seems analogous to Ericsson and Kintsch's (1995) idea of long term working memory (LT-WM).

### **Teaching and future research considerations**

We believe this perspective on proving, using situation-action links and behavioral schemas, together with information from psychology, is mostly new to the field. Thus, it is likely to lead to additional insights and teaching interventions, which brings up the question of priorities. Which proving actions of the kinds discussed above are most useful for mid-level university mathematics students to automate when they are learning how to construct proofs? Since such students are often asked to prove relatively easy theorems—ones that follow directly from definitions and recently proved theorems—it would seem that noting the kinds of structures that occur most often might be a place to start. Indeed, since every proof can be constructed using a proof framework, we consider constructing proof frameworks as a reasonable place to start. Furthermore, we have observed that some students do not write a second-level proof framework, perhaps because they have difficulty unpacking the meaning of the conclusion. This may be because a relevant definition needs to be converted into an operable interpretation in order to construct the second-level proof framework. Thus, helping students interpret formal mathematical definitions so that these become operable might be another place to start, even though students should eventually learn to make such operable interpretations themselves.

Finally, this theoretical perspective is likely to allow one to see parts of the teaching of proof construction in unusual ways and lead to new questions. For example, unguided exploration can be helpful for some proofs, but a student could easily feel the time required for exploration might reduce (timed) test grades. A feeling of self-efficacy might overcome that, but how are feelings "taught"? Early successes with proofs can help, but arranging for these might require detailed

planning of the course before it starts. Such planning could perhaps be aided by following a textbook, but most advanced mathematics textbooks prove the most important and useful theorems themselves, thereby taking away from students the opportunity to experience the proving of even parts of such theorems.

*The study presented in this report is part of a research project concerning the mediation of artifacts in teaching and learning geometry. In this paper we analyze the first step of our research which concerns the student-pantograph interaction and the identification of the math laws incorporated in the machine. During this interaction we are specifically interested in arguments that students produce for supporting their claims. Tools, especially mathematical machines, may support argumentation processes focusing either on the structure of the machine, or to the embodied math concepts that emerge from the machine's movement. Our research has shown that these arguments hold mainly on the topological conception of geometric figures.*

*Keywords: Argumentation, instrumentation, figural concept, topology, pantograph.*

### Introduction

Mathematics is in close relation with material and non- material artifacts. Artigue (2002, p. 245) points out that “the development of mathematics has always been dependent upon the material and symbolic tools available for mathematics computations”. Teaching and learning geometry may be mediated by visual or design artifacts. Research on the use of artifacts in Geometry teaching as means to facilitate understanding and learning, has tended to focus mainly on technology integration into curriculum- such as computer software packages focusing on how learning takes place when students use such artifacts. In addition to the use of information technology in schools, the MMLab researchers (e.g., Bartolini Bussi, 2010; Mariotti et al., 1997) have recommended and investigated from an epistemological and pedagogical aspect the use of mechanical artifacts -mathematical machines- as a way to generate mathematical ideas or concepts in the classroom. The geometrical machine “is a tool that forces a point to follow a trajectory or to be transformed according to a given law” (Bartolini Bussi & Maschietto, 2008). These machines (for example pantographs) are linkages that allow the implementation of geometrical transformations, such as symmetry, reflection, translation, and homothety.

The study presented in this report is part of a research project concerning the teaching of geometry at an upper secondary school in Greece (early 2016). Our research project was conducted in the framework of an attempt to incorporate artifacts that bear geometrical machine characteristics, in the instruction of Euclidean geometry.

### Theoretical framework

The theoretical framework of the instrumental approach was used for analyzing our observations (Verillon & Rabardel, 1995). According to this approach, the artifact is the material or symbolic object, while the instrument is defined as a mixed entity made up of both artifact and utilization schemes. In order for an artifact to lead to the development of an instrument, “the user has to develop mental schemes, which involve skills to use the artifact [...] the birth of an instrument requires a process of appropriation, which allows the artifact to mediate the activity. This complex process is

called the instrumental genesis” (Drijvers & Trouche, 2008, p. 370). “The instrumental genesis, is a two sided process. On the one side, the construction of schemes is oriented toward the use of the artefact: the instrumentalisation. On the other side, the construction of schemes is oriented toward the task to be achieved: the instrumentation.” (Goos et al., 2009, p.313). In our study we investigate the instrumentalisation process, i.e. the discovery of the elements and qualities of the artifact by the user. For our purpose, teaching homothety, the pantograph was the most convenient tool. Following Drijvers and Trouche (2008, p.369) we consider that the utilization schemes students construct during the instrumentalisation process, contain operational invariants that consist of – explicit or implicit – knowledge in the form of concepts-in-action or theorems-in-action.

Martignone and Antonini (2009) analyze more specifically the pantograph utilization schemes. They identified the “utilization schemes linked to the components of the articulated system (as the constraints, the measure of rods, the geometric figures representing a configuration of rods, ect.) and the utilization schemes linked to the machine movements” (p. 1253). In the second case, they distinguished two main sub-families: (1) the utilization schemes aimed at finding particular configurations obtained stopping the action in specific moments (limit zones; generic or particular or limit configurations) and (2) the utilization schemes aimed at analysing invariants or changes during continuous movements (wandering, bounded, guided; of particular configuration; between limit configuration; of dependence or in the action zones) (p. 1254). They have also conducted research on the argumentations produced in activities employing the pantograph (Antonini & Martignone, 2011). They distinguish between arguments about a) the drawings traced by the machine, b) the movement of the machine (as some dynamic properties of the articulated system), and c) the structure of the machine. Arguments about the structure are distinguished between referring to the figural aspect of the machine and the conceptual component of the geometric figure, which they discern in the structure.

In this paper we analyze the kind of argumentation produced by 16-17 year old students during the phase of investigating (a) the structure of a pantograph and (b) the configurations and (con) formations produced by the movements of its structural components.

Our research hypothesis was that the argumentation produced by the students, is in close relation with the machine’s characteristics: students’ explanations in the form of concepts or theorems in action are the exteriorization of precise utilization schemes developed by investigating the structure and the movement of the pantograph.

## **Methodology**

The first step of our research, that is the subject of this paper, concerns the student-pantograph interaction. 26 students of an 11<sup>th</sup> grade class (16-17 years old), of different learning abilities and interests, took part voluntarily in the experiment. Participating students worked in 6 groups (4 groups of 4 people, and 2 groups of 5 people). All the participating students had no prior experience with any artifact, except for compasses and rulers. Two meetings were carried out with the groups, of four hours in totals, and members of two groups (A and B) were interviewed. The working sessions and interviews were audio recorded, and afterwards transcribed. The transcripts, visual material (photographs), and written reports of the groups constitute the data for the analysis.

The artifact, with which the students were asked to work, is a geometrical machine (linkage) with the characteristics of a pantograph, specifically a version of Scheiner's pantograph (Figures 1, 2). The building blocks of the pantograph model were two equally-sized wooden rods 30 cm long [ $OD=AE=AC=BD$ ], held together by the links/pivots [A, L, D, and K] in the middle, thus forming a parallelogram [ALDK]. The rods had notches allowing reassembly of the linkage while maintaining its properties, provided that the links were placed in such a way that the ratios of the lengths of rod's parts were equal in each rod. The pantograph's linkage was mounted on a wooden platform (60cmx60cm).

**Figure 1: The linkage**

**Figure 2: Schematic representation of the linkage**

The tasks given to be treated by students concerned exploring the pantograph's structure and the investigation of special configurations and formations produced by the movements of the structural components of the linkage. The choice of the tasks was made following the distinction by Martignone and Antonini (2009) of the utilization schemes during pantograph exploration: the utilization schemes linked to the components of the articulated systems and the machine movements. The students invited to observe carefully the articulated system and to describe elements and characteristics of its structure such as length relationships and the mode of the rods' connection; to try to detect schematic shapes, properties and relationships that comprise its form and to create schematic representations of the articulated system (forms of system).

The analysis of the transcript was done following the classification of Martignone and Antonini (2009) about mathematical machine utilisation schemes and the kinds of arguments students use during the exploration of a geometrical machine, as a pantograph (Antonini & Martignone, 2011). In our research we examine utilization schemes linked to the structure of the machine in a static and in a dynamic status (: movement of the machine). For the first case (: static structure), hereafter, we use the symbols SF and SC, for the figural aspect of the machine and the conceptual component of the geometric figure which students discern in the structure, respectively. For the second case (: dynamic structure) we use the symbols MF and MC. In fact, in this second case we investigate the way students justify the embodied mathematics in the structure of the machine.

In this paper, we present and analyze the arguments produced by Group A -four girls hereby referred to as S1, S2, S3 and S4- as they investigate the configurations produced by the movements of the pantograph's structural components. Apart from space constraints, the omitted group (B) was already familiar with the abstract math concepts involved, as opposed to group A whose gradual discovery of the tool yielded high resolution into the thought process addressed by our research hypotheses.

### **Analysis of a transcript**

The students of Group A took advantage of the capability of the linkage pivots to alter its form by opening and closing its parts, identified the property of the midpoint for the position of the pivots (as K, L in Figure 2) and inferred the equality of their lengths (equal rods).

S1: We identify a rhombus configuration (Figure 4), because the sides are equal as half of equal segments (SF, MC).

The student S1 perceives the components of the machine's structure as geometric objects and identifies in them geometrical relations. The equality of segments arose as an ascertainment while opening and closing the linkage. She uses the definition of rhombus (: because the sides are equal) and together with the figural aspect of the linkage's structure (: half of equal segments) to argue that the quadrilateral ALDK is a rhombus (Figure 2).

S2: Can we mention implied properties too?

Interviewer: Describe what you consider important.

This encouragement led the students to operate the artifact more dynamically, not only by opening and closing the rods, but also exploring characteristics and properties of specific conformations and support their claims, taking advantage of the capabilities provided by the pivots.

S2: Isosceles triangles are formed (*with her finger traces on the artifact the triangles OKA and ALB in Figure 2*) ... if we assume that the articulated system can close its ends (*she points at the end of the rods and moves them until the linkage is closed, Figure 3*) and if we assume that it has a base because those (*she points at the pivots K and L, Figure 2*) are midpoints of equal sides (MF, MC).

The student executes the motion mentally ("if we assume ... that it closes ... and if it possesses a base"). They envision triangles in the linkage structure, though triangles do not exist. For these students the triangles they refer to are figural concepts (Fischbein, 1993). The students imagined the triangle and the reason that it is isosceles by moving the rods so that one rod meets the other (MF), while they deduce the equality of sides as halves of equal segments (MC).

S3: Maybe they're not triangles because they don't close?

The dimensions (thickness) of the rods don't allow them to coincide. The limitations of the artifact create a conflict between the figural aspects of the structure and the conceptual aspects of the geometrical figures of the articulated system. The students doubt whether they can actually consider it as a triangle.

S1: If we move the linkage, in a special position, we have a square (MC).

**Figure 3: Closed linkage**

**Figure 4: The rhombus**

**Figure 5: The square**

The student mentions the word "square" without justification. They have been taught that square is a special case of the rhombus. By moving the artifact, they predict that for a specific position of the rods, a square will be formed (Figure 5). Their square is of a conceptual nature. At the same time, it has an intrinsic figural nature: only while referring to the artifact one may consider operations like "if we move....we have a square". As a matter of fact, the square to which they refer cannot be considered as either a pure concept or a mere concrete representation.

Interviewer: How do you know it's a square?

S1: We have a right angle.

Interviewer: How do you know the angle is right?

S1: Since we have the capability of opening and closing an angle, then it can take all values between 0 and 180 ... then definitely one of these values will be 90 ... so one (angle) will be 90 degrees (MC).

The students imagine through the rod motion a continuous creation of angles between  $0^\circ$ - $180^\circ$  and that obviously  $90^\circ$  will exist as mean of the interval, and consequently will correspond to an angle.

S3: It is not just one particular (right) angle ... but anyone... for a specific position of the rods (MC).

Here is shown clearly the conceptual aspect of the argument. To the students the angle is not a characteristic of a static position of the artifact, but is dynamically created independently of the nature and position of the artifact on the planar surface (generalization). The right angle has been disconnected from the particular tool and is being described dynamically through its measure as a specific value in the interval  $0^\circ$ - $180^\circ$ .

S4: (*She opens and closes the rods and observes where the ends move and where the joint*) ... the ends of the rods (the points O, A and B in Figure 2) ... remain always on the same line as O (MF).

Interviewer: How do you know that those are on the same line?

S2: From the triangles [...]

Interviewer: You assume that the base of one isosceles is an extension of the other, how do you know?

The student assumes that the bases of two isosceles triangles are on the same line. The researcher's intervention is critical. She is suspecting that parallelism will allow her to transfer angles so as to justify the conjecture of the points' co-linearity.

S1: Those (*points at pairs of opposite rods*) ... are parallel ... they are always parallel (MF)... from construction ... because their distance remains always equal.

Parallelism is suggested to the students by the artifact's structure, and is reinforced during the artifact's movement. Substantiation of equal distance bears is theoretically unfounded.

The fact that the distance between the rods is always the same does not arise from a mathematical justification, but from analysis of the tool's structure. The student considers the tool as embodiment of some geometrical properties. From the moment they regarded the square as a special case of rhombus, they pointed out the constant distance (: opposite sides of the square) between the lines containing opposite rods, a fact that leads them to parallelism. In fact the student overgeneralizes (Gärdenfors, 2004, p.151) the equal distances in the case of the square, to any other position of the rods. She implies that in any configuration (even in the case of rhombus) the distances are equal.

Interviewer: How do you know this distance is always equal?

S1: The distance from here (*the student opening two fingers represents the supposed distance between two opposite rods*) is always equal to this one (DH=DZ, in Figure

6) and are equal in all positions (Figure 7) ... same with this one (Figure 8-a square) ... they can also be unequal, of course they're not always the same but they're equal in every position (MF) and the maximum distance is when it (the tool) forms a square (MC).

Figure 6

Figure 7

Figure 8

**Figures 6,7,8: Schematically represent the conformations of the artifact that the student trace on the drawing paper.**

The student's spatial conception is topological in nature. This conception appears first as an overgeneralization, and following the interviewer's persistence, it is expressed clearly through the movement of the artifact. For S1 rhombus and square are topologically equivalent (homeomorphic), leading to the conservation of equal distances (Figures 6, 7, 8). Piaget and Inhelder (1967) consider the structures of topology, to be the origin of the ontogenesis of spatial thinking.

Interviewer: Why is it the maximum distance?

S1: Because if I go over here (*she refers to her equivalent to Figure 6 drawing on the board*) from a right triangle (*shows on the drawing the triangle DZL to which she's referring*) I have a smaller distance, because this distance (DZ) is the smallest, as it's a leg ... so these form this angle equal to this angle (*referring to the right angles of the right triangles DHK and DZL in her drawing*).

The argument the student formulates in her attempt to justify why the distance of opposite rods becomes maximum, in the case of a square, has two components. One concerns a geometrical property (: the perpendicular segment is shorter than any oblique) (MC), while the second component is based on figural characteristics related to the conformations of the tool (rhombus –square) (MF). In line with Radford (2003), we could consider the student's argument as a factual generalization: "A factual generalization is a generalization of actions in the form of an operational scheme that remains bound to the concrete level." (Radford, 2003, p.65).

Interviewer: But why are they parallel?

S3: Since the general shape is a rhombus (MC) and the distances between them (*meaning the opposite sides*) are always equal (MC).

The students identify the characteristics of a geometrical problem they have tackled in the past (distances of opposite sides in a rhombus are equal), but being unable to give a geometric proof, remain on a topological approach.

## Discussion and conclusions

Our research hypothesis was that the argumentation produced by the students, is in close relation with the machine's characteristics. In fact, in agreement with the findings of Antonini and Martignone

(2011) students produce arguments both on a figural and a conceptual level even for the same investigation. The arguments used by the students are supported by the linkage's continuous movements in the action zones or between limit configurations.

Students produce arguments based on the figural characteristics of the tool mainly in two cases: when the structure of the tool renders their observation probable (3 collinear points), or when the tool produces the “proof” mainly through the linkage's continuous movements (: the triangle is isosceles, because the rods overlap). The figural characteristics make some facts “obvious” for the students to the point to give to the observer the impression of lack of substantial comprehension of geometrical definitions. For example, the students, in spite of recognizing the rhombus, do not readily deduce the parallelism of its side, and seek more complex proof, mainly via the artifact's attributes.

The instrument's structure may favor the theorems-in-action formulation (Fischbein, 1993), providing convincing argumentation: an angle is right, as it can be constructed by the artifact on a specific moment of its movement. Although the students were familiar with elementary proof in the framework of Euclidean geometry, their way of thinking was mainly topological. It seems that the mathematical tool, through its capacity for motion, favors such approaches. This was demonstrated not only in the justification that an angle is right, but also in the justification of two lines' parallelism. This fact implies the benefit of artifact use in Geometry teaching, before a formal introduction to the concept of proof.

Nevertheless, the tool's restrictions (e.g. rods not fully overlapping), create a conflict between the figural aspects of the structure and the conceptual aspects of the geometrical figures of the articulated system. For example, when trying to superimpose the wooden sides of the triangle in order to check if they are equal, students face the tool's restriction. Nevertheless, they can imagine it as an isosceles triangle. Those restrictions have two outcomes: a positive one being that students are forced to think in a more abstract manner and the negative one that the restrictions may lead them to false conclusions, giving the occasion of fruitful discussions.

*The paper describes a game-activity proposed to 7<sup>th</sup> grade students with the goal to make them discover the geometric property concerning the mutual relationship between two circles. The activity, called “the game of the two circles”, is composed of a strategic game that students play in GeoGebra and an investigative task which requires conjecturing and generalization. The aim of the activity is to trigger an approach to mathematics based on the logic of inquiry. We analyse students’ dialogues and actions paying particular attention to the additional values the game confers to the more traditional exploratory activities with dynamic geometry software.*

*Keyword: DGE game-activity, played-game, reflected-game, inquiring and justifying processes.*

## Introduction

Many studies in mathematics education have documented the importance of making students explore mathematical situations before asking them to construct proofs (Boero et al. 1996, Pedemonte 2007). The exploration triggers the formulation and the checking of conjectures, introducing students into logical ways of reasoning. As pointed out by Dewey, all forms of logics, included the deductive logic, are consequence of inquiry processes:

all logical forms (with their characteristic properties) arise within the operation of inquiry and are concerned with control of inquiry so that it may yield warranted assertions. This conception implies much more than that logical forms are disclosed or come to light when we reflect upon processes of inquiry that are in use. Of course it means that; but it also means that the forms originate in operations of inquiry. (Dewey, 1938, p.3,4)

Boero et al. (1996) have observed the possibility of a *cognitive continuity* between the processes of discovering and justifying. It occurs when the students, in the construction of the proof, exploit the argumentations employed for producing the conjecture. Pedemonte (2007) has distinguished between a cognitive unity in the *referential system* and in its *structure*. The first occurs if some expressions, drawings, or theorems used in the proof have already been used in the argumentation for supporting the conjecture. The second occurs if the inferences produced in the argumentation and in the proof are connected through the same structure (abduction, induction, deduction). Hintikka (1999), an eminent Finnish logician, analyzing Sherlock Holmes way of reasoning in inquiry processes, showed that the clever deductions he made are obtained by reversing the abductions (Peirce, 1960) produced while investigating. His works demonstrates the existence of an *epistemic unity* between inquiring and justifying processes.

In this study, we favor and emphasize the possibility of connections between the discovery and justifying processes by introducing *strategic games* within Dynamic Geometry Environments (DGEs): these are games in which players have to make strategic choices meant for setting up and coordinating actions aimed at the achievement of a goal. As it is known from the literature (Arzarello

et al. 2002, Baccaglini-Frank & Mariotti, 2010), DGEs are particularly apt for triggering inquiring processes. Our conjecture is that in virtue of the game, the conjectures and abductions produced inside the DGE are not left isolated but can be connected together and reorganized in logical chains. In fact, for making a strategic choice within a game situation, players reflect backward on the moves made and forward on the possible moves to make. These reflections can support the construction of logical links through which reorganize the geometrical invariants observed during the players' moves. In fact, since the moves are made on dynamic figures and involve geometric elements, we wish that the strategic reflections made on the moves could affect also the geometric elements involved in the moves. For this reason, *DGE game-activities* can promote a kind of thinking which is different from the one triggered by more traditional explorative activities with DGS.

## Theoretical framework

The interrogative logic or logic of inquiry, introduced by Jaako Hintikka (1999), proposes a back to the origin consideration of the discipline. According to Hintikka, the modern logic switched from the study of excellence in reasoning to the study of infallibility in reasoning: “preserving one’s logical virtue becomes a more important concern than developing virtuosity in drawing logical inferences” (Hintikka, 1999, p.28). The rules of inference are definitory rules, which inform us about the possible inferences, but do not say anything about which inferences are appropriate in the current moment, which are not so and which ones are better than others. These types of considerations are the concern of strategic principles.

Hintikka conceives the process of seeking new knowledge as an *interrogative game*, which is a two-player game between an *inquirer*, who asks the questions and an *oracle*, who answers him. Observations can be thought of as answers put to an environment, a controlled experiments, a database stored in the memory of a computer, a diagnostic handbook, a witness in a court of law, or one's own tacit knowledge partly based on one's memory can be considered as questions asked to nature. “Strategies of questioning play a central role in interrogative games, these include strategies of information seeking by means of different choices of questions to be asked and of the order in which they are asked.” (Hintikka, 1999, p.34).

Hintikka models the processes of verification and falsifications through a *semantical game* (Hintikka, 1998), which is a two-player game between a verifier, whose goal is to show the truth of a mathematical formula or statement and a falsifier, whose goal is to confute it. In order to establish the truth of the mathematical formula  $\forall x \exists y \mid S[x, y]$  it is possible to imagine a game in which the falsifier choses a value  $x_0$  “in the most unfavorable way as far as the interests of the verifier are concerned” and the verifier should find a value  $y_0$  for  $y$  such that  $S[x_0, y_0]$  is true. The formula is true if there exists a winning strategy for the verifier of the game, while it is false if there exists a winning strategy for the falsifier of the game.

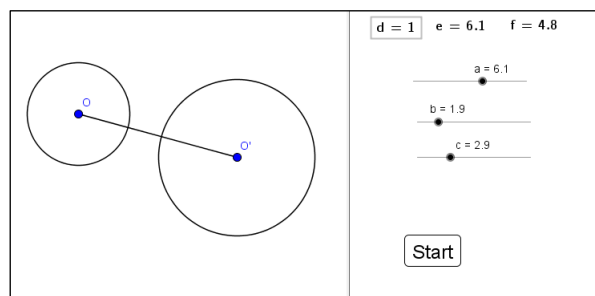

In our study, taking inspiration from Hintikka’s semantical game, we designed DGE game-activities in order to aid students in their discovery of geometric properties, through the game-play and the guiding questions. Analysing students’ actions, we distinguish between two ways of using the game: the played-game and the reflected-game (Soldano & Arzarello, 2016). In the *played-game*, the students’ aim is to win against their opponent. To reach this goal they activate strategic principles which help them to select the best move to make in a given situation. In the *reflected-game* students

play the game in order to answer the questionnaire and to communicate with each other. They play the game in a fictitious way: the game helps students to formulate the correct answer. In the reflected game we distinguish between the two main cognitive processes that characterizes dragging practices (Saada-Robert, 1989; Arzarello, 2002; Olivero, 1999): ascending and descending processes. We recognize ascending processes when students use the game in order to explore the situation and formulate a conjecture and descending processes when they use the game to check it. We have integrated this analytical tool with a new cognitive modality: the detached modality, in which students refer with words to the dynamic observed in the game, but they do not use it concretely.

### The game of the two circles

The game-activity presented in this paper is based on the relationship between the distance between the centres of tangent circles and the sum/difference between their radii. Students play the game on the GeoGebra file shown in Figure 1. The GeoGebra window is divided in two parts: on the right there is the numerical window with sliders and variables, in the left the graphic window here is a graphic representation of the geometric objects.

Sliders  $a$ ,  $b$ , and  $c$  control respectively the distance between the centres, the radius of the circle with centre  $O$  and the radius of the circle with centre  $O'$ . The variables  $d$ ,  $e$ ,  $f$  are respectively the absolute value of the difference between the radii ( $d=|b-c|$ ), the distance between the centres and the sum of the radii ( $f=b+c$ ). When students drag sliders  $b$  or  $c$ , they can observe the synchronic variation of the values of  $d$  and  $f$  and of the length of one circumference.

**Figure 1: Game-activity**

The game develops as follows: player B, the verifier, controls slider  $b$ , player C, the falsifier, controls slider  $c$  while player A, the referee, controls slider  $a$  and the hourglass. The goal of player B is to make  $e=d$  or  $e=f$ , the goal of player C is to make  $e \neq d$  and  $e \neq f$ . At the beginning of each match, the referee chooses the value of  $a$  and turns the hourglass over. Each time a player reaches his goal, the referee turns the hourglass over and the turn moves to the opponent. If the player cannot reach the aim within the time on his/her hands, he/she loses. The dynamic described is that of a semantical game played on the following statement: for every value of  $c$  there exists a value of  $b$  such that the circles are internally or externally tangent.

Each time that player B reaches his goal he produces an example of internally or externally tangent circles (look at Figure 2 a, b). Contrastingly, each time player C reaches his goal he produces an example of non-tangent circles (look at Figure 2 c, d, e). Since the interval of the sliders can take values from 0 to 10, players can produce also degenerate configurations (look at Figure 2 f, g). Player B can win also in this situation (look at Figure 2 h).

a)	b)	c)	d)
Externally tangent circles $e=f$	Internally tangent circles $e=d$	Non-tangent circles $e \neq d \wedge e \neq f$	Non-tangent circles $e \neq d \wedge e \neq f$
e)	f)	g)	h)
Non-tangent circles $e \neq d \wedge e \neq f$	Degenerate non-tangent circles $e \neq d \wedge e \neq f \wedge c=0$	Degenerate non-tangent circles $e \neq d \wedge e \neq f \wedge c=0$	Degenerate tangent circles $d=e=f \wedge c=0$

**Figure 2: Example space associate with “the game of the two circles”**

Theoretically it is always possible for players to reach their goals. Therefore the outcome of the game is determined by the time limit.

After playing the game, students are required to answer to the following questions:

1. Which are the mutual positions between the two circles each time player B reaches his aim?
2. Which are the mutual positions between the two circles each time player C reaches his aim?
3. What do the sliders a, b and c represent?
4. What do the value of d, e and f represent?

The questionnaire is intended to help students shift their frame of reference from the game to the geometric theory. In particular, the first two questions are intended to change the focus of attention from the numerical values of variables  $d$ ,  $e$  and  $f$  to the mutual positions between circles. In this way students discover the geometric invariants which characterizes player B's moves: each time the verifier reaches the goal the circles are tangent. Question number three is intended to link the values of the sliders to the length of the radii and the distance between the centres. Finally, question number four is intended to link the values of the parameters to the sum and difference of the radii. In this way students can discover another invariant which characterized player B's moves: each time the verifier reaches the goal the distance between the centres is equal to the sum or difference between the radii

## Methodology and data collection

The study reported in this paper involves one classroom of 7<sup>th</sup> grade Italian students. The game of the two circles is the first of a group of four game-activities related to the geometry topic of circles. Note that the properties on which the game are designed are not part of the classroom knowledge: the goal of the activity is to guide students in their discovery. Each activity lasts almost two hours: in the first hour and half students are divided into groups of three students and they play the game and answer a questionnaire using a computer or a tablet. In the last half an hour the teacher revisits students discoveries and systematizes the mathematical knowledge. The data for the analysis includes the transcript of students' dialogue and the GeoGebra diagrams explored during the game and the

questionnaire. We videotaped two groups and the final class discussion but, for space reason, we will represent only one group's work.

## Analysis

The videotaped group is composed by three students: Gu and Al are males, Bia is a female. They play the game on the computer. In the first match Bia is the referee, she chooses the value of  $a$  and she turns the hourglass. Gu is player C, the falsifier. He has to move slider  $c$  so that  $e \neq d$  and  $e \neq f$ . Al is player B, the verifier. He has to move slider  $b$  so that  $e = d$  or  $e = f$ . Figure 3 contains, in the first row, the diagrams produced during the first match. Below each diagram are the reported values of sliders and variables which appear in the numerical window. Finally the last row contains students' role (Falsifier (F), Verifier (V)) who produces the diagram, the type of example created and the time spent producing it. Remember that slider  $a$  controls the distance between the centres, slider  $b$  the radius of the circle with centre  $O$  and the slider  $c$  the radius of the circle with centre  $O'$ . The values of  $d$ ,  $e$  and  $f$  are, instead, the respective absolute values of the difference between the radii, the distance between the centres and the sum of the radii.

a) 	b) 	c) 	d) 
$a = 8 \quad b = 5.1 \quad c = 3$	$a = 8 \quad b = 5 \quad c = 3$	$a = 8 \quad b = 5 \quad c = 10$	$a = 8 \quad b = 3.3 \quad c = 10$
$d = 2.1 \quad e = 8 \quad f = 8.1$	$d = 2 \quad e = 8 \quad f = 8$	$d = 5 \quad e = 8 \quad f = 15$	$d = 7.7 \quad e = 8 \quad f = 13.3$

**Figure 3: First match**

The match lasts short length time and it ends with the winning of the falsifier (Figure 3). In the last move the time ends before Al reaches his goal, hence Al loses even if, theoretically, he could have won. Al knows that he could have won if he had had more time, in fact he says “it should have been like this”, making internally tangent circles. After Al demonstrates the winning configuration, Bia says “So B should always win”. This sentence reveals the activation of the anticipatory thinking (Harel, 2001). After playing another match, students move to the first question.

- Gu: In order to reach the goal they have to touch each other in only one point.
- Al: On the other hand the answer to the question: ‘In which mutual positions are the two circles when C reaches his/her goal?’ is any position. They can touch each other in two points or nowhere.
- Bia: No, they always touch each other in exactly two points. (looking at an example of secant circles).
- Gu: They can touch each other in two points, but they can also not touch each other.
- Bia: Ah... (moving  $c$  so that the circles do not intersect each other. Then she moves  $c$  back and forth for 30 seconds) Yes, that's right!

Al and Gu approach the question in a different way from Bia. They are in detached modality, they rethink what has happened in the played-game and then they answer the question. Bia, instead, uses

the game in order to investigate the situation, she is in descending modality: she is using the reflected-game in order to check her schoolmates' claims. The group repeats this approach (detached versus descending) in answering the subsequent questions. When they get to the last one, the students do not agree with each other: according to Al and Bia,  $d$  and  $f$  are the radii of the circles, while Gu does not agree with them. The disagreement invokes the need of a justification.

- Al: Let me prove that it's the radius (taking the mouse)! They have to coincide perfectly... (moving the centre  $O'$  on the other circumference, see Figure 4e)
- Gu: It's not the radius... Because if you change the radius of a circle, you don't automatically change the radius of the other one! Both values [ $d$  and  $f$ ] change! You should change just one [ $d$  or  $f$ ] by moving it [ $b$ ] by changing the length of one radius... you are not changing the other one!
- Al: Don't you notice? Don't you see? (he moved  $c$  to 0, obtaining that  $e$  is equal to  $d$  and  $f$ , see Figure 4f). Point  $T$  just appeared and, putting this on zero. Do you notice? It's 2.9 2.9 2.9.

In order to refute Al's conjecture, Gu tries to explain the contradiction he noticed between the graphic and the numerical window. In detached modality, Gu explains why Al's claims creates a dynamic contradiction in the conversion (Duval, 2006) from the numerical to the graphic register. Al, instead, tries to provide evidence for explaining that what he claims is true. In this attempt, he uses the value of the parameter  $e$  (distance between the centres) in order to measure the length of the radius of one circle. His goal is to show that this value is equal to the value of  $d$  or  $f$ . If this process were to be applied on a generic example, it would have led to a contradiction, but since Al moves the value of the radius of the circle  $O'$  to 0, he produces a supporting example.

**Figure 4: Reflected-game**

After exploring silently the situation, Bia who at first supports Al's claim, changes her mind.

- Bia: Anyway he's right... If you put them like this (each centre belongs to the other circle, see Figure 4g), the radius is the same thing, isn't it? I mean, it's the same here and here (pointing at the two circles), but here they are different (pointing at the values of sliders  $d$ ,  $f$ )... Then it must be another thing, do you get it?

Adopting Al's strategy, she uses the distance between the centres to create two circles with the same radii in the graphic window. She notices that the two parameters which are supposed to be the radii are not equal in the numerical window. In contrast to Gu, who creates a dynamic counterexample, Bia exhibits a static counterexample, but this one also fails to convince Al that he is mistaken. The discussion continues with Gu who repeats his dynamic example, Bia who produces other static counterexample and Al who moves back to his supporting special example and cannot understand why he is wrong. Finally, observing the value  $d=0$  when circles are externally tangent (Figure 4h)

and with the same radii, Al formulate a new conjecture:  $d$  is the difference between the radii of the circles. This discovery allows him to unlock the situation and to explain his special example.

## Discussion and conclusion

Game-activities can operationalize a functional approach to geometry. Within these activities, students deal with *soft* tangent circles, namely dynamic circles in which some constructive steps that make the circles *robustly* tangent (the tangency is preserved by dragging) are voluntarily not performed (Healy, 2000). A constructive step creates a functional dependence between the geometric elements, which is hidden in the robust construction of the figure. In DGE game-activities, this functional dependence is made explicit through the verifier/falsifier's dialectic. More precisely, when the verifier has observed the invariant tangent configuration produced by his/her moves, he/she can create a cause-effect link between his/her goal and the invariant produced.

We describe the verifier's dragging as follows:  $b \xrightarrow{\text{values of the sliders}} \text{tangent circles}$  which indicates that the verifier, by moving the slider  $b$ , can observe the invariant tangent configuration as the effect of making sliders values coincide. Once discovered the invariant, the verifier can accomplish the move with the goal of building tangent circles. In this case, he observes the coincidence of the values of the slider as the effect of making tangent circles. This time the verifier's dragging is described in this way:  $b \xrightarrow{\text{tangent circles}} \text{values of the slider}$ . By switching the focus of attention of the move, the DGE game-activities, create a sort of frame, which helps students to appreciate the "if and only if" relationship between tangent circles and the fact that the distance between the centres is equal to the sum or absolute values of the difference of the radii.

DGE game-activities enrich the exploration supporting the in-depth investigation of situations: the presence of the falsifier, who tries to create trouble to the verifier, exposes the verifier to different initial situations triggering the exploration of both standard and non-prototypical examples of tangent circles. In this way, the game-activities enlarge students' *accessible example space* (Goldenberg & Mason, 2008) associated with tangent circle configuration. This is a very important aspect for the construction of mathematical concepts: proposing students only standard configurations can be source of mathematical misconceptions.

Finally, the game tool enriches and supports students' arguing abilities and the coordination of numerical and graphic information. In order to communicate their claim, students activate a versatile use of the game: not only for formulating and checking conjectures but also for supporting their claim, confuting different opinions and explaining ones' point of view. The game assumes a fundamental role in promoting mathematical ways of reasoning. Al, for example, uses the game to show evidences of the truth of his claim, hence uses the game for constructing a supporting example, while Bia and Gu use it to show that he is wrong, hence for constructing counterexamples to what has been claimed by Al. In producing these arguments, students make conversion between numerical and graphic registers. Concluding, the game instruments help students not to assume the absolute truth of external opinions, but to establish a dialectic approach to them.

# Reasoning-and-proving in geometry in school mathematics textbooks in Hong Kong

Kwong-Cheong Wong

The Hong Kong Polytechnic University, Hong Kong SAR, China; [wongkwongcheong@gmail.com](mailto:wongkwongcheong@gmail.com)

*To promote learning mathematics with understanding, mathematics educators in many countries recommend that proof play a central role in school mathematics. In response to this recommendation, this study examines the opportunities for students to learn reasoning-and-proving from the geometry strand of a popular school mathematics textbook in Hong Kong. The study adopts the methodology of Stylianides (2009). Results show that Hong Kong takes the traditional but problematic approach in which proof is taught mainly in geometry and in which two-column proof is emphasized. Overall, results suggest that proof plays a marginal role in school mathematics in Hong Kong.*

**Keywords:** Reasoning-and-proving, school mathematics textbooks, geometry, Hong Kong.

## Introduction

In addition to verifying the truth of a mathematical statement, proof can have many other important functions in mathematics, including explanation, which can promote sense making and understanding in mathematics (de Villiers, 1990). As a consequence, many mathematics educators around the world, especially those in the US, recommend that proof (and proof-related reasoning) permeate school mathematics at all levels and in all content areas (e.g. Ball et al., 2002; NCTM, 2000). Furthermore, since textbooks can have an influence on what students learn, many studies have been conducted in different national curricula (e.g. US, Israel, Australia) to examine the opportunities for students to learn reasoning and proof from school mathematics textbooks. These studies were conducted at various grade levels (e.g. middle school, high school) and content areas (e.g. algebra, geometry); for example, see Stylianides (2009) and the articles devoted to this topic in Stylianides (2014). However, almost all of these studies were conducted in Western countries whereas only few studies have been conducted in East Asian countries (e.g. Singapore, South Korea, Hong Kong) where students have consistently performed very well in international studies of mathematics achievement such as TIMSS (e.g. Mullis et al., 2012). The present study is part of an on-going project aimed to complement the international research knowledge by examining the opportunities for students to learn reasoning and proof when they are using a popular secondary school mathematics textbook from Hong Kong. It is expected that the results obtained will shed light on how proof is being treated in school mathematics in one of those high-achieving countries (or regions) and provide insights into the influences that Chinese culture may have on issues concerning understanding in school mathematics. This paper reports our findings in geometry; for our findings in algebra, see Wong & Sutherland (2016).

## The context: Hong Kong SAR

Being a special administrative region (SAR) of China, Hong Kong enjoys curriculum independence, in the sense that Hong Kong designs her own school curriculum, which is different from that in China. In 2009, Hong Kong launched her new academic structure, under which the number of years for senior secondary school changed from four years to just three years (Secondary 4, 5 and 6). Accordingly, at the same time Hong Kong initiated her New Senior Secondary Mathematics

Curriculum (Education Bureau HKSARG, 2007). This new curriculum consists of two parts: the Compulsory Part and the Elective Part (also called the Extended Part). It should be pointed out that teaching proof is not one of the stated goals (or processes) of the curriculum, which mentions proof only locally in the learning targets of geometry, namely, to “formulate and write geometric proofs involving 2-dimensional shapes with appropriate symbols, terminology and reasons” (ibid, p.15). The textbook series chosen for this study is the popular *New Century Mathematics* (2<sup>nd</sup> edition, Leung, Frederick K. S. et al., 2014–16). There were three reasons for choosing this textbook series: (a) this textbook series was one of the most popular ones in Hong Kong (if not the most popular one), (b) it was on the recommended booklist by the Educational Bureau, which means that it was guaranteed to be fully aligned with the new mathematics curriculum, and (c) it was coauthored by a prominent mathematics educator. Within this textbook series, there were two books (Books 4A and 4B) for Secondary 4, two books (Books 5A and 5B) for Secondary 5 and one book (Book 6) for Secondary 6. All topics in these five books were categorized into three strands: Number and Algebra, Data Handling, and Geometry (in the curriculum document (ibid.) the name “Measures, Shape and Space” was used instead).

### Analytic framework and method

We followed the methodology of Stylianides (2009) in his investigation into reasoning and proof in school mathematics textbooks in the US. The framework he used was based on his conceptualization of *reasoning-and-proving* (RP), a term describing the overarching activity encompassing all of the four major proof-related mathematical activities: (a) identifying patterns, (b) making conjectures, (c) providing proofs, and (d) providing non-proof arguments. As shown in Table 1 below, the first two activities were grouped into the category of making mathematical generalizations and the latter two into the category of providing support to mathematical claims. The idea behind this conceptualization was that making mathematical generalizations (*identifying a pattern* and *conjecturing*) and providing support to mathematical claims (*proving*) are two fundamental and interrelated aspects of doing mathematics (Boero et al., 2007). Further, there were two kinds of pattern: plausible and definite; two kinds of proof: generic example and demonstration; and two kinds of non-proof argument: empirical argument and rationale. For the exact definitions of these terms, see Stylianides (2009).

<i>Reasoning-and-Proving</i>			
I. Making Mathematical Generalizations		II. Providing Support to Mathematical Claims	
(a) Identifying a Pattern	(b) Making a Conjecture	(c) Providing a Proof	(d) Providing a Non-proof Argument
1. Plausible Pattern 2. Definite Pattern	3. Conjecture	4. Generic Example 5. Demonstration	6. Empirical Argument 7. Rationale

**Table 1: The analytic framework (Stylianides, 2009, p. 262)**

In this study, we focused on the Compulsory Part of the curriculum. We examined all of the eight chapters comprising the Geometry strand (see Table 4 below for the names of these chapters). Following Stylianides (2009), we focused on the exercises in these chapters and examined all of them. In each of these chapters, exercises were categorized under various headings: Q&A, Review Exercise, Instant Drill, Instant Drill Corner, Exercise, Supplementary Exercise, Class Activity, Inquiry & Investigation, and Unit Test. Within each category of these exercises, there were many tasks. A *task*

here means any problem in the exercises or parts thereof that have a separate marker (Stylianides, 2009, p. 270). *Task* served as unit of analysis in this study and there were totally 2,929 tasks to be analyzed and categorized into the seven subcategories of the constituent activities of reasoning-and-proving set out in Table 1 above. Additionally, we extended Stylianides' framework by further dividing the subcategory "Demonstration" into seven (sub)subcategories that correspond specifically to the different proof methods that were used in the exercises of the Geometry strand of our chosen textbook series; these included (i) Proof by Definition, (ii) Proof by Calculation, (iii) Proof by Calculation and Definition, (iv) Paragraph Proof, (v) 2-Column Proof, (vi) Proof by Contradiction, and (vii) Existence Proof (see Table 3 below). To decide if a task was an RP task, we considered how it appeared in the textbook (e.g. key phrases "Prove that", "Explain your answer"). In cases where the requirements were not clear, we consulted the Teacher's Manual (which contained suggested solutions, but only suggested solutions) in order to infer what types of response was expected for students.

## Examples of analysis

Although there was a considerable amount of tasks, the forms of expression of tasks providing RP opportunities were very limited. Tasks phrased with the obvious "Prove that" or "Show that" were treated as RP activities (see Examples 2, 4 and 5 below). Those tasks ending in "Explain your answer." were also treated as RP activities, because they were asking for some kind of justification (see Examples 1 and 3 below). However, in some cases there was no explicit request to explain the answer, but judging from the solutions in the Teacher's Manuals, justifications were actually expected and hence these tasks were also treated as RP activities (see Task 3 of Example 5 below). Some tasks, usually in Class Activity or Inquiry & Investigation, were special in that they were part of a template for illustrating reasoning-and-proving. Such tasks were *dually* coded: on the one hand as a unit of analysis on its own, and on the other hand as part of the constituent activity (or activities) of reasoning-and-proving being illustrated (see Example 5 below).

### Example 1

4.  $Q(-1, 3)$  is rotated anticlockwise about the origin  $O$  through  $90^\circ$  to  $Q_1$ .  
 (a) Write down the coordinates of  $Q_1$ .  
 (b) If  $Q_1$  is reflected in the  $x$ -axis to  $Q_2$ , are  $Q$  and  $Q_2$  the same point? Explain your answer.

*Solution (from Teacher's Manual 4B, p.228):*

- (a) Coordinates of  $Q_1 = (-3, -1)$   
 (b) Coordinates of  $Q_2 = (-3, 1)$   
 Coordinates of  $Q \neq$  Coordinates of  $Q_2$   
 $\therefore Q$  and  $Q_2$  are not the same point.

**Figure 1: Task 4(b) of Supplementary Exercise of Ch. 12 of Book 4B**

Here Task 4(a) was not coded as any RP activity. Task 4(b) was coded as "Demonstration – Proof by Definition," by which we mean *one-step* deductive reasoning which can be derived directly from some definition (or property or theorem). This type of tasks does not involve substantive reasoning – its aim is simply to check students' understanding of the definition (or property or theorem).

*Example 2*

58.  $A(0, \sqrt{2} + 1)$ ,  $B(-\sqrt{2} - 1, 0)$  and  $C(\sqrt{2} + 1, 0)$  are the three vertices of  $\triangle ABC$ .

(a) Show that  $AC = 2 + \sqrt{2}$ .

*Solution (from Teacher's Manual 5B, p.96):*

$$\begin{aligned} \text{(a)} \quad AC &= \sqrt{[0 - (\sqrt{2} + 1)]^2 + (\sqrt{2} + 1 - 0)^2} \\ &= \sqrt{2(\sqrt{2} + 1)^2} = \sqrt{2}(\sqrt{2} + 1) = 2 + \sqrt{2} \\ \therefore AC &= 2 + \sqrt{2} \end{aligned}$$

**Figure 2: Task 58(a) of Supplementary Exercise of Ch. 7 of Book 5B**

As shown, the solution involved substitution of values into the distance formula and algebraic manipulations to calculate  $AC$ . This task was coded as "Demonstration – Proof by Calculation". This proof method is also called "Mechanical Deduction" in the literature (e.g. Reid & Knipping, 2010, p. 124). Though involving mechanical algebraic manipulations and little reasoning, logically it should be regarded as a proof (for more on this point, see Slomson, 1996, p.11, "Proofs as Calculations").

*Example 3*

5. In the figure,  $BM = CM = 6$  cm,  $AM = 8$  cm and  $AB = 10$  cm.  $AMD$  is a straight line. Is  $AD$  a diameter of the circle? Explain your answer.

*Solution (from Teacher's Manual 4B, p.135):*

$$AM^2 + BM^2 = (8^2 + 6^2) \text{ cm}^2 = 100 \text{ cm}^2$$

$$AB^2 = 10^2 = 100 \text{ cm}^2$$

$$\therefore AM^2 + BM^2 = AB^2$$

$$\therefore \angle AMB = 90^\circ$$

$$\therefore AM \perp CB$$

$\therefore AD$  is the perpendicular bisector of  $BC$ .

$\therefore AD$  passes through the centre of the circle.

$\therefore AD$  is a diameter of the circle.

**Figure 3: Task 5 of Supplementary Exercise of Ch. 10 of Book 4B**

This task was coded as "Demonstration – Paragraph Proof", because it involved not just algebraic manipulations, and was written in the paragraph (or narrative) form – a less formal form in which it is not required to provide justification for every step. Paragraph proofs in geometry correspond to level 2 (informal deduction) of van Hiele Levels (Usiskin, 1982).

*Example 4*

11. In the figure,  $PCQ$  is a straight line. Chord  $AB$  is parallel to  $PQ$ . If  $\widehat{AC} = \widehat{BC}$ , prove that  $PQ$  touches the circle at  $C$ .

*Solution (from Teacher's Manual 4B, p.182):*

$$\therefore \widehat{AC} = \widehat{BC}$$

given

$$\therefore \angle ABC = \angle BAC$$

equal arcs, equal angles

$$\angle BCQ = \angle ABC$$

alt.  $\angle$ s,  $AB \parallel PQ$

$$\therefore \angle BAC = \angle BCQ$$

$$\therefore PQ \text{ touches the circle at } C.$$

converse of  $\angle$  in alt. segment

**Figure 4: Task 11 of Exercise 11F of Ch. 11 of Book 4B**

This task was coded as "Demonstration – 2-Column Proof", because it involved not just algebraic manipulations, and was written in the traditional two-column form – a more formal form in which every step is required to be justified with a reason and to be presented in the rigid two-column format as shown in Figure 4 above. Two-column proofs in geometry correspond to level 3 (formal deduction) of van Hiele Levels (Usiskin, 1982).

### Example 5

Inquiry & Investigation 9.1: Alternative proof for the sine formula

#### Inquiry

In  $\triangle ABC$ , what is the relationship among the radius  $r$  of the circumcircle,  $\frac{a}{\sin A}$ ,  $\frac{b}{\sin B}$  and  $\frac{c}{\sin C}$ ?

#### Investigation Steps

In the figure,  $O$  is the centre of the circumcircle of  $\triangle ABC$ . The radius of the circumcircle is  $r$ . Produce  $AO$  to meet the circle at  $X$ . Join  $BX$ .

1. Find  $\angle ABX$ .
2. Consider  $\triangle ABX$ . Express  $\sin X$  in terms of  $c$  and  $r$ .
3. What is the relationship between angles  $C$  and  $X$ ?
4. (a) Use the results of Questions 2-3 to express  $\frac{c}{\sin C}$  in terms of  $r$ .  
(b) Use similar method to express  $\frac{a}{\sin A}$  and  $\frac{b}{\sin B}$  in terms of  $r$ .

#### Conclusion

$$\frac{a}{\sin A} = \frac{b}{\sin B} = \frac{c}{\sin C} = \underline{\hspace{2cm}}$$

**Figure 5: Task of Inquiry & Investigation 9.1 of Ch. 9 of Book 5B**

This exercise consisted of six tasks (1, 2, 3, 4(a), 4(b) and Conclusion). It was a template for illustrating a direct proof. So these tasks were dually coded. First, each task was coded as a unit of analysis on its own. In this example, Task 3, and only Task 3, could be interpreted as an RP activity (Demonstration – Paragraph Proof or 2-Column Proof) in case the solution given in the Teacher's Manual would include a justification (e.g. "Angles in the same segment"). However, the solution given was just " $C = X$ ", so it was not regarded as a reasoning-and-proving task. Neither were the tasks 1, 2, 4(a), 4(b) and Conclusion. Then, each task was coded as part of the template illustrating RP activities. In this case, all of them were coded as "Demonstration – Paragraph Proof". For more examples, see the full version of this paper.

## Results and Discussion

We have three major findings. Firstly, as shown in Table 2 below there were relatively limited opportunities (444 out of 2,929 tasks, i.e., 15.2%) for students to learn RP from the exercises of the Geometry strand of the chosen textbook series (Secondary 4 – 6). The majority of these exercises were to drill procedural skills. Secondly, there was a large difference between Making Mathematical Generalizations (24 tasks) and Providing Support to Mathematical Claims (420 tasks). This suggests that these two categories of activities were treated, in large part, in isolation from each other. This is problematic as they are two fundamental and interrelated aspects of doing mathematics (Boero et al., 2007; Cañadas et al., 2007; Hsieh et al., 2012). Thirdly, the majority of the RP opportunities were Demonstration (364 out of 444, i.e., 82%). However, as shown in Table 3 below, out of these 364 demonstrations, 32.1% were Proof by Definition or Proof by Calculation or Proof by Calculation and

Definition, all of which involve little reasoning. If we excluded them from Demonstration, the total RP opportunities would reduce to 11.2% (= 444 – 83 – 26 – 8 out of 2,929 tasks). A consequence that might be attributed to this lack of sufficient emphasis on proof even in geometry is that, as informed by TIMSS 2011 (Mullis et al., 2012, p.148 & p.150), “Hong Kong students in general do well in Knowing items, and relatively badly in Reasoning items” (Leung, 2015, p. 3).

<i>Reasoning-and-proving subcategory</i>	<i>Frequency</i>	<i>(Percent)</i>
I. Making Mathematical Generalizations:	24	(5.4%)
(a) Identifying a Pattern:		
1. Plausible Pattern	0	(0.0%)
2. Definite Pattern	12	(2.7%)
(b) Making a Conjecture:		
3. Conjecture	12	(2.7%)
II. Providing Support to Mathematical Claims:	420	(94.6%)
(c) Providing a Proof:		
4. Generic Example	18	(4.1%)
5. Demonstration	364	(82.0%)
(d) Providing a Non-proof Argument:		
6. Empirical Argument	38	(8.6%)
7. Rationale	0	(0.0%)
Total:	444	(100%)

**Table 2: Frequency and Distribution of RP Tasks across RP Subcategories**

On the other hand, as shown in Table 4, 36% of the total RP tasks were concentrated in one chapter, namely, Book 4B Ch. 11 *More about Basic Properties of Circles* – more specifically, in Section 11.5 *Geometric Proofs on Circles*, which began with “We learnt many theorems relating to properties of circles in Book 4B Chapter 10 and this chapter. In this section we will learn how to use these theorems to prove more geometric properties.” In the exercises of this section, almost every task asked for a 2-column proof, suggesting that the curriculum took a traditional approach in which proof is taught mainly in geometry and in which 2-column proof is emphasized. However, this approach to proof is problematic as it gives a misrepresentation of the nature of proof in mathematics (Wu, 1996) and its emphasis on form over meaning can lead to a shallow, syntactic kind of knowledge, rather than a connected understanding of the mathematics involved (Schoenfeld, 1988).

Given that Hong Kong teachers rely heavily on textbooks in their teaching (Tam et al., 2014), the above results not only confirm that in secondary school classrooms in Hong Kong students’ activities mainly focus on practicing and memorizing mathematical concepts and procedures (Leung, 2001), but also suggest that proof plays a marginal role in school mathematics in Hong Kong. The fact that school mathematics textbooks in Hong Kong stress drilling on procedural (or calculation) skills far more than reasoning and proof may be due to influences from Chinese culture (or, more specifically, the Confucian heritage culture or CHC). According to Leung (2006, p. 43), CHC believes that “the

process of learning often starts with gaining competence in the procedure, and then through repeated practice, students gain understanding.” Additionally, CHC is an examination-oriented culture. In fact, the curriculum in Hong Kong is highly examination-driven. The fact that Hong Kong school mathematics textbooks stress practicing procedural (or calculation) skills far more than reasoning and proof may be a reflection of the strong influence of public examinations on textbook design. For more on how Chinese learn mathematics, see for example Fan et al. (2004).

# An exploratory teaching style in promoting the learning of proof

Xiaoheng Yan<sup>1</sup>, John Mason<sup>2</sup> and Gila Hanna<sup>1</sup>

<sup>1</sup>OISE, University of Toronto, Canada; [xh.yan@mail.utoronto.ca](mailto:xh.yan@mail.utoronto.ca); [gila.hanna@utoronto.ca](mailto:gila.hanna@utoronto.ca)

<sup>2</sup>University of Oxford, United Kingdom; [John.Mason@open.ac.uk](mailto:John.Mason@open.ac.uk)

*Our overall concern is with helping students learn to construct and re-construct proofs. Here we investigate an exploratory style which invites learners to think for themselves, with the instructor circulating among them while listening, probing, and suggesting. The objectives of this investigation are, to understand how the actions of teachers can contribute to the development of their students' thinking, and to provide explicit pedagogic strategies that teachers can use to promote their students' appreciation and understanding of mathematical proof.*

**Keywords:** *Explanation, exploration, proof, proof construction.*

## Theoretical underpinnings

Our paper adopts the notion of acts of teaching (Mason, 2009; 2004): something that initiates and directs; something which is acted upon; and something which mediates between these, enabling the action to take place. We proceed from this stance to analyse an exploratory style as it was observed in an advanced undergraduate geometry class, with the aim of identifying what specific contributions this style brings to the learning process.

When teachers introduce a proof task, they are likely to have a complex set of expectations of what learners will get from engaging with the task. They are (we hope) aware of, or have access to connections with pervasive mathematical themes, with other contexts in which similar ideas arise, and with the specific powers that learners have. Teachers will have views on how these powers might be developed through working on the task, and on opportunities to interact with learners during which both mathematical thinking and appreciation and comprehension of some particular mathematical topic will be deepened and enriched. Tasks can vary from following an exposition, through exploring relationships, exercising new-found procedures, and making use of newly encountered technical terms as part of their personal and collective developing narrative.

Following the *Systematics* of Bennett (1956-1966; 1993), we distinguish six modes of interaction which arise from the teacher, the learner and the content playing the roles of the three impulses comprising any action: initiating, responding and mediating, and conveniently labelled by six 'exs': *expounding*, *explaining*, *exploring*, *examining*, *expressing* and *exercising* (Mason, 2004). In *expounding*, the initiative is with the teacher who uses the presence of learners (actual or virtual) as the mediator to make contact with the mathematical content in a significant way. The teacher draws the learners into the teacher's world and ways of perceiving and acting. By contrast to expounding, and also in contrast to its every-day sense, *explaining* in this framework involves the teacher using the content as a mediator in order to make contact with the student, through listening, watching and probing. The teacher tries to enter the world of the learner. As soon as the teacher thinks they 'know' where the learner's difficulty lies, the action usually reverts to exposition. *Exploring* involves students taking initiative, mediated by the teacher who may suggest a starting point for exploration, and may

make suggestions based on what students are saying and doing. *Examining* in this framework involves the student seeking to validate their own criteria against those of the teacher'. *Expressing* is what the student does when they feel the urge to articulate insights or make conjectures. This can occur for example in response to a teacher asking probing questions. *Exercising* is what a student does when they feel the desire to practice in order to gain fluency. Our interest here is on the interactions labelled as *exploring*, *expressing*, and *explaining* in the technical sense used in this framework.

Our investigation builds upon previous research. Grenier (2013) has shown that an experimental teaching approach focusing on various “research situations” can succeed in helping students master mathematical reasoning and proving. Selden and Selden (2013) considered a division of proofs into a *formal-rhetorical* part and a *problem-centered* part. In their view, the formal-rhetorical part of a proof depends only on unpacking and using the logical structure of a theorem, while the problem-centered part depends on exploration and understanding, which is essential to the learning of proof.

Several researchers have investigated the use of explorations in various learning contexts. In the use of dynamic geometry, for example, Mariotti (2000), and others have shown the value of teaching proof through exploration. In the context of argumentation and proof and of the axiomatic organization of mathematics, several other researchers have examined students' use of empirical explorations (Durand-Guerrier et al., 2012; Hanna, 2010; Hemmi, 2010; Jahnke & Wambach, 2013; Reid & Knipping, 2010; Stylianides & Stylianides, 2009). Additionally, Garuti et al. (1998) and Pedemonte (2007) highlighted what they termed *cognitive unity*, the continuity between the process of conjecturing achieved through exploration and the production of an acceptable proof.

## **The exploratory style in this study**

We investigate a particular exploratory style in which university students already familiar with linear algebra are taking an advanced geometry course in which they are exposed to proofs by means of explorations that invite them to think for themselves, with the instructor circulating among the students, listening to their discussions, asking probing questions intended to help the students think more deeply about the issue at hand, and at times offering suggestions.

## **Participants and classroom setting**

The 24 participants were undergraduate mathematics students in a mixed-year class (2<sup>nd</sup> to 4<sup>th</sup> year) at a large urban university in central Canada. The advanced geometry course covered plane geometry, spherical geometry, and briefly, some hyperbolic geometry. It addressed the critical role of transformations (symmetries and isometries) in all of these geometries, the use of dynamic geometry software (The Geometer's Sketchpad), and proof. The instructor of the course was a geometer. The class met once a week for 3-hour sessions, 20 classroom meetings in total. The course was intended to keep equal proportion of instruction time and exploration time to facilitate the exploratory style of teaching and learning. Three classroom sequences were assigned to the investigations on conic sections. This paper focuses on one of the sessions – the exploration of ellipse.

To facilitate investigations and communication, the classroom setting of the geometry course was unconventional: 7 large round tables with chairs around each filled up the classroom, with 5 large blackboards mounted on three walls. In addition, manipulatives and visual aids associated with geometry were kept in the closet at the back of the classroom with free access for the students.

## Data collection and analysis

The exploratory style of learning proofs was documented through (1) classroom observations in the form of audio recordings and field notes; (2) follow-up questions for students; (3) students' course reflections on the explorations; and (4) the researcher's research journal. In particular, the follow-up questions consist of 4 open-ended questions about students' explorations in geometry throughout the course. 17 out of 24 students completed the follow-up question sheets. All students submitted the course reflections.

The data drawn through classroom observations was organized and analyzed by the framework of 6 'exs'. The data from students' written reflections was analyzed using NVivo 10 software to explore themes and patterns of responses. The unit of analysis was a statement. Each participant's work was divided into statements and grouped in categories.

## Investigations of conic sections: Findings and analysis

This paper focuses on how proving was promoted through the initiative taken by the instructor and the students, while the content connects the instructor and the students. It does not measure the students' achievement because it is concerned with perceptions of their own understanding of proof.

### Initiatives of the instructor – Expounding and Explaining

The class made use of a hands-on investigation involving flashlights to explore conic sections. The instructor held a flashlight aimed at a wall at different angles. "The flashlight bulb and reflector make a "cone" of light. The wall cuts the cone with a plane, making a conic section. So moving the light changes which section we have," the instructor explained. As the beam was forming a circle, ellipse or parabola, he asked students to identify the particular shape made on the wall and to pay attention to the critical points where there was a change from one conic section to another, as the angle changed. Then the instructor raised a question about hyperbolae with a suggestion, "Now, what features will confirm the shadow is a hyperbola? You may look for asymptotes - lines which the light approaches as it goes up the wall."

### Initiatives of the students - Exploring and Examining

After the demonstration, students worked in groups to create all four conic sections by using the light source of their smartphones or the flashlights provided. Students quickly discovered that when the beam was perpendicular to the wall, it gave a circle; when it was tilted a bit, it gave an ellipse; when it was tilted more, with the ellipse vanishing, a parabola emerged. Group discussions mainly focused on the creation of a hyperbola and the difference between hyperbolae and parabolae.

- S8: How do you know it is a parabola or hyperbola?
- S22: It depends on the angle you hold it at.
- S8: Right, but how does an angle tell us whether it is a parabola or hyperbola?
- S12: Well... if you look at this graph I found online, the parabola's axis is parallel to the cone's side. If it were not parallel, it would become a hyperbola.
- S8: I see. So how is this related to what we are doing? The wall is the cutting plane and the light source is the cone. When the wall is not parallel to the borderline of the beam, it is a hyperbola. I cannot make them parallel precisely, but I get it.

This group discussion shows that in the course of their exploration, students did not limit their exploration to the flashlight demonstration but went on to research the problem by retrieving information online so as to better understand the features that confirm that the shadow was a hyperbola, the difference between hyperbolae and parabolae, and also to explain it to their peers.

Following the flashlight investigation, a series of paper folding activities was carried out. Taking the ellipse as an example, each student was given a clean sheet of paper with a circle and a point P inside the circle but away from the center (Figure 1a). Students were first asked to pick a point on the circle, say G, and fold the paper until P was lying directly on top of G (Figure 1b), and then to make a neat crease. Then students were asked to repeat the fold and crease action for a few dozen relatively evenly spaced points on the circle and to observe what shape emerged (Figure 1c).

**Figure 1: The sheet of paper for folding to create an ellipse**

Some students struggled to work out which point was being folded and to where – mistakenly folding a chosen point onto some other point on the circle, while others struggled to create a precise fold, due to the nontransparent nature of paper sheets. Although students worked on the folding at their own pace, within groups, they were talking to and helping each other as they proceeded, which allowed the ones who were struggling to listen, watch and move forward. With a number of creases created, conjectures were emerging in groups. For instance:

S6: I know that it is not going to be a circle. It is not circular. It would only be a circle if you can fold it onto the middle point. If you can fold it onto other point, it will be off-site the shape.

S17: I think it is going to be a parabola and P is going to be the focal point of the parabola. It makes sense.

Instructor: You need more folds. You can select a few more points on this side of circle (pointing at the sheet that S7 was holding).

S7: Oh, wait. It is an ellipse! I have a lot of lines. You can envision other points are going to be there. It is very clear it is an ellipse. You can really see it!

S17: (looking at S7's paper) Yeah, it is an ellipse... P looks like one of the focal point.

S6: Where is the other focal point?

Here we see that the students did not always do more than offer a conjecture about the shape of the conic created by the creases. The instructor felt it necessary to intervene and re-direct the students' attention to the core idea (the content) of the session.

### **Initiatives of the content - Exercising and Expressing**

With more questions raised, the instructor asked each group to focus on the following questions:

- (1) Now you have this ellipse, you know how to paper fold it. How do you prove it is an ellipse?
- (2) If you pick one of the folds, how does this fold help us prove it is an ellipse?
- (3) What can you say about this ellipse and the circle? How and why are they related?

S17: If you have this fold, and you have this distance from point P, then this distance (PE+EC) is going to equal to that distance (GC) because this is a reflection.

S6: Yes, but what does that have to do with the ellipse?

Instructor: Note: GC is the radius. These two distances (PE and EC)...

S6: No, I didn't get it.

Though the students had all the information they needed, they still had difficulty reaching the final step of the proof. By posing a prompt and question, the instructor tried to direct students' attention to the sum of the two distances (PE+EC) and the fact that it is equal to the radius. Then, a GSP graph, similar to the folding sheet in Figure 1 above, was shown to have students focus on the relationship between the two (see Figure 2a).

S17: OK. We are looking at P to E and E to C. The distance is equal to GC, which is the radius of the circle. Oh... That makes an ellipse because this distance (PE) plus this distance (EC) is fixed, the radius of the circle.

S6: And the ellipse must have something to do with the center as a focal point. If P is moving around according to the center point, the ellipse will just move as you move the P. So the center is another focal point. You can take any circle and a point off the center of the circle, and it will always be the case.

**Figure 2: A GSP graph (a) and animation of the formation of an ellipse (b and c)**

A Geometer's Sketchpad (GSP) animation was shown at the very end of the class. Figures 2(b) and 2(c) were two snapshots of the GSP animation indicating how an ellipse was constructed. This process taught them that, "A hypothesis is evaluated by deductively drawing consequences and by investigating whether these consequences agree with experience or should be accepted for other reasons" (Jahnke & Wambach, 2013, p. 469).

In a subsequent class, students were shown a demonstration in which sand was poured onto a circular disk with an off-center hole in it corresponding to the point in Figure 1a. A number of the students voluntarily poured the sand through a plastic strainer. As more sand poured onto the board, more a "ridge" clearly emerged. Looking down on it from above, it appeared to be an ellipse.

## Students' reflections

### Paper folding and sand pouring

More than half of the students admitted that they found paper folding complicated. While struggling with the first step, they missed the instructions for the second step. Following what was being said and doing folds correctly was an obvious challenge. Despite the confusion and the errors they made in folding, students appreciated the geometry embedded in the experiments. As S3 put it: "The reason for why the specific folds result in the shape never bothered me until I had this experience. I felt that I had a teacher explained the mathematical relevance." S4 observed that seeing the ellipse emerge during the sand pouring, was completely unexpected: "You can actually see an ellipse due to gravity pulling the excess parts down, forming a 'hill'." When asked about the definitions of conic sections, S14 stated that, "it is much easier, at least for me, to recall a process or property that I have physically manipulated or seen carried out visually than to recall a written definition."

### The GSP demonstrations

The students were asked whether the GSP graph and demonstration directly or indirectly helped them with the proof of ellipse. The majority of the students claimed that the animation directly helped with the proof. The responses that support this claim can be categorized as follows:

- *Have attention focused.* "We had all the information but we couldn't prove it until we saw this picture (Figure 2a) which has all the lines with the colors" (S6).
- *Accuracy.* "The animation is more visual and accurate than the paper folding" (S7); "The animation showed an infinite number of straight lines without making mistakes" (S12).
- *Legitimate process.* "The animation presented a 3D visual to experiment with" (S6); and "It provided an extended version of the folds we did in class and allowed me to continue my experience in a less time consuming and more efficient way (S17).
- *Exposure of the final product.* "It showed the final product of paper folds when you fold 100 or 1000 times" (S4).

However, 2 students claimed that the GSP indirectly helped with the proof. One student explained that the animation "helped more with my understanding as opposed to helping me write down the formal proof" (S16), whereas the other student believed that the role of the GSP was to show how the ellipse was constructed and to show how the proof connects to the demonstration (S5). Compared to the hands-on investigations, S7 and S20 claimed that the GSP animation presented in class did help with their understanding, but they had difficulty interacting with it. This is so because they did not know how to use the geometry software. As S11 said, "If I knew how to use the software, I would definitely use it more".

## Discussion

Adopting an exploratory style of teaching is metaphorically a bit like heading off into unknown territory; perhaps a city or forest not previously visited, and coming across blaze marks. On the surface, the 'exploratory style' of teaching involved initial stimuli provided by the instructor, then the instructor circulating listening, probing and suggesting. Questions raised by group members were fundamental and critical for the trajectory of the sessions. Beneath the surface lie the subtleties in how much time students were given to think for themselves, to discuss with each other, to try to

resolve questions that arose, and to seek assistance from the instructor. Three different contexts in which the same shapes emerge can be seen as a form of variation (Marton, 2015) with both conceptual and procedural aspects. The instructor's commitment to experiential style of engaging students with the mathematical content provided opportunity for different forms of interaction: students were stimulated to explore, to express, to seek explanation when they felt they needed it, and even to exercise their developing ideas. This prepared them to be able to make sense of what little exposition was provided during the sessions. Being fully engaged, with their hands, their own thoughts, and discussing with their peers, enabled them to produce a proof in which they had a high degree of confidence. Because the conjectures came mostly from them, they had an interest in proving, and a desire to find a proof. The physical and virtual phenomena directed student attention to the dynamic changes and alterations of the objects that they were creating, particularly when the instructor noticed students' struggles during the exploration. Student attention was directed by their peers through formulating conjectures, raising questions, and communicating their thoughts. These allowed learners to be immersed in an environment which engaged them to make conjectures, to try to express their vague thoughts, to modify their own conjectures and to challenge the conjectures of their peers, which is in line with the observations of Grenier (2013) and Hemmi (2010).

### **Pedagogical implications**

One of the features that distinguish mathematics from other disciplines is that mathematical conjectures ultimately require proof. One importance of exposure to mathematical reasoning and proof is that it provides learners with an opportunity to "know that they know", not because someone has asserted something but because they can justify it on the basis of previously agreed properties. In the case of the paper folding and sand pouring, it is a means to provoke students' curiosity of why it works and invite them to discover a geometric proof of ellipse on their own. The exposure to the necessity of 'why' could have great impact on promoting students' learning of proof when the activity is carefully designed and chosen.

The Geometer's Sketchpad was used in the classroom throughout the course. Introducing and using geometry software in the classroom at a regular basis can gradually change the way that students approach geometry. However, as a teacher, exploiting manipulatives and geometry software effectively requires familiarity with the materials. Each context has its own trajectory, in terms of time required to make sense of the actions and to interpret the effects. Perhaps the most important pedagogic implication is the need to stimulate students to make connections, to develop their own personal narrative concerning the connections between different manifestations of the same mathematical object.

For the student teachers in the class, we believe that the exploratory teaching style allowed them to grow as a student and as a teacher. At first they looked to be told what they must do and how they will be assessed. By engaging them in mathematical activity, they had a chance to experience themselves as mathematician-learners, and to exercise and develop their own powers to imagine and express, specialize and generalize, conjecture and convince (Mason, 2004). As S3 put it, "My focus throughout the course remained on learning rather than passing, as it should be."

Thinking in terms of modes of interaction has enabled us to add a little bit of detail to the notion of an ‘exploratory style’ of teaching. However, in order to provide specific advice for teachers, it will be necessary to discern even finer details, which deserves further studies.

# Looking for the roots of an argument: Textbook, teacher, and student influence on arguments in a traditional Czech classroom

Jana Žalská<sup>1</sup>

<sup>1</sup>Charles University, Faculty of Education, Prague, Czech Republic; [zalska@hotmail.com](mailto:zalska@hotmail.com)

*As part of a larger investigation aimed at getting a deeper insight into how particular teacher beliefs influence the role of the teacher, the students, and textbook materials in arguments that take place in one classroom, this study shows specific teacher beliefs that determine the role of each of the two other factors: the students' contributions and the textbook influence. This paper presents findings observed in a case study of a teacher who holds more traditional beliefs about teaching and learning of mathematics, in a 7<sup>th</sup> grade classroom. Namely, I present cases of conflict in preferences for particular warrant forms between: a) the teacher and the textbook authors b) the teacher's own beliefs, and c) the teacher and the students. I then interpret these in terms of the teacher's particular beliefs and show how they affect the theoretical model.*

**Keywords:** *Mathematical argument, teacher mathematical beliefs, textbook curriculum.*

## Introduction

Whether providing a mathematical proof of a theorem, explaining a formula, or a solution to a word problem, arguments are an inseparable part of mathematics teaching and learning. A lot has been said about argumentation practices and norms that guide those practices in various contexts. Literature has focused on the role of argumentation in textbooks, uncovering differences among textbooks in terms of arguments presented (Stacey & Vincent, 2009; Thompson, Sharon, & Johnson, 2012; Zalska, 2012), opportunities for arguments (Stylianides, 2009), and in providing teachers with support in argument-based tasks (Stylianides, 2008). The differences become even more complex when researchers describe mathematics teachers' beliefs concerning argumentation in their classrooms (e.g., Staples & Bartlo, 2012), the acceptability of certain types of arguments (Biza, Nardi, & Zachariades, 2009), and students' perceptions and preferences of arguments (e.g., Levenson, 2013; Levenson et al., 2006).

But what specific arguments actually take place when the teacher's beliefs meet the textbook authors' and the students' in a classroom? What is the role of the textbook and what role do students' contributions play in the class conducted by a teacher with a specific set of beliefs?

## Theoretical framework

According to Remillard's (2005) review, the textbook curriculum's role is important but the levels of participation in the intended curriculum vary greatly. The general model holds that a teacher selects tasks from the text, designs their implementation, supplements it with other tasks, and, finally, improvises based on the student contributions (Remillard, 2005). Sherin and Drake (2006) further find that teachers approach these activities in different ways and link these to teachers' experiences as mathematical learners. Schoenfeld (2010) argues that the actions an individual takes can be explained by their enacted beliefs, goals, and resources (including knowledge).

The individual students' mathematical knowledge and their perceptions of the expectations put on arguments they produce, as well as their own preferences and beliefs, can differ from their teacher's

expectations (Planas & Gorgorió, 2004; Levenson et al., 2006). The students' contributions, requests or choices of arguments are the result of their own knowledge, beliefs, and goals; they have their weight in the negotiation of socio-mathematical norms regarding mathematical arguments and explanations.

Based on the above literature, I adapt Remillard's (2005) model to propose a framework for studying the potential influence of the three main participants on the arguments, or the "enacted" arguments. Namely, the model theorizes that: 1) the curriculum may: provide examples of, requests and opportunities for arguments (tasks) to be enacted; it may also provide guidance for the teacher, based on the textbook authors set of beliefs, resources and goals; 2) the teacher may, based on their own set of beliefs, resources and goals: evaluate (select), design and provide the examples, requests and opportunities for particular arguments and may need to make immediate decisions about arguments prompted by students, and 3) the students' actual requests for arguments, for clarifications of arguments, as well as their own arguments or claims, which in turn are given by their own beliefs, goals and resources.

In my research, I focus on the similarities and differences between the interactions of the three participants in this model, in classrooms with teachers with different general beliefs about mathematics and its teaching and learning. Further, I investigate what specific teacher beliefs underlie the particular interactions when it comes to specific types of arguments or warrants. In this paper, I present some findings in the case of a teacher who holds a set of beliefs that tend to be associated with traditional views.

## Participants and data

Karen is an experienced mathematics teacher who was identified, within a broader investigation (see Zalska & Tumova, 2012), as a teacher with strong utilitarian beliefs about mathematics education. Two extensive interviews as well as short post-lesson interviews were conducted with Karen to infer her professional beliefs as well as her own intentions and interpretations of events in the lesson. She had been working with her class for almost two years prior to the data collection, to ensure that social norms in the classroom have been established. The number of students ranged from 15 to 18, with about an equal distribution of male and female students. The class use a main-stream textbook series, one of the most popular ones in the country. Karen was among the teachers who approved the choice of the textbook in her school, and her students each have a copy of it.

The data consists of interview and lesson audio-recordings, fully transcribed, and photographs from series of five lessons that Karen taught on the topic of percent. The analyzed textbook text included the unit on percent and the corresponding text in the teacher's book where authors provide teachers with commentaries for particular parts of the text and the tasks.

## Data analysis

In order to be able to establish differences between mathematical arguments, I will adopt the following terms from the widely used Toulmin's model in the following way: a (mathematical) *argument* denotes a sequence of statements (including visual statements) that is provided with the intention to show that a mathematical *claim* (specific or general) is true (or not). In this study, arguments include explaining of an answer to a problem, as well as the working out of the answer to a problem. A *warrant* is one such statement that directly supports the claim. In the context of a

classroom, it is a statement that does not require further explanation, i.e. is accepted as true. I will consider two arguments to be different if they contain different forms of warrants (e.g. representations) or a different sequence of warrants.

The textbook data was analyzed in accordance with the theoretical framework: the arguments that were provided were analyzed in terms of warrant forms and sequences. The tasks were analyzed as requests and opportunities for arguments (towards a claim that contains a problem's solution). There were no specific requests for arguments.

The transcript of the lessons and the text was first analyzed for episodes of argumentation to establish specific context for argumentation and social norms in the classroom. Next, the identified episodes of argumentation were broken down to individual arguments and warrants and warrant forms were identified in order to investigate where differences between arguments were present. The kind of student and teacher participation on the argument was also taken into account, in order to separate the cases of arguments provided by the teacher (i.e. when Karen elicited an argument step by step and students only provided the final part of a requested warrant) from those suggested by students themselves.

The arguments observed were then compared to the examples of arguments in the textbook, comparing warrants and warrant forms. Further, the relevant part of teacher's manual was analyzed for commentaries and any additional rationale given a particular argument in order to get insight into the text author's beliefs. Karen's own comments about particular arguments and warrant forms, in class and during interviews, were also analyzed to gain insight into the beliefs behind her decisions.

In this paper, I present the instances when an argument chosen by Karen did not correspond with a) the textbook, b) her own belief about mathematics, and c) her students' contributions. I selected them to illustrate the choices made by Karen, to pinpoint her specific beliefs, linking them with the students' and textbook influence.

### Efficiency and insight: Karen and the textbook

The arguments that Karen exemplifies in her classes when she teaches her students to solve problems involving percent differ from those in the textbook in two aspects. The textbook introduces the rectangular representation (see Figure 1) as part of problem-solving, a form of warrant(s); the authors sketch out the known and unknown quantities.

**Figure 1: A rectangular representation of a 15% percent discount**

Similarly, the textbook introduces one method for solving word problems with percent. The authors base the arguments on the concept of direct proportion, in particular, on the fact that the percent part changes in the same ratio as the percent. This idea is then used as a warrant in the method of the ratio-based rule of three (see Figure 2), which is explained and practiced in an earlier chapter in the book, the unit on ratios.

Zkus nejdříve podle obrázku odhadnout výsledek.  
K přesnému výpočtu použijeme trojčlenku.

počet procent	4	100 %	...	125 Kč	2	základ
	3	108 %	...	x Kč	1	procentová část

$$\begin{array}{rcl}
 x : 125 & = & 108 : 100 \\
 \frac{x}{125} & = & \frac{108}{100} \\
 x & = & 125 \cdot \frac{108}{100} \\
 x & = & 125 \cdot 1,08 \\
 x & = & 135
 \end{array}$$

Obchodník prodává trička po 135 Kč.

**Figure 2: The rule-of-three method**

In contrast, Karen does not use the rectangular representation at any moment in her classes. The arguments that she does show students are given names ("one percent", "with a decimal", and "ratio") and referred to as "methods". The majority of warrants for methods are based on the multiplicative relationship of percent part and the base, and on the definition of one percent, as corresponding to one hundredth, either as a fraction or decimal.

In the authors view, in the teacher's book, the geometrical representation helps students to get a better insight into the problem. Similarly, the authors assign the use of the ratio warrant the prominent role of helping students to get an insight into the problem.

This belief about a need to understand the problem through the use of a particular method or warrant seems to collide with Karen's beliefs about what is important for her students. Rather, she values efficiency and straightforwardness in problem-solving. Hence, she introduces neither the rectangular representation nor the rule-of-three arguments when solving word problems in her teaching. In fact, she discourages her students from using it (albeit acknowledging its existence and its effectiveness):

Teacher: Someone mentioned a third method, in case you study from your textbook, [I don't recommend it, only if someone gets] really lost and needs a crutch [...] but in the time you write it all out (referring to the method), you might as well have finished other three problems [using the other methods].

### Choosing not to justify – Karen's beliefs in conflict

The below example of a dialogue gives us a sense of how Karen's beliefs about the need to provide mathematical arguments for methods and general mathematical statements manifest themselves when the class discuss the percent – decimal relationship.

Teacher: So, if we have 18% (writing on the board), how do we get a decimal?

Students: Eighteen divided by 100.

Teacher: We divide by 100. Why? Because 18% is 18 hundredths (writing  $18\% = 18/100 = 0.18$  on the board), to divide by a 100 means 18 hundredths.

Karen expressed her belief in having the responsibility to provide students with justification of mathematical statements. This responsibility is felt even in the one moment in the observed lessons when Karen acknowledges that she doesn't know how to provide a mathematical argument for the procedure, and states that students just "have to remember". The problem Karen posed to class is: "From a class of 22 students, six participated in a math competition. What percent of the class was that?" Karen goes on to exemplify two methods for solving the argument.

Teacher: The first one is the 1% method. Again, I think that this method is more convenient and easier... ok, what's the base in this problem?

Students: [suggest ideas]

Teacher: Yes, base or 100% is 22 pupils. There are 22 pupils [She writes a record of the solution on the board, writes "1% = ".]. Now, we'll calculate, Ada?

Ada: 1% will be 0.22. [Karen writes this on the board.]

Teacher: Now you just have to remember that the percent, [...] I don't know how to help you remember ... you need to remember. You can calculate the percent this way [...] we divide the percent part we want to express in percent by one percent.

The argument that she is reluctant to share with her students is in fact the ratio argument used in the rule-of-three method: firstly, that the *percent part* : *percent* ratio is a constant, and for all non-zero real numbers  $a$ ,  $b$ ,  $c$ , and  $d$ , if  $a : b = c : d$  then  $a = c \cdot b / d$ . Clearly, this presents a conflict of beliefs for her, and she chooses not to present the argument, because this, in her mind, is too complicated and not possible to grasp with their current knowledge, especially for some students.

In the textbook, authors let the reader observe the first warrant through a series of examples, and then simply refer to the rule-of-three as practice established in the previous unit (on proportion). However, in the teacher's book they also admit that the equivalence of the two equations is, as yet in the curriculum, inaccessible to students and has not been established with students at this particular stage.

### **The stronger and the weaker: students' and Karen's preferences**

The following passages will show examples when different arguments are provided by students. The exchanges take place at the beginning of the second lesson, students were converting a series of fractions into percent. They had just converted  $4/5$  by expanding to tenths and then hundredths. Now Sam tries to convert  $3/8$  in the same way:

Sam: I'll multiply the fraction by twelve and a half.

Teacher: Why twelve and a half?

Sam: Because if I multiplied 8 times 125 [unintelligible]

Teacher: So by 125, right?

Sam: But that will be a thousand, so ...

Teacher: Doesn't matter. But (writing on the board) 8 times 125 is 1000. What is 3 times 125?

Student: 375.

Sam is trying to expand the fraction to hundredths (realizing that expanding by 125 and simplifying to hundredths is the same as expanding by 12.5) but the teacher feels that this is not straightforward and accessible to all pupils, so she takes over and breaks the argument down. After a few more simple problems, where students don't need to calculate, they are asked to convert the fraction  $9/40$ . At first, a student (Will) suggests to reduce by two and expand by five. Then he adds:

Will: Or multiply (sic) by two and a half.

Teacher: Excellent, two and a half. Do you [all] agree?

Kim: And couldn't you expand to thousands?

Teacher: Also. And if you were to do that, by what number would you expand?

Kim: So, that would be times ... (thinking) ... two hundr ...

Teacher: Twenty five. Either, as Will said, we expand by two and a half, which is not very common, (she turns to the board and writes) if we want hundredths in the denominator we expand by two and a half (she writes this on the board), do you agree? Forty times two and a half is one hundred, right? And the numerator ... 18 and 4 and a half [...] 22 and a half. So what percent is  $9/40$ ?

Students: Twenty two and a half.

Teacher: Or, as Kim said, expand by 25 (she writes on the board), the numerator (sic) is 1000, do you agree? And the denominator (sic) is ...

Students: 225.

Teacher: And we got the same thing, 22.5 %.

At this point, Karen allows a student (Will) to carry out an argument that is (like Sam's) based on expanding by decimals, but this time the student breaks it down into two warrants first, and Karen praises it. Will feels encouraged to suggest expanding by a decimal. Finally, another student supplies an argument based on the expansion to thousands (which had been shown by Karen before, see the transcript above). Both methods are now endorsed by the teacher, publicly, as valid arguments, and demonstrated on the board. When Karen summarizes these approaches, however, she qualifies Will's solution as "not very common".

## Conclusions

The above examples illustrate how the enacted arguments were influenced by the three participants, the teacher, the textbook, and the students. Even though Karen was the most influential provider of mathematical arguments, arguments that were made in the classroom included students' own warrants, and became accepted as correct and valid by the teacher. At the same time, even as Karen acted as the decision-maker when it comes to choosing what representations are useful in warrants, i.e. efficient, for her class, what was her choice not to include the textbook's geometrical representation warrants based on? Clearly, the textbook does not give it a utilitarian value, i.e. it does not provide opportunities for its direct use, and makes the representation void of value, outside the possible provision of better insight, as the authors claim, but Karen did not find the claim convincing enough. In that sense, her decision was very much determined by two factors: a) by her pedagogical

content belief about the efficiency of a certain type of arguments and b) by the problems (opportunities for arguments rather than argument forms themselves) presented by the textbook authors in the unit. The second factor, in turn, is given weight by Karen's utilitarian view of the goals of mathematics education, i.e. being able to correctly solve problems provided by the curriculum.

The case of the rule-of-three method is perhaps even more interesting, especially as the ratio warrant that underlies it is also at the heart of a method Karen presents when she shows the procedure for finding the percent in a word problem, but decides that the justification is not straightforward enough for her class, and backs the procedure up with her own authority. What made her do that? When asked about the need to mathematically justify mathematical statements, Karen conceded that not all arguments are accessible to students (or not all of them). As I showed above, the textbook authors also use a warrant that they acknowledge is out of the students' immediate reach. Again, we observe similar tendencies, and at the same time it appears that in this case Karen's perception of her students' abilities accounted for her decision not to justify.

In her classes, Karen also allowed students to provide arguments that she had not intended to take place, and accepted them as long as they were mathematically correct. At the same time, she manipulated such publicly expressed arguments according to her perception of accessibility to all students and made frequent evaluative comments about the methods and arguments, labeling them as efficient, common practice, convenient, easier, or universal. This qualitative evaluation springs from her beliefs about her students' mathematical ability and what it means to be good in mathematics: in her view, some students are better at understanding the problem, and innately capable of finding and choosing the most efficient, original, or convenient method, an attribute she also gives mathematicians in general. For the others, she needs to show simply which method to use, and they need to learn it by solving many similar problems, i.e. for some students drilling is the only way to succeeding in mathematics. The episodes seemed to confirm that this belief corresponds with the students' contributions: the weaker students would rely on arguments promoted by Karen, while students who feel confident in their own warrants, could keep using their own.

In terms of the teacher's influence, it appears that the teacher is independently imposing her own beliefs that are very local, e.g. the choice of method, but the choice of representation is also clearly determined by the curriculum (and its tasks) and beliefs that are much more global. Further, the teacher's choice of not justifying mathematically can be caused by her own belief but also reinforced by similar examples in the textbook. Finally, the students' arguments are evaluated by the teacher in terms of their mathematical correctness, their efficiency, and their accessibility to all other students (as perceived by the teacher). They are then often re-formulated by the teacher, which potentially reinforces the dependency of the weaker students on the teacher's choice of argument.

# Identifying phases and activities in the proving process of first-year undergraduates

Katharina Kirsten

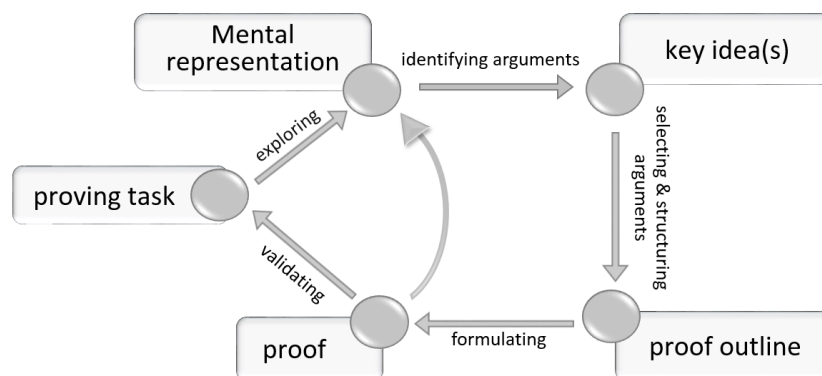

University of Münster, Germany; [k.kirsten@uni-muenster.de](mailto:k.kirsten@uni-muenster.de)

*Keywords: Proof, process-oriented perspective, proving cycle, undergraduate.*

It is well known that undergraduates commonly have to deal with great difficulties in constructing proofs, especially at the beginning of their mathematical studies (e.g. Weber, 2001). In the presented study, students' approaches to proving are analysed from a process-oriented perspective. The primary aim is to empirically confirm a process-oriented model for the proving competence of undergraduates. This model may be used to analyse proving processes at an individual level and, therefore, to gain more detailed information about proving process and its phases in general.

## Theoretical framework

The study is based on a theoretical model of the proving process that describes different phases and activities in proof construction and which is mainly following the considerations of Boero (1999). Boero (1999) describes a proving process that starts with conjecturing and exploration activities and ends up in selecting arguments and linking them to a deductive chain. However, proving tasks at university level often consist of a statement estimated to be true, especially during the first year of studies. The construction of a proof is in this case rather aimed at justification instead of conjecturing and problem exploration. According to this, we suggest the following variation of Boero's model.

**Figure 1: Proving cycle**

This model differs from the existing model in three ways:

1. The model focuses on proving activities concerned with the justification of a given statement. In particular conjecturing activities are excluded. However, reducing the process described above does not mean to exclude all exploration activities, but locating them at the beginning of the proof construction. Leaning on Reusser's (1997) approach of a situation model, a mental representation of the given statement is estimated to be developed by exploring the proving task. This representation could affect the proving process in a meaningful way.
2. The model includes validating activities at the end of the process. In this phase, which is already implicitly considered by Boero (1999), the final proof is reviewed regarding content, structure and linguistics. Besides, further (shorter or more elegant) proofs can be considered.

3. The underlying structure of the model is a cycle. This kind of structure provides the assumption that proving processes are not supposed to be linear. In fact, the proving process is shaped by interruptions, revisions and turns.

## Research question and method

The modifications lead to the following research question: Is the proving cycle an appropriate tool for analysing proving processes? That means, is it possible to reconstruct the different phases and activities stated in the proving cycle empirically? Is there in particular evidence for the existence of an exploration phase? In accordance with the research question, a qualitative study has been designed with the purpose to provide evidence of the proving cycle and to gain more detailed information about the different phases. Therefore, first year undergraduates and first year pre-service mathematics teachers (grammar school) are asked to work on proving tasks in the field of real analysis. To encourage the participants to talk about their ideas and approaches, the working processes are organized in pairs. The proving process of each pair is videotaped, transcribed and finally encoded according to Mayring's (2007) structuring content analysis. The coding is based on a system of categories, which consists of the five theoretical stated phases in the proving cycle.

## Results

The analysis of data from six cases shows that the system of categories seems to be well suited to describe proving approaches of undergraduates. Each of the suggested phases could be empirically confirmed in nearly all cases. However, formulating a precise and clear proof is an activity, which is sometimes omitted. An exploration phase could be reconstructed in all cases, although it varies in quality and quantity. The structure of the analysed proving processes is linear insofar as many phases could be reconstructed in the suggested order and turns mainly concern consecutive phases. Only in those cases, where the identified key ideas turn out to be inadequate, the proving process starts with repeated exploration cyclically. As there is no need for further categories the proving cycle can be used as a tool for analysing proving processes. Additionally, this tool can serve as a basis for deeper inductive investigations of the proving competence from a process-oriented perspective.

<sup>3</sup> Stockholm University, Sweden

<sup>4</sup> Charles University in Prague, Czech Republic

### Introduction

Working Group 2 was formed in 2011 in Rzeszów, Poland (CERME 7) as a forum for presenting and discussing theoretical and empirical research on the teaching and learning of arithmetic and number systems. The scope of the working group comprises grades 1-12 and emphasizes research-based specifications of domain-specific goals, analysis of learning processes and learning outcomes in domain-specific learning environments and classroom cultures, new approaches to the design of meaningful and rich learning environments and assessments as well as research on teachers' professional development.

According to the great variety in the field of learning arithmetic and number systems, the group intensively discussed fifteen papers and one poster addressing research for different ages and different approaches<sup>1</sup>. The key themes were number sense and structure sense, estimation and estimation tasks, flexibility in mental calculation, derived fact based strategies of multiplication in low-achieving students, understanding of rational numbers and ratio, didactical models as scaffolds for the evolution of mathematical knowledge as well as teachers' knowledge about rational numbers, ratio and place value according to big numbers.

In comparison to former working groups, we had an even greater variety of themes, and therefore the challenges and opportunities to identify common ideas and approaches in the papers presented. Two papers put the emphasis on teaching arithmetic, five on learning arithmetic, five followed a design based research approach with combining teaching and learning, and two papers focused on teachers' professional development.

### Teaching arithmetic and number systems

The topics of the two papers focusing teaching were diverse. One paper reflected the role and function of didactical models, the other analyzed and compared textbooks.

*Marita Barabash and Raisa Guberman* presented a theoretical study on didactical models (DMs) to support students' development of mathematical concepts and ideas. The authors discuss didactical models as a mathematical model (supporting the development of appropriate and consistent

---

<sup>1</sup> Fourteen papers were resubmitted after the conference and are published in the proceedings.

concepts) as well as a learning tool (providing an experience of using models). In this sense, DMs may help to cope some discontinuity in mathematics teaching across different levels.

With the focus on a foundational number sense, *Anna Löwenhielm Gosia Marschall, Judy Sayers and Paul Andrews* analyzed and compared how English and Swedish textbook tasks facilitate children's learning of those number-related competences that require instruction. Analyses identified both similarities and differences. Swedish pre-school curriculum seems to have prompted a conceptually focused textbook, while the strongly framed English pre-school curriculum seems to have precipitated a procedurally focused textbook.

## **Learning arithmetic and number systems**

The subject area “learning arithmetic and number systems” includes papers on number sense, structure sense, and understanding of rational numbers and ratio.

Students' development of structure sense in arithmetic is the focus of *Andrea Maffia and Maria Alessandra Mariotti*. Structure sense can be mobilized by students to compare and to transform arithmetical expressions, however sometimes it can lead to mathematical inconsistency that pupils might not be aware of. Their paper provides evidence of this type of phenomenon through syntactical transformations.

The assessment of students' ability in number estimation is the topic of a study conducted with Brazilian second and third graders. *Beatriz Vargas Dorneles, Mariana Lima Duro, Nohemy Marcela Bedoya Rios, Camila Peres Nogues and Clarissa dos Santos Pereira* compare a Number Line Estimation Task and a Numeroisty Task. Results show that the Number Line Estimation Task is more accurate in assessing students' performance in estimation.

*Luciana Corso and Beatriz Vargas Dorneles* put the emphasis on number sense and investigate the relation between three domains: working memory (especially the central executive and the phonological component), number sense and arithmetical performance. Based on different valid instruments, data was collected regarding each single component. The analyses reveal a significant correlation between the central executive component of working memory and number sense.

*Ayşenur Yılmaz and Mine Işıksal-Bostan* examine to what extent middle-grade students agree on statements about the ordering of two negative integers given within a real-life context, and what kind of procedural and conceptual strategies do middle-grade students generate to order those numbers. The results reveal that students did not explain the concept of ordering in daily life considering their conceptual meanings, and have problems in their procedural knowledge repertoire.

*Ozur Soyak* examines students' difficulties in proportional reasoning in rate and ratio problems. Students' difficulties are caused by the confusion of unit rate identification and by algorithmically based mistakes. A lack of understanding in the unit of measurement, the difference between additive and multiplicative reasoning, and some errors in the computation process seems to underlie such difficulties. The study suggests emphasizing proportional reasoning in the learning process.

## Teaching and learning arithmetic and number systems

This time we had a considerable amount of papers following a design based research approach. All studies were characterized by designing a teaching and learning arrangement and investigating students learning and understanding according to this specific context.

With the focus on students' development, *Laura Korton* explores a teaching-learning arrangement for the inclusive mathematics classroom to foster flexible mental calculation. The approach considered both the level of design (consideration for use) and the level of research (quest for fundamental understanding). Initial findings appear to suggest positive outcomes when Mutual Learning processes are integrated.

*Michael Gaidoschik, Kora Maria Deweis and Silvia Guggenbichler* exhibit results of an ongoing design research project. Based on a specific instructional design that emphasizes conceptual understanding and derived fact strategies, the study investigates the exhibited strategies in basic multiplication of lower- achieving students. Within the analyses three different strategy types could be developed. Results also show the influence of the instructional context.

*Cristina Moraes and Lurdes Serrazinha* describe an approach to develop conceptual understanding of decimal numbers by using and adapting the hundred square model. Within a teaching experiment 3<sup>rd</sup> and 4<sup>th</sup> grade students worked with three different models focusing on part-whole meaning. Results indicate that models promote students understanding of rational numbers, and suggest the decimat as an important part-whole model.

*Helena Gil Guerreiro and Lurdes Serrazina* discuss an approach to focus students' conceptual understanding of rational numbers based on teaching percentages in elementary school. Within a teaching experiment, the authors collected data by logbook, audio and video-recording, and analyzed qualitatively. Results suggest that this specific approach supports to understand multiplicative relations and rational numbers.

The pilot study of *Carlos Valenzuela García, Olimpia Figueras, David Arnau and Juan Gutierrez-Soto* contributes to the development of better mental objects for fractions. Using a Theoretical Model for fractions, they designed and developed a seven stage teaching sequence based on the use of applets created with GeoGebra and the number line as a conceptual and didactical resource. Results of the first two stages suggest students' preferences to represent fractions as proper fractions (unit segment). The majority of the participants paid more attention to the graphical aspects of the applet.

## Teachers' professional development

The two papers in this field focused on teachers' knowledge and its impact on students' learning.

*Frédérick Tempier and Christine Chambris* paper aims to reveal teachers understanding of place value related to larger numbers, and its impact on teaching and students understanding. Based on the "Theory of Didactic Transposition" the authors investigate the relations between all three aspects. The qualitative analyses of a teachers' lesson compared with the results of a questionnaire of students' knowledge provide interesting insights in teaching large numbers.

*Gulseren Karagoz Akar* conducted a single case study on teachers reasoning about ratio. Using a theoretical framework based on the concepts *within (state) ratios* and *between (state) ratios*, the teachers' conceptions of ratio are discussed. The results suggest different levels of reasoning in between-state ratios (as an operator and a combination of two extensive quantities), but some lack understanding about in between-state ratios as a single intensive quantity.

## Summary and outcomes

The great variety of papers provided a fruitful base for interesting and often animated discussions in a supportive quizzical environment. We agreed that we were able to broaden our own perspectives in terms of new perspectives on different mathematics educational research domains, and different uses of terms, concepts and theoretical frameworks. In our discussions, we went far beyond the specific themes of the single papers and covered general aspects that influence our work as international and interdisciplinary group of researchers. Those were

- the synergy of cognitive science and mathematics education,
- the similarity and differences in research paradigms and approaches,
- the intercultural differences,
- the different terminologies and the relevance of creating common terminologies and
- the necessity to clarify concepts and theoretical frameworks.

This spectrum of research focus in the papers reflect the number of open questions that still persist in the teaching and learning of arithmetic and number systems, and in need of further research. The intense group discussions raised further awareness amongst the group and questioned some positions that were taken for granted in both the field and in specific contexts. With the commonly perused aim improving mathematics education in the field of arithmetic and number systems in all academic levels, we perceived common ideas as a base for further research and discussion: (1) The importance of number sense regarding different age levels, number systems and perspectives form different domains. (2) The necessity to develop models for fostering flexible relational thinking about numbers. (3) The requirement to enhance our notion of number literacy as interaction of various components.

For our further work, the group agreed on enhancing the exchange of research on arithmetic and number systems from cognitive psychologists and mathematics education researchers, and work on specifying terms for both fields to agree on.

## A conception of between-state ratio in fraction form

Gulseren Karagoz Akar

Boğaziçi University, Turkey; [gulserenkaragoz@yahoo.com](mailto:gulserenkaragoz@yahoo.com)

*This study investigated one prospective secondary mathematics teacher's (Jana's) reasoning on between-state ratios in missing value problems and comparison problems. In two one-and-one-half hour written problem solving sessions followed by one hour-long clinical interview, Jana's use of informal and formal strategies and justifications behind those strategies in the context of ratio were examined. Extending previous research, results of this study showed that someone could quantify between-state ratios acting as an operator in fraction form once she has understood ratio as an association of amounts of quantities in within-state ratios. Results indicated a dichotomy within the boundaries of identical groups conception in terms of within-state ratios and between-state ratios prior to an understanding of between-state ratios as a single intensive quantity.*

*Keywords: Between-state ratio, within-state ratio, division, multiplication, extensive and intensive quantity.*

### Theoretical framework

Students might approach to a proportion such as  $a/b=c/d$  by comparing the first set of ratios  $a/b$  or  $c/d$  or the second set of ratios  $a/c$  or  $b/d$  (Noelting, 1980). In the first case, the ratios  $a/b$  or  $c/d$  are called *within (state) ratios*, where the ratio represents the original quantities within one state. In the second case, the ratios  $a/c$  or  $b/d$  are called *between (state) ratios*, where the ratio represents quantities between two situations (Noelting, 1980). For instance, envision the Recipe 1 Problem in this study. The original quantities of 9 tablespoons of oil and 4 tablespoons of vinegar could be represented by the within-state ratio,  $9/4$ ; and, the 4 tablespoons of vinegar and the 7 tablespoons of vinegar from two situations could be represented by the between-state ratio,  $7/4$ .

Researchers investigating prospective teachers' conceptions of ratio have revealed how teachers interpreted the relationships between quantities in ratio situations to quantify some attribute of interest such as lemon-lime flavor (Heinz, 2000; Karagoz Akar, 2007; Simon & Blume, 1994; Simon & Placa, 2012; Thompson, 1994). For instance, envision the Mixture Problem in this study. For this problem, research has shown that one might interpret the relationship between the quantities of 36 grams of pure lemon juice and 32 grams of pure lime juice in the following three different ways: First, someone having a robust conception of ratio conceptualizes that ratio is a *single intensive quantity* that expresses the size of one quantity (i.e., amount of lemon) relative to the size of the other quantity (i.e., amount of lime) represented by within-state ratios (Simon & Placa, 2012). In this conception one can utilize both partitive and quotitive division of the quantities in within-state ratios to quantify the attribute (i.e., lemon-lime flavor) in the situation. That is, either engaging in partitive or quotitive division, one might interpret the quotient (i.e., 1.125) of the original quantities represented in the within-state ratios,  $36/32$ , as a single intensive quantity representing the invariant multiplicative relationship between the quantities (Simon & Placa, 2012). This concept of ratio is also called as ratio as measure conception (Simon & Blume, 1994).

Secondly, in order to quantify the lemon-lime flavor, one might think of the within-state ratio,  $36/32$ , as representing an association of amounts of two quantities (Johnson, 2015). In this regard, s/he thinks of the quantities making up a particular combination that quantifies the taste of the mixture. This understanding

aligns with the identical groups conception (Heinz, 2000) and ratio as a composed unit (e.g., Lobato & Ellis, 2010). Within the boundaries of such conception, one might find equivalent ratios by dividing for instance, 36 and 32, simultaneously with 4 and come up with  $9/8$  ratio (i.e., as a composed unit, Lobato & Ellis, 2010), representing the same lemon-lime flavor (Beckmann, 2011). Third, to quantify the attribute, one might engage in partitive division of quantities in within-state ratios,  $36/32$  (Heinz, 2000; Karagoz Akar, 2007; Johnson, 2015). The quotient 1.125 then represents an association between the quantities of 1.125 grams of pure lemon juice per one gram of pure lime juice. Therefore, ratio as identical groups conception (Heinz, 2000) and ratio as per-one conception (Simon & Placa, 2012) involves one's interpreting within-state ratios as an extensive quantity rather than a single intensive quantity (Heinz, 2000; Karagoz Akar, 2007; Johnson, 2015). The study reported in this paper attempted at extending the previous research results in the following way: As the previous research has shown, students interpreting within-state ratios as representing an association between quantities (i.e., identical groups conception) could utilize equivalent fractions to handle missing value problems and /or comparison problems (Heinz, 2000; Lobato & Ellis, 2010). However, they cannot reason in missing value and/or comparison problems with quantities non-integer multiples of each other (Heinz, 2000). In this study, data from one prospective teacher documented that given that she interpreted within-state ratios as representing an association of quantities, she could reason with between-state ratios for situations involving quantities non-integer multiples of each other. In particular, Jana quantified the relationship between the quantities in between-state ratios as representing a particular combination and acted it on the within-state ratios as an operator. This is important because earlier research focused *only* on students' reasoning on the relationship between the quantities in within-state ratios. However, there is also need to focus on how someone reasons with between-state ratios; because, the conceptions of between-state ratios and within-state ratios have cognitively different underpinnings and that the understanding of proportion integrates both of these conceptions (Noelting, 1980). Also, the results from Karagoz Akar (2007) study showed that an understanding of between-state ratios as an intensive quantity (as percent-increase/ decrease) does not necessarily depend on an understanding of within-state ratios as per-one. Together with the results of Karagoz Akar (2007) study, the results of this study indicated a dichotomy within the boundaries of identical groups conception without having within-state ratios as per-one. Also, knowing about different levels of sophistication in the conception of ratio might shed light on determining and detecting students' reasoning along the way to advanced understandings of ratio, such as ratio as measure. In this regard, this study scrutinized the following research question: How might a prospective secondary mathematics teacher quantify the relationship between the quantities in between-state ratios and within-state ratios in missing value and comparison problems?

## Methodology

The voluntary participant was a prospective secondary mathematics teacher, Jana, at one of the universities in the United States. In this study data was collected through the structured task-based clinical interviewing method (Clement, 2000) following two one-and-one-half-hour long written problem solving sessions. During the written sessions, Jana, was asked to provide solutions with explanations and justifications to the tasks. The reason for doing written sessions was to determine Jana's solution processes prior to the clinical interviewing so that her reasoning, justifications of her solution processes, and the connections she made

among her interpretations of multiplication, division and part-part-whole relationships in missing value problems and comparison problems could be further elucidated. The interview was videotaped. The transcript of the interview and artifacts from written problem solving sessions and the interview were all used as data sources in the analysis.

In analyzing clinical interviews, the researcher "...is constructing a model of hidden mental structures and processes that are grounded in detailed observations from protocols" (Clement, 2000, p. 549). In this regard, the unit of analysis was Jana's strategies, solution processes and justifications she provided in externally written or uttered arguments (the observations from the point of view of the researcher). The goal was to determine what underlying conceptions of ratio Jana might be revealing. Thus, the analysis was interpretive (Clement, 2000). In this respect, reading the whole transcript line-by-line having in mind previous research, I determined chunks of relevant data that would allow generate the descriptions of Jana's mental structures such as her thinking of ratio as extensive or intensive quantities. Then, to further validate interpretations I went back to how she reasoned during the written sessions and how she reasoned on different tasks. Then I wrote a narrative. Following, another researcher was consulted to challenge the conjectures and/or to affirm their reasonableness to further validate the plausibleness of the interpretations.

### **Tasks (used in the study)**

For the study, I wrote the Hair Color 1 and 2 problems and adopted the others from the existing literature (see Table-1). The rationale for the choice of problems was the following: Heinz (2000) study showed that prospective teachers had quantified ratio at different levels. For instance, within the identical groups conception, some teachers engaged in partitive division of the quantities in within-state ratios and quantified within-state ratios as an association of amount of one quantity per one unit of another quantity. To the contrary, some teachers engaged in quotitive division to quantify the within-state ratios as a single intensive quantity. Thus, I wrote The Mixture Problem in reference to the distinctions in partitioning and measuring. Also, Heinz (2000) stated that within the identical groups conception someone might have used either their part-whole understanding to make sense of the problems, or have gone back to additive thinking. Thus, I wrote The Hair Color-1 Problem. Further, within the identical groups conception teachers were not able to deal with the quantities non integer multiples of each other (in between-state ratios). So I hypothesized that there might have been teachers who could do so by using adjustment strategies (e.g., Kaput & West, 1994). Thus, I adopted and modified the Recipe-1 Problem from Kaput and West (1994) since also they ranked it among the highest levels of difficulty (13th out of 15th difficulty). I also wrote The Hair Color-2 Problem based on the research results on rational number as operator (Marshall, 1993).

<p><b>Hair Color-2 Problem:</b> Kelly likes to color her hair with a mixture of red and brown dyes. When her hair was shorter, she used 15 grams of red and 17 grams of brown dye. Now, her hair is longer. She knows that the original mixture of 15 grams of red and 17 grams of brown will not be enough to color all of her hair. So she thinks that if she adds 7 grams of red dye to the original amount of 15 grams of red dye, some amount of brown dye to the original amount of 17 grams of brown dye, she can color her hair. How much of brown dye do you think she needs to use to make sure that she has the original color? In a group of 7th graders, following two solutions were given:</p> <p>a) The amount of brown dye Kelly needs to add to the original amount is <math>17 \times (22/15)</math>.</p> <p>b) The amount of brown dye Kelly needs to add to the original amount is <math>22 \times (17/15)</math>.</p> <p>Explain how each answer fits or does not fit the story? Depending of your choice of answer, explain what <math>(22/15)</math> represents and what <math>(17/15)</math> represents. You can use diagrams, shapes, graphs etc in explaining your answer (Karagoz Akar, 2007)</p>
<p><b>Recipe-1 Problem:</b> A recipe for salad dressing asks for 9 tablespoons of oil for every 4 tablespoons of vinegar. If we want to make a batch that includes 7 tablespoons of vinegar, how much oil we need to be consistent with the recipe? How do you know that the result makes sense? [adopted from Kaput &amp; West, 1994] You can use diagrams, shapes, graph etc in explaining your answer.</p>
<p><b>Mixture Problem:</b> A groups of 5th graders are given a project. In the project, they will create two mixtures and will put them in two jars to keep in the refrigerator in the kitchen so that during the break they can serve it to kindergartens. In the first jar, there is a mixture made up of 36 grams of pure lemon juice and 32 grams of pure lime juice. In the second jar, there is a mixture made up of 20 grams of pure lemon juice and 16 grams of pure lime juice. To label the jars, 5th graders want to use one number representing the lemon-lime flavor in the mixture. As a solution to their problem, three ways these students provided are as follows:</p> <p>a) There is 4 more lemons than limes in each mixture. So, put 4 on the labels.</p> <p>b) The ratio of 36/32 and the ratio of 20/16.</p> <p>c) 1.125, by dividing 36 with 32 and 1.25 by dividing 20 with 16.</p> <p>Which one(s) would indicate the lemon-lime flavor? Why? Please, in explaining your reasons for why some of these options would indicate the mixture's lemon-lime flavor, feel free to provide any kind of diagram, figure, or graphs. (Karagoz Akar, 2007)</p>
<p><b>Hair Color-1 Problem:</b> Kelly likes to color her hair with a mixture of red and brown dyes. When her hair was shorter, she used 4 grams of red and 5 grams of brown dye. Now, her hair is longer. She knows that the original mixture of 4 grams of red and 5 grams of brown will not be enough to color all of her hair. So she thinks that if she adds 1 gram each of red and brown dyes to the original 4 and 5 grams, respectively, she will preserve the color. Will the new mixture be the same color as the original? Explain your reasoning. You can use diagrams, shapes, graphs etc in explaining your answer. (Karagoz Akar, 2007)</p>

Table-1: Tasks used in the study

## Results

### Jana's understanding of between-state ratios

Data from the “b” option of The Hair Color-2 Problem and the Recipe-1 Problem showed that Jana left the between-state ratio in the fraction form, contrary to the previous research results (e.g., Karagoz Akar, 2007; Heinz, 2000). She did not think of finding the quotient in between-state ratios once the problem required her to think of it as quantifying percent decrease/increase. On the other hand, data from the interview showed that once *her goal* was to find out *how many times the quantities were incremented*, she was able to divide the quantities in between-state ratios. Jana had solved the Hair Color-2 Problem using the cross and multiply rule during the written sessions. So, during the interview, the first question I asked Jana was The Hair Color-2 Problem “a” and “b” options.

R: All right, okay, without solving the problem. What does that 22 divided by 15 represent in the problem?

J: It doesn't represent. Umm, 22 over 15, it kind of just says that she is adding 7 grams to the new amount over and it is over the old amount... well, 17, She put it in a fraction that new amount over the old amount, 22 over 15, she multiplied it by 17 because that was the old amount of brown, so that is what she was doing...she already know what she wants to change the red one to, so, she has to make one of the numbers and she has to make sure that the other color is the same ratio as before.

It is interesting that, although I told her “22 divided by 15” Jana thought that  $22/15$  represented the change in color, as in a fraction of the new amount of red to the old amount of red. She knew that the other color needed to be kept in the same ratio, and she knew that she could do it by multiplying the other quantity in

the original ratio with the same number. Yet, whether she thought of the 22/15 as the “change factor” was not clear. In fact, further data clarified this. Jana’s reasoning about the between-state ratios, once given in the simplest, reduced form, was the same on The Recipe-1 Problem, too. During the written sessions, Jana had written the following (see Figure-1):

original ratio  
 $\frac{9}{4}$  oil  
 vinegar  
 7-4 = 3 add vinegar  
 if you add vinegar you need to add the same amount of oil

so  $\frac{9}{4} + 3 = \frac{12}{7}$

Add 3 tablespoons of oil to be consistent  
 can check to see if the fractions are equal by  
 create denominators that are the same

$\frac{9 \times 7}{4 \times 7} = \frac{12}{7}$   
 $\frac{63}{28} = \frac{48}{28}$  that didn't work so we'll try it  
 with fractions  
 $\frac{9}{4} = \frac{x}{7}$  and cross multiply  
 $63 = 4x$  x is what we want the new amount of oil to be  
 how much we need to add we

**Figure-1: Jana’s reasoning on the Recipe-1 Problem in problem solving sessions**

Two interesting points need to be considered: Jana thought of adding 3 grams to both ingredients, which was a characteristic of the identical groups conception. Kaput & West (1994) also stated that students revert back to additive reasoning once the numbers used in the original ratio are very close to each other. Thus, first, if Jana had the conception of ratio as a single intensive quantity, she would not have thought of subtracting the quantities magnitudes of which are close to each other; rather, she would have thought of dividing (e.g., Heinz, 2000; Karagoz Akar, 2007). Secondly, Jana used equivalent fractions, after her addition strategy, to check her solution, leading her to the conclusion that her solution was not correct. Her use of equivalent fractions indicated that she did not have any other way of verifying whether the proportion held. This claim will be further supported by her reasoning on the Hair-Color-1 Problem. To figure out the extent of her knowledge, I asked Jana during the interview to account for a solution for The Recipe-1 Problem provided by another student as  $9 \times (7/4)$ . Jana said, “Because you are trying to get the same combination, so this is like the new combination of the vinegar where it changes from 4 to 7 so it is like a new ratio and you want the ratio of oil to be the same as it was before so you are allowed to multiply the old oil times its new ratio in order to get the new oil”. Her reasoning on this problem was similar to the Hair-Color-2 Problem option “b,” a between-state ratio represented a particular combination in fraction form. Taken together, data indicated a deviation from the identical groups conception: She did not solely go back to additive reasoning when the numbers in the original ratio were very close to each other. Also, she interpreted the fraction form of the between-state ratio as an extensive quantity, creating a particular combination, representing so many of the old quantity (from the first situation) for so many of new quantity (from the second situation).

Short Hair

red	brown
red	brown
red	brown
4	5

Long Hair

red	brown
red	brown
red	brown
red	brown
5	6

These diagrams represent the amount of dye Kelly is using depending on her length of hair.

4 : 5  
 5 : 6

If we set the ratios equal we get

$\frac{4 \times 6}{5 \times 5} = \frac{5 \times 5}{6 \times 5}$  now make equivalent denominators in order to compare the two fractions

$\frac{24}{30} = \frac{25}{30}$  The two amounts are very close but not exactly. The second amount will have more red in it so her hair color won't be the same as the original.

### Figure-2: Jana's reasoning on The Hair Color-1 Problem in problem solving

Data above (see Figure-2) together with her statement in the interview below, once again indicated why Jana's stage of knowing was within the scope of the identical groups conception, albeit with deviations from it. During the interview, Jana stated "this[referring to equivalent fractions] helps us to compare because you need to make one of them the same in order to compare actually compare". The excerpt and her solution above (see Figure-2) are important in two ways: first, it shows that Jana used the equivalence of fractions as a way to *compare* whether two different dyes are the same color. Second, it shows how she related the equivalence of fractions and the common denominator algorithm. Jana thought that the within-state ratio represented an association between two extensive quantities, representing so many for so many other parts. This was evident when she said she could *change the order* (brown to red) of the ratios. So she did not need the second quantity to compare the ratios once she equaled them out. Here, she again deviated from identical groups conception since she was able to deal with quantities non-integer multiples of each other.

### Limitations of Jana's understanding in within-state ratio context

Jana's understanding in the within-state ratio context showed some limitations and deviations from the identical groups conception. During the interview, for the "c" option of The Mixture Problem, Jana claimed the following:

[First Part] J: Yeah, fractions even though when you actually these fractions, when you divide the fractions you get this number 1.125 but you when you look at that number you don't know how much lemon juice there is and how much actual lime juice.

[Second Part] R: Does this tell like tell you anything like the lemon and lime about the juice or does this represent anything [referring to 1.125]

J: Well, if you have different number which I don't, I can't calculate numbers, where you have a different amount of like I don't know if you have like  $x$  and  $y$  this is lemon over lime and when you divide it you get 1.125 then you know this combination [referring to b option] equals this one [referring to the ratio of  $x$  to  $y$ ], that they will taste the same... because they are in the same ratio, so that kind of.

[Third Part] R: other than that this is going to help you?

J: No, actually, you can't, you can't, it is not going to help because you can't create more juice like this from just this number, you have to, because you don't know how much lemon juice is in there compared to actually how much lime.

The first part shows that Jana understood that, given the fractions of  $36/32$  and  $20/16$ , when she divided those numbers she got 1.125 and 1.25 respectively. However, although she realized that when she divided 36 by 32 she would get 1.125, she *had not abstracted* the fact that the quotient was the invariant multiplicative relationship that quantifies the taste. In the Second Part, data also suggested that Jana could tell that two fractions are equal if they equal the same decimal, but she did not think of the quotient as indicating something about the situation modeled by the ratios (Simon & Blume, 1994). Data from the Third Part suggest that Jana did not realize 1.125 lemons per lime as *at least the representation of a particular mixture*: for 1.125 grams of lemon there is 1 gram of lime. This indicates that Jana *did not anticipate* the quotient as per-one. If she had, she would have been able to add the quantities of 1.125

lemons and 1 lime until she reached the targeted quantities. To the contrary, she claimed “you can't create more juice like this from just this number [referring to 1.125]”, deviating from the identical groups conception.

## Discussion

Results showed that, regardless of the type of tasks, Jana interpreted the relationship between quantities in within-state ratios as association of amounts of quantities. This is similar to the previous research results (Heinz, 2000; Johnson, 2015). Yet, she deviated from such level of reasoning by interpreting the between-state ratios as an operator acting on the quantities in the original ratio situation (i.e., within-state ratios) since she was able to deal with the non-integer multiples of quantities. Also data from the Hair-Color 1 and 2 and the Recipe-1 Problems indicated that Jana understood between-states ratios as a particular combination of two extensive quantities. For instance, for her, the  $7/4$  ratio from one situation to the other in the Recipe-1 Problem was a new combination of vinegar, a new ratio, acting as an operator (Noelting, 1980). Also, deviating from the identical groups conception, when the numbers in the original ratio were very close to each other, she did not go back to additive reasoning, though attempting at it. Such attempt indicated that she did not have an understanding of between-state ratios as an intensive quantity, quantifying the change from one situation to the other in percent-increase decrease Karagoz Akar (2007). She also deviated from the identical groups conception (Heinz, 2000) and ratio as per-one (Johnson, 2015; Simon & Placa, 2012), such that she was not able to anticipate the quotient in The Mixture Problem as how much of one quantity associates with one unit of another quantity even when she divided it. These results suggested a different level of reasoning in between-state ratios and also a dichotomy within the continuum of identical groups conception in term of the conceptions of within-state and between state ratios prior to interpreting between-state ratios as a single intensive quantity. These results also have some implications for teaching ratio to both students and prospective teachers: The tasks in the study might be used to introduce prospective teachers with different strategies students might engage in while solving missing value and comparison problems. Secondly, Jana's reasoning seem to be at a higher stage than an understanding of ratio as an association of quantities, as reported in the field (e.g., Johnson, 2015). Teachers and teacher educators might expect to observe these different kinds of reasoning while developing an understanding of ratio on the part of their students. Also, they might refer to these kinds of reasoning while assessing their students' understanding of ratio at different levels.

# The double nature of didactic models in conceptualizing the evolution of number systems: A mathematical model and a learning tool

Marita Barabash and Raisa Guberman

Mathematics Department, Achva Academic College, Israel; [maritab@013.net](mailto:maritab@013.net)

*This paper is a small part of an on-going theoretical study on didactic models as a form of didactic transformations of mathematical notions, concepts and ideas, i.e. of adjusting mathematics for teaching. In what we propose here we argue that regarding this adjustment as mathematical modeling should be inherent to the mathematics teaching: they may enhance the concept development as the on-going result of students' learning; foster embedding the "big ideas" approach to mathematics learning, and lead to more self-consistently evolving mathematical knowledge. The "big idea" is that numbers are to be studied in the context of number structures, i.e. together with operations defined on them and properties of these operations, and that a familiar number system may serve a model for studying a new one. We illustrate the didactical model's approach at the initial stage of learning fractions.*

## Introduction

This paper is a small part of an on-going theoretical study on didactic models as a form of didactic transformations of mathematical notions, concepts and ideas, i.e. of adjusting mathematics for teaching in a way that would preserve to a maximal possible extent its structure and spirit. "We want the students to be exposed as early as possible to the idea that beyond the nuts and bolts of mathematics, there are unifying undercurrents that connect disparate pieces" (Wu, 2009). The theoretical framework for the research is inspired by ideas such as Wu's idea cited above, and sprouts from the works by Freudenthal (in particular, Freudenthal, 1975), Kirsch (2000) and from the discussion on applied-mathematic nature of didactic transformations (Borovik, 2012). These and other sources reflect the need for the merged input of deep mathematical, psychological and didactic considerations in constructing the mathematics feasible and meaningful for students of various ages and levels of mathematics learning.

Any form of teaching mathematics involves adjusting it for the students. In what we propose here we argue that regarding this adjustment as mathematical modeling should be inherent to the mathematics teaching. The philosophy behind mathematic models is applying a user-attainable mathematical apparatus to study an unknown subject or phenomenon. No mathematical model fully represents the subject being studied. One should always be aware of limitations of a model being used along with its purpose and benefits, and also of what Freudenthal (1975) presents as the dual character of mathematical models: "*Models of something* are after-images of a piece of given reality; *models for something* are pre-images for a piece of to be created reality" (p. 6).

An educated usage of models is supposed to shed light on phenomena and subjects being studied and seems to be indispensable as a tool at any level of mathematic studies. This implies that the mathematical models usage should become an integral part of the teaching/learning procedure in

mathematics lessons. In particular, concerning the *models for something* – the “to be created reality” in school mathematics is first and foremost the new mathematical knowledge hopefully to become in due time reality for the pupils. Thus, when the unknown subject to be studied belongs to mathematics, the model illustrating it serves didactic purposes; in this case, we are referring to didactic models (DMs) (see Figure 1):

**Figure 1. Didactic models as mathematical models and as a learning tool**

Examples of well-known and widely used DMs are the Dienes model demonstrating the principles of the decimal system, and the rectangle-area model used to impart some properties of multiplication and division. In this paper, we would like to look closer at didactic models as mathematical models of the *to be created reality*, in order to appreciate their educational value provided they are used knowingly and systematically. We suggest that mindfully and systematically applied to teaching, they may enhance the concept development as the on-going result of students’ learning; foster embedding the “big ideas” approach to mathematics learning, and lead to more self-consistently evolving mathematical knowledge.

A more-or less usual applied-mathematics scheme for the mathematical model usage is (Figure 2):

**Figure 2. Applied- mathematics scheme for the mathematical model**

An initial model is the result of a simplification rendering the phenomenon being studied mathematically feasible, solvable, analyzable. The mathematical model is applied to obtain results, which are supposed to reflect at least to a certain extent the “real thing” – the phenomenon or object being studied. The analysis of the results of the model application usually indicates situations at which the model fails to reflect adequately and fully the “real thing”, and should therefore be improved to better reflect it. The improved model leads to more understandings concerning the object, provided it is mathematically feasible for the user. This looks like a never-ending story, and in mathematics it usually is.

Applying this concept of mathematical model *as is* in the didactic context, i.e., as a didactic model, does not differ conceptually from application of mathematical models to any other field. It is just that the “real thing” being studied is of mathematical nature. In what follows, we illustrate the approach, emphasizing the need for the expertise in using it, which means knowledgeably following the main steps represented in the scheme above, accounting for the students’ level, so that the model being used is feasible to them; otherwise it cannot serve a basis for the further learning.

## Didactic models

Didactic models are the result of didactic transformation, being a form of applied mathematical activity aimed at teaching: „We have to accept that, in mathematics, didactic transformation is indeed a form of mathematical practice. Moreover, it is in a sense applied research since it is aimed at a specific application of mathematics teaching.” (Borovik, 2012, p.99). Didactically transforming a mathematical concept is no trivial matter, since it is supposed to cater to both the mathematical and the didactic aspects of the concept: to simplify without distorting the mathematical concept and to present it to pupils in an accessible form.

Shternberg & Yerushalmy consider didactic models to be a means for learning mathematics on the basis of mathematics already familiar to the students and rigorous mapping of learned operations onto the formal mathematical operations (2004). In line with this, we argue that a properly and consistently applied DM approach is a way to enhance the concept-development aspect of mathematical learning.

Prior to presenting the examples illustrating this assertion, we will sum up the main principles on which we propose to base the DMs approach in school. First of all, following Kirsch who claims that activating the existing knowledge is the way to attain accessibility of the new knowledge; DMs should be based on the existing mathematical knowledge, skills and understandings of a student (Kirsch, 2000). Second, the mathematical idea in the basis of the notion should not be distorted as a result of simplifications leading to a didactic model. The definition, operations and properties of a mathematical object should be lucid to those who construct a DM for its learning and to those who use it in its teaching (teachers, textbook writers, curriculum designers etc.)<sup>1</sup> Kirsch (2000) asserts that simplification is a way of making mathematics accessible, but explicitly refers to the “dividing line between legitimate simplification and falsification that does not get past critical pupils” (p. 267). “Not getting past critical pupils” does not ensure that less critical and mathematically aware students do not acquire the falsification as a true image of the mathematical concept. Third, properly used DM approach is a link between the student’s existing mathematical knowledge, the knowledge being currently acquired and the future study of the subject, exactly as the mathematical model is the main tool of the on-going upgrading of the mathematics-based understanding of a phenomenon or an object. Thus, properly used DM approach is a tool for inherently mathematical way of studying it.

In addition, no DM is unique in presentation of a mathematical object (as any mathematical model is not the unique mathematical presentation of any object, for that matter). No contradiction should exist between various DMs; they are supposed to complete each other in the representation of the mathematical object. A student may be exposed only to some DMs representing the concept, appropriate to the didactic circumstances (such as the stage of acquaintance with the subject; level of mathematical development of the students; aims of the specific lesson etc.); the properties represented by a DM must be coherent with mathematics, even if it is not explicitly presented to a student.

The efficient usage of DMs involves two equally important components of the DM-based approach: regarding DM as a mathematical model and as a learning tool. As a mathematical model, the proposed approach enables gradual building-up of an appropriate and consistent concept using the mathematical phenomena, objects and skills familiar to a student. As a learning tool, it provides a

---

<sup>1</sup> This is obviously the matter of Specialized Mathematics Knowledge for Teaching (see Hill et al., 2004).

precious experience of utilizing models in the process of acquiring a new piece of mathematical knowledge, which necessitates critical and mindful insight into the existing knowledge being used. In what follows, we consider two possible appearances of DMs at school. The outline of the first one appearance is presented in Examples 1-4. The reference to the second one we found appropriate to include as a part of the Discussion.

## **The beginning of fractions**

To illustrate what we consider to be a consistent and educated mode of DMs usage in elementary school, we will apply it to the initial stage of fractions learning. This is an example that we believe to be especially valuable at the elementary school level, when the young pupils do not yet have experience in the process of developing a mathematical concept, while they gradually accumulate some mathematical knowledge. Beliefs, skills and concepts they have acquired are supposed to serve them for the further study. The properly planned and applied model usage for learning may be one of the most important experiences in learning mathematics (Van Den Heuvel-Panhuizen, 2003).

Much too often the term “fraction” is used as a synonym to “a number smaller than 1”, which is the more problematic since in the very beginning of fractions learning the pupils really meet mostly fractions smaller than 1. Moreover, dominating approaches to the beginning of the fractions teaching are based on the “part-of-the-whole” concept and on geometric-visual representations (Hurst & Hurrel, 2014). Important and intuitively supportive as they are, they are detached from the only arithmetic and the only number system the students have come to know to a certain extent at this stage, which is the system of natural numbers. Hurst & Hurrel (ibid.) suggest that it might be plausible to present fractions already at the early stages of learning in a way that will not inhibit, but rather support the future acquiring of the fraction concept without having to significantly change it. Their approach is that of “big ideas”, which we interpret as constructing coherent DMs consistent with the future evolution of fractions into (final and infinite) decimal fractions, notion of ratio, algebraic fractions, the slope of a line and the derivative, and other advanced mathematical appearances of fractions. We suggest that the big idea behind the notion of fraction is the division operation (Mamede & Vasconcelos, 2016). In mathematics, a fraction is either the division operation itself or its result (quotient) (not necessarily a number). If the numerator and the denominator are both natural numbers, the fraction represents a rational number. Fraction is also an operator acting on other mathematical objects, and this is also directly related to its being the division operation. Hence, “the big idea” we propose as the mathematical background, is fraction as division: operation or result. Needless to mention that the idea itself is not intended for elementary school pupils, but the teachers should be cognizant of it.

We illustrate the DMs approach at the initial stage of learning fractions, the model being the arithmetic of natural numbers. We are fully aware of the risk of inhibition effect of this approach. Davis (1989) includes whole number schemes among inhibitors on the way to the rational numbers. Nevertheless, we assert that there is no other mathematical knowledge to build upon for the simple reason that the natural number arithmetic is more or less everything the pupils know before their first encounter with fractions, but for their possible acquaintance with  $\frac{1}{2}$  (also justly included by Davis among inhibitors), some primary geometric intuition and some idea of a number line.

Following Shternberg & Yerushalmy (2004), we provide here examples of “mapping” ideas familiar to pupils from the natural numbers arithmetic onto the new mathematical object - fractions, applying the usual scheme for a mathematical model use presented above.

We use it in the first example to impart a meaning of fractions needed for the understanding of addition of fractions; in the second example - to impart conventions of fractions presentations; in the third example – to adjust to fractions a handy geometric model used for integers. In all three examples we refer briefly both to advantages and to limitations of the chosen model, and propose an improved model. Last but not the least is the fourth example of a meaning of natural numbers inapplicable to fractions.

### **Example 1: Addition of fractions.**

*The model: a natural number as a cardinal number of a finite set of objects.* In a fraction whose numerator and denominator are natural numbers, the numerator serves as a *cardinal number* of a set of equal parts - unit fractions, into which the whole is divided. The denominator indicates the number of parts and their magnitude. Different unit fractions are different objects and cannot be added, unless they are united into one set, just as apples and pears are to be united into the set of fruit to be counted together. For unit fractions, this means representing them with a common denominator. *Limitations:* applicable only to rational numbers. Any other fraction, for example,  $\frac{\sqrt{2}}{1+a}$ , has to be understood otherwise, namely, as the division operation  $\sqrt{2}:(1+a)$  written in another form.

### **Example 2: Conventions concerning representation of fractions.**

*The model: the decimal representation of natural numbers.* The decimal representation is an equally important appearance of two ideas: of a *representation* of numbers *per se*, and of *conventions* in mathematics. As a decimal representation, it is the *model* applied almost as is to decimal fractions, when the pupils are prepared to deal with them. As an example of a *representation convention*, it may pave the way to the understanding that in mathematics there may be different forms of presenting commonly used objects; these forms should be familiar to everybody; this is the part of the mathematical language.  $\frac{7}{5}$  is just another form of writing 7:5, meaning either the operation or the number resulting from it. *Limitations:* the final decimal representation is inapplicable for some numbers; it has to undergo adjustments to infinite (periodic or non-periodic) decimal representations, and provide meanings for their truncations of various kinds.

### **Example 3: The area model**

To adjust the useful *area model* from a rectangle whose sides' length are integers to the rectangle whose sides are rational numbers, it suffices to count “unit rectangles” whose sides are unit fractions corresponding to the factors' denominators, instead of unit squares. *Limitations:* the area model “as is” is hardly applicable, for example, to infinite decimal fractions<sup>2</sup>, to fractions with irrational nominators or denominators, and would demand serious amendment to apply it to negative rational

---

<sup>2</sup> Some ideas as presented e.g. in Nelsen (1993, pp.118-122) are based on this type of visual reasoning linking the area notion to numerical reasoning and convergence ideas.

numbers. Nevertheless, speaking of irrational numbers - the segments division in an arbitrary ratio is defined for incommensurable segments as well, for example, by Thales similarity theorems in geometry, on the basis of segments measurement directly related to the number line. Having recognized that the segments ratios is attainable for irrational lengths as well, one can happily keep using the rectangle model for distribution properties of multiplication and division provided it is transfigured so that a subdivision neither into unit squares nor into small “unit” rectangles is needed anymore to apply it. Moreover, the basic fact that the whole segment of length  $a$  may be represented as the sum of the two parts, for example,  $\frac{a}{(1+\sqrt{2})}$  and  $\frac{a\sqrt{2}}{(1+\sqrt{2})}$ , is consistent with a similar idea for rational ratio, which again is beneficial for the further goal of regarding the system of real numbers as a whole.

#### **Example 4: Addition of natural numbers as continued counting.**

Consider the addition of natural numbers as continued counting:  $m+n$  as  $n$  times the addition of 1 to  $m$ , or  $m$  times the addition of 1 to  $n$ . Here the *limitations* of the model render it inapplicable as a model for fractions. Obviously, these examples are not meant to be used simultaneously and immediately and not necessarily explicitly in the beginning of acquaintance with the notion of fraction. We do assert though that the ideas represented in these examples must be intertwined in appropriate detail in the course of primary school arithmetic as a general approach to mathematics teaching and learning (DM being a learning tool) and as a groundwork to further encounter with irrational numbers (DM being a mathematical model).

### **Discussion**

The examples above include instances of appearance of new features when the object evolves from an existing one, of transforming the existing feature to adjust to the evolving object, and instances when some features disappear in the new object. Systematically focusing on such occurrences as a teaching norm may foster the concept development as an integral part of learning, provided the notion being taught is regarded as a concept to be permanently developed as a result of teaching and not merely as a topic in a curriculum. One important observation should be made here: should this approach be adopted for fractions or for real numbers, it has to be kept in mind already in the natural numbers teaching. More generally, it will hardly be useful if applied sporadically instead of being a systematic mindful approach. The more so in view of constraints of educational systems: in Israel, for example, and in many other countries, the primary schools are separated from the secondary and the mode of mathematics teaching at different levels is not always coordinated. This transition between the levels is therefore intrinsically discontinuous. We believe that systematic adoption in the primary school of DMs may help to cope with this discontinuity. We regard this to be an issue worth theoretical and empiric study.

Speaking of the encounter with the real number system, we refer here again to the double-sided role of DMs. *DMs as a mathematical model*: similarly to the initial encounter with fractions which is based on natural numbers as a model, in the case of irrational and in general, real numbers, the initial models to build upon are those originating from the system of rational numbers more or less familiar to the students. *DMs as a learning tool*: should the students have acquired appropriate mathematical concepts and learning skills prior to the encounter with real numbers system, these will determine their ability to take-in this new, rather advanced concept, and the extent to which they may take it in. They should have experienced testing the properties of new numbers and operations on them vs. the

familiar ones and the appearance of a new system that includes the previous one not only as a set of numbers, but also as a number system.

Examples of the challenges anticipating the students in their encounter with irrational and in general with real numbers in which the DM approach seems to be promising and worth a close empiric study, are appearance of the root operation and sign; operations on roots (arithmetic and later - algebraic), on expressions of like  $a + \sqrt{b}$ , and rules of these operations; decimal representations, in particular, decimal approximations of irrational numbers and the necessity to decide when, whether and how to approximate; inclusion of rational and irrational numbers in the same number system, etc. One of the key problems with the notion of irrational numbers is based first and foremost on *impossibility* of writing an irrational number as a fraction of two integers. Thus, their mere existence seems to claim for a new model because of the impossibility of using the previous one. On the other hand, *any* number  $a$  may be written as a fraction at least in a trivial way as  $\frac{a}{1}$  meaning nothing more than  $a:1$ . A representation of an irrational number by a fraction means just that at least one of the two parts of the fraction: its nominator or denominator or both, are not rational<sup>3</sup>. This does not prevent one from using operations on these fractions the way they were used on fractions as rational numbers; sometimes this representation calls for formulation of new rules. For example, to avoid fractions with irrational denominator, the students are sometimes taught to expand them following the rule familiar from rational fractions and based on division properties, for example,  $\frac{1}{\sqrt{2}} = \frac{1}{\sqrt{2}} \frac{\sqrt{2}}{\sqrt{2}} = \frac{\sqrt{2}}{2}$ . On the other hand, an equality like  $\frac{\sqrt{3}}{\sqrt{5}} = \sqrt{\frac{3}{5}}$  represents actually a new rule, to be both understood and adopted into the set of mathematical skills. Thus, the notion of fraction as division operation and its properties retains its usefulness. Comprehension of this can be the result of recurrent examination of the notion of fraction and operations defined on it and by it for “new” numbers, based on the DM approach.

Not less important, we suggest that a process of learning that systematically involves DMs is intrinsic to mathematics. No DM adequately represents “the real thing”, in our case eventually the system of real numbers. Various facets of the same complicated mathematical object awaiting the students in their forthcoming studies based, at least to some extent, on the analytic abilities acquired with the help of DMs, is a didactic challenge not less that it was a mathematical challenge, and mathematical and didactic tools should be combined in their teaching and learning. We suggest that the didactic models should be seriously regarded as a tool for this type of learning and closely studied in various theoretical and empiric aspects.

# Dealing with large numbers: What is important for students and teachers to know?

Christine Chambris<sup>1</sup> and Frédéric Tempier<sup>2</sup>

<sup>1</sup>LDAR, Université de Cergy-Pontoise, France; [christine.chambris@u-cergy.fr](mailto:christine.chambris@u-cergy.fr)

*National French assessment shows difficulties with writing large numbers at the beginning of the 6th grade. But, what do students need to learn and teachers need to teach? What do they actually learn or teach? We investigate these questions at different levels of the didactical transposition: students' knowledge, teaching practices and reference knowledge. We show a lack of mathematical understanding of large numbers and make a proposal for teaching knowledge which provides justifications for the use of large numbers which could foster a 'number sense' understanding of such numbers.*

**Keywords:** Large numbers, numeration, units, teaching, knowledge.

## Introduction

The topic of place value related to whole numbers is a major one in the primary grades, especially because it is the fundament of basic arithmetic. There is an abundant research literature on the issue. Most often it focuses on “small numbers”: from two to four digits. Several authors (Wagner and Davis, 2010; Howe, 2015) consider larger whole numbers, and specific issues on this topic. In this literature, order of magnitude – even more relative magnitudes - appears as a key one. For instance, it is needed for a thorough understanding of economic, political and scientific issues. National French assessment shows difficulties in writing large numbers at the beginning of the 6<sup>th</sup> grade. The latter can be seen as an anecdotal subject compared to number sense understanding of this kind of numbers. Yet, is there any link between both? How writing and reading large number tasks can be connected to quantity sense or number sense? What do students need to learn and teachers need to teach? What do they actually learn or teach?

## Theoretical framework, previous works, and methodology

### Theoretical framework

The Theory of Didactic Transposition (TDT) (Chevallard, 1985) (figure 1) considers school mathematics as a reconstruction by the educational institutions from the mathematical knowledge produced by academic scholars. The TDT has been often used for secondary school, more rarely for primary school where scholarly knowledge as a reference is not always taken for granted.

**Figure 1: The didactic transposition process (Bosch and Gascon, 2006, p. 56)**

The Anthropological Theory of Didactics (ATD) (*ibid.*) extends the TDT. It postulates that practicing math, as any human practice, can be described with the model of *praxeology*. It is constituted by four

pieces: a *type of tasks* -a set of similar problems-, a *technique* -a “way of doing” for all the tasks of the type-, a *technology* justifies the technique and is justified by a *theory*.

### Previous works

Chambris (2008, 2015), Tempier (2016) have analyzed teaching and learning of decimal numeration in French context, notably in second and third grades. *Classical* mathematical theory in numeration which embeds units (tens, hundreds, etc.) and relations between them was the reference knowledge up to the New Math. Chambris (2008) proposed the wording “numeration unit” for the units used in numeration (ones, tens, hundreds, etc.). Beginning in the 1980s, classical “scholarly knowledge” has been replaced by transposition of *academic* theory (polynomial decomposition with the exponential notation) within which there is no unit. This might explain why relations between units (e.g. 10 tens = 1 hundred) are little mastered –sometimes not taught at all- in present French context. In turn, Houdement & Chambris (2013), Tempier (2016) designed interventions for reintroducing units for “small numbers” in teaching practices, especially the relations between units, as well as explicit properties of positional notation: 1) The position of each digit in a written number corresponds to a unit (for example hundreds stand in the third place) (“positional principle”); 2) Each unit is equal to ten units of the immediately lower order (e.g. one hundred = ten tens) (“decimal principle”). Ten digits are enough to write any whole number thanks to an iterative process. The names of small numbers present many irregularities: numeration units provide a way to bridge the gap between irregular number names and positional notation. In short: thirty  $\leftrightarrow$  three tens  $\leftrightarrow$  3 tens  $\leftrightarrow$  3 in the second place (Houdement & Chambris 2013).

In a broader francophone context (France and Switzerland), there is a range of literature (e.g. Mercier 1997, Ligozat & Leutenegger 2004) on another issue in numeration: students’ and teachers’ difficulties in the topic “how to write large numbers”. Here we present some of their findings. The teachers being observed seem to consider relations between number names and positional notation as a linguistic issue which does not require mathematical knowledge. This generally leads them to teach two rules for writing numbers: 1) replace the words thousand, million by a space<sup>1</sup> (sometimes a dot), 2) put three digits between two spaces. These rules appear to be little powerful to solve the most complex problems with “mute zeros”. Mercier (1997) (related to French context) argues this reflects an institutional problem: the lack of mathematical knowledge on the topic, in the teaching system for several decades. Moreover, only one of the five teachers observed attempts to teach general base ten property of positional notation for large numbers. In all these contexts, it is finally social knowledge which leads to validate (or not) an answer! About “13180” “St.: One-hundred-thirty-one-hundreds and eighty. (...) T.: This would be one of the ways to name this number; but: will everybody understand immediately?” (Ligozat & Leutenegger 2004 p. 15).

These scholars present mathematical knowledge to fill the vacuum: Mercier (1997) indicated the general rule for positional notation using exponential notation algebraically, as well as a brief history of number names. Ligozat and Leutenegger (2004) proposed to distinguish and link two pieces of knowledge: for positional notation (base ten), for number names (base 1000). They formulate this using “powers of ten written with figures” (Chambris 2015, p. 57) notation:

---

<sup>1</sup> In France (among other countries), a space is used between the periods for writing large numbers: 34 020 (unlike 34,020 in some other countries). This space is sometimes replaced by a dot (34.020) but never by a comma. The latter is dedicated to decimal numbers: 34,020 is thirty four ones and twenty thousandths. This paper uses “French” notation.

$\bullet 17002058$ $1 \times 10\,000\,000 + 7 \times 1\,000\,000 + 0 \times 100\,000 + 0 \times 10\,000 + 2 \times 1000 + 0 \times 100 + 5 \times 10 + 8 \times 1 \quad (1)$	
$\bullet \text{Trente-cinq millions deux cent quarante et un mille neuf cent treize}$ $\bullet (30+5) \times 1\,000\,000 + [(2 \times 100) + 40 + 1] \times 1000 + 9 \times 100 + 10 + 3 \quad (2)$ $\bullet 35\,241\,913$	$\bullet \text{Dix-sept millions deux mille cinquante-huit}$ $\bullet (10+7) \times 1\,000\,000 + 2 \times 1000 + 50 + 8 \quad (3)$ $\bullet 17\,002\,058$

**Figure 2: Relations between positional notation and powers of ten (1), between number name and powers of thousand (2 & 3). (Ligozat & Leutenegger 2004, p. 3)**

They state: “the point is an institutional “foregone knowledge” phenomenon about how to name the numbers and how this (foregone) knowledge is linked with positional notation” (p. 17, our translation). They suggest tasks like  $13180 = 131 \text{ hundreds } 80 \text{ ones}$ . Years before, Fuson (1990) already indicated this in term of knowledge, the systems of multiunits that are intertwined (named base-ten numeration units, and base-1000 numeration units in the present paper). For large numbers, ten “thousands” make a new unit, a “ten of thousands” which is written in the 5<sup>th</sup> place; ten “tens of thousands” make a “hundred of thousands” which is written in the 6<sup>th</sup> place, etc. This reveals that the issue of large number names is mathematically connected with relations between units: in base-ten and in base-1000. That is clearly a first step to “quantity sense”.

### Research questions: Finding praxeologies

What are the relations between knowledge learned (by students), knowledge taught (by teachers) and scholarly knowledge? How do they contribute to give sense to large numbers?

### Method and data

Within praxeological analysis, exercises to be performed generally indicate the tasks, explanations related to students’ mistakes as well as introduction of new type of tasks often bring the teacher to make explicit the aimed technique and/or technology in classroom episodes, and definitions show technologies. Data will be analyzed in term of praxeologies. A mathematical analysis about reference knowledge is deepened. The data were designed and collected by the second author as follows. A teacher (Soline) was trained on 3-to-4-digit numbers teaching in a collaborative research project aiming at designing a resource for teachers paying specifically attention to the use of base-ten units in relation with written numbers (same vein as Tempier 2016). This grade-4 teacher was later observed during a lesson on another subject: numbers larger than 9999. The lesson was audio-recorded, transcribed, and notes were taken. During an interview (with note-taking by interviewer) just before the lesson, Soline was asked to explain her plan for this lesson. The different tasks of the lesson have been identified then three episodes corresponding to three tasks have been selected as follows. The two first ones are related to students’ mistakes (1- in relation with the introduction of the first 5-digit number, 2- in relation with the first mute zero in a 5-digit number). The third one is the introduction of one million. Finally, a written questionnaire was designed to better identify students’ knowledge and difficulties (n=159, end of grade 6).

## Results

### A teacher’s mathematical praxeology about large numbers (taught praxeology)

#### *Planning the lesson*

Reading and writing numbers (in digits) is the only explicit task (“to be taught”) in the French syllabus. The preparation plan shows that Soline chose this writing task with increasingly large numbers from 4 to 8 digits, with various places for “mute zeroes”. She was also planning to introduce the definition of the million

as one thousand thousands, but no base-ten relation with the new units (despite the previous study). The teacher wonders whether it is enough to teach how to write large numbers, and that a million is one thousand groups of one thousand.

### *Implementing the lesson*

The first number greater than 9999 to write in digits is "twelve thousand five hundred". A student, Anaïs, is not able to write it. Perhaps she refrains from writing a two digits number in the thousands place in accordance with the technique learned before. The teacher does not identify this cognitive conflict. She shows some confusion by calling out to the researcher; then she tries to help Anaïs.

You see [...] I already have Anaïs who has troubles. She is able to write three thousand but does not know how to write twelve thousand. Does it change something Anaïs? Think about it. Twelllllllve thousand. Twelllllllve thousand five hundred. Twelve thousand it is twelve groups of one thousand.

While the students learn for the first time to write a five-digit number, the teacher seems to consider there is nothing new to know about the *new* 5<sup>th</sup> place in the written number and about the *old* word (thousand) in the number name. She tries to help the student by emphasizing "twelve". The technique aimed is to write the number heard before "thousand" (here 12) and then the next number (here 500) with eventually a dot between them.

Later, the teacher asks to write "thirty four thousand and twenty". It is the first time with a "mute zero". Axel writes "34.20": it is what he hears: 34 and 20 with a point instead of the word "thousand".

Soline (T): Thirty four **thousand**. Twenty. It doesn't look strange? After the word one thousand how many digits are there?

Axel: Three

Soline (T): And here you have only two digits. How could you make to have three?

*Soline writes on the black board "34.20" and underline 20.*

Axel: To put a zero?

Soline (T): Where? (*Axel's answer is inaudible. But Soline writes "34.200" on the board*).

Soline (T): Look Axel (*and Soline writes on the board: "34.020"*).

Once again, the teacher seems powerless in front of a student's mistake. She gives then the answer without any explanation. With this case the technique to write a number in digits incorporates a new element: after "thousand" there must be three digits. Thus, when there is a two digits number after the thousands it is necessary to write a zero.

Later, after the writing of the number 999 000, Soline intends to introduce the millions. She asks the students how many groups of one thousand there are just after 999 000 and introduces the million thereby:

Soline (T): One thousand times one thousand is called otherwise. How it is called?

A pupil: One million.

Soline (T): One million, it is a new word. For the moment we said the word one thousand, now we say too one million.

A pupil: How we are going to write it?

Soline (T): This is what we are trying to discover together. It is necessary to make a kind of small chart (*Soline draws then this place value chart on the black board*).

The million is defined as one thousand thousands, what confirms Soline's plan. She tries to give meaning to large numbers relying on relations between base-thousand units. According to this point of view, the million doesn't appear as ten groups of hundred thousands. In the above table there are the names and places of periods but no reference to the name of base-ten places like the hundred thousands place for example. These technological elements rely only on a period viewpoint of the written number. The corresponding technique for writing numbers is: "write the number heard and points for the words *millions* and *thousand*". This is confirmed during the rest of the lesson. For example for the writing of two million, the teacher tells: "I write my *two* with my little point which means *million*". With this technique, teacher is not able to help students with mute zeros as a whole period or within a period. For example, at the end of the lesson, to write twelve million fifty some students write 12.50.000, 12.000.50 or 12.050.000 (with points or spaces). The teacher continues to explain the three digits in a period without a "base ten/place" viewpoint in addition to this "base 1000/period" viewpoint.

#### A questionnaire to inform about 6<sup>th</sup> grade students' knowledge (learned praxeologies)

The first part of our questionnaire concerns the writing of large numbers in digits (table 1).

Numbers to be written in digits	Beginning of gr. 6 (2008)	End of gr. 6 (2016)
Four hundred and seventy-five (475)	94%	
Three thousand and three (3 003)	96%	
Six hundred and twenty seven thousand (627 000)	76%	87 %
One million six hundred thousand (1 600 000)	76%	89 %
Three million fifty thousand three hundred and twenty (3 050 320)		79 %
Seventeen million two thousand and fifty-eight (17 002 058)		69 %
Five hundred and three million thirty-seven (503 000 037)		82 %

**Table 1: Results of national assessment (2008) and our assessment (2016) of 6<sup>th</sup> grade students**

To complement the data we also proposed conversions in order to examine the relations between large units and determine which of the relations between base-ten units and base-thousand units are better known. Such tasks are inspired from our prior research, and Ligozat & Leutenegger (2004)'s analysis. Both tasks raise as much difficulties. Approximately half of the students succeed in converting 4 millions into hundreds of thousands (48%) and 3 millions into thousands (50%). Many students did not write any answer. This was not the case for the "writing number" tasks. Perhaps they never performed conversion tasks before.

#### Complements for reference knowledge for teaching large numbers

We have already recalled some considerations about the specificity of the written and spoken numeration systems and their imbrications in a double system. The above lesson analysis and our previous studies

about “small” numbers show that there is a need for an intermediate system between these numeration systems in order to articulate this double system: the numeration units systems for bases ten and 1000. These systems of units enable various decompositions of numbers related to base 10 and base 1000. Up to 9999, number names can be linked with base ten numeration units, whereas beginning of 1000 they are linked with base 1000 numeration units. The transformation from a base-ten decomposition into a base-thousand decomposition is made by conversions.

**Figure 2: Links between numeration units, written numeration and spoken numeration**

The numeration units system supplies a way to justify the writing (in digits) of a number name. It enables to justify the mute zeros. See, for example, the task “writing eight millions thirty seven thousand fifty” (figure 2) in digits. The number can be written or spoken in numeration units “8 millions 37 thousands 50 units”, which can be converted in this register “8 millions 3 tens of thousands 7 thousands 5 tens”. It relies on conversion of 37 thousands in 3 tens of thousands and 7 thousands. The digit of millions is written in the 7<sup>th</sup> place, that of hundreds of thousands in the 6<sup>th</sup> place, etc. It is necessary to write a 0 to mark the lack of missing units. The obtained number can then spell 8, 0, 3, 7, 0, 5 and 0 by the positional principle of the written numeration. This example shows how this designation is relevant for reference knowledge for teaching. It enables to make links between the written and spoken system and to explicit the knowledge at stake.

## Discussion

The analysis of Soline’s lesson shows that her knowledge of the spoken numeration of large numbers, for one side, and her previous teaching of small numbers with an important concern about relations between base-ten units, on the other side, brought her to a beginning of a teaching of relations between base-thousand units. The latter seems not to be the case in the observations reported by Mercier (1997) or Ligozat and Leutenegger (2004) where only one teacher focused on the relation between base-ten units, and none on those between base-thousand units. Yet it is not enough to provide explanations for writing large numbers. Indeed, the teacher seems sometimes deprived to help her students during this lesson. In addition, our observation at the end of the lesson shows that it is insufficient to enable the students to avoid some mistakes, particularly those which are related to the mute zeros. The teacher explanations and her place value chart let us think that she assigns a base-thousand system to the written system and ignored its base ten operating. The two first episodes are coherent with our literature review considering large number names as an “institutional foregone knowledge”, and a linguistic issue.

By introducing numeration units in the reference knowledge to make links between base-ten and base-thousand units, we aim to provide a more explicit knowledge for teachers and students. It enables to take into account the double system units for large numbers (base ten and base 1000). It can, on one side, enrich the understanding of the written system by realizing that the system always works in the same way

according to the base ten and, on another side, learn the names of large numbers by putting them in connection with the written code. For example, to justify the writing of twelve thousand five hundred, the teacher has to clarify the link between ten thousands, the ten thousands unit and the corresponding places in the written number. In the writing of mute zeros, as in thirty four thousand twenty, the link between the values of 3 and 4 and the corresponding places in the written number can justify the writing of a zero in the hundreds place. Questionnaire results seem to confirm a more effective technique is needed for mute left-hand zeros.

This dual system of units can favor recognition of relative magnitudes of large numbers. For example, understanding the million involves the relation with smaller numbers. For example to understand the million involves the relation with smaller numbers: a million it is “ten times one hundred thousand” as well as “one thousand times one thousand”. Tasks of mental computation on numbers with only one non-zero digit can strengthen these relations. For example, “ten times two hundred thousand” could aim at leaning on the relation between one hundred thousand and one million, relation which does not explicitly appear in our way to speak these numbers. Other tasks aim at the extension of the written numeration. For example it is possible to recover and adapt small numbers tasks as the situations of collection counting and ordering (Tempier 2016). Counting a collection, with representations of large groups, can then be used to introduce new base-ten units. In addition, ordering a collection can be used to produce various decomposition of number under base ten and base 1000 with numeration units. Under this approach the spoken numeration could be secondly brought, in connection with these decompositions.

## Conclusion

Obviously students can succeed in writing numbers without knowing relative order of magnitude of numeration units in base ten and in base 1000. Yet, relations between units can provide justification for even writing numbers. This knowledge can be expressed with numeration units. It is missing in French institutional system. It might also contribute to the understanding of quantity sense. In this context, the work on small numbers is not enough to train teachers (even it is only for one case); surely, it helps the teacher to question her usual practices on large numbers. However, it does not provide tools for justification, neither the specific stakes of large numbers. Further research is needed in order to provide powerful tasks for teaching and learning large numbers.

*Studies correlating working memory, number sense and arithmetical performance show controversial results which create the need for further investigation. This research aims to verify the relationship between two working memory components (central executive and phonological loop) and numerical competence assessed through two different tasks: the Number Knowledge Test and the School Achievement Test. It involved 79 Brazilian students from 4<sup>th</sup> to 7<sup>th</sup> year of elementary school. The results suggest a significant correlation between the central executive and number sense. The same relationship was observed for the arithmetical performance. The phonological component showed no significant correlation with number sense nor arithmetical performance. The educational implications of the study are pointed out.*

*Keywords: Working memory, number sense, arithmetical performance.*

### **Background**

Both number sense and working memory are fundamental skills for arithmetical learning (Geary, 2011; Jordan et al, 2013). Studies investigating the relationship between working memory and arithmetical performance have been widely discussed in the literature (Anderson & Lyxell, 2007; Geary et al., 2007; Passolunghi & Siegel, 2004). However, the research that deals with the relationship between working memory and number sense is recent. Number sense is considered the basis of arithmetical learning and, consequently, it is assumed to be associated with working memory (Friso-Van Den Bos, Van Der Ven, Kroesbergen & Van Luit, 2013).

Working memory is a cognitive system that supports the development of various learning processes. It is a limited capacity system which allows the temporary storage and manipulation of verbal or visual information required for dealing with complex tasks. During learning the student constantly uses the resources of working memory to perform a series of activities, from the simplest tasks, such as remembering instructions, to the more complex ones, such as solving problems, that require the storage and processing of information and the control of learning progress. In the case of arithmetic, for example, a multidigit calculation ( $23 + 48$ ) requires several subprocesses (retrieval of arithmetic rules and arithmetic facts from long-term memory, calculation and storage of intermediate results, arithmetic procedures that involve carrying and borrowing operations) that must be coordinated and executed by the working memory system. Students with deficits in this ability would face problems. Thus, a difficulty especially related to the coordination of simultaneous operations of processing and storage can interfere in the execution of arithmetic tasks, resulting in slower performance and more errors in computation (Andersson & Lyxell, 2007).

Considering the tripartite model proposed by Baddeley and Hitch (1974), the working memory system is formed by three components: two storage systems (visuospatial component and the phonological loop) and the central executive, the nuclear component of working memory, responsible for the processing of cognitive tasks, coordinating the information stored within the other two components. It is generally agreed

that arithmetical achievement is associated with working memory performance (Alloway & Alloway, 2010; Andersson & Lyxell, 2007; Geary, Hoard, Byrd-Craven, Nugent, & Numtee, 2007). However, there is a lack of consensus regarding the relative importance of the central executive (Andersson, 2008; Geary et al., 2007; Passolunghi & Siegel, 2004), the phonological loop (Andersson & Lyxell, 2007; Passolunghi, Mammarella & Altoè, 2008) and the visuospatial component (Geary, Hamson & Hoard, 2000; Mclean & Hitch, 1999) in relation to arithmetical performance.

Some studies found that the central executive is the most affected working memory component (Corso & Dorneles, 2012; Geary, Hamson & Hoard, 2000; Geary, Hoard & Hamson, 1999). The central executive has three main functions: inhibition (prevent irrelevant information from entering or remaining in working memory), shifting (shifting between pieces of information and response sets) and updating (active processing and refreshing of information in working memory). There is no consensus regarding the role that each specific executive function plays in number sense. Some studies point out that inhibition is central to number sense development (Kroesbergen, Van Luit, Van Lieshout, Van Loosbroek & Van De Rijt, 2009), but such a result was not found by others (Lee et al., 2012; Navarro et al., 2011). Updating is usually seen as the most important predictor of number sense (Kroesbergen et al., 2009; Lee et al., 2012), but, it is important to emphasize that research focusing on the relation between number sense and executive function is still limited (Friso-Van Den Bos et al., 2013).

Concerning number sense, the literature shows consensus related to the important role that this construct plays to mathematical development, but there is a lack of consensus regarding the best way to define, assess and intervene in number sense (Gersten, Jordan & Flojo, 2005). Considering studies in the areas of mathematical education and cognitive development, Berch (2005) compiled a list of 30 characteristics presumed to compose the number sense concept. According to the author, number sense means awareness, intuition, recognition, knowledge, ability, desire, feeling, expectation, process, conceptual structure or mental number line. When defining number sense, some authors point out the conceptual, abstract aspect of numerical processing. For example, Dehaene (2001) emphasizes that number sense refers to the ability to mentally represent and manipulate numbers and quantities. Gersten and Chard (1999) define number sense as the flexibility with numbers and the understanding of the meaning of numbers and ideas related to them. Other researchers use definitions emphasizing the performance that is facilitated by that conceptual understanding of number, such as counting ability, number identification, number awareness, estimation, measurement, mental operations with numbers (Jordan, Glutting & Ramineni, 2010). We believe that both definitions of number sense are complementary: In order to succeed in the comprehension and execution of tasks involving numbers, relations and quantity, an abstract understanding of numerical processing is necessary. Therefore, the conception of number sense that characterizes this paper is that it is a general construct, which encompasses a very broad set of concepts, which the student develops gradually from his interactions with the social environment. Number sense is a way of interacting with numbers with its various uses and interpretations, enabling the individual to deal with daily situations that include quantification and the development of efficient strategies (including mental calculation and estimation) to deal with numerical problems (Corso & Dorneles, 2010).

Recently, researchers are interested in the association between the different components of working memory system, especially the central executive and the number sense. Children are expected to employ working memory capacity while experiencing number sense tasks such as counting, understanding magnitude, doing basic arithmetic calculation, using mental number line (Gersten, Jordan & Flojo, 2005).

However, there is a small body of literature targeting the association between working memory and number sense.

## The current study

The literature presented above suggests that working memory plays an important role for the development of numerical competence. However, the importance of each working memory component is not well defined. In order to contribute to this discussion, the present study aims to verify the relationship between two working memory components (central executive and phonological loop) and numerical competence assessed through two different tasks: the Number Knowledge Test and the School Achievement Test.

## Method

This is a cross-sectional study involving 79 (10- to 14- year-old) Brazilian students (36 girls and 43 boys) from the 4<sup>th</sup> to the 7<sup>th</sup> year of five public elementary schools. Mean age was 11.9 years. Students were indicated by their teachers considering the students' performance (average and low average) in the math curriculum according to each school year.

### Instruments

#### 1) Working Memory

- 1.1 The central executive component of working memory was measured using two different tasks: a non numerical - processing of verbal information (adapted from Hecht et al., 2001) and a numerical task - processing of numerical information (Yuill, Oakhill & Parkin, 1989). In the first task the students were required to answer yes or no to sets of two to four questions and then say the last word in each of the sentences, for example, in the two-question set, "Do tables walk?" and "Do lamps run?", a correct response would be "no" to each question and then "walk" and "run". For the numerical task, the students read aloud a growing sequence of three-digit sets and, at the end of each set, should remember, in order, the last digit of each set. For example, for the sets (2 5 7) and (1 8 6), the digits "7" and "8" must be remembered.
- 1.2 The phonological component of working memory was assessed through the Memory of Digits, Sentences and Short Stories task (Golbert, 1998). It consists of a growing sequence of digits, sentences and short stories to be repeated by the student.

#### 2) Numerical Competence

2.1 Number Knowledge Test (Okamoto & Case, 1996): This task is designed to assess the students' knowledge and comprehension about counting, numerical concepts and basic arithmetic calculation. The instrument is divided into four levels of complexity, being presented from the simplest (level 1) to the most complex (level 4). Although this instrument was designed for assessing students up to 10 years of age, we decided to use it, even having few students in the sample older than this age group. The students who were 13 and 14 years old were repeating students who were facing difficulties in some foundational components of numerical proficiency. The sample of this study was formed by average and low average arithmetic learners, but no ceiling effect in this task was observed.

2.2 School Achievement Test (Stein, 1994): This is a Brazilian standardized psychometric instrument designed to verify the students' arithmetical achievement. It presents 38 items (3 word problems and 35 written calculations). The word problems involve magnitude comparison and simple addition and

subtraction calculation. The written computations involve basic operations, operations with decimals, fractions, operations with integers and potentiation.

Data were analyzed using the correlation analysis between number sense and arithmetical achievement measures with the working memory tasks (central executive and phonological tasks), using the analysis of Pearson correlation at the significance level of  $p < .05$ .

## Results

Considering the central executive component of working memory, a significant correlation was found between the two working memory tasks and the tests that measured both number sense (WM1  $r = 0,449$ ,  $p = 0,000$ ; WM2  $r = 0,316$ ,  $p = 0,005$ ) and arithmetical achievement (WM1  $r = 0,303$ ,  $p = 0,007$ ; WM2  $r = 0,344$ ,  $p = 0,002$ ). The phonological component of working memory, though, did not reveal a significant correlation between the three tasks designed to assess the phonological loop neither with the number sense task nor with the arithmetical measure. Only a weak correlation was found between number sense and the task that assessed the recalling of short stories ( $r = 0,226$ ,  $p = 0,045$ ). Correlations among the measures are reported in Table 1.

**Table 1** - Pearson correlation coefficient ( $r$ ) and the significance level ( $p$ ) between the number sense test and the mathematical subtest of the TDE with the different components of working memory (central executive and phonological loop)

## Discussion

The results of the study presented a significant correlation between the two central executive tasks and the number sense test. This point emphasizes the fact that dealing with number sense activities requires working memory involvement, in this case, specially through the central executive system, since it was not found a positive relation between the phonological component of working memory and the number sense measure. This outcome reinforces what research has shown in relation to the strong association between the central executive (updating function) and number sense in children (Lee et al., 2012). Results in the same line are presented by Friso-van den Bos et al. (2013) who found that updating has the highest correlation with number sense, when compared to the shifting and inhibition functions of the central executive. As pointed out earlier, a small number of investigation has targeted the association between number sense and the central executive component of working memory and, therefore, more investigation is needed considering that research of this kind will bring contributions to preventing and remediating arithmetical difficulties.

The results of this research are in line with those that emphasize the positive association between working memory and arithmetical achievement (Geary, Hoard, Byrd-Craven & Desoto, 2004; Passolunghi, Mammarella & Altoè, 2008) reinforcing that the working memory is critically involved in a variety of numerical and arithmetical skills. In this study, this positive association refers to the executive component of working memory, but not to the phonological one. As mentioned before, there is a controversy in the literature regarding the role of each component of the working memory system in arithmetical achievement (Meyer, Salimpoor, Wu, Geary & Menon, 2010). Studies that include students with difficulties in mathematics in its sample indicate problems with the three components of the working memory system, but the central executive seems to be specially affected.

The non-conclusive results related to the contribution of each working memory component to numerical competence can be related to the following aspects: the large variability in the tasks used to assess the different components of working memory, the different kind of arithmetical tests being used and the ages of the subjects being assessed. We know that different cognitive demands require distinct working memory resources and these resources, in turn, can vary according to the age of the subject (Andersson & Lyxell, 2007). Therefore, although there have been advances in this area of study, more investigation is needed.

## Conclusion

The study showed a significant correlation between the central executive component of working memory (updating) and number sense. It contributed with more investigation with regard to the association between working memory and number sense, as studies linking these two domains are still scarce and present controversial results. The next steps for future investigation will involve more detailed analysis aiming to identify how the different tasks that compose the Number Knowledge Test (counting, numerical magnitude, mental number line, estimation, arithmetic calculation) are associated with the central executive, including in this analysis not only the updating component of the central executive, but also shifting and inhibition. This sort of analysis can give us a better view of the intensity of the involvement of the central executive function in different number sense tasks.

The outcomes of this investigation are in agreement with previous studies highlighting the significant correlation between working memory and arithmetical skills. The educational implication of such a finding deserves our attention. It is crucial to know the cognitive abilities that are impaired in the learner since the way the teaching process is conducted, will directly influence the effect that the cognitive deficit has on learning. For instance, students who are very slow to calculate, need the teaching of more efficient counting strategies and procedures in order to avoid being based overmuch on their working memory (when the counting all procedure is being used, for example), overloading it and increasing the chance of error in the calculation. Problems in working memory end up affecting the set of everyday situations in which mathematical tasks are involved. Those difficulties lead the students to present some characteristics that make the learning of mathematics more difficult, for example: counting on the fingers for a longer time, not performing mental calculation, forgetting the result of calculation they just made, not remembering the sequence of steps of an operation (Geary et al., 2007).

Studies are being designed focusing on the development of interventions to improve the working memory capacity by asking children to engage in tasks that require simultaneous processing and manipulation of information (Klingberg, 2010). However, the results of these studies are still controversial (Melby-Lervag & Hulme, 2013). Recent intervention research emphasizes the importance of combining working memory interventions with interventions that target the specific mathematical areas in which the student is showing

delay (Sperafico, 2016). This type of work has brought promising results to help students with working memory difficulties to learn mathematics.

Finally, this study contributed to the field of arithmetical learning by bringing some evidence of the positive associations between working memory and numerical competence (number sense and arithmetical achievement). Knowing the cognitive abilities underling arithmetical learning is fundamental to guide curriculum planning considering the working memory demands of the tasks, their level of difficulty and the characteristics of the learners. Further studies in this area will offer advances in the processes of preventing and remediating learning difficulties in mathematics. By identifying which components of working memory are weak, it is possible to avoid that at-risk students develop future problems. In the same way, research of this kind will support our understanding of possible cognitive obstacles that interfere in learning mathematics, so that we can face them trough the selection of adequate teaching resources and content as well as good teaching strategies. Maybe this is the most important contribution that the constructs of working memory and number sense can make to mathematical education.

*Number estimation is an important skill for both everyday and school situations that involve a group of cognitive abilities. The ability to estimate may provide a feedback tool to check performance in different mathematics learning contents. The most widely used task to assess number estimation is the Number Line Estimation Task (Siegler & Booth, 2004), and some researchers used a kind of Numerosity Task (Luwel, Verschaffel, Onghena & De Corte, 2003). This research compares the students' accuracy in two tasks that assess the ability of Brazilian children (N = 60), attending the 2nd and 3rd grades of a public school, to estimate. The children's success in the Number Line Estimation Task suggests it is more accurate than the Numerosity Estimation Task in assessing children's performance in estimation maybe because of the different cognitive functions required by the two tasks. The study's educational implications are discussed.*

*Key words: Number line estimation, numerical development, spatial representation of number magnitude.*

## Introduction

The decimal number system is used to establish exact quantifications, in contrast to quantity estimation processes. In everyday situations, we often use either exact quantification or number estimation (Feigenson, Libertus, & Halberd, 2013), and sometimes estimation can be easier than exact quantification (Siegler & Booth, 2004). Number estimation is a cognitive process used for quick or approximate answers or, for example, to calculate the duration of a movie or the distance between two places. It can be used as a feedback tool to check performance in different areas of mathematics including those requiring exact quantification. From our point of view, two complementary ideas define number estimation: a non-counting based quantitative answer to represent a set of objects; and a translation (Siegler and Booth, 2004) between two different ways of representing a number. We know that mathematical competence involves a group of abilities and cognitive processes. Number estimation has been considered one such process (Levine, 1982) despite the fact it has been less studied than exact quantification (Piazza, Mechelli, Price & Butterworth, 2006) although its importance has been highlighted (Rousselle & Noel, 2008). This can be explained by the variability of the tasks used to assess estimation skills in children, adolescents and adults as well as the different situations in which we use estimation (Siegler & Booth, 2004). The recognition of small amounts may be related to the ability to represent quantities in a mental number line and this ability would assist in comparing the magnitude between two numbers (Schneider, Grabner, & Paetsch, 2009). The estimation performance can be necessary in solving some mathematical tasks and the development of estimation is also considered a good predictor of later symbolic math skills (Park & Brannon, 2013). Despite the importance of its use, number estimation is not part of the school curriculum in many countries, including Brazil. Changes designed to improve mathematical achievement, including the introduction of number estimation in the curriculum, are currently being introduced in Brazil. For teachers, assessing the ability to estimate using different tasks might be a good starting point to analyze the

importance of the ability as well as to highlight the topic's importance in mathematics education. One of the most consistent conclusions reached by studies about the development of estimation is that children are not very able estimators, even when estimation is used in various daily applications. However, some researchers have hypothesized that children's estimations reflect their internal representation of numbers (Siegler & Opfer, 2003).

Moreover, there is some evidence to suggest estimation is related to mathematical competence in general and arithmetical performance in particular (Siegler & Booth, 2004; Booth & Siegler, 2006; Schneider et al., 2009; Mazzocco, Feigenson, & Halberda, 2011; Laski & Siegler, 2007) and can be improved (Park and Brannon, 2013). Recent research has highlighted the importance of estimation for mathematical development (Link, Nuerk, & Moeller, 2014; Laski & Yu, 2014). This research indicated that the better the students' accuracy in mental number line is, the better their performance in other numerical and arithmetic tasks (Link, Nuerk, & Moeller, 2014). Hence, it is important to understand the estimation process, the abilities involved, how to assess them and its role in mathematical performance, especially regarding the proposed changes to the curriculum in Brazil. It can be said that even though the estimation processes have been studied for the past twenty years, there is no consensus regarding the assumption that the estimations assessed by different tasks reflect a pure mental representation of numbers as proposed by Siegler and Booth (2004) and some new data indicate that it is affected by the limited knowledge of numbers (Ebersbach, Luwel & Verschaffel, 2015), as well as by visuospatial abilities (Crollen & Noël, 2014).

In the current scientific debate, among the explanations for the development of number estimation in children, two stand out. The first, the multiple representations of numbers model (Siegler & Booth, 2004), assumes that children initially represent numbers in a less accurate algorithmic way and develop a more accurate linear representation with age and experience. That is, in children the mental number line is compressed and they tend to maximize the distance between the magnitudes of numbers at the low end of the range and minimize the distance between the magnitudes of numbers in the middle and upper ends of the range. This tendency was named logarithmic representation. Gradually, children develop a linear representation, which maintains the same distance between the numerical magnitudes. Empirical evidence to support this logarithmic-to-linear shift model has largely come from the Number Line Estimation Task (NLET) proposed by Siegler and Booth (2004) in which children or adults must estimate the magnitude of a number by marking its proper position on a number line. However, the logarithmic-to-linear-shift hypothesis has been questioned by researchers studying number-line estimation (Barth & Palladino, 2011; Ebersbach, Luwel & Verschaffel, 2015). Some of the issues raised led to the development of a second explanation, the proportion-judgement strategies model (Barth & Palladino, 2011), which suggests that in the NLET children estimate the size of a part, the numerical magnitude of a specific number, relative to the size of the whole, thus making a judgement about the proportion of the size of the former. Hence, according to the numerical range, the more reference points (landmarks) made available, the more accurate the estimation will be, especially close to the landmarks. In other words, estimation performance reflects the strategies chosen to solve the tasks. Recently, a third model, the Two-Linear Account has been proposed as a plausible alternative (Ebersbach, Luwel, Frick, Onghena, & Verschaffel, 2008) and explains the developmental changes in number estimation as a result of children's familiarity with numbers. In this model, the mental numerical representation can be alternatively described as a combination of two linear patterns with different slopes, depending on number familiarity. In other words, this linear representation of numbers changes according to the age and numerical range known by children; the unknown numbers have

a slower linear representation than the known numbers. A recent paper (Dackermann, Huber, Bahnmueller, Nuerk & Moeller, 2015) proposes the integration of these accounts, which is a line of reasoning that we support as they introduce the idea that aspects of all three accounts may complement each other and facilitate a more comprehensive understanding of children's development of number line estimation.

Among the tasks most widely used to assess the ability to estimate are the NLET, described above, and the Numerosity Estimation Task (NET), which requires the subject to estimate the quantity of objects in a set (Luwel, Verschaffel, Onghena & De Corte, 2003; Barth, Starr & Sullivan, 2009). To the best of our knowledge, there is no research that indicates which of these tasks best assesses students' accuracy in estimation and therefore which would be best for application in research and in schools. Thus, the purpose of the study was to compare the accuracy in the numerical estimation of 60 children from the 2<sup>nd</sup> and 3<sup>rd</sup> grades of a public school in the city of Porto Alegre (Brazil) in order to determine which task (NLET or NET) best assesses the students' accuracy in number estimation. As the children in both grades were used to manipulating objects and completing tasks similar to the NET and admittedly had no contact with the number line before, we assumed the students would perform better in the NET than in the NLET. We chose the two tasks because the NLET is the most frequently used in estimation research and is widely used to examine how the human mind represents numbers (Barth & Palladino, 2011; Ebersbach, Luwel & Verschaffel, 2015), while the NET is similar to another task often used by some research groups that have a slightly different theoretical viewpoint regarding estimation, for example, Barth, Starr & Sullivan (2009). Both tasks are assumed to assess the same numerical estimation ability.

## Method

Using two different tasks, we compared performance in number estimation within a group of sixty children (mean age = 8.4, SD = .69, age range from 7.4 to 11.2 years) who were recruited from one public school, 37 boys and 23 girls: 28 from 2<sup>nd</sup> grade, (M = 7.8, SD = .29) and 32 from 3<sup>rd</sup> grade (M = 8.9, SD = .50). Two tasks were used: the NLET (Siegler & Booth, 2004) and the NET, adapted from Luwel, Verschaffel, Onghena & De Corte (2003). We used only one criterion to determine the students' accuracy in the presented tasks: the measure proposed by Siegler and Booth (2004), described below. The task was applied collectively in the classroom, the workplace and the school activities were affected as little as possible. The time to perform the activities in each class was about 40 minutes per task. The solution to both tasks involved the use of pen and paper.

The NLET requires the subjects to mark points corresponding to specific numbers along a number line bounded by 0 and 100. Children were asked to mark the place they considered most suitable for the position of the number to be estimated. Before each item, the experimenter said, "This number line goes from 0 at this end to 100 at this end. If this is 0 and this is 100, where would you put n?" (n being the number specified in the trial). 29 number estimations were required, one at a time. Each number was presented twice. Each child received a booklet with a number line drawn on each sheet to mark their answers. The difference between the two estimations of the same number provided a measure of the variability of the estimations. The 29 numbers comprised the 24 proposed by Siegler and Booth (2004), plus another 5 numbers that were also used in the second task. The 29 numbers presented were 3, 4, 6, 7, 8, 9, 12, 17, 21, 23, 25, 29, 33, 39, 43, 48, 49, 52, 57, 61, 64, 72, 78, 79, 81, 84, 90, 95, 96. They were presented in random order and then repeated in the same random order. Children had no pre-determined time to finish the task, each one could complete the task in the time they wanted.

The NET requires the children to estimate the amount of dots distributed in a checkered 10x10 grid. Before starting the task, the students were told the empty grid contained 0 dots and the full grid contained 100 dots. To reduce the possibility of verbal counting, the stimuli were presented quickly (1 second for each group of ten dots presented) and immediately followed by a white screen. Students were asked to perform a numerical estimation of the amount observed, writing them down in a notebook. They could not use any additional tool to solve the task. In the task, eight numbers from 0 to 100 were randomly matched (4, 7, 9, 17, 25, 49, 78, 95) in two different ways. In the first, the dots were presented in clusters and, in the second, they were presented dispersed. Both tasks were carried out collectively on different days. There was no feedback for correct or wrong answers.

## Results

To calculate the accuracy of the estimations given, the calculation of absolute percentage error of each child was used, adapted from Siegler and Booth (2004), and represented by the formula:

$$\frac{\text{Mean Estimation} - \text{Estimated Quantity}}{\text{Scale of Estimations (100)}}$$

To illustrate how this measure works, if a child was asked to estimate the location corresponding to the number 60 (or quantities of dots) in a number line from 0 to 100 (or 10X10 grid) and his/her answers were 65 in the first estimation and 75 in the second, we calculated the mean between the estimated values in the two attempts (in this example,  $(65+75)/2=70$ ). The absolute percentage error would be 10%, corresponding to the result of  $(70 - 60)/100$ , according to the above formula. We used this calculation because previous analysis showed that the difference between two answers for each number in both tasks was not significant ( $p=.24$ ) for NLET or ( $p=.06$ ) for NET.

After that, a descriptive analysis of the accuracy of each child was conducted to identify the general standard of performance for each task. These analyzes show the students' accuracy is higher in the NLET. The reported performance tends to be more cohesive in the NLET (Table 1).

	Mean	SD	Significance
Number Line Estimation Task	.089	(.050)	$p = .018^*$
Numerosity Estimation Task	.158	(.250)	

\* $p < .05$

**Table 1: Comparison of the Mean of Percentage Error in each task**

To determine the correlation between the two tasks, Pearson's correlation coefficient was carried out ( $r = .67, p < .01$ ), and indicated a positive correlation between both tasks, suggesting that either demand similar cognitive functions or both are related to other skills that were not measured.

To test for differences in the children's estimation accuracy when required to estimate smaller and larger amounts, we considered the same numbers estimated in both tasks. A paired-samples t-test only indicated difference when estimating the same number in each task in larger quantities (Table 2).

Number to be estimated	Number Line Estimation Task		Numerosity Estimation Task		Sig.
	Mean	SD	Mean	SD	
4	.034	(.043)	.086	(.333)	<i>ns</i>
7	.063	(.086)	.084	(.397)	<i>ns</i>
9	.081	(.101)	.083	(.229)	<i>ns</i>
17	.109	(.112)	.188	(.495)	<i>ns</i>
25	.117	(.087)	.151	(.184)	<i>ns</i>
49	.085	(.062)	.204	(.145)	.000*
78	.118	(.064)	.249	(.224)	.000*
95	.091	(.080)	.219	(.441)	.022*

\* $p < 0.5$

**Table 2: Comparison of estimations between the same numbers**

This analysis showed that the students' estimations were all more accurate in the NLET, however, these differences were only statistically significant with the numbers 49, 78 and 95 (Table 2), while there is greater variability in the children's estimation in the NET. This may suggest important differences between the tasks performed. Maybe the three numbers (49, 78 and 95) are closer to "quarters" (50, 75 and 100), which would help children to identify the position of the numbers in the number line. Hypotheses to explain these variations will be discussed later. In the NLET, one of the most common strategies used by students was to fill the number line with marks that represent the numbers before or after the number proposed, as illustrated in Figure 1. In the NET, some students tried counting groups of dots and imagining how many similar groups could be in the whole. Progressions related to the speed with which the children performed the estimations were not tested in this analysis, considering that the time for execution was the same for all participants.

**Figure 1. Example of marking strategy in two numbers of NLET**

## Discussion and conclusions

As we described above, number line estimation is related to both basic and complex arithmetical abilities. Moreover, there is evidence to suggest number estimation is related to mathematical achievement. Despite this, number estimation is rarely taught in Brazil and other countries. In our research, we observed children more accurately estimate numbers on a number line than dots on a grid. Although the two tasks measure the ability to estimate, as indicated by the general correlation between the students' accuracy in the two tasks, they may be linked to different cognitive functions, as suggested by the differential performance when the tasks involve numbers over 25. Although speculative in nature, some ideas help us to understand the results. The NLET requires transposition from numerical knowledge to a position on a line, whereas the NET requires transposition from a perceptual estimation (linked to quantities) to numerical knowledge. Both demand translation between different representations. However, unlike the NET, the NLET allows children to try a discrete quantity representation, sometimes marking the number line with lines or dots from the beginning to the point that could represent the required number. This marking strategy was the most widely used by the children and helped them identify an almost correct answer. Children used different strategies or representations when estimating. The linear distance of numbers along the number line seems to be an important support for the estimations, as Siegler and Booth (2004) have described. Additionally, children used decision-based strategies considering the proximity of the extremities, for example, to represent number 78, they made marks from 100 to 78 in descending order. Alternatively, some decided to begin from 50 and made marks from 50 to 78 in an ascending sequence. Another strategy was to mark the quarters (e.g. 25, 50, 75) as landmarks. All these strategies have been identified as means to improve the way children estimate (Siegler & Opfer, 2003; Siegler & Booth, 2004). The use of these strategies suggests the children did not estimate the numbers by chance, but instead coordinated mathematical knowledge and spatial skills to assess the place to mark. This tactic fits very well with the proportion-judgement strategies model (Barth & Palladino, 2011). The central number (50) was understood by some students as a reference mark used to estimate the other numbers.

The difference found in the tasks with the numbers 49, 78 and 95 can be explained by the fact the three numbers are close to “quarters”, which would help children to identify the position of the numbers on the number line. Also, we must remember that, generally, younger children tend to overestimate small numbers and compress large numbers toward the end of the scale, whereas older children, using the same number range, tend to estimate more accurately (Siegler & Booth, 2004). Moreover, in our research, it may be the

case that due to lack of familiarity with the number line task, the older children continued to overestimate small numbers, as described in the logarithmic model. Another possible factor influencing the results was the time. In the NLET, children have time to think about the relation between the number and the place on the line, while in the NET they have only a few seconds to observe the quantities and more time to estimate the quantity represented. The NLET requires the ability to coordinate the knowledge of number systems with a kind of spatial graphic representation on a line. Maybe the effort made by children to coordinate these two cognitive demands helps them to estimate more accurately, despite having little experience with number line tasks. Moreover, the NET may not help students to access their knowledge of the number system, since it provides no clues that would allow students to adopt some proportion-judgement strategies coordinated with their number system knowledge. We suggest the NET requires more “guessing” than the NLET because there is no opportunity to mark “quarters” or anything like that to help them to estimate. One limitation of the research is that only eight numbers were repeated in both tasks. For future research, we suggest amplifying the analysis of the cognitive processes involved in both tasks. We did not control the number system knowledge of the subjects. We do not discuss whether or not the number line task reflects an internal mental number line, since this was not the subject of the paper. However, considering the results of our research, we can say that the NLET is a relevant measure even if it does not reflect an internal mental number line. We support this idea because, although the children were not familiar with the number line estimation task and were more used to NET-like activities, they performed better in the NLET. This surprising result provides the opportunity to introduce the discussion about estimation in the Brazilian curriculum. Furthermore, considering that the ability to estimate is correlated to many aspects of mathematics, for example, number comparison, addition, and subtraction, it is important to take in consideration the assessment of this ability in mathematics education as well as the ways to improve it.

*We present findings made during the first cycle of an ongoing design research study on the working out of basic multiplication in 8 Austrian classes. Their teachers had tried to implement an instructional design that put conceptual understanding and derived facts strategies centre stage. Focusing on the degree of fact mastery reached at the end of grade 3, we present a typology of strategy use within a sample of 48 students. We take a closer look at lower-achieving students, in particular those 8 students who had little if any success in mastering basic multiplication. While 6 of them used derived facts strategies quite often, their deficiencies either in adding and subtracting or with regard to the conceptual basis of derived facts strategies seem to have hindered them from mastering more facts. We discuss implications for the planned second cycle of the study.*

*Keywords: Basic multiplication, derived facts strategies, lower-achieving students, design research.*

## Introduction

Sherin and Fuson (2005), in an overview of prior work on teaching and learning basic multiplication, refer to 4 different though interlinked threads of research. Like them, in this paper we focus on only one of these, namely the development of computational strategies. We agree with Sherin and Fuson's assertion that strategy development must be examined with close reference to the ways multiplication is taught. Hence, after looking over different ways learners solve multiplication tasks, we summarize contemporary approaches as to how to work out basic multiplication in primary grades. Against this backdrop, we focus on the multiplication learning of lower-achieving students. We contribute to that issue some findings of a design research study on 8 classes whose teachers had tried to base the learning of multiplication on the targeted working out and practicing of derived facts strategies.

## Empirical framework and research questions

### A taxonomy of strategies used for basic multiplication

Sherin and Fuson propose that the “most important changes” in the development of strategies for basic multiplication are primarily “driven by relatively incremental changes to number-specific computational resources” (Sherin & Fuson, 2005, pp. 353–354). So a child might solve, e.g.,  $3 \times 4$  initially by drawing 3 groups of 4 circles each and “counting all” of them; later by “rhythmic counting” (“one, two, three, *four*, five, six, seven, *eight*, nine, ten, eleven, *twelve*”); then by “repeated addition” of  $4+4+4$  or maybe by saying the “count-by sequence” (“four, eight, *twelve*”). Finally, the child may “retrieve from memory” that “ $3 \times 4 = 12$ ”. These strategies as well as “hybrids” such as applying a “derived facts strategy” (“ $2 \times 3 = 6$ , then  $4 \times 3$  must be twice as much”) form part of the taxonomy of strategies the authors devise drawing on prior research. But even if the strategies as listed follow a progression, this is not to be seen as the consequence of an increasingly sophisticated

understanding of multiplication, but mainly driven by a child's growing abilities to, e.g., add, subtract, double and halve, and thereby compute products with increasing ease (Sherin & Fuson, 2005).

This is why, for a long time during the learning process or even permanently, a single individual will presumably use a variety of strategies for solving different basic multiplication tasks, depending on the value of the operands and his or her computational resources. What is more, "because the learning of number-specific resources is very sensitive to instructional emphasis" (Sherin & Fuson, 2005, p. 379), strategy development may differ significantly across classrooms. Such differences are sufficiently documented. For instance, Sherin and Fuson (2005) report that rhythmic counting, while being ascribed an important role by Anghileri (1989), was not observed at all during the interviews they carried out with students whose teachers had not promoted that strategy. Steel and Funnell found no evidence for the use of repeated addition within a sample of 241 children in grades 3 to 7, but a large amount of children using count-by sequences. Their teachers stated they had not encouraged repeated addition, whereas writing down sequences had been used as a method (Steel & Funnell, 2001). This leads to the question of how basic multiplication *should* be taught at the beginning.

### **The need of further design research on the teaching and learning of basic multiplication**

There seems to be an international consensus nowadays that students should *both* acquire a sound conceptual understanding of multiplication *and* eventually solve all basic tasks accurately and effortlessly (cf., e.g., Padberg & Benz, 2011; CCSSI, 2016). It is also widely agreed that fact mastery should not be pursued by rote learning of multiplication tables. As an alternative, children should first learn how to solve harder problems by deriving them from those that are fairly easy to remember, i.e. the problems with 2, 5 and 10 as the multiplier. Only later should they move on to retrieving more and more facts directly from memory (cf. Gasteiger & Paluka-Graham, 2013; Van de Walle, 2007).

However, when it comes to "details of instruction" that might be relevant for teaching success (Sherin & Fuson, 2005), there remain a lot of unresolved issues. One of them is whether or not to make children work within separate multiplication tables (e.g., the "table of 6" from  $1 \times 6$  to  $10 \times 6$ ). A specific answer quite commonly given in Austrian textbooks is "short tables": Children are supposed to learn the whole body of basic facts by consecutively learning the facts of one table at a time before moving to the next table. Within each table, they are supposed first to automate 1 times, 2 times, 5 times, and 10 times the respective number and to derive from these core tasks the other tasks of that table. In the second step, they should practice all the tasks of the table with the objective of automation.

In contrast, Gaidoschik (2014) advocates what he calls a "consistent" approach to derived facts strategies. According to this, strategies should be worked out in a targeted manner without any consideration of separate tables. For example, as soon as children have learned that they can easily derive a 9-times fact from a 10-times fact, they should be encouraged to do so with *any* 9-times fact. The same applies to any other strategy like halving 10-times to derive 5-times facts or doubling 2-times to solve 4-times facts. If the commutative property is emphasized from the very beginning, there is little need for strategies that demand computations that are more difficult. For instance,  $7 \times 9$  can be done more easily by thinking of  $9 \times 7$ , which is  $10 \times 7 - 7$ , than by adding  $2 \times 9 + 5 \times 9$ . Therefore, to abandon activities that are restricted to single tables is supposed to reduce the overall workload. Secondly, it should help get a better understanding of any single strategy since it is applied to a wide range of numbers as soon as it has been established, and not just within a single table. Last but not

least, this approach emphasizes the wide reaching power of these strategies, which is supposed to contribute to the children's willingness to acquire them (Gaidoschik, 2014).

Evidence as to whether and how such differing approaches to the teaching of basic multiplication indeed have an impact on children's learning is rather scarce and fragmentary. Cook and Dossey (1982), comparing teaching the tables with a derived facts strategy approach, find empirical support for the latter, but remain vague about the specifics of either approach. Woodward (2006) gives more details about an integrated approach combining explicit teaching of derived facts strategies with timed practice drill which yielded significantly better results than drill only. However, he reports not on regular classroom activities, but on a remedial programme applied when multiplication had already been worked out. So do most other studies in this field (e.g., Kroesbergen, Van Luit, & Maas, 2004).

One of the few studies known to the authors that deal with the initial workout of basic multiplication in a regular classroom and try to deliver a "rich description of the way the design works" (Swan, 2014, p. 151) is Selter's (1994) report on a teaching experiment with one grade-2 class in Germany. The teaching in this class favoured derived facts strategies throughout the second half of the school year, while it deliberately downsized drill. The study indicates that this concept was quite successful with regard to its conceptual targets. However, the account of whether it worked out equally well regarding the development of fact mastery is less satisfying. The study is rather sketchy in that respect. Selter (1994, p. 106) rates it as the "preliminary ending to a research project" to be followed by more detailed inquiries into single issues, such as "learning processes of underachieving pupils" (p. 281).

### **Questions addressed in the study presented in this paper**

Teaching basic multiplication with a focus on derived facts strategies is still not at all common in Austria, where there is a long tradition of basically drilling tables with little, if any, consideration of derived facts strategies. Teachers particularly tend to be sceptical as to whether lower-achieving students would a) understand derived-facts strategies at all and b) reach fact mastery without rote-learning of the tables (Gaidoschik, 2014).

Against that backdrop and in consideration of the empirical framework outlined above, we started a design research project on the teaching and learning of multiplication in grades 2 to 3. In this paper, we present some findings collected during the first cycle of the project that lasted from September 2014 to June 2016. Out of the numerous issues we address in that project, in this paper we have to restrict ourselves to the following:

- 1) If multiplication is taught with a clear focus on derived facts strategies in the "consistent" way suggested by Gaidoschik (2014) and shortly outlined above, what types of strategy performance can be identified at the end of grade 3 with respect to the target of fact mastery?
- 2) To what extent, when taught like this, do children who have been identified by their teachers as mathematically lower achieving actually use derived facts strategies and reach fact mastery?

### **Method**

We report on 48 students from 8 classes in Carinthia, Austria. Their teachers had volunteered to participate in a design research study aiming at evaluating and refining the concept of teaching multiplication in grades 2 to 3 as formulated in Gaidoschik (2014), with the following main ideas:

- 1) In the first half of the second school year, arithmetic lessons should have a clear focus on what children need to understand and be able to compute fluently in order to get comfortable with the strategies that are useful to derive multiplication facts. That is, they should be able to double and halve two-digit numbers effortlessly and to add and subtract fluently up to 100.
- 2) Subsequently, instruction should concentrate on the conceptual understanding of multiplication and its properties, particularly commutativity and distributivity. At the end of this stage, children should be able to translate smoothly terms such as  $3 \times 4$  into actions, visual representations (identical groups as well as arrays), word problems, and vice versa.
- 3) In the next step, teachers should secure that all children know how to double and decuple any number at least up to 10 with ease, then learn how to derive the 5-times facts from the 10-times facts by halving and do so more and more effortlessly.
- 4) On that basis, a *guided discovery-learning* approach should be complemented with *direct instruction when needed* by single children to convey derived fact strategies as a convenient way to solve multiplication tasks. To this end, single lessons should be devoted to groups of facts as defined through the multiplier, for instance 9-times facts, 6-times facts, and so on. Children should be encouraged to find an easy way for themselves to solve tasks of such a group by deriving the solution from facts they already know, using representations such as arrays of dots or equal groups of interlocking cubes. Strategies found by the children should be discussed and compared in the classroom. Different strategies for the same task are welcome as long as they are mathematically correct. However, children who constantly fall into cumbersome ways to derive a task (such as, e.g., computing  $6 \times 9$  as  $10 \times 9 - 9 - 9 - 9 - 9$  instead of  $10 \times 6 - 6$  or  $5 \times 9 + 9$ ) or even resort to repeated addition or counting strategies should receive direct instruction to develop understanding for one derived facts strategy after the other, including the knowledge for which tasks that strategy fits well.
- 5) Subsequent practice should comprise substantial tasks such as explorations of mathematical patterns as well as timely restricted “strategy drill” (Van de Walle, 2007), e.g. using flash cards with the objective of performing a certain strategy with growing ease and speed.

To convey and discuss this concept in detail, the researchers met the participating teachers for 8 working sessions (3 hours each) once a month during the second and 4 follow-up sessions once every 2 months during the third school year of their classes. During each session, the researchers would give theoretical inputs and make concrete proposals for daily classroom activities. Each teacher was visited in the classroom 3 times by one of the researchers to receive feedback on his or her teaching practices. The teachers were interviewed individually 4 times during the cycle to cover as comprehensively as possible if and how closely they had followed the researchers’ recommendations.

To assess the children’s development, we selected 6 children out of each class to be interviewed a total of 7 times, from October 2014, at the beginning of their second school year, till the end of April 2016, before the classes started to move on to multi-digit multiplication. Always 2 of the 6 children had been rated as being above average, average, and below average with respect to their arithmetical performance as perceived by their teacher at the beginning of grade 2. The students were interviewed by the researchers during school time in some quiet extra rooms of the school. The first interviews were centred on addition and subtraction up to 20, which had been the main contents of arithmetic instruction till then. The semi-structured qualitative interviews to follow each reflected what had been the major classroom topics since the previous interview, from the base-10-system in January 2015 to

a focus on multiplication in the later interviews. In accordance with the instructional design, the interviews were restricted to the conceptual understanding of multiplication in March 2015, but starting with May 2015 encompassed both understanding and computation of multiplication tasks.

In the computation part of the interviews the children were presented always with the same 15 tasks, each of them written on a DIN A7 card, 7 being core tasks ( $10 \times 7$ ,  $2 \times 8$ ,  $4 \times 10$ ,  $9 \times 2$ ,  $5 \times 7$ ,  $8 \times 5$ ,  $5 \times 5$ ), and 8 harder tasks (in the order of the interview:  $9 \times 4$ ,  $7 \times 7$ ,  $6 \times 4$ ,  $6 \times 9$ ,  $7 \times 8$ ,  $6 \times 7$ ,  $8 \times 8$ ,  $4 \times 7$ ). The children were requested to solve each task mentally the way they usually would, and to state the result verbally as soon as they knew it. Immediately thereafter they were invited to explain or show how they had arrived at the solution. Strategies were evaluated on the basis of video recordings. “Fact mastery” was assigned to any solution that was accurately produced within 3 seconds (cf. Van de Walle, 2007).

Apart from computing, we invited the children *inter alia* to explain verbally to a fictitious first-grader the meaning of a task such as  $3 \times 5$  and demonstrate that meaning with different materials (wooden cubes, arrays of dots). Moreover, we asked them to clarify whether and how an easier multiplication task could be of help to solve the not so easy tasks  $9 \times 7$  and  $4 \times 8$ , respectively.

## Findings

### Types of strategy use in solving basic multiplication tasks

Based on the multiplication strategies exhibited by the children in April 2016, we performed an empirically grounded construction of types and distinguished 3 main-types of strategy performance at the end of grade 3:

- A) “Masters”: These students solved all tasks accurately either by retrieval or effortless derivation within about 3 seconds or, in most cases, instantly. Only in single cases, if at all, they would give a wrong answer or take slightly longer to produce a correct one. 19 out of the 48 children go smoothly with this type, and 5 children fall somewhere in between Type A and B (see below).
- B) “Experienced users of derived facts strategies with limited fact mastery”: These children, while exhibiting mastery of the core tasks, relied on derived facts for at least 3 of the 8 harder tasks. As a rule, these tasks were solved with rather little effort in 6 seconds or less. However, up to 2 of the 8 harder tasks still posed quite a challenge to these children, either taking more than 9 seconds or being answered incorrectly. 15 to 20 (see above) of the 48 children rank among this type.
- C) “Users of derived facts with limited mastery and some trouble in deriving”: These children typically solved core tasks by retrieval and harder ones by using derived facts strategies. At least 3 tasks caused them perceivable trouble, with solution times in excess of 9 seconds and/or resulting in incorrect solutions. 6 of the 48 children quite clearly fulfil this description.

These 3 types cover 45 of the sample’s 48 children fairly adequately. Note that fact retrieval and derived facts strategies were the only strategies to be found within these types at the end of grade 3, with no single child relying on strategies like counting all, counting by or repeated addition.

3 children do not fit into this typology. One of them, whom we refer to by the fake name Leo, was the only child in the sample that relied on count-by sequences. He did so when solving  $9 \times 4$ ,  $6 \times 4$ , and  $4 \times 7$ , all of them within 3 or 4 seconds. All the other facts he solved by retrieval, except  $6 \times 7$ , which

he derived from  $6 \times 6$ . Leo's teacher reported that Leo had consistently been getting "a great deal of support" by his mother. The teacher had "not been able to convince her of not drilling the tables".

Whereas Leo had reached a high degree of fact mastery, this clearly is not true for 2 other children. One of them, we call her Mia, had only mastered  $4 \times 10$ ,  $10 \times 7$ ,  $2 \times 8$ ,  $5 \times 7$ , and  $5 \times 5$ . Whereas she retrieved these facts accurately, all the other tasks she either refused to try at all, or admittedly guessed upon. Only  $4 \times 7$  did she solve correctly by a rhythmic count-all supported by her fingers. In no case did she use a derived facts strategy. The other child, whom we name Lara, solved all the core tasks as well as  $7 \times 7$  and  $8 \times 8$  by retrieval. On  $7 \times 8$ , she used a hybrid strategy by counting down 8 and another 8 from  $9 \times 8 = 72$ , which she had retrieved from memory. She tried to derive  $6 \times 4$  as well, this time incorrectly by computing  $5 \times 4 + 5$ .  $9 \times 4$  she rated as her "battleground task"; she eventually solved it by drawing 4 rows of 9 circles each and counting them all, which took her about 90 seconds.

Out of the 16 children who had initially been selected as below average, 3 were assigned to Type A at the end of their third year, 6 more to Type B, and one child between A and B. Out of the other 6 students who started as below average, 4 finally belonged to Type C, whereas the remaining 2 of this group have been introduced as Mia and Lara. There were 2 other children who had been rated as average by their teachers at the beginning of the second year but were finally assigned to Type C.

### **Interrelations with the performances on other tasks**

As set forth, 8 children within our sample demonstrated only very moderate, if any, success in having mastered basic fact multiplication by the end of their third school year. To help better understand this, we refer to some of the findings we made aside from the computation part of the interviews. First, the tasks that were conceived to test the conceptual understanding of multiplication unsurprisingly revealed considerable differences, in particular with regard to the verbal competences of the children. However, all 48 children, including the 8 lowest achieving, could without any exception give a comprehensible and adequate verbal explication of what meaning could be ascribed to a term like  $3 \times 5$ , and support this by laying equal groups or arrays of wooden cubes.

What is more, all these 8 children seemed to have at least some clue of how to derive facts from other facts. This even applies for Mia, albeit in a very restricted way. She was the only child of this subgroup who had not used one single derived facts strategy during the computation part of the interview. Subsequently, when questioned whether there was an easier task that could help her solve  $9 \times 7$ , she spontaneously answered: "No idea". However, when directly asked whether  $10 \times 7$  could be helpful, she said without any hesitation: "Yes, you just have to take away 7." Significantly, though, when asked whether knowing  $5 \times 8$  could help a child solve  $4 \times 8$ , she stated: "Yes, you have to take away 4." The same mistake was made by Lara. Lara also erred in computing  $6 \times 4$  as  $5 \times 4 + 5$  in the computation part (see above), but she, too, stated that  $9 \times 7$  could be derived as "10 times 7, then take away 7".

Only 2 other of the 8 lowest achieving children made such mistakes with regard to the *logic* of a derived facts strategy (as distinguished from *calculation errors* in executing a mathematically correct strategy; such errors were made by other children, too). For instance, one child said that to get  $6 \times 9$  you have to compute  $60 - 9$ , and the other that  $10 \times 8 - 2 \times 7$  equals  $7 \times 8$ .

The other 4 children of Type C not only used a variety of derived facts strategies in a mathematically correct way during the computation part, but also gave comprehensible explanations of how to derive  $9 \times 7$  and  $4 \times 8$ . It seems to be noteworthy that these 4 children as well as Mia and Lara and 2 children

of Type B were the only ones in the whole sample who had considerable trouble with the addition and even more with the subtraction tasks they had to solve in a separate section of the interviews.

## Discussion and final remarks

We are well aware of the limitations of our paper. As stated by Swan (2014, p. 151), “writing up design research is problematic”. Due to space restrictions, the design is presented rather sketchily, as is the account of its implementation and the ways different children performed. Having conceded this, we still hope that some of our findings are of use and interest for other researchers in this field.

First, our results seem to corroborate the view of Sherin and Fuson (2005) that the development of strategies for solving multiplication tasks is to a high degree dependent on instruction. We recorded the tedious use of count-by sequences known to be rather typical of low-achievers in higher grades for only one out of 48 students at the end of grade 3. In that case, we have clear indications of parental drill. We may add that this strategy had been equally rare in the preceding interviews. On the other hand, all but one student used derived facts strategies autonomously for those facts that they had not yet automatized. Both occurrences correspond with the applied instructional approach that, as outlined, deliberately neglects working within single multiplication tables, thus aiming to prevent children from using count-by sequences as a solution strategy. As far as can be judged from teacher interviews, classroom visits and the examination of working sheets used in the classrooms, all teachers basically adhered to that concept.

This leads to a second finding: Teaching multiplication with a clear focus on derived facts strategies yielded what might be seen as quite satisfying results even for lower-achieving students. Of course, the study was not conceived to prove the superiority of one design over another, but to examine qualitatively whether and how certain measures may contribute to children’s learning. With regard to lower-achieving students, it can be stated that the chosen combination of discovery-learning and direct instruction of single strategies followed by strategy drill seems to have helped almost all of them *use* these strategies *correctly* (as can be judged from the computation tasks) on the basis of a sufficient conceptual *understanding* (as can be judged from the additional tasks described above).

Thirdly, 8 students in the sample show severe problems with basic multiplication at the end of grade 3. 6 of them, constituting the Type C, still use derivations and do so quite frequently. But they do it in a way which indicates what may contribute to their struggling with multiplication: 4 of them, while apparently knowing how to use known facts as a basis for deriving unknown ones, are not able to add and subtract efficiently. That is why they often need considerable time to solve a task and sometimes miscalculate. We assume that out of the same reason their repeated use of derived facts strategies on harder tasks has not resulted in the mental linking of these tasks and the respective solutions (cf. Van de Walle, 2007) and therefore not contributed to the automating of basic facts to the same extent as it has done for their more successful peers. In this regard, their learning difficulties differ *qualitatively* from those of the other 2 children within Type C who are indeed quite proficient at adding and subtracting, but then again seem to have a limited conceptual basis of their strategy use.

All in all, these 6 children and so much the more Lara and Mia, who were least successful within this sample, have severe problems not only in multiplication but also in areas of elementary arithmetic that form a prerequisite for learning multiplication on a conceptual basis (Gaidoschik, 2014). That is why in a second cycle of this design research project we will focus on how to better foster children

who lag behind in adding and subtracting at the start of grade 2 before and while working on multiplication. From where we stand in our analysis, we assume such measures will have to include individual support for some children additional to what a single teacher can manage in the classroom.

*This paper discusses an approach that fosters students' conceptual understandings of rational numbers with an initial focus on percentage, in elementary school years. This approach enables students to work with multiple representations associated with percentage which are taken as models of contextualized situation and reconstructed as models for reasoning through an emergent modeling process. A classroom teaching experiment was developed following the methodological procedures of a Design Research. Data were collected through participant observation, supported in a logbook, audio- and video-recorded lessons and students' productions in the classroom. The analysis of data reported in this paper seems to highlight that through this approach, percentage - if privileged in the introductory steps of its learning - strengthens the interpretation of multiplicative relations and fosters understanding of rational numbers through an emergent modeling process.*

*Keywords: Elementary school mathematics, rational numbers, models, percentage.*

## Introduction

The development of rational number understanding is considered a very important, but also a complex mathematical topic (Behr, Lesh, Post & Silver, 1983). It involves conceptual understanding that is the entwined comprehension of concepts, operations, and relations (NCTM, 2014). Students are called to construct new knowledge supported by multiplicative relations, through active sense making and extending previous knowledge and experiences with whole numbers. This conceptual understanding is closely related to number sense, which is an essential competence that students should gradually develop from an early age. Percentage, with its changing nature and multiple interpretations, can be more than a representation of rational numbers (Parker & Leinhardt, 1995). Percentage is itself a useful topic to learn rational numbers with understanding (Moss & Case, 1999).

The purpose of this paper is to provide useful insights into how percentage can be powerful, when privileged in elementary years, to foster rational numbers' learning process with understanding. This should be addressed with an active involvement of students through an emergent modeling process supported by multiple representations.

## Percentage for a meaningful learning of rational numbers

Percentage is part of student's everyday contexts. Although, as a mathematical content, compared to other areas of arithmetic, there are few recent researches that discuss the issues surrounding its learning in the classroom (Pöhler, Prediger & Weinert, 2015). Since early years, students become familiarized with percentage in real life situations, for instance, on food labels, clothes tags, in discounts. Its practical use develops children's intuitive sense in dealing with it before being at school (Moss & Case, 1999). This very common use of percentage points to its introduction in elementary education, within rational numbers domain (Hunter & Anthony, 2003; Moss & Case, 1999). Percentage is "a language of privileged

proportion” (Parker & Leinhardt, 1995, pp. 472) that is based on multiplicative comparison to 100. Exploring percentage can be an opportunity to begin thinking relatively and to deal with multiplicative situations, enhanced on students’ early intuitive understandings of proportional relations (Lamon, 2007). Being a language, percentage has different interpretations as it assumes properties of number, part-whole, ratio, function or statistic (Parker & Leinhardt, 1995). Grounded in real-world experience percentage can be a way to start the work of developing a solid understanding of those meanings as rational numbers subconstructs, which highlight essential characteristics of rational numbers (Lamon, 2007).

Learning percentage should begin with understanding its relational language using elementary strategies, including benchmarks, proportional reasoning, and additive building-up strategies, rather than learning formal calculation procedures (Moss & Case, 1999; Parker & Leinhardt, 1995). This process might start in elementary grades, but the concept of percentage at its very rich sense will be reached later. Thus, understanding percentage requires the development of appropriate models to grasp its various meanings and its relational features in order to support students’ attempts to make sense of the numbers and the relationships that connect them (Dole, Shelley, Cooper, Baturo, Conoplia, 1997; Parker & Leinhardt, 1995). In problem solving, models can arise from the use of multiple representations – enactive, iconic, symbolic (Bruner, 1962) and oral and written language (Ponte & Serrazina, 2000), when associated with percentage can provide support to develop its conceptual understanding. Models should display the relationship between quantities and allow to describe comparisons in multiple ways, encouraging proportional reasoning (Parker & Leinhardt, 1995). Gravemeijer (2002) refers to emergent modeling process to explain both the “process by which models emerge” (p.3), as representations are used and progressively become models and the “process by which these models support the emergence of more formal mathematical knowledge” (p.3). Gradually models of contextualized situation are reconstructed and evolve to models for reasoning through this emergent modeling process.

The above ideas are the key components of the conceptual framework that supports this research. They seek to associate conceptual understanding, number sense and emergent modeling process to support percentage as an entry point for developing students’ understanding of the rational numbers. The interrelationship between these components sets a developing framework for analysis, which will provide the lens to describe and analyze how rational numbers’ conceptual understanding takes place in a specific classroom learning ecology (Gravemeijer & Cobb, 2006).

## Methodology

Data reported in this paper was collected as part of a classroom teaching experiment in a design research approach (Gravemeijer & Cobb, 2006), within a broader study that aims to deepen how students construct their understandings of rational numbers through a learning trajectory with an initial focus on percentage. The cyclic process of the design research involved a first phase where a conjectured local instruction theory was defined supported by design principles, used to guide the design and development of the classroom teaching experiment. In the second phase, the teaching experiment took place and, through micro-cycles of design and analysis, the process of the students’ participation and learning was analyzed. The last phase involved a retrospective analysis, which is still running. The conjectured local instruction theory, which is about a possible learning process together with theories about possible means of

supporting that learning process, is refined and improved all along, supporting a revised local instruction theory (Gravemeijer & Cobb, 2006).

The classroom teaching experiment was designed considering a mathematical content dimension and a pedagogical one. The first one is based on an hypothetical learning trajectory, inspired by Moss and Case (1999) experimental curriculum for teaching rational numbers. The first stage of this trajectory begins with the understanding of percentage in a linear-measurement context. Then two-place decimals are introduced. Finally, fractions are the focus concerning the use of different interchangeable representations. The pedagogical dimension attempts to account for the means of supporting the co-participated learning process as it occurs in the social context of the classroom. The classroom experiment involved a total of 20 lessons spread across two three-month periods (Grade 3 and Grade 4) in the same classroom, where the first author was also the teacher. It took place in a public elementary school in Lisboa with students aged between 8 and 10 years. In this paper, we analyze some episodes that took place in the first period when the students were in third grade.

The dual role as teacher and researcher raised significant ethical challenges. To avoid potential conflicts and assure students' and families' protection, an informed and voluntary consent was taken. Anonymity and confidentiality were guaranteed to be maintained. To establish credibility and allow convergence, multiple sources of evidence were chosen (Confrey & Lachance, 2000). For data collection, we used the transcript of video and audio recorded moments of all classroom sessions, students' written work, and teacher's research journal.

A preliminary analysis was developed during the classroom teaching experiment, which supported the process of redesigning and testing instructional activities and other aspects of the design. (Gravemeijer & Cobb, 2006). This analysis involved an analytic induction strategy where we identified significant episodes from students' activity while exploring tasks. Then, we scanned those episodes for evidence of students' conceptual understandings related to rational numbers and for relationships among them. Thereafter, a retrospective analysis was made through content analysis. In this analysis, all data was revisited and divided into content categories generated from the interrelationship between the conceptual framework components through a typological analysis (Goetz & LeCompte, 1984). This analysis process creates a cross-coding system that evidence relationships among the various categories, emerged from data and anchored in the conceptual framework, which is still in progress. The analysis discussed in the next section of this paper focuses on students' activity with meaningful representations during four lessons of the classroom teaching experiment. It was carried out using three interrelated categories as indicators of students' conceptual understandings of rational numbers through percentage learning. Each of these categories involves working subcategories, handling percentage to: (1) support reasoning strategies (decomposition/composition; half/double; 10%; multiples of; unitizing/reuniting); (2) foster numerical relations (benchmarks; magnitude of numbers; orderliness and comparison; equivalence) (3) encourage a modeling process (mobilize familiar representations; interpret subconstruct situations; emerge of symbolic representations).

## **Learning rational numbers by focusing on understanding percentage**

A mobile phone battery was one of the first iconic representations related to percentage chosen to be used in a problem-solving context. In this task, students were asked to estimate the percentage represented in batteries in Figure 1.

**Figure 1: Ana's group resolution using a battery representation**

Considering battery C, some students stated that the shaded part would represent 25% of charge, and others claimed that it would be 20%. During the discussion, students' arguments were shared in order to justify their reasoning strategy.

Simão: That is not 25 percent.

Teacher: [...] So, what do you think it is?

Students: 20 percent.

Teacher: Why? Marco.

Marco: Because it fits 5 times.

Students who claimed 20% reasoned that if the shaded part was iterated it would fit the unit five times, so, it should be 20% and not 25%. This idea expresses a reasoning strategy drawn on division and laid out on numerical relations. The measure subconstruct allowed students to see the unit represented by the full battery as a distance, and the percentage as a relative quantity of that distance. Familiar battery representations were used to encourage a modeling process. They are used as models to think about the task as a measurement situation, allowing percentage to be conceived as an iteration of a unit part, rather than representing a part out of a whole.

Status bar (Figure 2) was another iconic representation regarding percentage that was privileged. Students interpreted status bar in an easy way by analyzing its fullness, as they are used to do it when downloading a file.

**Figure 2: A task that privileged status bar representation**

They perceived the comparison of quantities using proportional relationships. Percentage allowed students to see the multiplicative relation between the minutes taken to save the complete program and the amount of program saved shown by the status bar. "The whole program took forty minutes to save because if a half is twenty, the double is forty" as Mafalda's group explained. This use of splitting/doubling procedure seemed to make sense to the others as it expressed the multiplicative relation between half and double, keeping the ratio constant.

The students were able to see that saving half of the program would take as long as the remaining half, although not all students have yet clearly perceived it as a ratio. Status bar seems to encourage the modeling process during the teaching experiment while supporting intuitive ratio understanding, involving quantities of a standard unit.

Thereafter, the proportional judgments established with the status bar were mobilized to work percentage using another representation – the ratio table (Figure 3).

Porcentagem	10%	20%	30%	40%	50%	60%	70%	80%	90%	100%
Tempo (min)	4	8	12	16	20	24	28	32	36	40

**Figure 3: Clara's group resolution using a ratio table**

This representation was used to make comparisons between entities in multiplicative terms, applying to multiples of 10%, as reasoning strategies. Percentage benchmarks allowed to foster numerical relations highlighting the relationship between time and the amount of program saved. Students could realize multiple numerical strategies through collaborative engagement.

Heitor: The process was always four in four minutes.

Simão: 10% are 4, is always times 4.

Mafalda: The all process took ten times four minutes.

Teacher: The whole process of saving the program took ten times four minutes...

Hélio: We could also look at 36 minutes and see which would be the number that could give 40.

The ratio table seemed to be powerful in the modeling process as it supported different reasoning strategies suggested by percentage, such as halving, doubling, multiplying by 4, showing why the relationship between quantities is multiplicative.

Some less stereotyped representations came up in classroom from other contexts. For example, during a specific group project work about dogs, the representation of a dog food bag was used to encourage the modeling process as it becomes a model of acting in a real meaningful situation. In this task, the representation of the dog food bag was tailored to consider its fullness (100%) that is 20kg as the top of the bag. To this iconic representation, two vertical number lines were added to foster numerical relations allowing to relate weight with the percentage of the amount of food in the bag. In this way, the dual set of numbers involved in percentage comparisons become explicit and can be used for calculations.

**Figure 4: Carolina's group resolution using the bag representation**

All groups found out immediately that 50% of the weight of the bag was 10 kilograms, as shown in the example on figure 4. When students had to compute other amounts of food, they consider percentage as a relative quantity according to the attained unit and applied to multiplicative reasoning strategies. Some divided using halving strategy, and reconstructed the unit, considering the unit the bag weight in each moment (Figure 5).

### Figure 5: Mafalda's group resolution using the bag representation

Students understood that the relationship between the quantities in both number lines kept constant and perceived that they vary together, even though they have different magnitudes, interpreting ratio subconstruct. In this modeling process, the food bag representation became a model that supported reasoning strategies and proportional relationships.

Later on, this modeling process was extended to the double number line. Double number line fostered the emergence of numerical relations, as it allowed ordering and establishing equivalences, invoking benchmark percentage values in a measure context (Figure 6).

Figure 6: Dina's group resolution using the double number line

The double number line became a model of a measurement situation in which students supported their reasoning strategies (Figure 7). They established comparative relations between equivalent representations, as percentage and measure of an amount (e.g. 9% and 9/100). For this, a key aspect is the unit identification. Considering one as the unit, the decimal numbers representation emerged when a number was located. Together with percentage, this allowed students to invoke whole number's knowledge, establishing numerical relations between each decimal number and its position.

Figure 7: Whole-class resolution using the double number line

Two-place decimals were used as a symbolic representation by students to express an equivalent percentage of "fullness" of the unit, when the unit is 1, applying to establish numerical relations.

Simão – It's not enough to make up one meter...

Clara – ...You have zero comma ninety-one meters.

Teacher – Then, this is Clara's suggestion [writes 0,91 at the number line]

Clara – Because it's not enough to make up one meter, so it's zero meters and then we write ninety-one centimeters.

In this situation, the decimal representation was convened to identify a quantity less than one in a measurement context, fostering a modeling process as the number line became a model for a more formal reasoning.

## Final remarks

As data analysis highlight, percentage enables an approach to multiplicative situations, describing comparisons in multiple ways and exploring relationships, enhancing an introductory step to rational numbers conceptual understanding (Lamon, 2007; NCTM, 2014; Parker & Leinhardt, 1995). The context within percentage appears in these tasks and suggests it can be linked with ratio and measure subconstructs of rational numbers, which are important although less common in these years of elementary school (Parker & Leinhardt, 1995). The meaning of percentage, supported by the use of number line in the dog food bag representation allowed to show the relation between the four numbers that make up the percent proportion, in an intuitive way. The focus on measurement revealed a growing flexibility of the reasoning strategies and provided opportunities for students to build a meaningful connection between percentage and decimal numbers notation. Ratio situations allow to recognize the importance of 100 as a privileged base and to develop sensitivity for the comparative uses of percentage, fostering numerical relations. Representations associated with percentage, drawn from students' real-life experience, like the mobile phone battery or the status bar, revealed to be essential. Students used them to make sense of problem situations and to solve them. Gradually, those representations became models as they encouraged students' reasoning strategies and promote rational numbers' conceptual understanding. In this emergent modeling process, as called by Gravemeijer (2002), percentage had a key role. It contributed to disclosure the multiplicative nature of rational numbers, connecting prior whole numbers' knowledge with intuitive understandings regarding relative proportion (Moss & Case, 1999).

# The fostering of flexible mental calculation in an inclusive mathematics classroom during *Mutual Learning*

Laura Korten

TU Dortmund University, Germany; [laura.korten@math.tu-dortmund.de](mailto:laura.korten@math.tu-dortmund.de)

*The topic of teaching mathematics in an inclusive classroom provides – by the increased heterogeneity range – a big challenge between individualizing and mutual learning. (How) Can we make sure that all children work and progress on their individual level but at the same time learn with and from each other? Based on this question the aims of this project are the development of, and the research on a teaching-learning arrangement for the inclusive mathematics classroom to foster flexible mental calculation. The approach is a Design Research approach to face research interests on the level of design (consideration for use) and on the level of research (quest for fundamental understanding). This contribution focuses on the research level: first insights about mutual learning processes of elementary students with and without cognitive learning disabilities concerning flexible mental calculation will be presented.*

*Keywords: Inclusive education, heterogeneity, cooperative learning, flexible mental calculation.*

## Theoretical framework

Developing flexible mental calculation has been considered as a ‘central goal’ for more than a decade, not only for middle and high achievers, but also for less advanced children. However, empirical insights about teaching and learning processes of flexible mental calculation in inclusive classrooms do not exist. Although, *inclusive education* is a current international discussion, based on the UN-Convention on the ‘Rights of Persons with Disabilities’. *Supporting everyone’s learning process* and at the same time *encourage cooperative learning with and from each other* are the two central matters of inclusive education, which imply more than sharing a room. But, in school practice, teachers emphasize the difficulty of learning with and from each other in arithmetic (Korff, 2015). Building on the two matters of inclusive education, this study focuses on the *goal-differentiated fostering of flexible mental calculation* in an inclusive classroom during *Mutual Learning* takes place.

## The goal-differentiated fostering of flexible mental calculation in an inclusive classroom

Developing flexible mental calculation is not only a central goal but also a ‘critical point’ in everyone’s learning process (Heinze, Star, & Verschaffel, 2009), especially for students with cognitive learning disabilities. In this process, error-prone counting strategies should be replaced with more beneficial calculating strategies. Current literature offers different definitions, which commonly include the two aspects of ‘flexibility’ and ‘adaptivity’. In most of the cases flexibility is understood as the ability to switch between different solution tools (Rathgeb-Schnierer & Green, 2013), while adaptivity is more emphasizing on the selection of the most appropriate strategy. In this project ‘adaptivity’ is related to the recognition of problem characteristics, number patterns and numerical relations. Consequently, *flexible mental calculating* is a situation-dependent and individual response to specific number and task characteristics and the corresponding construction of a solution process using strategic tools (ibid.).

The fostering of flexible mental calculation competences is influenced by the outlined general assumptions. If flexible calculation is related to number and task characteristics and relations, activities have to be chosen, which support children to focus on these. Thus, the crucial aim is to develop the competence to recognize problem characteristics, number patterns and numerical relations, and to use them for solving problems. Rechtsteiner-Merz and Rathgeb-Schnierer (2016) call this “Zahlenblick” and found out that it is a good vehicle for developing flexible calculation.

Today it is proven that also less advanced students can develop flexible mental calculation (Verschaffel, Luwel, Torbeyns, & van Dooren, 2009) and that the focus on developing “Zahlenblick” especially supports less advanced students (Rechtsteiner-Merz & Rathgeb-Schnierer, 2016). Schröder (2007) points out their problems in the usage of flexible strategies: Even if they know strategies, they very often cannot adapt and use those. Reflecting on characteristics and relations is especially essential for children with cognitive learning disabilities (ibid.) and at the same time supportive and preventive for everyone’s learning process, because generally all children show little task-adequate action (Selter, 2000). Further, the content provides opportunities for high-performing students to establish mathematical structures and to generalize. Consequently, flexible mental calculating meets the requirements for a *common content* for an inclusive classroom to encounter the diversity of abilities and skills and to make goal-differentiated learning possible.

### ***Mutual Learning in an inclusive mathematics classroom***

The expression of *Mutual Learning* as it is used here combines the two central matters of inclusive education, which were mentioned above: individualizing as well as interacting and cooperating. Mutual Learning means to consciously induce learning situations *as often as possible* in which all children work and learn at a common content, in cooperation with each other, on their individual level, and by use of their current individual skills (Feuser, 1997). This definition is based on a wide sense of inclusion, acknowledging the diversity of all children and counteracting all forms of discrimination and special learning needs. Nonetheless this research project focuses on learning and interaction processes of children with and without *cognitive learning disabilities*. (This distinction is not used to label deficits, but rather with regard to make research and communication possible.)

In consideration of the two central matters of individualized learning and at the same time learning with and from each other, first supportive principles for successful Mutual Learning can be derived: ‘*content variability*’, ‘*goal-differentiated learning process*’, and ‘*interaction orientation*’. As already outlined, the content of flexible mental calculation meets the requirements of the first two. Having regard to the principle of ‘*interaction orientation*’, the construction of mathematical knowledge is understood as an active, social and explorative process; also for children with cognitive learning disabilities as today several studies show. Gaidoschik (2009) points out, children with problems need more time and more support to learn arithmetic but they don't need something different. The exploration, understanding and use of arithmetical patterns and particularly the communication about number and task characteristics and strategic tools is especially important for children with cognitive learning disabilities (ibid.; Schröder, 2007). In social-communicative processes, individual mathematical learning develops through ‘irritations’, ‘contradictions’ and ‘re-interpretations’ on the basis of individual interpretation processes (e.g. Steinbring, 2005). Therefore, this very *individual processes of learning flexible mental calculation in the context of interaction processes*, needs to be fostered on different cognitive levels for successful Mutual Learning.

## Research question and methodological design

For this purpose, it seems important to research when and how successful Mutual Learning occurs and which support means can be reconstructed. Therefore, it is necessary to reconstruct the *individual learning processes* concerning flexible mental calculation as well as the *interaction processes* to be able to evaluate whether Mutual Learning with its two central matters took place.

To meet the aspiration of designing a teaching-learning-arrangement to foster flexible mental calculation on the one side, and to investigate learning and interaction processes on the other, a *Design Research* approach is used (Prediger & Zwetzschler, 2013). This requires research questions on the level of design and research. Nevertheless, this contribution focuses only on the level of research and the investigation of individual learning processes. The following question will be addressed: *How do individual learning processes of elementary students with and without cognitive learning disabilities concerning flexible mental calculation develop during the cooperative-interactive phase of Mutual Learning?*

### Iterative design research cycles as an approach for answering the question

To investigate this, a teaching-learning arrangement was designed, tested and refined by conducting *design experiments* in three iterative cycles. Within each cycle the *individual learning processes* as well as the *interaction processes* were reconstructed to be able to evaluate whether Mutual Learning took place. To, in a next step, reconstruct support means for successful Mutual Learning.

*Theoretical sample:* The design experiments were conducted in classes two and three (7-9 years old), at three different German primary schools. Laboratory situations with couples of learners allowed to learn more about their thinking, their individual learning and interaction processes. Each design experiment consisted of three phases (Figure 1) and took place in a pair setting with one child tested and “termed” with and one child without learning disabilities. The participants were selected with the help of the class teacher and the special needs teacher in order to find pairs of children who like each other to have a positive basis of communication. In the design experiments, the learners processed the learning activities largely by themselves. The researcher, on the one hand, acts as a teacher, in order to give the learner a stimulus or help, and on the other hand as a researcher, who wishes to learn more about the thinking processes and the ways of proceeding by means of observation and targeted inquiry.

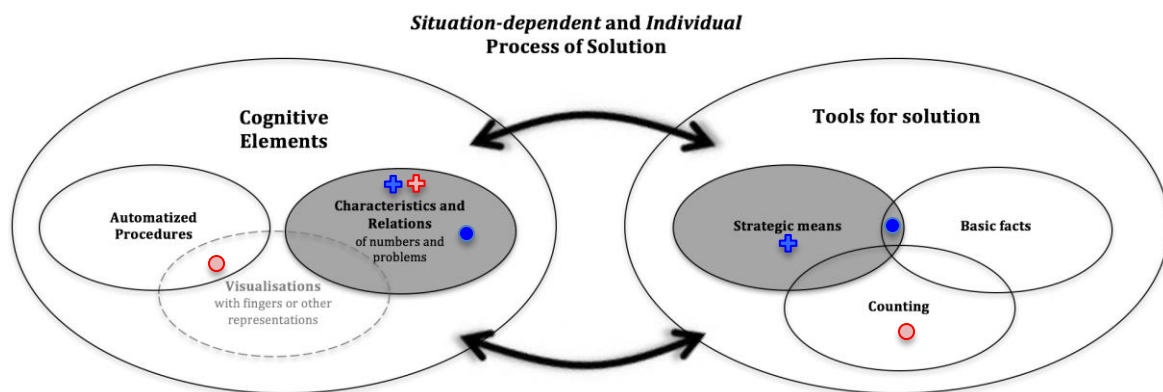

**Figure 1: The structure of a design experiment**

*The teaching-learning arrangement - "We explore neighboring sums":* After a mutual introduction (Figure 1), the children individually explore neighboring numbers on a 20frame (*I-/individual-phase*). The focus on neighbors – which are *next to*, *under* or *crosswise* to each other – and their sums enables them to discover number and problem characteristics and relations, as well as to develop mental calculating strategies based on individual abilities, arithmetic-, and context-characteristics. In the following, two children – one with and one without learning disabilities –

work together (*You-/cooperative-interactive-phase*), which enables them to communicate, use, reflect, refine, and/or improve their discoveries and strategic tools. In this way, singular accesses and comprehensions can evolve, through communicative exchange, to new comprehension and understanding. Due to the focus on neighboring sums the arithmetical patterns stay the same even in higher number ranges. This makes communication possible, even though some children already transfer their discoveries to neighbors on the 100frame or generalize the mathematical structures.

In order to reconstruct and categorize the development of goal-differentiate heterogeneous learning processes concerning flexible mental calculation, a model (Figure 2) has been drafted on the basis of previous research (Rathgeb-Schnierer & Green, 2013; Rechtsteiner-Merz, 2013). As mentioned before, a '*process of solution*' is a situation-dependent and individual response to specific '*cognitive elements*' (Rathgeb-Schnierer & Green, 354) (e.g. 'characteristics and relations of numbers and problems' or 'automatized procedures') and the corresponding construction of the actual solution process using '*tools for solution*' (Rathgeb-Schnierer & Green, 2013, 355). In this sense, 'cognitive elements' are individual experiences, which comprise background-knowledge and -expertise for the individual process of solution. Referring to the theoretical background, the grey fields in Figure 2 are predictors of flexible calculation. Those will be fostered on different cognitive levels as an aim of the designed teaching-learning arrangement.

**Figure 2: A model to reconstruct children's learning paths (cf. section 'Selected Results')**

Each field of this model is described and defined by certain characteristics in order to group children's learning paths (for more information see Korten, i.V.).

### **Two analytical perspectives for answering the question and for developing local theories**

The process of generating local theories gets content-specific theoretically and empirically justified. The data was collected in form of transcribed videos and gets analysed from two perspectives: 1) An *epistemological perspective*, to learn about individual learning processes on different cognitive levels in terms of the common content. 2) An *interactionist perspective*, to learn about the interactive structures during the cooperative-interactive phase of student with and without learning disabilities, and how these interaction processes influence the learning processes.

In order to address the two central matters of successful Mutual Learning, both perspectives are essential to evaluate if the children progress on their individual level and at the same time learn with and from each other. The interpretation of statements and actions, reconstructs interactive knowledge construction. Accordingly, an Interpretatively Epistemological Analysis Approach of Interactive Knowledge Construction (Krummheuer & Naujok, 1999; Steinbring, 2005) gets used.

At the same time this reveals information for the analysis of the teaching-learning arrangement and gives answers whether Mutual Learning in the sense of inclusion is supported or not. Thus, the empirical findings allow elaborating and enhancing the teaching-learning arrangement, as well as local theory building about mutual learning processes. Here the focus will be on the latter.

## Selected results

In this section, the described analysis approach is illustrated with a short exemplary cooperative-interactive phase. Afterwards, selected general results concerning the research question addressed in this contribution will be presented. In the exemplary situation, a child with learning disabilities (S1) and a child with average mathematical skills (S2) work together. They explore crosswise neighboring numbers and their sums. Figure 3 shows an example.

Figure 3: Crosswise neighboring numbers

- S1: We need [the sum] 24 in between... 23 (points on  $7+16=23$ ) #, 24 (points between  $7+16=23$  and  $7+18=25$ ), 25 (points on  $7+18=25$ )
- S2: # No, this is... No... Here is the same. (points on  $4+13=17$ ) Also always one. (points on  $3+12=15$ ) See, there is 16 missing... here 14 is missing. (points between  $2+11=13$  and  $2+13=15$ ) Here 18. (points between  $4+13=17$  and  $4+15=19$ ) Oh here even (points between  $5+14=19$  and  $6+17=23$ ) two ... no, 3...

- S1: What? Now I am confused.
- S2: Why? Ah! See, ...

*Interactionist perspective:* S1 assumes that the sum 24 is missing and questions the completeness of the sums. This ‘incorrect assumption’ (key impulse) leads S2 to exemplify relations between the sums. Her empirical argumentation leads to the hypothesis that the sum 24 does not exist. Both participants communicate with each other about the common content, according to individual assets. A ‘balanced cooperation’, in which both are involved and utterances are linked can be observed. Regarding to Naujok (2000) they are ‘collaborating’ with the focus on the same topic. Additionally, both develop on their individual level as the reconstruction of learning processes reveals:

*Epistemological perspective:* The children respond to the same ‘incorrect assumption’ (Figure 4, sign/symbol) in different ways by referring to *number relations* on the basis of their individual cognitive abilities. Figure 4 and 5 show the progress of the scene from an epistemological

perspective: S1 argues with counting and refers to the number word series (ordinal). S2 uses empirical arguments to prove that the sum of 24 does not exist by referring to arithmetical patterns (relational). Due to S1's incorrect assumption, S2 discovers, exemplifies and later even generalizes number relations between the addition problems. S1, like this situation shows, is able to see and to question number patterns. This focus of attention on number characteristics and relations only started due to the interaction with S2. In the following, this situation leads S2 even to explore, explain and generalize the *constancy of two sums*  $(a+b)=(a-10)+(b+10)$  (Figure 5). From this point on, as a reaction on the interactive situation, she is not only referring to numbers characteristics and relations anymore but to *problem relations*, which she is using later to solve new problems.

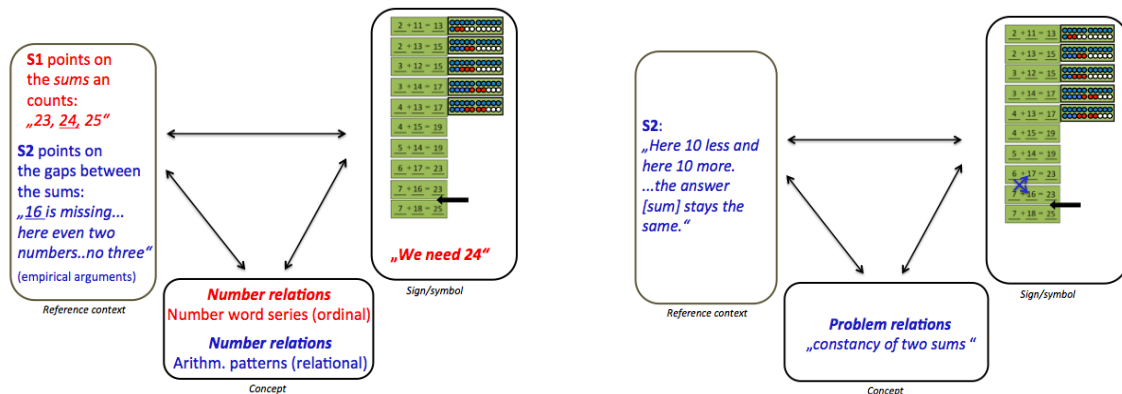

Figure 4 & 5: Analysis of interactive learning processes (Steinbring, 2005)

The example shows how the individual learning processes developed during the cooperative-interactive phase of Mutual Learning. Both progressed according to their individual levels, triggered by a key impulse in the interaction, in this case an ‘incorrect assumption’. These key impulses – here called ‘*productive moments*’ – seem to be opportunities for fruitful Mutual Learning (Korten, 2017). Previously to the cooperative-interactive phase, S1 exclusively refers to ‘*automatized procedures*’ and used ‘*counting*’ as her ‘tool for solution’ with the help of counters as ‘*visualisations*’ (cf. Figure 2, red dots). She only relied on the procedure of counting, which seems to be like a “dead-end road” for developing flexibility in calculating (Rechtsteiner-Merz & Rathgeb-Schnierer, 2016, p. 359). But due to the impulses resulting from the interactive-cooperative phase she starts to look at *number characteristics and relations*. She is able to sort the addition problems according to characteristics and puts them into relation (cf. Figure 2, red cross). This recognition of number patterns and numerical relations is after Rechtsteiner-Merz and Rathgeb-Schnierer (2016) an important skill to overcome counting on the way to flexible calculation. S2 was also stimulated by the exchange with S1: She was a flexible calculator from the start on. She used ‘*basic facts*’ and adequate ‘*strategic means*’ (e.g. decomposing and composing, using decade analogies, deriving solutions from similar problems such as 2 more and 20 more) by recognizing *relations* (cf. Figure 2, blue dots). Due to the interaction with S1 she was forced to explain and argue, which led her to discover new relations (*constancy of two sums*), which she used to refine her ‘*strategic means*’ later (cf. Figure 2, blue cross). It can be concluded that it was rewarding for both children to work in heterogeneous pairs in an arithmetic classroom. A study of Häsel-Weide (2016) about replacing persistent counting strategies with cooperative learning, supports this finding.

These were typical *learning and interaction processes*, which took place in all design experiments. In regard to the research question, which is addressed here, five types of individual learning paths

and their development during the cooperative-interactive phase of Mutual Learning could be reconstructed: 1) Children, who did not progress during the cooperative-interactive phase and used none or pre-existing individual insights into number/task characteristics and relations. 2) Children, who gained *new insights* into number/task characteristics and relations due to the task's context. 3) Children, who gained *new insights* into number/task characteristics and relations due to impulses in the cooperative-interactive phase (e.g. S1). 4) Children, who *refined* their strategic means by taking advantage of new insights into number/task characteristics and relations due to the task's context. 5) Children, who *refined* their strategic means by reflecting, inquiring and evolving insights into number/task characteristics and relations due to impulses in the cooperative-interactive phase (e.g. S2). In the cases 2)–5) changes could be identified because *new insights* were gained or strategic means were *refined*. Concluding, a development of learning process concerning flexible mental calculation was reconstructed for these situations. With respect to the title of this article and the definition given at the beginning, successful Mutual Learning took place and flexible mental calculation competencies were fostered on different cognitive levels in this inclusive situation.

## Outlook

All research cycles demonstrated regularity in the appearance of the 'productive moments' in the interaction, which trigger individual learning as shown in the example. These moments mainly appeared during a 'balanced cooperation'. Generally, a distinction can be made between '*direct-didactical*, *indirect-didactical* and *interactive* productive moments' (Korten, 2017). In the future, research questions on the level of design will be addressed in order to reconstruct support means for successful Mutual Learning. It will be investigated in more detail how the developed teaching-learning-arrangement can specifically foster these 'balanced cooperation' and the 'productive moments'. First analyses show that beneficial and meaningful interaction must be specifically encouraged by an emotional benefit for all participants, which must be created from the outside. This, for example, can be a goal, which they can only reach together and functions as an '*extrinsic positive dependence*' (Korten, i.V.). This idea takes up the principle of 'positive dependency' from the concept of 'cooperative learning' (e.g. Johnson, Johnson, & Holubec, 1994) and advances it for the conditions of an inclusive classroom. Without this 'extrinsic positive dependence' a 'balanced cooperation' with 'productive moments' seems to be impossible in an inclusive setting. With this Topic-specific Design Research Approach the two interests of the goal-differentiated fostering of flexible mental calculation in an inclusive classroom and the general understanding and supporting of Mutual Learning processes could be integrated and first local findings were presented.

*In this paper, we present analyses of popular grade one textbooks, one from each of England and Sweden. Focused on Foundational Number Sense, we examine how each book's tasks facilitate children's learning of those number-related competences that require instruction and which underpin later mathematical learning. Analyses identified both similarities and differences. Similarities lay in books' extensive opportunities for children to recognise and write numbers and undertake simple arithmetical operations. However, neither offered more than a few tasks related to estimation or simple number patterns. Differences lay in the Swedish book's greater emphases on different representations of number, quantity discrimination and relating numbers to quantity, highlighting conceptual emphases on number. The English book offers substantially more opportunity for students to count systematically, highlighting procedural emphases.*

*Keywords: Foundational number sense, mathematics textbooks, England, Sweden, grade one.*

## Introduction

In this paper we offer a comparative analysis of how commonly used textbooks, one from each of England and Sweden, enable year one pupils' acquisition of foundational number sense (FoNS). FoNS, which has been discussed in earlier CERME papers (Back, Sayers & Andrews, 2013; Andrews, Sayers & Marschall, 2015; Sayers & Andrews, 2015), comprises those number-related competences that underpin later mathematical learning, both in the short and the long term, and require instruction. Derived from a systematic review of the literature (Andrews & Sayers, 2015), FoNS comprises the eight broad categories shown in Table 1. Focused on the FoNS-related opportunities initiated during whole class teaching, the framework has structured analyses of grade one lessons in various European countries (Back et al., 2013; Andrews et al., 2015; Sayers, Andrews & Björklund Boistrup, 2016) and identified didactical emphases commensurate with earlier research undertaken in the same countries.

Until now, we have not examined the framework's effectiveness with respect to identifying FoNS-related opportunities in textbooks. This is a significant omission, particularly as both textbook production and deployment are unregulated in England and Sweden. This significance is heightened by uncertainty with respect to pre-school students' likely FoNS-related experiences. On the one hand, the English pre-school curriculum specifies that children should "count reliably with numbers from 1 to 20, place them in order and say which number is one more or one less than a given number. Using quantities and objects, they add and subtract two single-digit numbers and count on or back to find the answer" (Department for Education, 2014, p.11). On the other hand, the Swedish pre-school curriculum, which specifies no such detail, expects children to develop an understanding of the basic properties of quantity, number and number concepts (Skolverket, 2016). Thus, while there are no explicit FoNS-related expectations in the Swedish pre-school curriculum, a number, but not all, are addressed in the English.

FoNS Characteristic	Learners are encouraged to
Number recognition	Identify, name and write particular number symbol
Systematic counting	Count systematically, forwards and backwards, from arbitrary starting points
Number and quantity	Understand the one-to-one correspondence between number and quantity
Quantity discrimination	Compare magnitudes and deploy language like ‘bigger than’ or ‘smaller than’
Different representations	Recognise and make connections between different representations of number
Estimation	Estimate, whether it be the size of a set or an object
Simple arithmetic	Perform simple addition and subtraction operations
Number patterns	Recognise and extend number patterns, identify a missing number

**Table 1: Summaries of the eight FoNS categories**

Of particular interest to this paper is Bierhoff’s (1996) comparison of the number-related opportunities offered in commonly used English, German and Swiss textbooks. Focused on the transition from “working with numbers up to 20... to working with two-digit numbers” (p. 143), she found that English textbooks were the least coherently structured. Also, students were expected to calculate with large numbers before consolidating their understanding of the integers up to 20, a situation made problematic by the English overemphasis on place value. Turning more explicitly to studies focused solely on English textbooks, Newton and Newton (2007), in an evaluation of the professional support school textbooks might afford primary teachers, examined eighteen textbooks written for use with English 7-11 students. They found few tasks that would facilitate mathematical reasoning, being primarily focused on skills acquisition.

With respect to Sweden, as in England, the production of textbooks has been unregulated since 1991 (Ahl, 2016) and several recent studies have examined Swedish mathematics textbooks against various criteria. For example, at the university level, Lithner (2004) found tasks typically promoting low levels of imitative reasoning. At the upper secondary, or post-compulsory, level Nordström and Löfwall (2005) analysed the extent to which students were offered opportunities to engage with proof in two commonly used sets of textbooks. They found little evidence of proof in any of their examined topics, although there were many implicit opportunities in many of the tasks analysed. In similar vein, Lundberg (2011) compared three of the most commonly used textbooks from the perspective of proportional reasoning and found not only that direct proportion dominated but also that while both dynamic and static notions of proportion were present in all three textbooks, justifications were rare. With respect to the final years of compulsory school, Ahl (2016) examined the proportional reasoning in two popular textbooks. She found that “the impact of research findings on the representation of proportional reasoning is scant” in both (Ahl, 2016, p. 198) and that the books failed to encourage learners to understand the distinction between additive and multiplicative situations. In short, the limited available evidence indicates that textbooks written for older Swedish students present few opportunities for them to make mathematical connections or engage in mathematical reasoning.

However, little is yet known about the ways in which textbooks written for young children present mathematical ideas.

This study is a first attempt to evaluate the FoNS framework as a tool for analysing grade one textbooks. Thus, while it is not an explicit attempt to evaluate the content of the books themselves, it is an important first comparison of textbooks from the two countries. In making this comparison, we acknowledge Reza's (2006, p. 482) position that the mathematics textbook “can be regarded as an artefact in the broad sense of the term. It is historically developed, culturally formed, produced for certain ends and used with particular intentions”. In other words, comparative analyses of this nature highlight well cultural differences in expected learning outcomes.

## Methods

Two popular textbooks, one from England and one from Sweden, were identified for analytical purposes. In focusing on popular textbooks, we believed we would gain insight into not only how a reasonably high proportion of children in both countries experiences FoNS but also what teachers and schools value in their choice of textbooks. Before formal analyses were undertaken, all four authors met for two days to discuss and evaluate a range of textbook tasks in order to operationalise the FoNS categories. Drawing on the studies of Li (2000) and others, only those tasks explicitly addressed to the student were analysed. For example, both of the examined textbooks included instructions or suggested activities that teachers might use. However, these were not analysed as they did not explicitly address the learner and typically included too little detail to show how they might have been used with children. For similar reasons, since tasks included in teacher guides were not focused directly on students, teacher guides were not included in the analyses. After this first pass, each of the first two authors took responsibility for analyses of the Swedish and English textbooks respectively. In these roles, each was supported by the third and fourth authors with respect to ambiguous or difficult to interpret tasks. In addition, random exercises from each textbook were also coded by both the third and fourth authors as part of a moderation process.

## Operationalising the codes

**Figure 1: Additive tasks from the Swedish and English textbooks respectively**

Figure 1 shows one example from each of the textbooks, Swedish on the left and English on the right. In one of several similar tasks in one exercise, Swedish students were asked to “compare the number of dots” and then “write either = or  $\neq$ ” in the box. This particular task, which occurred before the introduction of addition, was thought to encourage completion by counting and coded for *systematic counting*. The expectation that students would address issues of equality or inequality led to its also being coded for *quantity discrimination*. In addition, the dot patterns not only offered *different*

*representations of number* but allowed for subitising and an *awareness of the relationship between number and quantity*. The goal of the English task, based on a coat hanger with ten pegs of which some of which had been covered with a cloth, was to identify the number of hidden pegs. The way in which the task was presented explicitly involved *number recognition*, while its focus was on *simple arithmetic*. In addition, its allusion to cardinality led to its being coded for *awareness of the relationship between number and quantity*. In short, many tasks attracted multiple codes.

**Figure 2: Number patterns tasks from the Swedish and English textbooks respectively**

Some FoNS categories, as shown in Table 3, were rare in both textbooks. In this respect, Figure 2 shows tasks, one from each textbook, with explicit foci on *number patterns*. The Swedish task on the left was based on a section of a hundred square, with students being expected to complete the missing values. In addition to being coded for *number patterns*, the explicit focus of the task, it was also coded for *systematic counting*, *number recognition* and, implicitly, *simple arithmetical operations*. These decisions drew on the facts that the task required students to count on, recognise numbers and, in moving from one row to another, add or subtract ten. The English task on the right was one of several based around a section of a multiplication table torn from a longer strip of paper that invited students to count on in fives and enter the missing numbers. In addition to being coded for *number patterns*, these tasks were also coded for *number recognition*, *systematic counting* and *simple arithmetical operations*.

## Results

Below we present two analyses offering similar but importantly different perspectives on the data. The first is based on frequencies and the second on proportions.

### A frequency analysis

The figures of Table 2 show the distribution of the eight FoNS categories across the two textbooks, one from England and one from Sweden. The first thing to notice, acknowledging that both books are intended to provide the complete learning experience for year one students, is that the Swedish book offered 444 tasks appropriate for FoNS coding, while the English only 257. That is, while both figures represented similar proportions of the totality of tasks within their respective books, the Swedish textbook comprised 187 (73%) more FoNS-related tasks than the English. Table 2 also shows that of the eight FoNS categories, number recognition was the most frequently observed, with 532 out of 691 tasks providing opportunities for learners to recognise, write and say numbers. In similar vein, *simple arithmetical operations* were common occurrences throughout both books. Neither of these results, we suggest, is surprising as arithmetical competence is an unequivocal curricular goal, which

relies extensively on number recognition. The least commonly observed FoNS category was estimation, with just 18 occurrences.

Category present in task (444 Swedish tasks and 257 English tasks)								
	No	Yes		No	Yes		No	Yes
	Number recognition			Systematic counting			Number and quantity	
England	29	228		145	112		194	63
Sweden	130	304		354	80		259	175
	159	532		499	192		453	238
	$\chi^2 = 31.8$ (A)			$\chi^2 = 50.9$ (A)			$\chi^2 = 17.9$ (A)	
	Quantity discrimination			Different representations			Estimation	
England	237	20		202	55		250	7
Sweden	370	64		181	253		423	11
	607	84		383	308		672	18
	$\chi^2 = 7.33$ (B)			$\chi^2 = 88.9$ (A)			$\chi^2 = 0.03$ (C)	
	Simple arithmetic			Number patterns				
England	154	103		232	25			
Sweden	232	202		406	28			
	386	305		638	53			
	$\chi^2 = 2.74$ (C)			$\chi^2 = 2.45$ (C)				

Chi squares marked A yielded  $p < 0.0005$ , B yielded  $p < 0.01$  and C were not significant

**Table 2: Frequencies and chi square tests for each category for each country.**

When data are compared, some interesting results emerge. On the one hand the English books comprised significantly higher proportions of tasks involving *number recognition* ( $\chi^2=31.8$ ,  $p < 0.0005$ ) and *systematic counting* ( $\chi^2=50.9$ ,  $p < 0.0005$ ) than the Swedish. On the other hand, the Swedish books offered significantly higher proportions of tasks involving opportunities for students to *relate numbers to quantity* ( $\chi^2=17.9$ ,  $p < 0.0005$ ), engage in *quantity discrimination* ( $\chi^2=7.33$ ,  $p=0.007$ ) and experience *different representations of number* ( $\chi^2=88.9$ ,  $p < 0.0005$ ). Proportionally, the figures of Table 2 show no significant differences with respect to *estimation*, *simple arithmetical operations* or *number patterns*. These results take us to the second step of the analysis.

### A proportional analysis

A second perspective on the data can be seen in Table 3. Firstly, several FoNS categories were found in similar proportions in both textbooks. These included relatively high occurrences of *simple arithmetical operations*, implicated in just under half of all tasks in both textbooks. In smaller proportions, around a quarter of all tasks in both books, were opportunities for students to *relate number to quantities*. In very small proportions in both books, were found *number patterns* and *estimation*. Secondly, several categories distinguished the expectations found in one book from the other. On the one hand, the English textbook comprised a significantly higher percentage of number recognition tasks (89%) than the Swedish (70%) ( $t=6.31$ ,  $p < 0.0005$ ). Also, almost half of all English tasks involved systematic counting in comparison with less than a fifth in the Swedish ( $t=6.95$ ,  $p < 0.0005$ ). Alternatively, the Swedish textbook comprised nearly three times as many tasks involving different representations of number as the English ( $t=10.57$ ,  $p < 0.0005$ ), twice as many tasks focused

on quantity discrimination ( $t=2.92$ ,  $p=0.004$ ) and almost twice as many tasks relating numbers to quantity ( $t=4.42$ ,  $p<0.0005$ ). Finally, Table 3 shows that the percentage of tasks coded for *estimation*, *simple arithmetical operations* and *number patterns* were comparable in both books, confirming that the two analyses, one essentially parametric and the other non-parametric, yielded equivalent results.

	E%	S%	t	p
Number recognition	89	70	6.31	0.000
Systematic counting	44	18	6.95	0.000
Relating number to quantity	25	40	-4.42	0.000
Quantity discrimination	8	15	-2.92	0.004
Different representations	21	58	-10.57	0.000
Estimation	3	3	0.16	0.874
Simple arithmetical operations	40	47	-1.66	0.097
Number patterns	10	6	1.49	0.136

**Table 3: Percentage of all tasks coded for each FoNS category along with t-tests**

## Discussion

In this paper our objective was to examine the efficacy of the FoNS framework as tool for evaluating the learning opportunities embedded in commonly used textbooks and to undertake a comparative analysis to determine the framework's sensitivity to different cultural expectations. In both cases, we believe the study to have been successful. For example, with respect to the identification of the different FoNS categories, very few tasks were identified with an emphasis on *estimation*, a finding resonating closely with earlier classroom observations showing no evidence of teachers in England, Hungary, Poland, Russia or Sweden emphasising it in their teaching (Back et al., 2013; Andrews et al., 2015; Sayers et al., 2016). This, it seems to us, is an issue of some concern and the basis of further systematic inquiry. Indeed, acknowledging that estimation skills are important indicators of later mathematical competence (Booth & Sigler, 2006), that both older students (Sowder & Wheeler, 1989) and many otherwise competent adults (Hanson & Hogan, 2000) are uncomfortable with estimation tasks, it seems sensible to ask; why does estimation play such a lowly role in the classroom practice and textbooks of these two countries? This, we argue, is particularly pertinent in light of evidence from other countries that teachers see little relevance in teaching estimation (Alajmi, 2009). Furthermore, the similar frequencies of other FoNS categories are unsurprising. For example, it is reasonable to assume that the relative lack, in both textbooks, of tasks focused on *number patterns* may be explained by the fact that most year one curricular goals emphasise learners' *number recognition*, *relating number to quantity* and the beginnings of *arithmetic*. In other words, while number patterns are important in preparing students for later mathematical learning (Lembke & Foegen, 2009), they may be subordinated in children's early number experiences to more pressing developmental needs.

With respect to cultural sensitivity the data yielded several hitherto uncovered insights. For example, on the one hand, the higher proportions of Swedish tasks coded for *different representations of number*, *relating number to quantity* and *quantity discrimination* allude to a book focused on conceptual understanding. On the other hand, the apparent lack of a conceptual emphasis in the English book finds further support in the high proportions of tasks coded for *systematic counting* and extremely high proportions of tasks addressing *number recognition*, which tend to suggest a book

focused on the development of procedural knowledge commensurate with the low levels of mathematical challenge found in earlier studies of English textbooks (Bierhoff, 1999; Haggarty & Pepin, 2002; Newton & Newton, 2007). However, the conceptual emphasis found in the Swedish textbooks seemed not to match the generally negative findings of earlier Swedish studies (Ahl, 2016; Lundberg, 2011; Nordström & Löfwall, 2005). In this respect, it is not improbable that these differences may be because these earlier studies addressed textbooks for students in grades 7 and upward rather than on those for young children. Finally, drawing on Bernstein's (1990) notion of curricular framing, it is interesting to note that the weakly framed Swedish pre-school curriculum seems to have prompted a conceptually focused textbook, while the strongly framed English pre-school curriculum seems to have precipitated a procedurally focused textbook. Such matters allude to research beyond the scope of this paper but which will form a key aspect of any further analyses we make.

*Structure sense can be mobilized by pupils to compare and to transform arithmetical expressions, however sometimes it can lead to mathematical inconsistency that pupils might be not aware of. This paper provides evidence of this type of phenomenon. Through the analysis of an interview with a third grader, it is shown that the development of structure sense can result in transformations as  $a \times b + a \times c \rightarrow (a+a) \times (b+c)$ . It is concluded that a development of structure sense requires a dialectical control between the syntactic and semantic interpretations of symbolic sentences.*

*Keywords: Structure sense, distributive property, arithmetic, syntactical transformations.*

### Learning distributivity

Distributive property appears to be less accessible to young students if compared to other multiplication's properties (Larsson, 2016). This phenomenon could depend on the fact that it is not a property of one operation but it states a relation *between* two operations. Lo and colleagues (2008) found that many prospective primary teachers show difficulties in applying the distributive property: a frequent erroneous transformation is  $18 \times 26 = 10 \times 20 + 8 \times 6$  in which tens are multiplied just by tens and units are multiplied just by units (*ibidem*).

According to Carpenter et al. (2005) “an implicit understanding of the distributive property can provide students a framework for learning multiplication number facts by relating unknown facts to known facts” (Carpenter et al., 2005, p.55). For this reason they sustain that it is important to foster the use of fundamental properties of operations to transform mathematical expressions rather than simply calculating. An awareness of the structure of arithmetical expressions appears as fundamental to recognize the equivalence of two arithmetical sentences without carrying out calculations. Mason et al. (2009) use the expression ‘*structural thinking*’ to refer to such awareness.

We wonder which difficulties might students face when they are introduced to structural thinking, and specifically when they elaborate expressions through operations’ properties – distributive property in particular.

### Structure sense in arithmetic

Apparently, before Mason et al. (2009) introduced the construct of structural thinking, different words have been used to express similar ideas. Linchevski and Livneh (1999) found that many of the typical difficulties faced by students while interpreting algebraic expressions can be found also in the arithmetical context. In particular, they notice students’ difficulties in determining the order in which additions and subtractions have to be performed both in the arithmetical and in the algebraic context. These authors conclude that “difficulties revealed in children’s understanding of structural properties of the algebraic system originate in their understanding of the number system” (Linchevski & Livneh, 1999, p.192).

Undoubtedly, students must be exposed to the structure of algebraic expressions. However, it must be done in a way that enables them to develop *structure sense*. This means that they will be able to use equivalent structures of an expression flexibly and creatively. (*ibidem*, p. 191)

Similarly, Caspi and Sfard remarked how “structures of algebraic formulas are not unlike those of arithmetic expressions” (Caspi & Sfard, 2012, p. 64) and they interpreted such similarity as based on the fact that school algebra can be conceived as a gradual formalization of meta-arithmetic (*ibidem*); thus the development of an effective algebraic calculation competence has been referred to as the development of structure sense in arithmetic.

Hoch and Dreyfus (2004) characterize structure sense in the context of high school algebra. They define it in terms of a collection of abilities. According to the cited literature, these abilities can be related to similar abilities in arithmetic. So we propose to modify Hoch and Dreyfus’ (*ibidem*) definition to adapt it to the context of primary arithmetic. Thus, structure sense in arithmetic can be described as a set of competences:

1. recognising an arithmetical expression or sentence as an entity, for instance comparing two arithmetical sentences without calculating partial results.
2. Recognising an arithmetical expression or sentence as a previously met structure, for example noticing that  $3 \times 4 + 5$  is less than  $10 + 3 \times 4 + 5$  because the second one is a sum which includes the first one.
3. Recognising sub-expressions in which an arithmetical expression can be divided, as in the case of a student who can describe  $5 \times 7 + 8 \times 7$  as composed by two multiplications.
4. Recognising mutual connections between sub-expressions, that means being able to identify which are the operations connecting the terms of an arithmetical sentence, even when such terms are not just single numbers but shorter expressions.
5. Recognising which manipulations are possible to perform. For instance, on an arithmetical sentence like  $7 + 8 \times 7 + 3 + 4$ , many transformations could be done ( $9 \times 7 + 7$  or  $14 + 8 \times 7$ ) but there are also transformations that are not executable (as  $15 \times 7 + 3 + 4$ ).
6. Recognising which manipulations are useful to perform. According to the aim of transformations (comparing or calculating), some manipulations can be more useful. In the case mentioned above, the usage of associative property of sum ( $3 + 4 = 7$ ) and distributive property ( $7 + 8 \times 7 + 7 = 10 \times 7$ ) allows to notice that  $7 + 8 \times 7 + 3 + 4$  is equivalent to  $10 \times 7$ .

This definition is coherent with and specifies those given by Mason et al. (2009) and Linchevski and Livneh (1999). Some of the competences listed above can be activated by pupils to compare and to transform arithmetical expressions: thus, the presence of these abilities can witness the emergence of structure sense, however sometimes this same abilities can lead to mathematical inconsistency that pupils might be not aware of.

This paper aims to provide evidence of this type of phenomenon, that can be considered as a an indication of an incomplete development of structure sense due to a lack of control on the numerical interpretation of a specific structure.

## Data collection and analysis

The results that we are going to present are part of broader research study (Maffia & Mariotti, 2016) aimed at investigating the teaching/learning of multiplication properties in the primary school. The empirical design included long-term teaching experiments involving, among others, a group of second graders. The results presented in this paper concern data coming from this specific group. Grade 2 was chosen to promote structural thinking in the case of multiplication since the very first introduction of this operation, that usually takes place at this school level in Italy. Among others, following Linchevski and Livneh's suggestion to "promote the search for decomposition and recomposition of expressions" (1999, p. 191), we designed and implemented activities aimed at introducing the pupils to the distributive property as a transformation of numerical expressions (Maffia & Mariotti, 2015). The rectangular model of multiplication was introduced: activities of cutting and pasting rectangles with the same height (or width) were proposed to explore the relationship between different arithmetical expressions, eventually generalized and symbolically expressed in the distributive property. Examples of such cutting and pasting are given in Figure 1.

**Figure 1: Composition and decomposition of rectangles**

Starting from the activities with paper rectangles, the teacher realizes a mediation process to guide students till the usage of conventional arithmetical symbols to represent the relation between multiplication and sum according to the distributive property (*ibidem*).

In this paper, we show data from semi-structured interviews conducted one year after the end of the teaching experiment. Thus, at the moment of the interviews the children are third graders (aged 8-9).

The interviewer shows an image of two children who are writing the equalities  $4 \times 7 = 7 \times 4$  and  $6 \times 8 + 6 \times 3 = 6 \times 11$  on a blackboard (Figure 2) and he asks if what these children are writing can be considered correct. During the teaching experiment, children were asked to produce compositions and decompositions of multiplications, using paper rectangles and then writing them with arithmetical symbols. This is the first time that they have to validate or refute an already written equation.

After the equalities shown in Figure 2, three other numerical sentences are shown and the interviewee is asked to comment about their correctness. These sentences are  $5 \times 6 = 5 \times 2 + 5 \times 4$ ;  $5 \times 6 = 5 \times 3 + 5 \times 4$ ;  $5 \times 4 + 5 \times 3 = 5 \times 2 + 5 \times 5$ . The structure of the first one is similar to the one shown in the image, but the position of expressions is inverted in respect to the equal symbol. The second one is like the first one, except for one number (so it is wrong), and the last one has a different structure but it relates two expressions with the same structure – a sum of products – and specifically, the structure of one of the members of the other equalities. So, the different sentences are designed to allow the child to compare or contrast the structures in the different equalities and, eventually, to apply arithmetical properties. During the interview, paper and pen are provided.

**Figure 2: Image showed to students at the beginning of the interview**

The interviews have been videotaped and then fully transcribed. Students' transcribed utterances were analysed seeking for evidences of structure sense, through identifying instances of the characterizing abilities. In the following section we discuss some examples, showing specific aspects emerging from this analysis. In the analysis, the six competences of the list are indicated through the corresponding number in the list that is indicated between square brackets.

### Seeking symmetry in distributive property

We begin with some excerpts, starting from the end of an interview: Francis comments about the equality  $5 \times 4 + 5 \times 3 = 5 \times 2 + 5 \times 5$ .

- 53 Interviewer: Now I will show you a very long one. What do you think about this one [he shows the equality  $5 \times 4 + 5 \times 3 = 5 \times 2 + 5 \times 5$ ]?  
 54 Francis: [he writes the equality on his paper and then he answers quickly] It's right!  
 55 Interviewer: Did you already do it?  
 56 Francis: Yes.  
 57 Interviewer: Tell me how. I am not as fast as you are.  
 58 Francis: Wait. I'll write it.  $5 \times 4$ , is 20. [he writes 20 under the first multiplication. Then he writes the results of the other multiplications; second line in Figure 3] If I would put the 3 and I put 2 [he circles the 3 and he writes a 2 above it] and here I put a 5 [he circles the 4 and he writes a 5 above it] it would be the same operation.

**Figure 3: Francis' inscriptions for the last equality**

In his explanation (line 58) Francis recognises the possibility of decreasing one of the factors of the second multiplication and increasing one of the factors of the first one, still maintaining the same result (he says "it would be the same operation"). We can recognize an occurrence of the first component of structure sense because Francis is jointly and consistently acting on each part of the arithmetical sentence to maintain its value: he is recognising that the transformation of one multiplication affects the other one, thus he is considering the arithmetical expression on the left side as a unique entity [1].

The expression  $5 \times 4 + 5 \times 3$  is transformed in  $5 \times 5 + 5 \times 2$  to show the equivalence with  $5 \times 2 + 5 \times 5$ ; so Francis recognises a useful transformation for his purpose [6]. However, in the obtained expression  $5 \times 5 + 5 \times 2$ , the order of the two multiplications is inverted in respect to  $5 \times 2 + 5 \times 5$ . Stating that the two

expressions are equivalent, Francis is considering the expression as a sum of two multiplications [4] and so – according to addition’s commutative property – the order of the addends  $5 \times 2$  and  $5 \times 5$  can be inverted [5]. The child is also recognising that the expression is composed of two multiplications [3]; this interpretation is strengthened by the written operations in the second line of Figure 3.

So far, we have instances of five of the competences that characterize the structure sense; we can say that Francis is showing some evidence of structure sense. As a matter of fact, Francis’ explanation not only shows his awareness of structure regularities, but it is completely consistent in terms of the mathematical meaning of the expressions.

However, this has not always been the case. At the very beginning, when the image (Figure 2) was firstly showed, he recognized the equality  $6 \times 8 + 6 \times 3 = 6 \times 11$  as incorrect and stated that the equivalence would have been true if  $6 \times 11$  was replaced with  $12 \times 12$ . Here is his explication:

- 11 Interviewer: Wait. Tell me how did you get twelve and twelve.  
 12 Francis: Six times eight plus six times three [he writes it] I would do six plus six [he draws circles around the 6s, as shown in Figure 4a] that makes twelve.  
 13 Interviewer: I understand. So you get the first twelve.  
 14 Francis: And eight plus three [he circles 8 and 3, Figure 4a] that makes twelve.  
 15 Interviewer: I don’t agree. How much is eight plus three?  
 16 Francis: Eight plus three... eleven [he corrects the second 12 writing a 1 over the 2].  
 17 Interviewer: Eleven. Ok.  
 18 Francis: So it wouldn’t be twelve times twelve but twelve times eleven.

Figure 4 consists of three handwritten mathematical inscriptions on grid paper. (a) shows the expression  $6 \times 8 + 6 \times 3$  with circles around the 6s and arrows pointing to  $12 \times 12$ . (b) shows a multiplication table for  $6 \times 12$  with the result 72. (c) shows a multiplication table for  $12 \times 12$  with the result 144.

**Figure 4: Francis’ inscriptions for the first equality**

Francis seems to recognize the expression  $6 \times 8 + 6 \times 3$  as relating two parts [3], two multiplications connected by an addition [4], and he elaborates this structure according to a *syntactic rule* clearly respecting some kind of “structure sense”, but unfortunately it is inconsistent from the mathematical point of view. The transformations he operates (Figure 4a) are strictly at the syntactical level: he is transforming the expression as if the addition would operate in the same way on both the first and second factors of the two multiplications.

The interviewer asks Francis to check the correctness of his conjecture. Francis proposes to calculate the operations’ results.

- 27 Interviewer: How can we get the result of this thing?  
 28 Francis: We calculate forty-eight plus six times three that is... eighteen. Forty-eight plus eighteen is... and six times eleven is... [he performs the written calculation in Figure 4b]. Forty-eight plus eighteen... is... [he performs the written calculation in Figure 4c] sixty-six. So it’s right!

- 29 Interviewer: Is it? So, what was wrong here? [he points Francis inscription in Figure 4a]  
In your initial check. Because you said that it wasn't right.
- 30 Francis: I thought we had to do  $12 \times 11$ .
- 31 Interviewer: And is  $6 \times 11$  enough?
- 32 Francis: [...] Yes, because we have to calculate the results of the two multiplications,  
to calculate the result of the third one and see if the first two ones equal that...  
their result.

In line 28, Francis is able to divide the expression into its parts: he recognizes that it is composed of two multiplications [3], then he recognizes that he has to sum the two products, so he is recognizing the connection between the two parts [4]. This interpretation is made explicit again in line 32. Francis is showing two of the competences that characterize structure sense: number 3 and 4 in the list. This time, though using his structure sense, the pupil is interpreting the equivalence between the two expressions in a different way. Previously he considered the expressions  $6 \times 8 + 6 \times 3$  and  $12 \times 11$  to be equivalent because one could be transformed into the other according to a syntactical manipulation. In the following, he recognizes two expressions to be equivalent when they give the same result (lines 28 and 32). We consider the first case an occurrence of a *syntactical interpretation* of the equivalence between numerical expressions, the second one as an occurrence of a *semantic interpretation*. Though not yet well harmonized, both types of interpretations seem to be available to Francis, at the same time, the semantic interpretation seems to maintain its primacy.

When the other two equalities are shown, Francis resorts again to the semantic interpretation. He calculates the results of the expressions on the two sides of the equal sign and then he checks if the results equal each other:

- 43 Interviewer: What if I show you this one? [he shows  $5 \times 6 = 5 \times 3 + 5 \times 4$ ]
- 44 Francis: Thirty [he writes 30]. Fifteen, [he writes 15] twenty [he writes 20 next to 15  
and then he puts a + sign between the last two numbers. Then he writes  $=35$   
obtaining the inscription shown in Figure 5a]. It doesn't work.
- 45 Interviewer: Can we modify it to make it correct? [Francis doesn't answer] If I would keep  
this as it is [he points the right side of the equality] what should I write on this  
side? [he points the left side of the equality]
- 46 Francis: Ehm... [he puts the pen on the sheet of paper]
- 47 Interviewer: Let's write it on the paper [Francis writes the equality] Ok. Let's say that I  
want this [he points the right side of the equality in Francis' inscription] as it  
is, but I would change the other to make it correct.
- 48 Francis: We should change the 6 [he circles it] into a 7 [he writes 7 above the 6, Figure  
5b]

In this excerpt the interviewer tries to push Francis to go back to a syntactical interpretation. However, though Francis responds in a mathematically consistent way, it is impossible to determine if the proposed modification depends on a syntactical transformation ( $3+4=7$ ) or on a comparison of the expressions' results. His behaviour in lines 27-32 and 53-58 suggests that both the interpretations are plausible.

(a)  $15 + 20 = 35$

(b)  $5 \times 6 = 5 \times 3 + 5 \times 4$

Figure 5: Francis' inscriptions for the third equality

## Discussion and conclusion

As discussed in the introduction of this paper, the development of what we have called “structure sense” can be considered a main objective of the teaching and learning of algebra.

Starting from adapting the definition given by Hoch and Dreyfus (2004) to the case of arithmetic expressions, we set up a list of competences characterizing structure sense and we used it to evaluate students' behaviours as evidences of the presence of structure sense. The aim of this paper is not to discuss about the effectiveness of the classroom intervention; indeed, it presents a recurrent phenomenon that was possible to identify in the development of the structure sense: it is characterized by an unstable relationship between the syntactic and the semantic level in treating numerical expressions. The case of Francis can be considered a paradigmatic example.

The pupil shows all the competences we used to characterize structure sense but in order to check the correctness of an equality he adopts a syntactical manipulation of operations that is not mathematically consistent: an expression as  $a \times b + a \times c$  is transformed into  $(a+a) \times (b+c)$ . We interpret this behaviour as coherent with a structural sense, but also as a case of corrective action aimed at overcoming what can be seen as a structural flaw, a *seeking for symmetry* in the distributive property. The perceived lack of symmetry could be twofold. On the one hand there is no symmetry in the role of the terms: the common factor in the multiplications plays a different role than the others. On the other hand the structure of the equality  $a \times b + a \times c = a \times (b+c)$  is asymmetrical because there is a sum of multiplications on one side of the equal sign and just one multiplication on the other side. This interpretative hypothesis is reinforced by the fact that the student does not show difficulties in treating an equality like  $5 \times 4 + 5 \times 3 = 5 \times 2 + 5 \times 5$ , which has a symmetrical structure. This urgent demand of symmetry may be based also on the experience with other properties, such as the commutative and associative properties, and can be considered as a particular source of difficulty in dealing with distributive property.

The wrong transformation  $(a+c) \times (b+d) \rightarrow a \times b + c \times d$  is well known in the context of school algebra and it is found also in the arithmetic context in equalities like  $18 \times 26 = 10 \times 20 + 8 \times 6$  (Larsson, 2015; Lo et al., 2008). In this paper we have evidence of the application of the *opposite* transformation  $a \times b + c \times d \rightarrow (a+c) \times (b+d)$  in the arithmetic context. As far as we know, this particular transformation has not been documented in literature before. It has to be stressed that this transformation is shown by four students out of nineteen pupils who were involved in our research. So, we have a too small sample to state anything about its spreading.

In any case, the emergence of this kind of erroneous transformation appears relevant from the didactic point of view: if we expect teachers to promote structural thinking they have to know the potential difficulties that students could meet. Literature shows that this is not always the case (Lo et al., 2008). One clear suggestion emerging from our study is that an approach privileging pure syntactical

transformations seems risky, whilst educating pupils on the danger of losing the semantic interpretation of an expression can help them to reach mathematical consistency.

Fostering structural thinking requires the development of semantic control assuring that any syntactic transformation has a consistent arithmetical interpretation. Further investigation is needed in order to fully describe how such a semantic control can be efficiently developed.

*In this paper, we report part of a study carried out within a design research methodology. An initial conjecture was made that included the importance of the hundred square model to facilitate the discussion about decimal number system features and connections among and within different rational numbers' representations. We present how this model was used and why it led to changes into different models, 10x100 grid, and decimat, during the teaching experiment. Finally, we reflect on how these changes inform the initial conjecture.*

## Introduction

Currently, in the Portuguese official curriculum (Ministério da Educação, 2013), rational numbers are first approached in Grade 2 (7/8 years old students), in its fraction representation and measure meaning. This meaning has a central role and the use of line segments in the number line is recommended. Decimal numbers<sup>1</sup> are first introduced in Grade 3 and operations with both representations are highly valued. Given the students' age, we believe that these guidelines are too focused on procedures, and, instead, a learning path aiming at conceptual understanding should be privileged.

We will focus part of a broader study in which we follow a design research methodology. In this paper, we discuss how the decimal number system features can be addressed and discussed in the hundred square model, and why this representation was changed into other representations, during the teaching experiment. In order to better frame this paper, we first present an overview of the characteristics of design research methodology, because the use of this approach allowed the constant analysis and adaptation of the model explored during the teaching experiment. We then organize the paper according to the different stages of design research: in the preparation phase section, we present how the literature informed the design principles and initial conjecture; in the experimentation phase, episodes regarding the use and adaptations of the hundred square model will be presented, and in the third phase a deeper analysis of the episodes will be made as well as its impact on the initial conjecture.

## Design research methodology

Design research is a methodology that has gaining ground in Mathematics Education research. It can allow the construction, or “engineering”, as Cobb, Jackson, and Dunlap (2016) describe it, of

---

<sup>1</sup> Term used in this paper to identify positive rational numbers written accordingly to the decimal system notation, using the decimal comma or point.

instructional means to promote the learning of a particular topic, while constantly studying the development of that learning, considering all elements of the instructional means, not only the designed tasks but also the context in which they are carried on. Therefore, in design research theoretical and pragmatic components are highly dependent on each other.

There are five crosscutting features of design research that, together, distinguish it from other methodologies: (i) the purpose is to develop theories about both the learning process and the means designed to support it; (ii) it has a highly interventionist nature, since it can be a powerful methodology to design an approach to promote the development of a particular content or form of practice, in a real classroom; (iii) it has two interrelated components, a conjecture is made regarding students' learning (prospective component), that is constantly confronted to the actual learning (reflective component); which can lead to changes in the initial conjecture that is tested again, giving design research its (iv) iterative design; and finally there is an attempt to (v) develop humble theories that address the learning of a particular topic (Cobb et al., 2016).

One of the main characteristics of this methodology is its cyclic nature. Each cycle develops in three phases: (i) teaching experiment preparation and design; (ii) teaching experiment; and (iii) retrospective analysis that can lead to revisions and a new cycle (Cobb et al., 2016). The conjecture can be refined during the teaching experiment, resulting in micro cycles, or in between experiments, in macro cycles, or both types of refinements can happen (Prediger, Gravemeijer, & Confrey, 2015). The present study builds on micro cycles.

### **Study's rationale (*preparation and design phase*)**

#### **Decimal numbers in the research field**

Studies related to decimal numbers reveal important evidence regarding difficulties that arise when dealing and operating with this number representation (e.g., Steinle & Stacey, 2003), whole numbers' knowledge influence (e.g., Resnick, Nesher, Leonard, Magone, Omanson, & Peled, 1989) or about knowledge of the decimal number system, specific of this representation (e.g., Baturo, 2000). Studies present evidence that those difficulties and whole number interference can remain in adulthood (e.g., Vamvakoussi, Van Dooren, & Verschaffel, 2012), which reveals the demanding conceptual understanding needed regarding this representation of rational numbers.

According to Post, Cramer, Behr, Lesh, and Harel (1993), the development of rational number understanding is related to (i) flexibility with translations between rational number representations; (ii) flexibility with transformations within a representation; and (iii) progressive independence from concrete embodiments of rational numbers. In a broader perspective, representations can be a tool to or reflect students' development of mathematical ideas of a particular concept. Therefore, representations that can become models assume an important role, establishing a link between knowledge connected to reality and the mathematical knowledge to be developed (Van den Heuvel-Panhuizen, 2003). Initially, models named as models of (Gravemeijer, 1999), are closely connected with the task context and cannot be used in other situations. This type of model should evolve to a model for (Gravemeijer, 1999), that can be applied in various situations, focusing mathematical connections and not the situation described in the task. In order for this development to happen, the model should have certain characteristics that make it suitable to be used in diverse situations. As

Van den Heuvel-Panhuizen (2003) highlights, to support learning, the model should allow students not only to progress into the mathematical ideas but also to go back to the reality context if needed.

Research show evidence of decimal numbers' learning fostered by the appropriation of different models. We will now focus two of the models considered in the teaching experiment: the hundred square and the decimat. The hundred square is a model often used when teaching decimal numbers, until hundredths, that allows connections between the iconic representation of the grid and symbolic representations, not only decimals but also fractions and percentages. The grid also facilitates students to understand the meaning of each digit and, consequently, its decimal number system notation. It is also an important model to compare and order decimal numbers and, later on, can be used to add and subtract decimal numbers (Cramer, Monson, Wyberg, Leavitt, & Whitney, 2009). Decimat is a similar model, however, by being rectangular and divided into two rows and five columns, allows a clear visualization of each part again divided by 10, emphasizing the multiplicative structure of the decimal place value in the decimal number system (Roche, 2010).

### **Structuring the cycle**

Based on literature review, the following six design principles were elaborated to guide the conjecture and instructional means: (1) use of tasks which context appeals to the use of rational numbers in its decimal representation; (2) promote movements among decimal numbers and other rational number's representations highlighting their relations; (3) promote the use of representations that support their transformations into models to think about rational numbers in its decimal representation; (4) encourage the use of prior knowledge; (5) promote the discussion of whole number interferences and common misconceptions; and (6) establish a learning environment where students are encouraged and feel confident to share and discuss their own mathematical ideas.

Supported by these principles, an initial conjecture was made: A teaching experiment comprised by different types of sequenced tasks, explorations and exercises, focusing decimal numbers in measure and part-whole meanings and the use of number line and hundred square model, considering students' whole number and informal knowledges and evoking the need for the use of decimal numbers, as well as its connections with other rational numbers representations, in a learning environment where students have an active role and small group work and whole-class discussions are privileged, will promote a meaningful understanding of decimal numbers.

A set of tasks was planned (some new and others adapted from existing materials) and students' understanding was anticipated. Tasks were open to adjustments or to be completely revised depending on the understanding students revealed along the way. The teaching experiment was intended to be carried out in Grade 3, from February to June 2014, however, the last tasks were conducted at Grade 4. The teaching experiment was, generally, carried out once per week, in one 90 minutes lesson, involving a total of 16 weeks over the two school years.

The participants were 25 students and their teacher. A diagnostic study was made with the same students, in Grade 2, that provided information about students' ideas of different rational numbers' representations, which supported the design of the initial tasks and also help to gather information concerning the teacher's role. Consequently, the classroom teacher asked for a detailed plan for each task. The plan was made by the researcher (first author) and discussed previously with the

teacher, and included suggestions to support teacher inquiry, possible students' answers and solutions and potential students' difficulties.

In the data presented in the next section, students will be referred to with fictitious names. The tasks were solved in small group work or in pairs, and whole-class discussions were privileged. Records of all the students' written work, along with participant observation by the researcher supported by audio/video recordings and field notes, constituted the main data sources. Meetings between the researcher and the teacher, prior and after each lesson, were also audio-recorded.

One of the expected products of the broader study is a set of indicators of decimal number understanding that can be helpful both for teachers and researchers. We intend that these indicators address two different levels: (i) what is specific of this rational number representation, and, (ii) the intertwinement between this representation and other rational number representations. In this paper, we outlined some indicators of students' understanding of decimal numbers to be supported by the appropriation of the models here presented. As an ongoing research, these indicators are preliminary and open to revision. Regarding the first level, we consider identifying the partitioning and grouping by powers of ten to create units of tenths, hundredths, and thousandths, and reveal an understanding of the decimal numeration properties (positional value, multiplication and addition properties, in addition to base ten property). In relation to the second level, we consider recognition of a decimal number in different representations; identifying the unit, and establish equivalences between numbers represented as decimals, percentages, and fractions.

### **Classroom episodes (*teaching experiment phase*)**

We present three illustrative episodes of the use of three models throughout the teaching experiment, focusing on part-whole meaning. The examples presented concern the use of each model by students (representations as models of). The first two occurred in Grade 3 and the third in Grade 4. We focus our analysis on the indicators of decimal number understanding as mentioned above.

The hundred square was presented to students as a towel, divided into tenths and hundredths. After some exploration of this model, a task was presented to promote the discussion of common misconceptions, such as the comparison of decimal numbers based on its number digits. The hundred square model was showed to help students explain their answers. One of the questions was "Do you think 0,67 is bigger than 0,9?". In whole-class discussion, Jorge revealed how he used the hundred square model to compare both numbers:

Jorge: Initially I thought that 0,67 was bigger than 0,9 because at first sight 67 seems bigger than 9. . . but then I realized that I could think in a different way. So, if we think that each column has ten-hundredths, we would have to paint six of these columns, without the seven (in 0,67) it would be only sixty. And the other one (0,9) would be 90, it was bigger, nine columns are 90 hundredths, so it was bigger than painting 67 hundredths.

Due to the appropriation of the hundred square, Jorge could visualize and compare the quantities represented by both numbers (Figure 1). The hundred square has shown to have great potential, as its use helped Jorge to overcome the initial, and expected, interference of whole number knowledge.

**Figure 1: Jorge's work record at a task with the hundred square model**

When preparing the teaching experiment, it was anticipated that students could visualize each small square in the model (one hundredth) divided into ten equal parts, each representing ten thousandths. However, it was important that students, in fact, saw the thousandths, instead of inferring that from this model. Given its shape, the hundred square doesn't allow further divisions into thousandths, in the same manner, thus another model was thought. Later, in the classroom, this model started to be called as "thousandths bar". With a rectangular shape, a bar represents the unit that is divided into ten large squares, representing tenths, and each one is then divided into ten columns, the hundredths, that are again divided into ten equal parts, the thousandths (Figure 2).

**Figure 2: Thousandths bar model**

At first, students were encouraged to find out how many "small squares" were in the whole bar. Many looked into one "big square" divided into quarters and calculated  $4 \times 25$ , which was 100, and then multiplied 100 by 10, reaching 1000. Initially, students thought that each "big square" was like the hundred square, representing a hundred hundredths, or one. This was probably due to the fact that each tenth in this model was similar to the hundred model. A unit change was implied: before, one big square represented one unit, now a similar but smaller square represents one tenth. Nonetheless, the model allowed students to relate tenths, hundredths, and thousandths.

An example of these connections made by students is shown in Figure 3. Artur's answer relates to a question where students were asked to paint in the thousandths bar 0,001 with green, 0,01 in red and 0,1 in yellow. After, they were asked about what connections they could find among these parts.

*As relações que encontramos: verde  $\times 100 =$  amarelo  
verde  $\times 10 =$  vermelho vermelho  $\times 10 =$  amarelo  
vermelho  $: 10 =$  verde amarelo  $: 10 =$  vermelho  
amarelo  $: 100 =$  verde*

"The relations we found were:  
green  $\times 100 =$  yellow, green  $\times 10 =$  red,  
red  $\times 10 =$  yellow, red  $: 10 =$  green,  
yellow  $: 10 =$  red, yellow  $: 100 =$  green"

**Figure 3: Artur's work record at a task with the thousandths bar model, with translation**

Artur, like other colleagues, could clearly state the partitioning and grouping by powers of 10 that create the units of tenths, hundredths, and thousandths. It is important to refer that it was the first time that these relations were clearly stated by the students. We believe that visualizing each painted unit in the same model promoted the establishment of these connections. On the other side, and even though some students correctly identified the tenth and the thousandth in the bar, they had painted one hundredth as one-quarter of one-tenth. Students said that 0,1 was the biggest square in the bar, then 0,01 was the “middle” square and 0,001 was the smallest square (Figure 4).

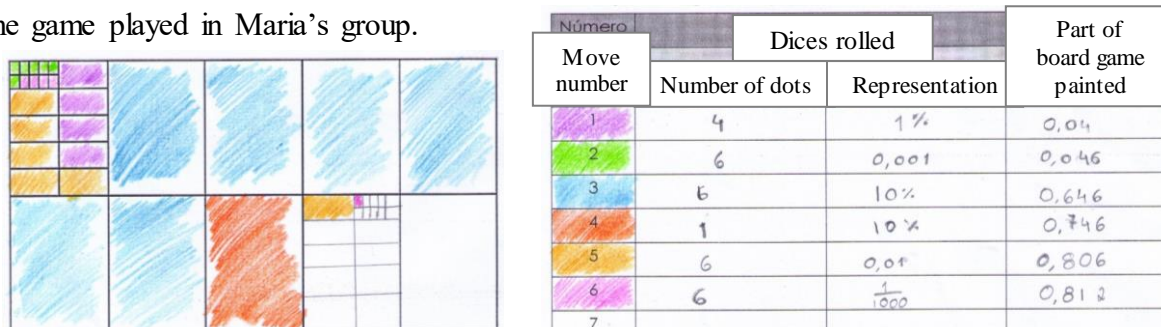

**Figure 4: Mafalda’s work record at a task with the thousandths bar model**

We weren’t expecting this response. It can be linked to two factors: due to the strategy used to count the total of “little squares” in the bar, or probably due to the bar layout that misleads students to think about the different decimal units in terms of squares. If a big square is 0,1 and a small square is 0,001, the middle square will be, incorrectly, 0,01.

Thus, together with the classroom teacher, we felt the need to adapt the model again. We needed a model that, like the hundred square, clearly allowed to see the connections between different units, and like the thousandths bar, allowed the extension to the thousandths and students’ inference of further partitions by powers of 10, to develop the idea of density. After scratching a model with such features, followed by searching for a similar model in the research field, we came across the decimat model, as described by Roche (2010). Therefore, we included some tasks adapted from this author’s work in the teaching experiment.

The model was presented with one tenth divided into hundredths, and one of which divided again into thousandths. When students first saw it, they called it “towel”, relating it to the hundred square. They immediately recognized the model shown tenths, one of which divided into hundredths and thousandths. It was said that the model could be further divided if they wanted or needed.

One of those tasks was a game adapted from the one proposed by Roche (2010). In groups of about four students, two dices were given: one regular dice with dots and other with different symbolic representations, specifically 0,01; 0,001;  $\frac{1}{1000}$ ,  $\frac{1}{10}$ , 1%, and 10%. The students had to roll both dices and multiply the numbers represented in them. Then, they had to color that part in the decimat and say which part of the decimat had already been painted, altogether. Figure 5 shows the record of the game played in Maria’s group.

**Figure 5: Maria’s group record of game plays using the decimat model, with translation**

Besides the flexibility in the movement within symbolic representations (decimal, percentage, and fraction) and the operations with decimal numbers as multiplication and addition, this example illustrates the potential of this model. Only one tenth is further divided, however, when needed, the students easily did the divisions on another tenth, revealing an at-ease use of the model.

### **Looking back and adjusting (*retrospective analysis phase*)**

We addressed the use of part-whole models to promote students' understanding of rational number in its decimal representation. Both the hundred square and the thousandths bar models can foster connections between the unit partitioning and grouping by powers of 10, and the decimal number system. However, the hundred square only extends to hundredths and the features of the thousandths bar can hinder the idea of partitioning the unit by powers of 10.

We want to highlight that students had already worked with the hundred square and thousandths bar when the decimat was introduced, which influenced its successful use. We also need to refer that we weren't seeking for a single and perfect model. In fact, students should explore different models. In the present study, the students continued to use all models. Nevertheless, a model should promote the visualization of specific mathematical connections to support student's learning (Van den Heuvel-Panhuizen, 2003), thus, the model's features should allow its evolving alongside the development of students' understanding. The adjustment of the initial model, done to highlight the decimal number system properties, such as the partitioning and grouping of units and place value, led us to the revision of our initial conjecture, in which we will now emphasize the decimat as an important part-whole model.

However, the use of a model by itself is not enough for students to establish mathematical connections, so the connections intended by the use of models should be focused (Prediger, 2013). The results help us to understand that the decimat can be the first model approached, initially divided into tenths, then fully divided into hundredths, in the same manner that the hundred square was also first approached, and, finally, divided into thousandths. We believe that such an approach can promote the understanding of partitioning by powers of ten connected with decimal place value. Besides that, it will allow to order and compare different representations, promote the development of a benchmark number system, unit conceptualization and support decimal numbers' operations. All these connections are strong foundations for the development of decimal number understanding.

*The purpose of this study was to investigate 6th, 7th and 8th grade students' common difficulties regarding rate and ratio problems. The data was collected from 149 sixth, seventh, and eighth grade students enrolled in public middle schools in Balıkesir in response to three typical proportionality questions. Data analysis revealed that the confusion of unit rate identification and algorithmically based mistakes were identified as major difficulties in solving the missing-value proportion and comparison problems. To address the potential difficulties students have regarding rate and ratio problems, students should be exposed to different types of proportional problems.*

*Keywords: Proportional reasoning, unit rate identification, algorithmically based mistakes.*

## Introduction

Proportional reasoning is considered to be a keystone of students' mathematical development and is required to access more advanced high school mathematics like algebra, geometry, probability, and statistics (Lesh, Post, & Behr, 1988). Lesh and his colleagues identify the proportional reasoning involving multiple comparisons between quantities (Lesh et al., 1988).

Previous studies have shown that children can manipulate part-whole relationships within sets of data, but they tend not to employ a systematic approach or to use categories (Inhelder & Piaget, 2013). Although children's mathematical development contains preproportional reasoning knowledge, which has always been seen as the hallmark of the formal operations stage (Inhelder & Piaget, 2013), this knowledge is insufficient for an understanding of proportional reasoning and the solution of ratio and proportion problems (Lamon, 1993).

In order to promote a conceptual understanding of ratio as the first step of proportional reasoning, it is necessary to create comparisons, beginning with additive and moving on to multiplicative comparisons. Additive comparisons compare two quantities to decide how much greater or less one quantity is than another by finding their difference, which is not the same thing as ratio. On the other hand, multiplicative comparisons provide a ratio by comparing two quantities to decide how many times larger one quantity is than another. Therefore, providing some key activities carefully designed to link these two concepts will be useful to help students to construct the aspect of ratio (Kaput, 1985).

## Difficulties in proportional reasoning

Teachers have focused on teaching how to arrive at correct answers by applying rules instead of explaining the reasons behind those rules (Hart, 1988). While most of the students will be able to do computation properly, they are not encouraged to build links between concepts. Furthermore, some of the methods used by students lead to problems due to incorrect solution strategies or incorrect use of correct strategies (Hart, 1988).

Regarding proportional difficulties, algorithmically based mistakes are usually the result of lack of attention during the learning process or weak conceptual understanding (Hart, 1988). According to

researchers, problems may also arise from the attempt to find a fast way to compute ratio problems. In other words, students may be rushing to solve the problem quickly without thinking about the relationship between the given quantities and tend to simply copy the procedures identically. In addition, even though they may be able to construct a correct algorithm for cross multiplication, some students may not correctly explain the reasoning behind the algorithm (Lobato, Ellis, & Zbiek, 2010). Routine problems may lead students to assume that they can mimic solution procedures, but when they come across different problem types or non-standard language, they may struggle. Literature review showed that a number of studies have dealt with the reasons for mathematical difficulties in the field of ratio (Ellis, 2013; Hart, 1988; Lamon, 1993; Misailidou & Williams, 2003; Sarwadi & Shahrill, 2014). However, few studies have examined common difficulties among 6<sup>th</sup>, 7<sup>th</sup> and 8<sup>th</sup> grades students connected with unit measures approach for the different types of proportionality problems.

### **Statement of the problem**

This study was conducted to investigate 6<sup>th</sup>, 7<sup>th</sup> and 8<sup>th</sup> grade students' difficulties regarding rate and ratio problems. To put it another way, study aimed to answer the research question: "What are the common difficulties encountered by 6<sup>th</sup>, 7<sup>th</sup> and 8<sup>th</sup> grade students' while the missing-value proportion and comparison problems involving rate and ratio concepts?"

### **Method**

#### **Sample**

The sample of this study, which included 66 males and 83 females, consisted of students from sixth to eighth grade at a public middle school in Balıkesir, Turkey. The school addresses a wide variety of neighborhoods and income levels ranging from low income to upper middle class.

#### **Measuring tool**

Three proportional word problems in real world contexts were used to investigate students' proportional reasoning difficulties by grade levels (see Table 1). When we reviewed the literature on proportional reasoning, these three questions were cited as the most widely known problems. The first and the second questions were chosen from Lamon's (1993, 1999) studies. The last question was an adapted version of an orange-juice task identified by Noelting's (1980). In terms of problem types in the domain of ratio, the first and third questions were comparative, and the second question was missing value problem. While comparison problems provide four values and the aim is to specify the order relation between the ratios, in a missing-value problem three of four values are given and the last value is asked (Karplus et. al, 1983b; Lamon, 2012). These adapted questions were applied to sixth, seventh and eighth grade students, and the students were given one class hour to complete the written test. The questions are given in Table 1 below.

**Ratio Achievement Test**

Please solve the problems by using appropriate strategies

1. Ayşe bought four bananas paid 3.6 liras from Market A. Berna bought three bananas paid 3.3 liras from Market B. Where would you buy your bananas to make profit?
2. Derya, Ahmet and Kaan bought three helium-filled balloons and paid 1.5 liras for all three. They decided to go back to the store and buy enough balloons for everyone in the class, How much did they pay for 24 balloons?
3. Zeynep and Sinan tested three juice mixes. Which juice will have the stronger lemon flavor?

Mix A

2 cups lemon concentrate  
3 cups cold water

Mix B

1 cup lemon concentrate  
4 cups cold water

Mix C

4 cups lemon concentrate  
8 cups cold water

**Table 1: Questions about proportional reasoning**

## Data analysis

The solution strategies were analyzed along the strategies as unit rate, scale factor, ratio tables, and cross multiplication (e.g., Bart, 1994; Hart, 1988; Lesh, Post, & Behr, 1988). Then, incorrect solutions were separated from correct solutions, and then qualitative analysis was conducted to capture the difficulties behind the incorrect answers. The students' solutions were categorized with regards to mistake (error) strategies that have been stated in the literature: misusing a correct strategy (e.g., Hart, 1988; Karplus et al, 1983), using additive strategy (e.g., Hart, 1988; Inhelder & Piaget, 2013) and faulty application of a correct results that deviates from the unit rate (e.g., Tourniaire & Pulos, 1985). These mistake strategies were used to characterize students' difficulties while solving the given proportional problems (see Table 1) involving rate and ratio concepts. Table 2 showed the types of difficulties.

Types of difficulties	Explanation	Example
Confusion of the unit rate identification	Using an arbitrary unit value (it is the guessing method without adjustment/ the unit value is the number of objects the problem starts with.	The student assumes that each banana is 3.6 liras in Market A (Q1)
Algorithmically based mistakes	Having computational mistakes	$\frac{4 \text{ cups}}{8 \text{ cups}} = 2$ Mixture C (Q3)

**Table 2: Classification of Student' difficulties on Ratio Achievement Test**

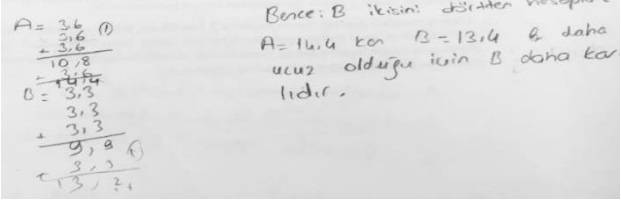

## Findings

Students' incorrect solutions in solving rate problems were analyzed through category building (see Table 2) to reveal their difficulties and grouped under two headings: "confusion of the unit rate identification" and "algorithmically based mistakes". These two difficulties were identified as the major problems in three typical proportionality questions. Data analysis revealed that of 149 students, 45 (27%) for the Q1, 25 (15%) for the Q2 and 94 (56%) students for the Q3 gave either no answer or an incorrect solution, as recorded in Table 3.

	6 Grade (69)			7 Grade (39)			8 Grade (41)		
	Q1	Q2	Q3	Q1	Q2	Q3	Q1	Q2	Q3
Incorrect Solutions	13(19%)	4(6%)	30(44%)	8(16%)	3(8%)	17(44%)	8(20%)	2(5%)	23(56%)
Confusion of the unit rate identification	<u>10 (77%)</u>	2(50%)	<u>30(100%)</u>	5(63%)	1(33%)	<u>12(71%)</u>	4(50%)	2(100%)	<u>20(87%)</u>
Algorithmically based mistakes	3 (23%)	2(50%)	0(0%)	3(37%)	2(67%)	5(19%)	4(50%)	0(0%)	3(13%)
No answer	7(7%)	8(12%)	9(13%)	5(13%)	2(5%)	8(16%)	4(10%)	6(15%)	7(17%)

**Table 3: Number and percentages of students' incorrect solutions****Confusion of the unit rate identification**

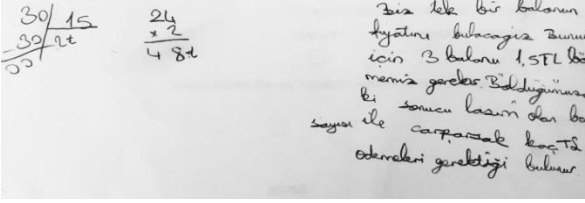

Unitizing is identified as a cognitive process that occurs after identifying the unit. This process allows subjective preference by composing two quantities to create a new unit called composed unit (Lobato et al., 2010). Students employed a number of different measurement units. However, some types of questions require the use of a standard measurement unit; the use of any other unit than this one was not allowed (Lamon, 1999). The main difficulty in answering these problems was the identification of the unit/rate. To answer the Q1 (see Table1), it was necessary to measure the amount of stuff using the concept of unit. Students can also find a different number of measures with regards to their measuring unit. When solutions to the first problem were analyzed, confusion about the unit rate could be plainly seen, indicating that the student was not able to conceptualize the unit of measurement.

(a)

I think the answer is B. We can compute [corresponding two prices] for 4 [bananas]. They [corresponding prices] are Market A=14.4 and Market B= 13.4. Therefore Market B is more economical.

(c)

(b)

We need to find price for one balloon. Therefore we should divide 3 balloons by 1.5 liras. And then we should multiply the result by the number of balloons that they need to get how much money is required.

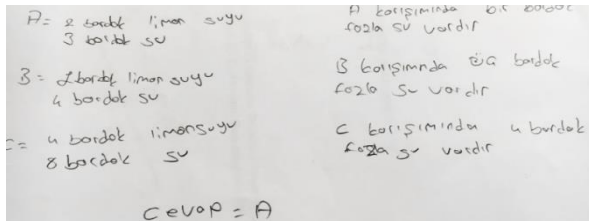

(d)

**Figure 1: Student's original (a) and translated (c) solution on ignoring the number of objects, Student's original (b) and translated (d) solution on finding the amount of balloons for one lira as original versions**

As can be clearly seen from Figure 1-a, although the unit was defined explicitly (single banana cost) the student thought that a banana cost 3.6 liras in Market A and 3.3 liras in Market B. In other words, the student ignored the number of objects. Then two prices 14.4 and 13.2 were compared and this solution did not contribute to the correct answer. 11 (16%) of 69 sixth grade students, 6 (15%) of 39 seventh grade students and 7 (17%) of 42 eight grade students stated that the best place to buy a banana was Market B because they spend 13.2 for four bananas and they get profit.

Another misunderstanding regarding the unit rate given in the question can be seen in Figure 1-b. This student could not decide the exact and correct numbers to find the unit rate in Q2. Therefore,

instead of finding the price for one balloon, as can be seen here, he calculated the amount of balloons for one lira by dividing 3 by 1.5. Then this value was multiplied by 24 to find the price of whole balloons. Indeed, it makes sense to divide 3 by 1.5 to find the amount of balloons per unit lira. This student seems to follow the directions provided in terms of finding single units. Even though in her written explanation on the right hand side of Figure 2 she stressed finding the value of one balloon, she noted that three would be divided by 1.5.

(a)

A=2 glasses of lemon concentrate  
3 glass of water  
B=1 glass of lemon concentrate  
4 glasses of water  
C=4 glasses of lemon concentrate  
8 glasses of water

Mixture A has one more glass of water,  
Mixture B has three more glasses of water  
Mixture C has 4 more glasses of water

**Answer: A**

(b)

**Figure 2: Student's original (a) and translated (b) solution on comparing the amount of lemon juice with the amount of water**

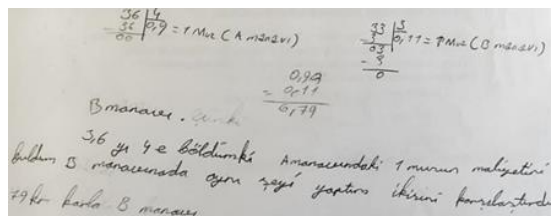

The Q3 provides more evidence for students' difficulties regarding typical ratio comparison unit rate problems. Findings revealed that 56% of 149 students think about the unit rate with given quantities in a reasonable way. For instance, as can be seen in Figure 2 without thinking about fractional relativity, the student compares the amount of lemon juice used (2 glasses, 1 glass and 4 glasses) with the amount of water to find the stronger tasting lemonade. Even though this student came to the correct solution that Mix A has a stronger taste than the others, this solution contains misconceptions. He matched the glass of water with the lemon concentrate, and decided that there is one extra cup of water in Mix A. However, if this student was asked to sort the concentration of juice for each mix, the answer would likely be wrong, because, according to his solution, the order would be Mixture A and then Mixture B and then Mixture C. Thus, the less tasty mixture would have been Mix C.

### Algorithmically based mistakes

The other difficulty which emerged from the data was algorithmically-based mistakes and emerged in the computation process. Ashlock (2001) identifies these errors as 'buggy' algorithms that involve more than one incorrect step in the procedure and do not attain the desired purpose. When the details of this difficulty were examined, it was revealed that 8% of the students made basic fact errors and conducted incorrect operations while dividing the decimals.

(a)

(b)

I divided [corresponding to price] 3.6 by [corresponding to amount] 4 to get the price of one banana for Market A. And I did the same computation for Market B. I made a comparison [between Market A and Market B]. Market B is more economical with 79 cent (kuruş).

(c)

**Figure 3: Students' original (a) solution on an algorithmically based mistake, Student's original (b) and (c) translated solutions on a difficulty with division**

Figure 3-a illustrates these algorithmically based difficulties for Q2. First, by dividing 24 by 3, this student got 8 groups. As shown above, this student attempted to add 1.5 eight times. She wrote 3 and left a space and then wrote 1.5. It can be seen in the calculation that the student first multiplied the whole part by 8 and then the decimal part by 8. However, she did not recognize the multiplicative structure even in a familiar computation and she started with an incorrect computation. Then it seems she apparently lost track and then made algorithmic error by adding .50 to 12. Another example for algorithmically based mistakes can be seen in Figure 3-b. This student divided 3.3 by 3 and found 0.11 as a cost of one banana. However, the correct answer was 1.1 and this mistake led the student to make the wrong comparison between the profits of two markets. According to this solution 0.9 is bigger than 0.11, so Market B is the best place to buy a banana.

## Discussion and conclusion

The aim of this study was to investigate the common difficulties faced by 6th, 7th and 8th grade students while solving typical proportionality problems involving rate and ratio concepts. The first common difficulty resulted from confusion of unit rate identification. The second major finding that algorithmically based mistakes were another common difficulty in computation process. These findings show that current difficulties are consistent with the Turkish context beginning from 6<sup>th</sup> grades (Kaplan, Isleyen, & Ozturk, 2011). Unitizing is a different process from determining the unit, because different systems of units are based on different choices of base units. The most obvious finding to emerge from this study is that students mostly preferred the unit rate method as a solution strategy. The reason might be related to their tendency to retreat to more familiar strategies in their solutions.

The cognitive process emerges after making a decision about the unit and misunderstanding arises when students think about the unit, from their computations especially while explaining unitizing (Lamon, 1999). The results of this study showed that sixth, seven and eight graders had problems about conceptualization of the unit of measurement. More specifically, the lemonade juice problem showed that students from all grades used unit rate strategy as a part of faulty application of a correct result by comparing the numerical differences additively rather than the multiplicatively. As Noelting (1980) states, they focused on the basis of the number of glasses of orange juice instead of proportional relations between given quantities. Especially sixth graders who offered a rich repertoire of unit rate mistakes tended to apply unit rate for the lemonade problem, and their incorrect results seems to be deviated from unit rate method (see Table 3). Based on this point, lemonade problem juice experiments might be beneficial for students in terms of experiencing their own strategies in real contexts instead of just explaining them verbally. Findings suggest that they might be performing this operation without realizing the difference between additive and multiplicative reasoning (Lamon, 2012; Lobato et al., 2010). This situation can make a noteworthy contribution in terms of providing some indications of the complexity of these mixture problems not only for sixth but also for seventh and eighth graders. This suggests the need for more in-depth investigation into student thought-processes when making these specific mistakes (Ashlock, 2001; Son, 2013). These results are consistent with other studies regarding emergent difficulties within Turkish context and suggest that proportional reasoning should involve more than just applying rules, and that there is a need for more information about what students perceive the unit to be (Sarwadi & Shahrill, 2014). Teachers should be more aware of student conceptions about unit rate while teaching proportional reasoning. This

corroborates with Lamon (1993) and Singh (2000) who state that teachers must encourage the spend time to connect composed units with multiplicative comparisons by setting different types of problems for students as much as possible to enable them to build flexible and complex unit structures develop thinking strategies.

Findings of the present study showed that algorithmically based mistakes are commonly seen in the student computation process. Son (2013) identifies three categories of error in the responses received in her study: concept-based errors, procedure-based errors and diagnosis errors. As Ashlock (2001) states, one of erroneous steps lead to emerge these kind of mistakes and then as a result the intended purpose is not systemically accomplished. On the other hand, the lack of clinic interviews with students in this study suggests caution in identifying the exact causes of these fundamental mistakes. In another words, it is difficult to decide whether students' algorithmically based mistakes stem from limited conceptualization of the problems or whether there was a mistake in their algorithmic procedures. It is possible that some of the difficulties revealed in this study may result from concentration on algorithmic computation. This suggests the need for further investigation into the exact reasons for algorithmically-based mistakes through clinical interviews.

The findings of the present study and previous research suggest several implications. As Lamon (1999) states, textbooks don't provide the flexibility of using unit rates, and under these limited conditions students will not be able to compose units. Turkish mathematics textbooks do not provide sufficient examples of these types of problems which might promote the development of an understanding of unit rate. Besides, exposing students to a variety of proportionality problems can help them to develop multiplicative reasoning skills, and to promote flexibility in unitizing.

Even though the scope of this study includes only determining the potential difficulties students have regarding rate and ratio problems, we might make some implications and suggestions to overcome those difficulties. Future research might continue to investigate students' verbal reasoning process and provide more detailed insight into the reasons for incorrect solutions. Such exploration might yield more informative insights into the reasons for student identification of unit-rate confusion and algorithmically-based errors, and provide valuable implication for the development of students' multiplicative reasoning ability.

*Results of secondary school students' performance who participated in a pilot study of a general research project whose purpose is to contribute to building better mental objects for fractions are described. A Local Theoretical Model for fractions is used as a theoretical and methodological framework to design and develop a seven stages teaching sequence based on the use of applets created with GeoGebra and the number line as a conceptual and didactical resource. In this paper details of the design, development, and results of the first two stages are given. Results show children's preferences to represent fractions on the unit segment, that is, they think of proper fractions. A majority of the participants paid more attention to the graphical aspects of the applet.*

*Keywords: Fractions, local theoretical models, applets for teaching, number line, improper fractions.*

### Introduction

The teaching and learning of fractions and rational numbers have been studied during several decades by researchers such as Freudenthal (1983), Behr, Lesh, Post and Silver (1983), Kieren (1988) and Figueras (1988). In the last decade, fractions have been considered as one of the most complex concepts studied in basic education (see for example López-Bustamante (2009) in Mexico, Contreras (2012) in Spain and Petit, Laird & Marsden (2010) in the United States of America).

The construction of better mental objects of fractions during elementary school is considered important because that concept is widely accepted as an integral part of mathematics curriculum. Moreover, Siegler, Duncan, Davis-Kean, et al (2012) characterized the knowledge of fractions and division as unique predictors of students' mathematics performance from elementary to high school.

On the other hand, the technological tools as a resource for teaching mathematics have been incorporated into the curriculum because there is evidence that those are cognitive resources (e.g., Kieran & Yerushalmy, 2004). In this sense, an attempt is made to design a teaching model that includes these tools to promote the building up of students' better mental objects of fractions.

### Research objectives

The principle aim of the general study is to construct a Local Theoretical Model for fractions in order to enrich the actual teaching model (in Figueras' sense, 1988, pp. 21- 22) for Mexican elementary school. To achieve this aim a seven stage teaching sequence based on the use of applets was designed. The focus of this paper is the design and results of the first two stages of a pilot study. The purposes of those stages are: 1) to characterize the type of fractions students keep in mind to represent them on the number line displayed on the screen, 2) to make an exploration inquiry about students' ideas

related to density and order of fractions, and 3) to identify if the students relate numerical aspects of fractions with their graphical representation.

## Theoretical framework and related literature

The idea of Local Theoretical Model (LTM) developed by Filloy (see Filloy, Rojano & Puig, 2008) is used as a theoretical and methodological framework. From the theoretical point of view, the LTM serves to focus on the object of study through four interrelated components: (1) formal competence, (2) teaching models, (3) models for cognitive processes, and (4) models of communication. The construction of these components allows having an interpretative framework to identify the different aspects of fractions, which according to Freudenthal (1983) appear as fracturer, comparer, measurer, fraction operator and numbers.

The building up of the teaching models component enabled the detection in Mexican and Spanish curricula, that the study of properties of order, density, the equivalence of fractions, and proper and improper fractions were considered in the last years of primary school. Bright, Behr, Post, and Wachsmuth (1988) and Saxe, Taylor, McIntosh, and Gearhart (2005) support the idea that working with the number line gives students an approach to the notion of above concepts. However, in some sixth-grade' textbooks used in Spain (e.g., González et al, 2015) continuous and discrete models are more often than not used for teaching fractions, and activities that include the number line are lacking. These are some reasons for using the number line in this research as a didactical resource.

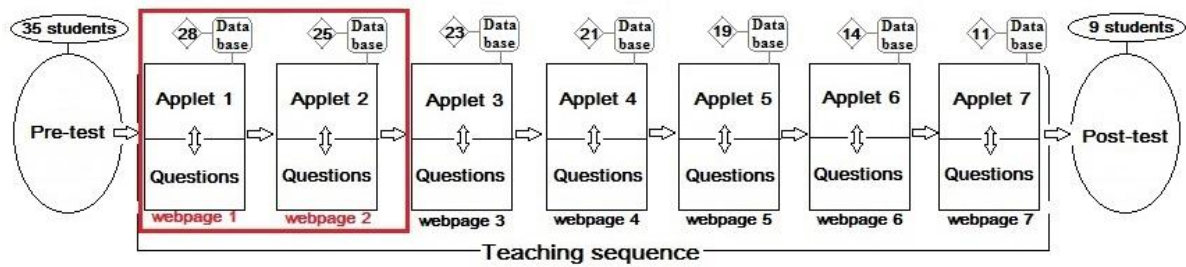

A revisiting of specialized literature was carried out to construct the cognitive processes' models component. Some of the papers analysed report students' difficulties faced when they learn with the number line. Michel and Horne (2008) mentioned three principal misconceptions: (1) *Instrumental part-whole knowledge* -difficulties with unit-forming, that is, children consider any line segment as a unit-. (2) *Counting lines, not spaces* -to represent a fraction on the number line some students count the lines or points (considering the zero point) instead of counting intervals-. (3) *Decimalising the count* -to represent any fraction, some children always divide the unit segment in ten parts-.

Finally, the communication component is formed by the observation of communication processes between student-applet interactions. The building up of the four components grounds the design of the teaching sequence and its trial. The latter is detailed in the following sections.

## Methodology and methods

From the methodological point of view the LTM serves to organize the research project in two main parts: (1) the building up of the four components of an initial LTM for fractions as a reference framework of the general research project and (2) an experimentation with students.

Three phases comprise the experimental part. The first one relates to the design of a pre-test, a post-test and a seven-stage teaching sequence. The second phase is the application of the teaching sequence and is structured as shown in Figure 1. Each stage is composed of two parts, one is a GeoGebra applet and the other a series of questions posed with the purpose that students show the ideas they bring into play about fractions when interacting with the applets. Applets and questions are set up on a Webpage that is associated with a database to record students' responses and interactions with the applets. The third phase corresponds to data analysis and characterization of students' performance.

**Figure 1: Structure of the teaching sequence design and its trial**

The first two stages of the teaching sequence were done in one 45-minute session. Student individual interactions with applets were collected in a non-invasive manner. Answers given were stored in a database and collected with computers provided by researchers. At the end of the experimental phase, stored information was joined and organized to proceed with its analysis. The applets are used as a resource to teach fractions and to collect data.

### Setting and participants

The pilot study was carried out with 45 students from 12 to 14 years old in a secondary school located in a troubled urban area of Valencia in Spain. According to their mathematics teacher, participants have a large history of difficulties in mathematics. The students have serious problems of truancy, for this reason, not all of them completed the trial of the teaching sequence. Due to this fact, only data from students that completed sequential steps were considered, that is, 28 students made the first stage and 25 completed the second stage and so on (see Figure 1). The students worked alone during the teaching sequence trial. In this study, the teacher applied the pre-test and post-test.

### Applets' design and results

The applets were constructed in a learning environment for fostering the development of conceptual understanding of fractions, taking into account the didactical functions of technology in mathematics education adapted by Drijvers (2013, p. 3). As aforementioned, each stage of the teaching sequence has an applet with an exploration/interaction component (Figure 2 and 4) and a list of questions for students to reflect on what they observe during the interaction. To respond, students can turn to applets and observe the animation or representations of fractions.

To characterize the answers given by students, schemes that enable a codification have been constructed (Figure 3 and 5). Answers given by pupils were grouped in different types determined by the form in which questions are posed. Type i are answers to questions that are general statements with diverse interpretations. Type ii collects answers that can be classified solely as correct or incorrect. Type iii groups answers to questions where a justification is required and Type iv are answers to questions that requires information students must write on the applets' windows.

**Applet design for the first stage.** The applet's tasks for the first stage were developed considering two parallel lines of action. One directed towards the student's familiarity with the interactive environment. The other leads the student to represent different aspects of fractions on the number line and to introduce them to a proper use of the fractions' mathematical sign system (Figure 2). Three indications appear on the screen in Figure 2. The first one - 'Move the sliders and watch what happens on the number line' -, has the purpose to focus students on the effects of the numerator and

denominator sliders that appear at the upper left corner of the screen and to relate those to the graphical and symbolic representations of fractions also shown on the screen.

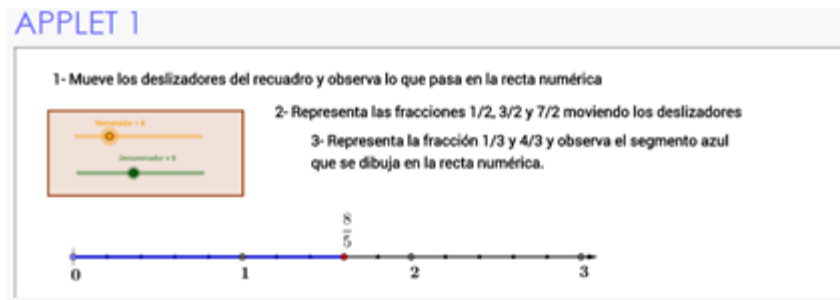

Figure 2: Screenshot of the applet for the first stage

With the second indication –“Represent fractions  $1/2$ ,  $3/2$  and  $7/2$  by moving the sliders”-, students are asked to represent the first two fractions to see them in the line segment on the screen. The main idea for asking students to represent  $7/2$  is to promote reflection regarding characteristics of fractions that can be visualized on the screen and of those that cannot.

The third indication –“Represent the fractions  $1/3$  and  $4/3$  and observe the blue segment that is drawn on the number line”- is provided in order to identify the point representing the fraction or the fraction as number, but also to focus students' attention on the magnitude representing the fraction, that is the length of the segment that represents the fraction. Thus, fraction as a measurer emerges, taking into account the part-whole relationship.

In addition to the above information, seven questions (Figure 3) are posed to make students write their ideas about the observations made during exploration/interaction period. Students can read questions and explore the applet as many times as necessary to answer them.

**Data analysis and results of the first stage.** For applet 1 there are only questions of types i and ii. The codification of students' answers is done using the scheme shown in Figure 3.

Questions (1, 2, 4, 5 y 6)		Type i	
Q1. Represent the fraction 1/4. What happens to the fraction if you move the numerator slider and the denominator slider is fixed? Q2. Represent the fraction 7/8. What happens with the fraction if you move the denominator slider and the numerator slider is fixed? Q4. What will happen if the number 25 is shown in the denominator slider? Q5. What happens when the numerator and the denominator are equal? Q6. Why the fraction 7/2 cannot be seen on the screen?		Students answers are referred to:	The interpretation is considered:
		1. Numerical aspects 2. Graphical aspects 3. Numerical and graphical aspects. 4. Could not be interpreted	a. Complete b. Incomplete c. Incorrect or ambiguous
Questions (3 y 7)		Type ii	
Q3. Represent the fraction 6/7. In how many parts does the line segment that starts at 0 and ends at 1 is divided? How many of those parts are coloured? Q7. Write two fractions that cannot be represented on the line segment shown on the screen.		The purpose of these questions is that the students observe the graphical representation (line segment). The answers can be:	
		a. Complete b. Incomplete c. Incorrect or ambiguous	

Figure 3: Scheme to characterize the answers to questions posed in the first stage

One of the most common mistakes to respond Q3 was that students focused on counting the lines or points considering the zero point instead of counting spaces. 22 students identified at least one fraction greater than three to respond Q7. In the answers to questions type i (for example, Q1, Q2,

Q4, Q5 and Q6), pupils orient their attention on what happens in the line segment that appears on the screen (Table 1). Of the 140 responses (28 students x 5 questions), 63 (45%) were classified in this group (code 2, in grey). Eight of these answers are considered complete (code 2a), since a consistent explanation is offered, 25 incomplete (code 2b) and 30 incorrect or ambiguous (code 2c). Two answers related to these results are included to exemplify the way the coding is done.

(1) The answer given by student S1 to question Q1 is: "the bar is moving to the right". This response is coded as 2b (see Table 1) because the focus is posed on what happens on the line segment. Specifically, it refers to the movement that occurs in the blue segment ("the bar" named by the student) representing the fraction when the slider moves to the right, that is when the value of the fraction is increased. The response is not considered complete because the student centres his attention on the movement to the right and presumably does not move the slider to the left. (2) The answer given by S3 to question Q1 is: "there are more points between numbers (denominators), in particular, four points between numbers". In this case, the answer also reveals a focus on the number line; the student observed the partition of the line segment, but the interpretation is incorrect or ambiguous because the student did not explore using the sliders (code 2c).

The focus on numerical aspects of the fraction (code 1, in green) was observed in 38 of the 140 responses to the questions of type i (27.15%); two answers were classified as complete (1a), 14 as incomplete (1b) and 22 as incorrect or ambiguous (1c). The answer given by student S17 to question Q6 is: "because the denominator is 2, and this is smaller than 7, so the numerator is bigger, so it is not possible". The student observed the values of the numerator and denominator, makes a comparison between the numerical values and justifies his answer; it was coded as 1c (see Table 1).

	S1	S2	S3	S4	S5	S6	S7	S8	S9	S10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28

**Table 1: Characterizations of students' answers in the first stage**

Only in 17 of the 140 (12.14%) answers to the questions of type i (in purple) the focus on numerical and graphical aspects is made evident. Five of them were classified as complete (3a) and twelve as incomplete (3b). The answer given by student S19 to Q6 is: "because in the line, one can only represent numbers between 0 and 3, and  $7/2$  is greater than 3". The student observed the structure of the line segment; his focus is posed on the graphical representation but also refers to the fraction as a number. For this reason, the answer was coded as 3a.

**Applet design for the second stage.** A new form of symbolic representation is introduced in this applet (see Figure 4). In this case, students are asked to write five fractions in a pop-up window when they click the start button (INICIO in Spanish). This button is associated to a JavaScript subroutine that offers feedback and stores the student actions.

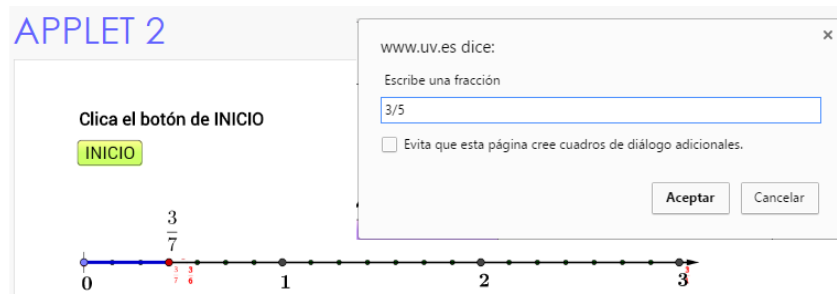

Figure 4: Screenshot of the applet for the second stage

Fractions are limited to those with denominator between 2 and 10 and numerator between 0 and 40. If a pupil writes a fraction that does not meet these conditions, a pop-up window appears with a message advising to take into account the characteristics of the numbers involved. When introducing a fraction greater than three, another alert window appears to indicate that the fraction cannot be seen on the number line. Fractions that are written by the user leave a trace in the form of red dots and the value of the fraction on the number line (see Figure 4). The visible trace on the screen helps the students answer questions posed in the Webpage in which the applet is embedded.

**Data analysis and results of the second stage.** In the applet that corresponds to the second stage, there are questions of type i, ii and iv. The codification is done using the scheme in Figure 5.

Questions (1, 3 and 4)		Type i	
Q1. The 5 fractions you wrote appear on the number line on the screen? Why?	}	Students answers are referred to:	The answer could be:
Q3. Of the 5 fractions written, which one is the smallest? Why?		}	a. Yes
Q4. Of the 5 fractions written, which one is the greatest? Why?			b. No
			a. Correct
			b. Incorrect
Questions (2, 5 and 6)		Type ii	
Q2. Write the fractions you wrote from greatest to smallest.	}	The answers can be:	
Q5. How many fractions could you write between 0 and 1?		a. Correct;                      b. Incorrect;                      c. Incomplete	
Q6. How many fractions could you write between 1 and 4?		a. Finite	
		b. Infinite, many, a lot of...	
		c. No answer (blank)	
Write 5 fractions		Type iv	
The student must write five fractions	}	Written fractions can be classified as:	
		1. Proper;                      2. Improper;                      3. Unit	

Figure 5: Scheme to characterize the questions of the second stage

Only 12 of 25 students were able to answer correctly Q2 (code 1). This result has an effect on the answers to questions Q3 and Q4, as shown in Table 2. The students who order fractions correctly chose correctly the greater or smallest fraction for questions Q3 and Q4 respectively. To justify the order of those fractions S1 considered the length of the blue segment that represents the fraction on the number line (2a). S2 considered the position of the point representing the fraction on the number line (2a), i.e. graphical aspects of fractions. Students S5 and S18 considered the characteristics of the numerator and denominator of the fraction, that is, numerical aspects of fractions (code 1a).

The justification for most students who do not respond correctly to questions Q3 and Q4 is based on comparing the numerators and denominators of the fractions. Two of these cases are the following: (1) Student S8 choose  $8/3$  as the smaller fraction, "because the denominator is the smallest." The

comparison made with fractions  $4/10$ ,  $3/9$  and  $12/5$ . He also chose  $4/10$  as the greater fraction "because the denominator is the largest." (2) Student S7 chose  $2/3$  as the smaller fraction between  $5/4$ ,  $3/7$ ,  $3/4$ , "Because that [fraction] has the smaller numbers."

	S1	S2	S3	S4	S5	S6	S7	S8	S9	S10	S11	S12	S13	S14	S15	S16	S17	S18	S19	S20	S21	S22	S23	S24	S25
Q1	2a	1a	2b	1b	4a	4b	2b	4b	4b	4b	4a	4a	4b	4b	4a	2a	4b	2b	1a	1b	4b	4a	4b	2a	4b
Q2	1	1	0	0	1	1	0	0	0	1	1	1	1	0	0	0	0	1	1	0	1	0	0	0	1
Q3	2a	2a	4b	1b	1a	4a	1b	1b	2b	4b	1a	1a	2a	4b	4b	2b	2b	1a	1a	1b	1a	4b	2b	2b	2a
Q4	2a	1a	4b	1b	1a	4a	4b	1b	2b	4b	4a	2b	4a	4b	4b	4b	2b	1a	2a	1b	1a	4b	2b	2b	2a
Q5	b	a	a	a	a	b	a	a	a	a	a	a	a	a	a	a	a	b	a	c	a	c	a	b	
Q6	b	a	a	a	a	b	a	c	a	c	a	a	b	a	a	a	a	b	a	c	a	c	a	b	
P	3	5	3	3	1	2	3	3	1	3	0	1	2	3	1	3	3	0	2	3	1	3	1	4	2
Im	0	0	0	2	1	3	1	2	2	1	4	2	2	1	4	1	1	2	1	0	3	0	3	1	1
U	0	0	0	0	2	0	0	0	1	0	0	0	1	0	0	0	0	1	0	0	0	0	0	0	5

**Table 2: Characterizations of students' answers in the second stage**

Of the 50 answers (25 students x 2 questions) related to the density of fractions (questions Q5 and Q6), 35 were classified with code a, because the answer refers to a finite number of fractions, 6 were blank (code c), and only in 9 answers the density property was mentioned in some sense (code b), because some of the responses were "infinite fractions" or "as much as one wants". Finally, Table 2 shows that students wrote more often proper (56) than improper fractions (38).

## Conclusions

Results of the first two stages described before allow to highlight the fact that few students were able to relate the numerical and graphical representation of fractions. However, students who are able to relate these two representations can give complete and correct answers. To justify questions related to fractions' order, some students relied solely on the numerical aspect, for example, comparing the numerator and the denominator, which led to incorrect or ambiguous answers. Whereas answers in which graphical aspects are used, for example, the position of the point on the number line or the length of the blue segment, led to correct answers. Although most students focused on the latter aspect, they encountered difficulties in representing a fraction on the number line. The most common mistakes are instrumental part-whole knowledge and counting lines, not spaces, also reported by Michel and Horne (2008).

On the other hand, the idea of density that students had seems to be strongly related to the number of fractions they represented during their interactions with the applet, these results are a warning to continue investigating these ideas in later stages and reflect the influence of applets. The students wrote more proper fractions even though the number of proper fractions with small denominators as 2 or 3 are few compared with the number of improper fractions. These results can be related to fact that teaching models favouring the recognition of proper fractions are widely used.

# How middle-grade students explain ordering statements within real life situation? An example of temperature context

Aysenur Yilmaz<sup>1</sup> and Mine Isiksal-Bostan<sup>2</sup>

<sup>1</sup>Middle East Technical University, Faculty of Education, Ankara, Turkey; [akubar@metu.edu.tr](mailto:akubar@metu.edu.tr)

<sup>2</sup>Middle East Technical University, Faculty of Education, Ankara, Turkey; [misiksal@metu.edu.tr](mailto:misiksal@metu.edu.tr)

*The purpose of the study is to examine the extent to which middle-grade students agree on statements about the ordering of two negative integers given within a real-life context, and what kind of procedural and conceptual strategies they generate to order those numbers. Data is collected through a questionnaire including two statements about ordering integers from fifty-seven middle-grade level students in a public school. The results show that even though students agreed with both of the statements, they did not explain the concept of ordering in daily life with regard to conceptual meanings and that they have problems in their procedural knowledge repertoire.*

*Keywords: Integers, contextual problems, negativity.*

## Introduction

Integers is one of the main topics that students have to understand to be successful in later contents such as algebra, geometry, or data analysis. While integers are required to solve algebraic expressions, sometimes it is required to understand the number system (Levenson, 2012). In particular, negative integers are hard for students to understand because of difficulty in representing those numbers physically (Davidson, 1992), locating them on the number line, performing four operations (e.g.: Ojose, 2015), or ordering them (e.g. Schindler & Hußmann, 2013). Ball (1993) exemplifies the dilemma of the case of teaching negative numbers regarding the ordering of two integers. Furthermore, according to Ball (1993), the transition among direction and magnitude aspects of negative integers are the heart of understanding negative integers.

## Students' solution strategies

Linchevski and Williams' (1999) study reports on a disco game supported by an abacus model that helps students make sense of net-change, zero situations, and develop strategies such as compensation and cancellation within the everyday life situations requiring operations of integers. In addition to this, students have solution strategies of four operations such as the tendency of using the first addend's sign, ignorance of the second addend's sign, or generalizing the statement by rote as 'two negatives make a positive' and so on (Ashlock, 2010). Considering the literature, it is seen that many studies focus on student solution strategies about operations on integers. However, in the available literature, there are limited studies that focus on students' strategies about ordering integers (Schindler & Hußmann, 2013; Ojose, 2015). Furthermore, what kind of pieces of information students have regarding ordering integers, is rare.

## Conceptual and procedural knowledge

According to Hiebert and Lefevre (1986), pieces of information might be separately located or are in closely related within the knowledge network in students' minds. Once students start learning, they can make links among those pieces or students keep in mind the necessary steps to solve problems and they apply the steps to solve the problems without questioning. The pieces of knowledge can be

constructed with appropriate links to make meaningful understanding and that can be accomplished by creating relationships among the separately existing pieces of knowledge. Hiebert and Lefevre (1986) define conceptual knowledge as ‘... knowledge that is rich in relationships. It can be thought of as a connected web of knowledge, a network in which the linking relationships are as prominent as the discrete pieces of information. Relationships pervade the individual facts and propositions so that all pieces of information are linked to some network’ (Hiebert & Lefevre, 1986, pp. 3-4). The other kind of knowledge which is used by students in learning mathematics while solving mathematical problems is procedural knowledge. Hiebert and Lefevre (1986) describe procedural knowledge through including parts as ‘one part is composed of the formal language, or symbol representation system of mathematics. The other part consists of the algorithms, or rules, for completing mathematical tasks’ (Hiebert & Lefevre, 1986, p.6). Both procedural and conceptual knowledge is necessary for students in order to finish the process with a correct answer and to understand the relationships among concepts. Students’ backgrounds include procedural and conceptual knowledge and both of them are required for mathematical proficiency (Kilpatrick, Swafford, & Findell, 2002). They are constantly interacting with each other and in light of instructions given to students, the kinds of knowledge can be revealed. In this regard, this study will examine students’ explaining strategies while ordering two negative integers through conceptual and procedural knowledge descriptions of Hiebert and Lefevre (1986). It gives information about how middle school students conceptualize ordering of integers, how they give meaning to integers in real life contexts, and what kind of procedural and conceptual strategies they have while ordering integers. With this study, possible explanations of the reasons behind middle-grade students’ difficulties and their understandings in integers, specifically about ordering integers are revealed. Thus, the aim of this study is to explore answer for the following questions: (1) To what extent do middle-grade students agree on statements about the ordering of two negative integers? (2) What kind of strategies do middle-grade students generate to order two negative integers given within a real-life context? Related with the second research question, this study examines how those strategies can be classified as procedural or conceptual.

### **Context of the study**

The context of the study might be understood better via curricular guidelines of ordering integers in Turkish middle school mathematics curriculum. The topic starts at the beginning of middle-grade levels. Objectives related to this topic are about interpreting integers, the meaning of absolute value, operations of integers, the meanings of the operations, comparing and ordering integers, solving integer-related problems, and relate exponential numbers to integers. Specifically, in learning to order integers, the objective says that: "Students should be able to compare and order integers" (MoNE, 2013, p.14). The curriculum advises teachers that the largest number is located to the right side in reference to the small number on the number line while ordering numbers. Therefore, it is seen that teachers are supported to use the link between number line location and integers’ ordering. In other words, the curriculum supports ‘direction’ aspects of negative integers while the magnitude aspect of negative integers within real life situations (e.g.: temperature, asset and debt, elevator and so on.) are an application of objective presented in the middle school curriculum (MoNE, 2013). In this sense, in their instruction, students are given real-life contexts to understand how integers are represented within real life contexts in a meaningful way (MoNE, 2013). For ordering integers, the location of numbers on a number line is the basis of teaching the content (MoNE, 2013). In this respect, ordering

integers is not interpreted on the basis of real life examples. Rather than that, interpretation of the ordering integers mostly depends on the location of numbers on the number line.

## Method

In this study, qualitative research method, specifically single case study approach, is used in order to reveal students' strategies and investigate students' understanding of contextual statements. The research method enables researchers analyzing data through creating a theme and codes (Creswell, 2005).

## Sampling

Fifty-seven middle-grade students participated in the study. These students are selected under the purposeful sampling and they are studying at the middle-grade level in a public school in Ankara, Turkey. The school could be regarded as successful on the basis that it accepts students with having higher grades in nationwide held examinations. Before conducting the main study, a pilot study was conducted in two classrooms together with another fifty-four middle-grade students at the same grade level as the school the main study was conducted. The purpose of the pilot study is to make the statements understandable to the participants and to minimize the misunderstandings derived from the format of the questionnaire. The objectives which are aimed to be evaluated in the study require middle school students interpret integers within real life situations and to compare and order integers. Within this context, the content validity of the questionnaire is validated with mathematics teachers and one mathematics education instructor in the university.

## Data collection tools

In this study to collect data the questionnaire given in Figure 1 is used. In order to understand middle grade students' general tendency of ideas about the different nature of ordering statements, students were asked whether they agree with the two ordering statements given in real life context. In addition, they were required to give details about the reason of agreement status in order to understand their reasoning in ordering two negative integers of strategies for explanation. As it is seen, there are two ordering statements given in the context of temperature. In this regard, questions were generated based on the context which middle grade students are familiar with and use the knowledge of ordering two negative integers by relating the direction and magnitude (quantity) aspects. The questionnaire has two statements pointing out two kinds of relations about ordering two negative integers. The first statement says that "As -10 degrees are less hot than -5, -10 is smaller than -5." The statement allows middle grade students to order two negative integers considering temperature as a quantity and direction. In other words, they can order two negative integers considering the mentioned degrees as similar to ordering two positive quantities. In line with this, -5 is more hot (more quantity of hot) than -10. In addition, temperature context enables students ordering integers considering direction integers. The second statement says that "As -10 degrees is situated on thermometer, lower than -5, -10 is smaller than -5. The statement allows students to interpret ordering of two negative integers based on their locations on the thermometer and their distance from zero. In this regard, whether they are using any conceptual or procedural strategies for using the nature of 'direction' and 'magnitude' meaning of two negative integers is examined.

"As -10 degrees are less hot than -5, -10 is smaller than -5. "	AGREE	NOT AGREE	NEUTRAL
	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>
"As -10 degrees situated on thermometer lower than -5, -10 is smaller than -5.	AGREE	NOT AGREE	NEUTRAL
	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>
Why do you think so?			

**Figure 1: Questionnaire items of the study**

### Data analysis

Similar and different categories of answers are grouped through content analysis. Explanation strategies are revealed by examining words or group of words students use in their answers (manifest content) and following this the underlying meaning of those wordings are revealed by investigating their explanation strategies deeply (latent content) (Fraenkel, Wallen, & Hyun, 2011, pp.483-484). Answers of the questions are analyzed for the agreement status, students' explanation strategies of the agreement status regarding conceptual and procedural strategies while explaining their responses. Data of the study are analyzed within Hiebert and Lefevre (1986)'s conceptual and procedural knowledge framework.

### Findings

#### Agreement status of students about the ordering statements

Based on the analysis, it is seen in Table 1 that participants are agree with both of the statements.

Temperature Context	A	NA	N	NM	Total
1.statement	75	16	7	2	100
2.statement	66	14	16	4	100

\*A: Agree, NA: Not Agree, N: neutral, NM: No marking

**Table 1: The percentage of agreements to the ordering statements**

The analysis of the results show that middle grade students agree with the idea that ordering two negative integers can be explained by using 'hot' concept together with the word 'less'. In this regard, they agree on the idea that two negative integers can be ordered by using the words 'more' and 'less' which express the quantity of something and came to the conclusion that 'hotter' is bigger than 'less hot'. Thus, for the first statement "As -10 degrees is less hot than -5 degree, -10 is smaller than -5", most of the students (75%) selected the choice *agree*. Parallel with this, for the second statement most of the students (67%) also agree on the idea that two negative integers can be ordered based on the location of the integers on the thermometer. In other words, the idea accepted by most of the participants is that the number which is below the other is much smaller.

### The explanation strategies of middle grade students

Table 2 shows that the most preferred explanation strategies for the given statements are related to the network of hot and cold (37%), and rule-based explanations in reference to zero or positive numbers (18%). The strategy of *network of hot and cold* represents a relationship between the concepts of temperature, coldness and integer in the minds of students. In line with this, students make transitions among those concepts. For example, students form a link between negative integers and coldness saying if negative numbers increase the weather gets cold. The strategy of rule-based explanation in reference to zero or positive numbers is about rules with which students are familiar and which are created using zero and positive numbers like negative numbers are [ordered as] opposite to positive numbers. This table also depicts that students do not tend to use *rule-based explanations* in both of the statements. Put differently, *rule-based explanations* are not a dominant strategy for explaining those two ordering statements. They are used in the second statement, which mentions the location of numbers on the thermometer, compared to the first statement which is about interpreting the coldness, hotness, and their relationship. Another unexpected result is that although not many, some students did not consider this sort of order and they agree with the idea that "the number -10 is more than -5". In other words, they reject the order and think that -10 is bigger than -5 or -10 is hotter than -5. Similar to this, some students criticize the statements saying 'they are illogical' or 'they [both of the statements] are the same' and so on. Besides, some students used *the copy of the statement* strategy which is related to writing the same statements given in the questionnaire. In this regard, a substantial portion of students (44% for the first statement; 62% for the second one) do not employ any kind of explanation strategies for ordering integers in a given context. Students who copy the statement, use no strategies (e.g.: I don't know), use unclear statements (e.g.: I don't know why I am saying that I agree with the statements), and left the answer blank did not give reasons in writing as if they could not interpret the situation.

### Conceptual and procedural strategies

Examination of students' written responses showed that students used conceptual and procedural strategies while explaining their agreement. Whether the strategy a student is used is related to procedures or concepts is determined considering how the concepts are interpreted in the statements, how transitions are made among the statements, and the content of the definition of Hiebert and Lefevre (1986). Students' responses of conceptual strategy were analyzed based on conceptual knowledge definition of Hiebert and Lefevre (1986). In this regard, *network of hot and cold* category was created when students interpret hot and cold concepts and make transitions between them saying that 'more hot' means 'less cold' etc. In addition to this, as Hiebert and Lefevre's definition for conceptual knowledge supports the relationship between pieces of information, *the network of hot and cold* was appropriate for this category. On the other hand, procedural strategy category was created based on Hiebert and Lefevre's (1986) procedural knowledge definition which supports the repertoire of basic factual knowledge and symbolic representation without interpretation of those facts and representations. In line with this, *rule-based explanation reference to zero or positive numbers* was categorized as procedural knowledge. *Rule-based explanation reference to zero or positive numbers* was related to the facts which are presented as context independent relations including facts of ordering two negative integers regarding their magnitude and direction.

Explanation Strategies		Example of students ‘ statements	Statements (%)	
			1.	2.
Conceptual strategy	Connected knowledge of zero	Closer to zero is connected to being hotter	2	6
	Network of hot and cold	The big number (-10) is colder than the smaller number (-5)	21	4
		As numbers increases hotness increases	5	2
		If negative numbers increase the weather gets cold	4	-
		-5 has more quantity of hot than -10	7	2
		Quantity of quicksilver is smaller at -10 degree	-	2
	Total		39	16
Procedural strategy	Rule-based explanation reference to zero or positive numbers	Bigger number is closer to zero (and the reverse of the statement)	9	14
		Numbers get smaller if you move to the left side of zero	4	4
		Negative numbers are ordered as opposite to positive numbers	5	-
		Numbers above the number line are bigger than the numbers below the number line	-	2
Total		18	20	
Other statements	Criticism of the content of the statement	No relationship between the given statements, they are contradictory to each other	5	9
	Rejecting the order	-10 is not less than -5	8	9
	Copying the statement	Student write the same statements given to them	7	14
	Unclear statements	For the reason that this is appropriate	7	1
		Drawings help ordering two negative integers	2	9
	Blank	-	5	4
	No strategy	I don’t know	12	18
Total		46*	64	
Total answers*			100*	100

\*One student suggested more than two ways for explanation

**Table 2: Explanation strategies and conceptual and procedural strategies of students**

Table 2 indicates that for the first statement, students used more conceptual strategies than the second one, and students used more procedural strategies for explaining the second statement than the first one. This might be derived from the nature of the statements which allow students to focus on the conceptual nature of the word 'less hot' and of allocating numbers on a number line. However, it seems that a considerable number of students used the procedural and conceptual strategies (20% and 16% for the first and second statement, respectively) regardless of the nature of the problem.

Most of the students used the *network of hot and cold* strategy with the conceptual strategy of ordering two negative integers using coldness (e.g.: -10 is colder than -5). In other words, most of the students made a transition from the word 'less hot' to the word 'colder'. As opposed to the expected interpretation of students, they explained ordering two negative integers considering the quantity of hotness concept (e.g.: -5 have more hotness than -10). Students used *connected knowledge of zero* strategy, for instance, saying that 'being closer to zero is connected to being hotter'. Similarly, in the first statement, the procedural strategy of 'bigger number is closer to zero' is used (e.g.: -5 is closer

to zero and so it is bigger and vice versa). Parallel with this, for the second statement, the same procedural strategy was mostly used by the participants.

Most of the participants supported the idea that two negative integers can be ordered by using *rule-based explanation in reference to zero or positive numbers*. In this regard, it might be said that students have pieces of knowledge about the nature of magnitude and direction of integers. Participants agreed that 1) the number which is located below the other on the thermometer is the smaller (direction) or (2) the number which is closer to zero is bigger than the other negative integer, which is less close to zero (magnitude).

## Discussion and conclusion

In this study, the two statements about ordering allow students to see how they interpret those statements and what kind of strategies they use. Moreover, this study helps reveal the difficulties students encounter in their learning process. As seen in Table 1, students agreed with the given statements; however, Table 2 showed that middle grade students have variety of conceptual and procedural strategies that might not support their agreement. The results of the study show that their dominant strategies are spread over the sample of the students and are rarely used. Table 1 shows that most of the participants supported the idea that negative integers can be ordered by the nature of the amount of hotness that each integer is assigned. In other words, each negative integer is assigned to the concept of being hotter or being less hot. A possible explanation might be that students conceptualize ordering with the help of quantity or cardinal conception of numbers (Davidson, 1992). It means that students agree that ordering negative integers can be thought as similar to ordering positive integers when giving meaning to hotness concept. In this regard, for the first statement, students changed the word *hotness* to the word coldness and explained the statement based on coldness. Most of the students interpreted the situation by transferring hotness to the cold. While comparing two negative integers, they used the ‘the hotter is less cold’ or ‘less hot is colder’ relationships. Thus, these kinds of explanations indicate students’ lack of interpretation of ordering as an amount of hotness because they might have a potential for interpreting the smaller number (-10) as a bigger number while ordering the concept of coldness a quantity. However, the relationship which indicates what being less cold or being colder means needs to be established within ordering context. Otherwise, it causes misconceptions or errors about misinterpreting what the integer statements or symbols mean (Ashlock, 2010). Moreover, this finding supports the idea that it is not easy to infer order relations from context-related statements, but teachers can integrate those strategies to classroom activities to establish a relationship between real life situations and negative numbers (Schindler & Hußmann, 2013). It is worth emphasizing that the procedural strategies illustrated in Table 2 might create faulty decision while comparing two negative integers. Students’ understanding of negative numbers might be achieved by using the procedural strategies carefully being aware of the overgeneralization. For instance, the procedural strategy of ‘bigger number is closer to zero’ might be problematic when the number is a whole number.

Taken together, students have a variety of conceptual or procedural strategies that can be used for interpreting ordering in real life situations. Those strategies are important to make instruction better and to facilitate student understanding. In future studies, the meaning of ordering negative integers within real life contexts and in mathematics can be examined to explain some students’ lack of interpretations of the given statements.

## TWG03: Algebraic thinking

## Introduction to the papers of TWG03: Algebraic thinking

Dave Hewitt<sup>1</sup>, Reinhard Oldenburg<sup>2</sup>, Valentina Postelnicu<sup>3</sup>, and Heidi Strømskag<sup>4</sup>

<sup>1</sup>University of Loughborough, UK,

<sup>2</sup>University of Augsburg, Germany,

<sup>3</sup>Texas A&M University-Corpus Christi, USA,

<sup>4</sup>Norwegian University of Science and Technology, Trondheim

*Keywords: Algebra, early algebra, functions, research frameworks, teaching and learning algebra.*

In CERME-10, the Thematic Working Group 3 “Algebraic thinking” continued the work carried out in previous CERME conferences. There were a total of 16 papers and 5 posters with a total of 29 group participants representing countries from Europe and other continents: Canada, Finland, Germany, Greece, Ireland, Norway, Portugal, Spain, Sweden, Tunisia, Turkey, UK, and USA.

### Recurring issues

While the importance of algebra education is universally acknowledged, the problem of teaching it successfully to most students is not yet solved. Thus, there is a need to go back to basics over and over again and a lot of issues occur repeatedly in the history of CERME working groups on algebra. A broader overview is given in Hodgen, Oldenburg and Strømskag (2017). The discussion during CERME 10 brought up the following fundamental issues:

- What is algebra? There is still no uniform definition of what is the particularity of this field and what are the relations to other mathematical fields like combinatorics or geometry (that use letters as well). Moreover, many notions are not fully defined.
- How can it be empirically determined what works? We still have no universal measures of algebraic competence. Hence, many ad hoc tests are used.
- What should be taught? Too little is known about how knowledge builds up in the long term. For instance, it may be that certain concepts and metaphors that work well in some grades will give rise to obstacles later on.

Regarding the first point in this list, the group discussed the question of whether it would be sensible to rename the group’s title just to “Algebra”, because the word “thinking” gives the cognitive a higher weight than it might deserve. But this was resolved by the shared understanding that “algebraic thinking” is interpreted to include language, affect and possibly further factors.

The second point was taken up in a series of discussions about the quality of research and communication. Conceptual validity is seen often to be a problem. To rely just on Cronbach’s alpha to ensure internal consistency seems not adequate. Perhaps the community should ensure that whole tests, measurement instruments and data are made accessible for other participants? Still, it will be difficult to ensure a common understanding of notions, given the plurality of theories and terminology used.

Despite these questions, there are substantial areas where a consensus has been reached: It is accepted that early algebra “works”, in the sense that it is possible to develop algebraic thinking using, or just beginning to use, formal symbolic notation. Furthermore, most researchers see structure as a guiding principle in algebra and especially the structure of equations and the role of the equal sign is identified as central. The context/environment of each research event is relevant and especially the tasks and its implementation by the teacher are crucial together with the role of the researcher. Regarding ideas

for the curriculum, we agreed that equation solving should not start with too simple equations. Filloy and Rojano's (1989) distinction between arithmetical and algebraic equations is important to exemplify the domain in which algebraic methods can show their power to students.

### **Some comments on issues dealt with in the papers**

Functions have been identified by many colleagues as a central issue in algebraic thinking and hence we have seen several papers (Isler et al., Pinto & Cañadas, Postelnicu, and Weber) that deepen the understanding of functions.

Isler et al. report results from a quantitative study in the US of Grade 6 students' written work on a functional thinking assessment item. The results show that students who experienced an early algebra intervention during Grades 3-5 were more likely to successfully represent a function rule in words and variables than students who did not. Also, both comparison and intervention groups of students were found to be more successful representing a function rule in variables than in words. The results underscore the impact of early algebra on students' later success in algebra, and challenge the view that the concept of variable should not be introduced until secondary school.

Pinto and Cañadas report from a study of 24 Spanish Grade 3 students' functional thinking during engagement with a contextualised linear problem (placing tiles). Two types of functional relationships were identified—*correspondence* and *covariation*—and the ability to generalise was observed in some of the students. The study was part of a broader teaching experiment, and the data were collected through a task-based questionnaire.

Postelnicu conducted a study of 58 US high school students' difficulties with writing equations of parallel and perpendicular lines (in the context of Algebra 1). Chevallard's theory of didactic transposition was employed to account for the relativity of the mathematical knowledge with respect to the institutions where the knowledge was created. The analysis shows that the mathematical knowledge (through the didactic transposition) lost its essential feature—the *proof*—with serious consequences for the curriculum. What remained to be learned was how to execute tasks.

Weber presents a theoretical paper, where vom Hofe's construct of 'Grundvorstellungen' and Sfard's distinction between operational and structural conceptions are used to analyse structural and operational models of logarithmic functions. Weber claims that logarithmic functions should not be introduced structurally, as inverse exponential functions. Instead, several operational models of the logarithmic concept are proposed, and their explanatory power for graphing is expounded.

Zindel presents a model for conceptualizing the core of the function concept, which is made up of those facets that are equally important for all types of functions and common to all representations. The so-called *facet model* enables the identification of potential obstacles and a detailed description of students' learning processes when connecting representations (e.g., verbal and symbolic representations when solving word problems). In total, 19 design experiments with overall 96 learners (mainly Grades 9-10) were conducted and qualitatively analyzed.

A focus on the thinking in algebraic thinking has been laid by four papers: Palatnik and Koichu; Twohill; Soneira, González-Calero and Arnau; and, Proulx.

Palatnik and Koichu took a detailed view on how students make sense of formula they found on various ways. The authors found that the process of sense making consists of formulating and

justifying claims, making generalizations, finding mechanisms and established coherence among the explored objects.

Twohill investigated number sequences from geometric patterns and the path of students to general terms. It turned out that between figural and numerical aspects of the patterns there is a whole continuum of ways that students think about these sequences. It is not easily said what aspects students should look at to be successful in finding a proper generalization.

Soneira et al. investigated in details the well-known error that students might produce expressions in which different occurrences of the same variable have different (but often related) reference. They explain this by idiosyncratic semiotic systems used by the students. The process of translation between algebra and natural language is highly complex.

Proulx investigated how teachers and students solve algebraic problems mentally. Forcing them not to use paper and pencil or other techniques allows to get close to their thinking. This revealed a wide variety of approaches and students and teachers differed in these. In the end, a sense for the diversity should be developed especially by the teachers.

Röj-Lindburg et al. considered the transition from informal to formal methods of equations solving in Grade 6 (12 years old) in Finland. The approaches taken by three teachers were analysed. One teacher used the image of a balance scale; another used uncomplicated ‘real-world’ situations; and the third had an emphasis on formal methods, in particular the need to ‘do the same thing on both sides’. The third teacher’s lesson was analysed and concluded that the discussion focused strongly on memorizing the procedure and did not develop an algebraic understanding of equality. In fact, it was concluded that in none of the teachers’ lessons was there a need for students to adopt an algebraic way of thinking about equality.

Steinweg brought out the fact that the mathematics teaching units in Germany primary education lack explicit algebra learning environments. She offered ways in which key algebraic ideas can be used as guiding principles to rethink ‘arithmetic’ topics in six German primary school classes so that they can be used as learning environments for algebraic thinking. She focused on work from a pupil who was working on a task to decompose the area of a given rectangle and who appeared to show an awareness of the inherent distributive structures. Pre- and post-tests showed an increase in the percentage of children giving answers deemed to be algebraic in nature.

Papadopoulos and Patsiala studied the use of a particular learning environment called “Father Woodland” with seventy Grade 3 students (8-9 year olds) from two different primary schools in Greece. The approaches taken by the students were categorized into four types and it was noted that over the course of eight tasks, there was increased use of approaches which were classified as either ‘combining words and symbolic language’ or ‘using symbolic language to express relationships’. An argument was made that the environment helped develop the students’ algebraic thinking.

As mentioned above, several researchers were concerned with the issues of “what should be taught” and what constitutes proficiency from the learners’ points of view. Pinkernell, Düsi and Vogel proposed a way to construct validity for the concept of proficiency in elementary algebra, and presented the methodology of constructing a “model” of proficiency, together with the resulting

product – the “revised model.” Wladis and colleagues described an instructor-generated “concept framework” for elementary algebra in the tertiary context.

Chimoni and Pitta-Pantazi addressed the issue of determining empirically “what works” for teaching algebra. They conducted a study with 96 early algebra students and compared two intervention courses. The first intervention course included real life scenarios and semi-structured tasks, while the second intervention course involved mathematical investigations and structured tasks. The results showed that the first course had better learning outcomes.

Two papers reported on structural aspects of algebra, at the elementary and university level, respectively. Strømskag and Valenta addressed the issue of justifying the commutative property of multiplication of natural numbers for Grade 6 students. At the heart of the study were the limitations of the visual representation used by the observed student teacher to help her students justify the property of commutativity of multiplication. Mutambara and Bansilal investigated the understanding of the concept of vector subspace. Participating students were 84 in-service teachers enrolled in a mathematics course at a Zimbabwean university. The action, process, object schema (APOS) theory, based on Piaget’s genetic epistemology, was proposed for the analysis of two tasks. The results highlighted the teachers’ difficulties with the concepts of sets, matrices, and vector subspace.

## Outlook

The synopsis of papers given above shows the wide variety of theories, topics and methods used in this group. Such a pluralistic situation is highly welcomed as it allows to test the validity of research results from multiple perspectives. Thus, the consensus described above, can be viewed as solidly grounded and form the base for further research that can and should address questions that are not yet understood well enough. One such area is the domain of high school algebra. Weber’s paper has shown the potential of better understanding such concepts. Another point to be developed further is the perspective of teachers and teacher education.

# The effect of two intervention courses on students' early algebraic thinking

Maria Chimoni and Demetra Pitta-Pantazi

University of Cyprus, Department of Education; [chimoni.maria@ucy.ac.cy](mailto:chimoni.maria@ucy.ac.cy), [dpitta@ucy.ac.cy](mailto:dpitta@ucy.ac.cy)

*The aim of this study is to investigate the nature and content of instruction that may facilitate the development of students' early algebraic thinking. 96 fifth-graders attended two different intervention courses. Both courses approached three basic content strands of algebra: generalized arithmetic, functional thinking, and modeling languages. The courses differed in respect to the characteristics of the tasks that were used. The first intervention included real life scenarios, and semi-structured tasks, with questions which were more exploratory in nature. The second intervention course involved mathematical investigations, and more structured tasks which were guided through supportive questions and scaffolding steps. The findings, yielded from the analysis of pre-test and post-test data, showed that the first course had better learning outcomes compared to the second, while controlling for preliminary differences regarding students' early algebraic thinking.*

*Keywords: Early algebraic thinking, teaching intervention, tasks.*

## Introduction

In response to calls for spreading the teaching and learning of algebra throughout K-12 grades (e.g. NCTM, 2000), a wealth of studies focused on the design and implementation of instructional interventions that facilitate the development of early algebraic thinking (e.g. Blanton & Kaput, 2005; Irwin & Britt, 2005; Warren & Cooper, 2008). These studies offered strong evidences that students are able to develop algebraic thinking as early as the primary grades. Moreover, these studies highlighted the key role of teachers in providing their students with rich opportunities to investigate and understand algebraic ideas from elementary school.

As Kieran, Pang, Schifter and Ng (2016) highlighted, a large number of past studies identified pattern generalization and functional thinking as important routes that foster the development of early algebraic thinking; however, little research has involved other aspects of algebra, such as properties of numbers and operations. This bring us to the question of the effectiveness of intervention courses that might involve a range of algebra content strands, such as functional thinking and generalized arithmetic. There is, therefore, still a need to extend our understanding of supportive instruction that aims to improve students' early algebraic thinking and further clarify the content of a corpus of lessons that capture the core content strands of algebra.

The current study addresses this issue. Furthermore, considering the suggestions of recent literature regarding the impact of different types of tasks on students' learning (e.g. Swan, 2011), this study raises the question of whether the nature and content of the tasks used in instructional interventions, regarding their structured or semi-structured nature, and the association of their context to real life scenarios or not, might affect students' early algebraic thinking.

## **Theoretical framework**

### **The notion of early algebraic thinking**

Several research studies addressed the multidimensional nature of early algebraic thinking. Kaput (2008) claimed that there are three fundamental content strands of algebra: (i) generalized arithmetic, (ii) functional thinking, and (iii) the application of modeling languages. Generalized arithmetic, involves generalizing rules about relationships between numbers, manipulating operations and exploring their properties, transforming and solving equations, and understanding the equal sign in number relations. Functional thinking, refers to the identification and description of functional relationships between independent and dependent variables. Modeling, refers to the generalization of regularities from mathematized situations or phenomena inside or outside mathematics.

The notion of early algebraic thinking has also been associated through literature with several mathematical processes. For example, Kieran (2004) suggested that early algebraic thinking is linked to problem solving, modeling, working with generalizable patterns, justifying and proving, making predictions and conjectures, analyzing relationships, and identifying structure.

Early algebraic thinking, therefore, is expected to emerge through intervention courses that capture a variety of areas and contexts related to algebra and assist students to use a range of mathematical processes.

### **Sources of meaning in algebraic problems and the importance of the nature of tasks**

Radford (2004) specified that there are three main sources of meaning within algebraic problems that trigger the development of early algebraic thinking: (a) the algebraic structure itself (e.g. the letter-symbolic representations, graphical representations), (b) the problem context (e.g. word problems, modeling activities) and (c) the exterior of the problem context (e.g. social and cultural features, such as language, body movements, and experience). Hence, the specific characteristics of these sources might facilitate or not the construction of meaning when students participate in algebra lessons.

Additionally, existing literature on the importance of tasks that students are engaged with, has shown that the nature and features of mathematical tasks influence learning, since they direct students' attention to specific content and specific ways of processing information (Jones & Pepin, 2016). For example, Sullivan, Clarke and Clarke (2012) suggested that problem-like tasks have a positive effect on students' mathematical thinking rather than step-by-step procedures. In this perspective, the extent to which a task involves problems that are more or less structured, is associated with an open question or a series of scaffolding questions, and represents situations related to students' experiences within real life contexts or not, may influence students' development of early algebraic thinking.

### **Aim of the study**

The aim of this study is the investigation of the effect of two different intervention courses in improving students' early algebraic thinking. Both courses involved the three content strands of algebra suggested by Kaput (2008), had the same duration, and were based on the inquiry-based learning approach. Nevertheless, they were implemented through different types of tasks. The first course, which we named "Semi-structured problem situations", used semi-structured tasks connected to real life scenarios and required students to identify the mathematics involved in order to answer to their main question. The second course, which we named "Structured mathematical investigations",

used more mathematical tasks that were supported by scaffolding questions. Hence, the two teaching interventions were compared in relation to the types of the tasks through which algebraic thinking was expected to emerge.

## Methodology

### Participants

The participants were 96 fifth-graders from 4 classes in 2 urban schools. The classes were selected by convenience. Two of the classes (one class from each school) formed the group that participated in the first course and the other two classes formed the group that participated in the second course.

### Test on early algebraic thinking

The same test was administered to the students before and after the conduction of the courses in order to measure their early algebraic thinking. The test consisted of 22 tasks that were accordingly categorized into three groups which reflected Kaput's (2008) three content strands of algebra. Table 1 presents examples of the tasks in each category. The first group (generalized arithmetic) involved tasks, such as determining whether the sum of two numbers will be odd or even, using the properties of operations, describing movements in the hundredths' table, and solving equations and inequalities. The second group of tasks involved finding the  $n^{\text{th}}$  term in geometrical and numerical patterns, interpreting graphs, and describing co-variational and correspondence relationships among quantities. The third group of tasks (modeling) required the generalization of regularities by observing the relationships involved in realistic situations. The internal consistency of scores measured by Cronbach's alpha was satisfactory for the test ( $\alpha=0.87$ ).

Algebraic Thinking as Generalized Arithmetic	Is the sum <b>245676 + 535731</b> an odd or even number? Explain your answer.		
Algebraic thinking as functional thinking	 Figure 1	 Figure 2	 Figure 3
	Bill is arranging squares. How many squares there will be in the 16 <sup>th</sup> figure? Show your work.		
Modeling as a domain for expressing and formalizing generalizations	Joanna will take computers lesson twice a week. Which is the best offer? Justify your answer.		
	<div style="border: 1px dashed black; padding: 5px; display: flex; justify-content: space-between;"> <div style="width: 45%;"> <b>OFFER A:</b> €8 for each lesson         </div> <div style="width: 45%;"> <b>OFFER B:</b> €50 for the first 5 lessons of the month and then €4 for every additional lesson         </div> </div>		

**Table 1: Examples of tasks included in the early algebraic thinking test**

### Teaching experiments

Both intervention courses addressed the same concepts and objectives, and were developed through ten lessons of 80-minutes duration each. The first researcher taught all the lessons. Table 2 presents the objectives of the lessons in each strand.

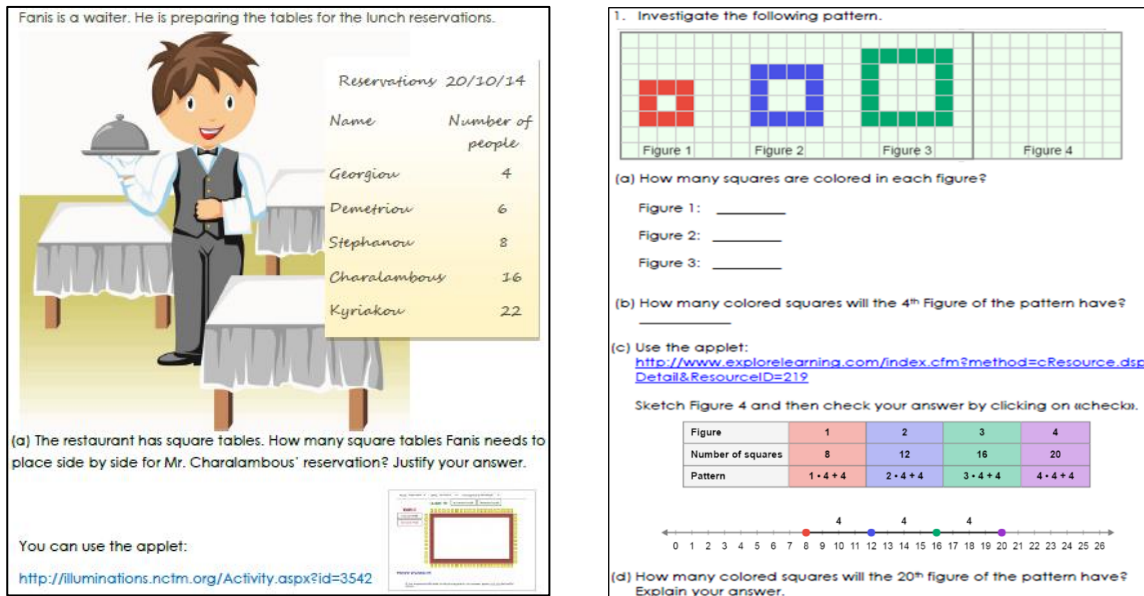

Lessons	Content strand	Objectives
3,4	Generalized arithmetic	Apply properties and relationships of whole numbers, apply properties of operations on whole numbers, treat numbers by attending structure rather than computations
1,2,6,7	Functional thinking	Encode information graphically for analyzing a functional relationship, identify correspondence or co-variation relationships, identify numerical and geometrical patterns
5,8,9,10	Modeling languages	Generalize regularities from mathematized situations inside or outside mathematics

**Table 2: Structure of Instructional Interventions and Objectives for each Lesson**

The “Semi-structured problem situations” course used semi-structured problems arising from real life situations. Students were confronted with a general question and were given time to explore the problem situation, analyze and combine information and apply their own strategies to solve the task. These tasks employed some features of modeling-like tasks. Specifically, modeling-like tasks were considered as appropriate for enhancing the development of algebraic thinking because they involve the description and interpretation of complex systems of information through the application of processes such as, constructing, explaining, justifying, predicting, generalizing, conjecturing, and representing (English, 2011).

The “Structured mathematical investigations” course reflected mathematical contexts that aimed to direct students to identify structure and relationships in mathematical concepts. Specifically, these tasks were more mathematical in nature, involved scaffolding steps and pathways which guided students to the extraction of an explicit conclusion. This kind of activities were considered as relevant and important for enhancing algebraic thinking since they apply fundamental processes, such as formulation and expression of relationships and generalizations, and progressive symbolization.

In order to ensure the content validity of the tasks we used for both interventions tasks of previous studies (e.g. Blanton & Kaput, 2005) or online resources (e.g. <https://illuminations.nctm.org/>) which seem to be well accepted by researchers and mathematics educators. Moreover, the authors consulted two other mathematics education experts about their judgment regarding the content validity of the tasks until consensus was reached. Figure 1 presents examples of tasks from each intervention course. The task on the left was adapted from a lesson presented in the website <https://illuminations.nctm.org>. Using a context of arranging chairs around tables, students were exposed to two different linear patterns. As specified in the website, this activity leads to an intuitive understanding of how to extend and describe a pattern using words or symbols. The task on the right was adapted from a lesson presented in the website [www.explorellearning.com](http://www.explorellearning.com). Students studied different patterns of squares in a grid. Each new pattern was more complex compared to the previous pattern (The pattern presented in Figure 1 was the third pattern). As stated in the website, this activity aims to the extension of figural patterns and the extraction of a general rule. In this sense, both tasks targeted on the description and generalization of figural and numeric patterns. However, the first task introduced from the beginning a complex pattern; the second started from a simple pattern and moved to more complex patterns.

**Figure 1: Semi-structured problem situation (left) and Structured mathematical investigation (right)**

## Analysis

The SPSS statistical package was used to analyze the results. Since the tasks in the pre-test and post-test were the same, gain scores were used (the difference between post-test and pre-test scores) as the dependent variable. The Kolmogorov-Smirnov and Shapiro-Wilk tests showed that the gain scores were normally distributed ( $p > .01$ ). The P-P and Q-Q plots did not show crucial variations. In order to compare the early algebraic thinking abilities of the two groups prior to the intervention, a multivariate analysis of variance (MANOVA) was conducted. MANCOVA was used to examine the impact of the intervention courses on participants' early algebraic thinking. The type of intervention was the independent variable, students' performance in early algebraic thinking pre-test was considered as the covariate, and the performance differences between the pre- and post- tests as the dependent variables. Moreover, paired-sample t-test was performed in order to measure the differences in the performance of students of the same group in the pre- and post-tests.

## Results

The results of the MANOVA analysis suggested that the two groups did not have any statistically significant differences in their early algebraic thinking abilities prior to the intervention ( $F = .576$ ,  $p > .05$ ). Table 3 presents the results of the MANCOVA analysis, regarding the comparison of the impact of the two teaching experiments on the groups' performance in the early algebraic thinking post-test, controlling for their pre-test scores.

The analysis indicated significant overall intervention effects, controlling for pre-test scores in the early algebraic thinking test (Pillai's  $F = 9.586$ ,  $p < .05$ ). The students in the "Semi-structured problem situations" group had a significantly higher overall performance in early algebraic thinking to students in the "Structured mathematical investigations" group. The effect size indices for the overall algebraic thinking ability (partial  $\eta^2 = .088$ ) suggested that the effect of the "Semi-structured problem situations" course over the "Structured mathematical investigations" course was moderate. The performance of the "Semi-structured problem situations" group in the generalized arithmetic tasks did not have any significant difference in relation to the performance of the "Structured mathematical investigations"

group (Pillai's  $F=.081$ ,  $p>.05$ ). The “Semi-structured problem situations” group had significantly higher performance in the functional thinking tasks (Pillai's  $F=26.845$ ,  $p<.01$ ) and the modeling tasks (Pillai's  $F=9.804$ ,  $p<.05$ ) in comparison to the “Structured mathematical investigations” group. The effect size indices for the functional thinking tasks (partial  $\eta^2=.286$ ) and the modeling tasks (partial  $\eta^2=.128$ ) suggested that the effect of the “Semi-structured problem situations” course over the “Structured mathematical investigations” course was moderate.

Ability	Structured		Semi-structured		<i>df</i>	<i>F</i>	<i>p</i>	$\eta_p^2$
	Mean <sup>1</sup>	<i>SE</i>	Mean <sup>1</sup>	<i>SE</i>

**Table 3: Results of the Multiple Covariance Analysis between the Two Intervention Groups Post-test Performance in Early Algebraic Thinking**

Table 4 presents the results of the paired-samples t-test regarding the differences in the pre- and post-test scores within the same group.

Ability		Pre-test		Post-test		<i>T(df)</i>	<i>p</i>
		<i>M</i>	<i>SD</i>	<i>M</i>	<i>SD</i>		
Overall Performance	Structured	.337	.195	.452	.206	-5.519(33)	.000**
	Semi-structured	.368	.151	.570	.179	-10.147(34)	.000**
Generalized Arithmetic	Structured	.467	.326	.663	.213	-4.112(33)	.000**
	Semi-structured	.473	.235	.647	.246	-4.818(34)	.000**
Functional Thinking	Structured	.302	.263	.369	.225	-2.774(33)	.09
	Semi-structured	.404	.228	.547	.270	-5.663(34)	.000**
Modeling	Structured	.223	.241	.291	.291	-1.231(33)	.227
	Semi-structured	.183	.202	.509	.319	-9.926(34)	.000**

\*\* $p<.01$

**Table 4: T-test Comparisons between Pre-test and Post-test Performance of the two groups**

The results showed statistically significant differences between the pre- and post-tests performance means of the “Structured mathematical investigations” group. Students in this group had a significant increase in their overall early algebraic thinking ability and in the generalized arithmetic tasks. The results also showed that no statistically significant differences existed between pre- and post-tests

performance means in the functional thinking and modeling tasks. Regarding the “Semi-structured problem situations” group, the results showed statistically significant differences in the mean difference between the pre- and post-tests means of performance. These students had a significant increase in their overall ability and in all types of tasks.

## Discussion and conclusion

This study compared the effect of two intervention courses on students’ early algebraic thinking. The results showed that instruction with “Semi-structured problem situations” had better learning outcomes compared to instruction with “Structured mathematical investigations”, while controlling for preliminary differences regarding students’ early algebraic thinking. Specifically, students who received instruction through the “Semi-structured problem situations” outperformed students who received instruction through the “Structured mathematical investigations” in the early algebraic thinking post-test. Nevertheless, more detailed results regarding the effect of the two types of courses have shown that both of them had positive impact in the generalized arithmetic strand. What seems to have influenced the overall outcome of the comparison between the two courses is the fact that students involved in the “Semi-structured problem situations” course had significantly higher performance in the functional thinking and modeling strands.

A possible explanation for this result seems to be the fact that the two intervention courses involved different types of tasks in respect to the way algebraic thinking was expected to emerge. While both interventions had high cognitive demands and were developed through activities that entailed cooperative learning, use of manipulatives, and technological tools, it appears that the nature and type of the tasks used had a significant role regarding the learning outcomes. As suggested by Stein and Lane (1996), the tasks determine not only the concepts and knowledge that students acquire but also the way students will come to process, use and make sense of those concepts and knowledge.

On the one hand, the tasks that were included in the “Semi-structured problem situations” course shared common features with modeling approaches to mathematical problem solving. As English (2011) described, modeling-like tasks offer enriched learning experiences that require students to extract meaning from open situations by mathematizing the situations in ways that are meaningful to them. This kind of processes are linked to early algebraic thinking. As Kieran (2004) supported, early algebraic thinking is related to several processes, including problem solving, modeling, justifying, proving, and predicting. Hence, modeling-like tasks seem to involve the majority of the processes that are related to early algebraic thinking. On the other, “Structured mathematical investigations” tasks appeared to be effective in helping students to notice the structure in arithmetical contexts and engage students to learning experiences that are mostly focused on the generalized arithmetic strand.

As Radford (2004) argued, the algebraic structure of a problem (e.g. the letter-symbolic representations), the problem context (e.g. word problems, modeling activities) and the exterior of the problem context (e.g. social and cultural features, such as language, body movements, and experience) constitute basic sources that students utilize in order to extract meaning. The results of the current study indicated that the “Semi-structured problem situations” tasks encompassed all of these sources in an effective way and enabled students to construct their own meaning and develop understanding of various algebra aspects. Thus we may say that the positive effect of an intervention course is in a great extend related to the design and implementation features of the tasks involved.

Future research might further investigate whether the effect of “semi-structured” or “structured” tasks is different with younger or older students. The effect of an intervention course that makes use of both “semi-structure” and “structured” tasks might also be addressed. Moreover, the qualitative characteristics of students’ behavior while participating in this kind of intervention courses needs to be investigated in detail, in order to better understand the nature of thinking they develop.

*This paper reports results from Grade 6 students' written work on a functional thinking assessment item. The results show that students who experienced an early algebra intervention during Grades 3-5 were more likely to successfully represent a function rule in words and variables than students who did not. Also, both comparison and intervention groups of students were found to be more successful representing a function rule in variables than in words. The results underscore the impact of early algebra on students' later success in algebra, specifically with functional thinking, and challenge the notion that variable as a varying quantity should not be introduced until secondary school.*

*Keywords: Early algebra, algebraic thinking, secondary school.*

### Background of the study

Algebra in the U.S. has long served as a gatekeeper to future academic and employment opportunities (Ingels, Curtin, Kaufman, Alt, & Chen, 2002). Thus, recent reform efforts have sought to integrate aspects of algebra into the elementary curriculum (National Council of Teachers of Mathematics [NCTM], 2000; National Governors Association Center for Best Practices and Council of Chief State School Officers [NGA Center & CCSSO], 2010). By algebra in the elementary grades (hereinafter, *early algebra*), we do not mean an add-on to the existing curriculum or a pre-algebra course that is typically taught at the secondary level. We follow instead the definition put forward by Blanton et al. (2007):

[Early algebra is] a way of thinking that brings meaning, depth and coherence to children's mathematical understanding by delving more deeply into concepts already being taught so that there is opportunity to generalize relationships and properties in mathematics. (p. 7)

Through a series of interrelated projects, Project LEAP [Learning through an Early Algebra Progression], has developed and investigated the efficacy of a learning progression for early algebra in Grades 3-5 (Grade 3 is the fourth year of elementary/primary school in the U.S. Students in this grade are typically 8-9 years old; Grade 5 students are typically 10-11 years old).

In the first project, we focused on developing the learning progression and its components: a curricular framework and progression, instructional sequence, written assessments, and levels of sophistication describing students' strategy use (see Fonger, Stephens, Blanton, & Knuth, 2015 for

more information about the development of the learning progression). This project also examined the effectiveness of the early algebra intervention (see Blanton et al., 2015 for the results of this study).

In the second project, from which the data for this paper came, we used a quasi-experimental design to follow two groups of students—one designated comparison and one designated intervention—across Grades 3-5. The intervention students were taught about 18 one-hour weekly early algebra lessons each year. These lessons replaced their mathematics instruction thus the total time spent on mathematics instruction remained unchanged. The lessons were taught by a member of the project team, a former Grade 3 teacher. Each lesson started with a “jumpstart” at the beginning of the class that included a review of previously-discussed topics. The lessons continued with group work and whole-class discussions centered on research-based tasks. The algebraic concepts were often revisited in the “jumpstarts” so that the intervention students were provided opportunities to revisit several concepts throughout the intervention. The comparison students did not receive any intervention and were exposed only to their traditional mathematics curriculum throughout the three years. Written assessments were administered to measure students’ early algebra understandings and skills at four time points: at the beginning of Grade 3 and at the end of Grades 3, 4 and 5 (see Blanton, Isler, Stephens, Gardiner, et al., 2016 for the preliminary results of this study). A year after this longitudinal study ended, both the intervention and the comparison students were administered a written assessment in Grade 6 (when students were about 11-12 years old). This paper reports results from a functional thinking item that was common across Grade 5 and 6 written assessments.

## **Theoretical framework**

Kaput (2008) conceptualized algebra as: (1) the study of structures and systems abstracted from computations and relations, including those arising in arithmetic (algebra as generalized arithmetic) and quantitative reasoning, (2) the study of functions, relations, and joint variation, and (3) the application of a cluster of modeling languages both inside and outside of mathematics. Building on Kaput’s content strands, we identified three “big ideas” (Shin, Stevens, Short, & Krajcik, 2009) of early algebra: generalized arithmetic; functional thinking; and equivalence, expressions, equations, and inequalities. In addition to the content strands for algebra, Kaput (2008) also identified algebraic thinking practices. We organized the content strands around four algebraic thinking practices: (1) generalizing, (2) representing, (3) justifying, and (4) reasoning with mathematical structure and relationships.

The focus of this paper is on students’ abilities to engage in the algebraic thinking practices of generalizing and representing in the context of the “big idea” functional thinking. Blanton, Levi, Crites and Dougherty (2011) described functional thinking as “generalizing relationships between covarying quantities, expressing those relationships in words, symbols, tables, or graphs, and reasoning with these various representations to analyze function behavior” (p. 47). In this paper, we explore students’ abilities to represent functional relationships in words and variables.

## Methods

### Participants

The participants were 80 Grade 6 students, 46 of whom were part of the intervention that took place during Grades 3-5 and 34 of whom were part of the comparison group in those grade levels. All of the students were from the same middle school. The teachers of these students reported using the *Connected Mathematics Project* (CMP3) curriculum for their mathematics instruction. The demographics for the district are 8% non-white, 5% English Language Learners, and 20% low socioeconomic status students.

### Data collection and analysis

An early algebra assessment was administered to students at the end of Grade 6. The assessment items were developed and validated in a prior project. The assessment consisted of 11 items, most including multiple parts that addressed the aforementioned big ideas, and took students approximately one hour to complete.

We focus on one item, the Brady task (parts c1, c2, e1, and e2) (see Figure 1), which was designed to assess student's functional thinking, one of the big ideas, fundamental to our learning progression. The student responses were coded for both correctness and strategy use (correct or incorrect). The strategies that are the focus in this paper are listed in Figure 2. For more information about the coding scheme for strategy use for this item and the levels of sophistication observed in students' written work, see Blanton et al. (2015), Stephens et al. (in press), and Strachota et al. (2016).

A second coder conducted reliability coding for all items and any disagreements were discussed and resolved until 80% inter-rater agreement score was reached for all items.

Brady is celebrating his birthday at school. He wants to make sure he has a seat for everyone. He has square desks.

He can seat 2 people at one desk in the following way:

If he joins another desk to the first one, he can seat 4 people:

If he joins another desk to the second one, he can seat 6 people:

a) Fill in the table below to show how many people Brady can seat at different numbers of desks.

Number of desks	Number of people
1	2
2	4
3	
4	
5	
6	
7	

b) Do you see any patterns in the table from part a? If so, describe them.

Think about the relationship between the number of desks and the number of people.

c1) Use words to write the rule that describes this relationship.

c2) Use variables (letters) to write the rule that describes this relationship.

d) If Brady has 100 desks, how many people can he seat? Show how you got your answer.

Brady figured out he could seat more people if two people sat on the ends of the row of desks. For example, if Brady had 3 desks, he could seat 8 people.

How does this new information affect the rule you wrote in part c?

e1) Use words to write your new rule.

e2) Use variables (letters) to write your new rule.

**Figure 1: The Brady task**

Strategy Code	Description	Example
Parts c1 and e1		
Functional-Condensed in Words	Student identifies a function rule in words that describes a generalized relationship between the two variables, including the transformation of one that would produce the second.	Part c1: <i>The number of people is 2 times the number of desks.</i>  Part e1: <i>The number of people is 2 times the number of desks plus 2.</i>
Parts c2 and e2		
Functional-Condensed in Variables	Student identifies a function rule using variables in an equation that describes a generalized relationship between the two variables, including the transformation of one that would produce the second.	Part c2: $2 \times d = p$  Part e2: $2 \times d + 2 = p$

**Figure 2: Functional-Condensed in Words and Functional-Condensed in Variables strategies for the Brady task**

Next, we focus on the results regarding the Grade 6 students' abilities to represent the function rules in words and variables (parts c1, c2, e1, and e2 of the Brady task) by comparing the performance of students who were exposed to the early algebra intervention during Grades 3-5 ( $n = 46$ ) to the performance of students who were not part of any early algebra intervention ( $n = 34$ ). We also compare Grade 6 results to the results we obtained at the end of the three-year intervention in Grade 5 ( $n = 90$  for the intervention group and  $n = 61$  for the comparison group).

## Results

Results for parts c1 and c2 showed that by the end of Grade 6, the intervention students used the functional-condensed in words strategy in part c1 and the functional-condensed in variables strategy in part c2 more frequently than the comparison students (48% vs. 26% for part c1 and 65% vs. 41% for part c2) (see Figure 3). Moreover, both the intervention and the comparison students were found to be more successful representing the function rule in variables than in words (65% vs. 48% for the intervention group and 41% vs. 26% for the comparison group, respectively stating the rule in variables vs. words).

**Figure 3. Percentage of Grade 6 students using the Functional-Condensed in Words strategy in part c1 and Functional-Condensed in Variables strategy in part c2**

**Figure 4. Percentage of Grade 6 students using the Functional-Condensed in Words strategy in part e1 and Functional-Condensed in Variables strategy in part e2**

Results for parts e1 and e2, which asked students to extend the rule, showed patterns similar to the results for parts c1 and c2, which asked students to write the rule. The intervention students used the functional-condensed in words strategy more frequently than the comparison students in part e1 (24% vs. 12%) and functional-condensed in variables strategy more frequently than the comparison students in part e2 (43% vs. 26%) (see Figure 4). Similarly, both groups of students were found to be more successful representing the rule in variables than in words (43% vs. 24% for the intervention group and 26% vs. 12% for the comparison group, respectively stating the rule in variables vs. words).

When we compared the Grade 6 results to the results we obtained at the end of the three-year intervention in Grade 5 ( $n = 90$  for the intervention group and  $n = 61$  for the comparison group) on the same item parts, we found out that the percentages of responses in which the intervention students represented the functional relationship in words and in variables stayed about the same from Grade 5 to Grade 6. The percentages of responses in which the comparison students represented the functional relationship in words and in variables increased from Grade 5 to Grade 6 (see Table 1 for students' percentages in Grade 5 and 6). However, the intervention students still outperformed the comparison students in Grade 6.

	Representing the function rule in words (part c1)		Representing the function rule in variables (part c2)		Extending the function rule in words (part e1)		Extending the function rule in variables (part e2)	
	Grade 5	Grade 6	Grade 5	Grade 6	Grade 5	Grade 6	Grade 5	Grade 6
Comparison	16%	26%	21%	41%	3%	12%	8%	26%
Intervention	50%	48%	67%	65%	27%	24%	40%	43%

**Table 1. Percentage of students using the Functional-Condensed in Words strategy in parts c1 and e1 and Functional-Condensed in Variables strategy in parts c2 and e2 in Grades 5 and 6**

Fisher's exact tests revealed that the students' performances significantly differed by group (intervention and comparison) in all parts in Grade 5 and in part c2 in Grade 6 ( $p < .05$ ). Although the intervention students outperformed the comparison students in all other parts in Grade 6, there was no significant association between performance and group. We discuss the results next.

## Discussion and conclusion

Results across items showed that a year after the conclusion of the early algebra intervention, the intervention students remained more successful in generalizing functional relationships and representing them in words and variables the comparison students. These results emphasize the impact of our Grades 3-5 early algebra intervention on students' success in algebra in the secondary school, and the importance of early algebra in helping students develop algebraic thinking practices, specifically, representing and generalizing (Kaput, 2008), as early as elementary school.

The results also showed that the comparison students' performance in representing functional relationships increased from Grade 5 to Grade 6 while the intervention students' performances stayed about the same. Based on our Grade 6 curriculum analysis (Connected Mathematics Project 3 [CMP3]), we suspect that the increase in comparison students' performance might be due to the focus on patterns and functions in the curriculum, which is covered in a unit called "Variables and Patterns" in CMP3 in Grade 6. In our analysis of CMP3, we found that the "Variables and Patterns" unit covers some of the same content that was addressed in the early algebra intervention during Grades 3-5 (e.g., analyzing relationships among variables, filling in tables, making graphs, investigating expressions, equations, and inequalities). Thus, while the CMP3 curriculum may have contributed to the intervention students' ability to retain knowledge and skills learned in the Grades 3-5 intervention, it might have helped the comparison students to "catch up" a bit with the intervention students in Grade 6.

Another important finding is that both groups of students were more successful in representing the function rule in variables than in words. This finding challenges the notion that variable as a varying quantity should not be introduced until Grade 6 (see the Common Core Grade 6 Expressions and Equations Standard #9, NGA Center & CCSSO, 2010), and suggests that an earlier introduction may support students in developing functional thinking. During the LEAP intervention, we observed that elementary students were successful using variables to represent generalizations in multiple contexts including representing unknown, varying quantities in algebraic expressions, representing equations with a fixed unknown, and using variables to represent and generalize a functional relationship (see Blanton, Isler, Stephens, Knuth, et al., 2016 for further details). Blanton et al. (2011) stated:

learning to express functional relationships in symbolic form not only strengthens understanding and facility in the use of a symbolic language—a skill that is so essential to algebra—but as the study of functions deepens, flexibility with symbolic rules also supports analysis of changes in the behavior of complex functions through more sophisticated techniques. (p. 63)

We therefore underline the importance of introducing functional thinking in the elementary school and using variables as varying quantities in functions to help students represent and generalize functional relationships. This study is also a first step towards measuring the impact of the early algebra instructional intervention on students' success in algebra in the secondary school.

# An APOS perspective of the understanding of the concept of vector subspace

Lillias H.N Mutambara and Sarah Bansilal

University of KwaZulu-Natal, School of Education, South Africa; [tendaimutambara@gmail.com](mailto:tendaimutambara@gmail.com)

*The content of Linear algebra is often considered to be difficult because of the formal logic required as well as the lack of connections to previous courses such as calculus. The purpose of this study was to explore the conceptions of vector subspace concepts, of 73 in-service mathematics teachers as revealed in their written responses to two tasks. The action, process, object, schema (APOS) theory was used to structure the analysis of the responses. The findings revealed that the teachers struggled with the vector sub-space concepts mainly because of poorly developed conceptions of prerequisite concepts of sets and binary operations.*

*Keywords: APOS, vector subspace, binary operations, vector space.*

## Introduction

Linear algebra is considered to be one of the most widely applicable subjects for students in the field of mathematics in that it can be applied to many different content areas, such as engineering and statistics and can be studied for mathematical abstraction. However, we noted that when the students take their first linear algebra course, they seem to encounter cognitive barriers. Dorier, Robert, Robinet and Rogalski (2000) noted that the teaching of vector spaces have completely disappeared in the secondary schools and the teaching has become less formal as there are no studies on algebraic structures. Some criticisms given by students about linear algebra concern the use of formalism and the lack of connections with what they already know since this is not done at secondary level. Dorier et al., (2000) elaborated that the formalism is experienced when students need to learn new definitions, symbols, words and theorems. Stewart and Thomas (2010) noted that many students in the first years cope well with the procedural aspects of solving systems of linear equations but struggle to understand the crucial concepts underpinning the material involving the study of vector space concepts such as subspace, linear independence and spanning. The teachers complain that the students have no skills in elementary cartesian geometry, and display an inconsistent use of the basic tools of logic or set theory (Dorier et al., 2000).

An APOS study set up to explore pre-service teachers' mental constructions of matrix algebra concepts, found that most of the participants were operating at the action and process level, with a few operating at the object level (Ndlovu & Brijlall, 2015). The authors argued that the lack of background knowledge of basic algebra schema hampered the teachers efforts to develop adequate schemas at the object level. Many preservice teachers could not manipulate numbers correctly when multiplying matrices and some of them failed to use notations correctly. They confused the notations  $A^T$  and  $A^{-1}$ . The goal of mathematics teaching is that students understand mathematical concepts presented to them or information that they discover for themselves. This is also supported by Hiebert and Carpenter (1992) who asserted that one of the most widely accepted ideas in mathematics education is that students should understand mathematics. The research described in this paper is concerned with students' difficulties with conceptual understanding of vector subspace.

Britton and Henderson (2009) in studying student's conceptual understanding of a subspace argued that the abstract "obstacle of formalism" and the theoretical nature of linear algebra are the root cause of the difficulties experienced. They believed that lecturers teach students for procedural rather than conceptual understanding and students have poor backgrounds of the concepts on proofs, logic and set theory. One of the questions asked the students to show that the set scalar multiples of a vector formed a subspace of  $\mathbb{R}^3$ . Most of the students could show that the set,  $V$ , is non empty but failed to prove the aspect on the closure property. Students chose particular vectors instead of arbitrary vectors, and some student worked out the sum of two vectors and assumed that the sum belonged to the set  $V$ . Some students had misconceptions about the definition of a subspace, while others mixed up concepts and showed rote learning of the concepts on vector subspace. The researchers also noted that students had problems with logic and set theory, moving from abstract to algebraic mode algebraic mode and failing to write a convincing proof.

### **Theoretical framework: APOS theory**

We use the action–process–object–schema (APOS) theory as a framework to make sense of the data. According to Arnon, Cottrill, Dubinsky, Oktac, Fuentes, Trigueros and Weller (2014) APOS theory is based on the extension of Piaget's principle that an individual learns mathematics by applying certain mental mechanisms to build specific mental structures. The main mental mechanisms for building the mental structures include interiorisation, coordination and encapsulation. The mental structures refer to the action, process, object and schema. As actions are repeated and reflected on, the student moves from relying on external cues to having internal control over them. This is characterized by an ability to imagine carrying out the steps without necessarily having to perform each one explicitly. Interiorisation is the mechanism that makes this mental shift possible. Encapsulation occurs when an individual becomes aware of a process as a totality upon which transformations can act. At this stage the student can analyse properties of the object and compare objects arising from the same process. (Arnon et al., 2014)

Many actions, objects and processes are interconnected in the individual's mind and these will be organised to form a coherent framework called a schema. An object can be assimilated by an existing schema, thus extending the span of the schema. According to Piaget, schema development also passes through stages of development. The Intra level is the preliminary level and is characterised by analysing particular events or objects in an isolated manner in terms of their properties, where explanations are local and not global and relationships between objects may not be perceived. At the Inter level, comparison and reflection upon properties of objects lead to the establishment of relationships. The individual can coordinate two different interpretations of the concept to mean the same thing. During the Trans stage, the student reflects upon and coordinates the relations and is aware of the complete structure. Using these definitions, we now present a genetic decomposition of the vector space concept.

### ***Genetic decomposition of the Vector Space concept***

We draw upon the work of Parraguez and Oktac (2010) and Arnon et al., (2014) to present a summarised description of the genetic decomposition of the vector space concept. The construction of the vector space concept is developed as the coordination of the prerequisite concepts of set and

binary operations. Hence, we refer to the set and binary operations Schema as abstraction layers of the vector space concept.

*Set Schema.* At an Action level, an individual conceives of a set when given a specific listing if a particular condition of set membership. The Action of gathering and putting objects together in a collection according to some condition is interiorised into a Process. This is encapsulated into an Object when an individual can apply actions or processes to the Process such as compare two sets, consider a set to be an element of another and analyse properties of the set. (Arnon et al., 2014)

*Binary operation Schema.* A binary operation is a function of two variables defined on a single set or on a Cartesian product of two sets. At an Action level, given a binary operation, an individual can take two specific elements of the sets and apply the formula. The individual interiorises the action into a Process that takes two objects (elements) and acts on these to produce a new Object (element) that is the result of the binary operation. At the Object level, an individual can distinguish between two binary operations, check whether a binary operation satisfies an axiom and compare Objects arising from two different binary operations. (Arnon et al., 2014)

Parraguez and Oktac (2010) describe how these two schema are drawn together to form the concept of vector space:

The Objects that are sets with two kinds of operations (addition and multiplication by a scalar) can be coordinated through the related processes and the vector space axioms that involve both operations, to give rise to a new Object that can be called a vector space. At the Intra level the object of vector space stays isolated from other actions, processes, objects and schemas. For example the student can verify different sets as being vector spaces or not, but does not see the vector space structure inherent in all of them. At the Inter level the object of vector space starts having relationships with other concepts such as subspace, linear transformations, basis, etc. When the student reflects upon these relations, through synthesis they can be recognized as part of a whole structure that makes up a vector space schema. This implies that the Trans level is reached and the student can recognize and work with non-standard examples of vector spaces and can invoke her/his schema when needed. (Parraguez & Oktac, 2010, p. 2116)

This description emphasises the complexity of the construction of the vector space concept which is built upon layers of abstraction. Firstly, the binary operation and set concepts are developed through to higher levels of abstraction via the Action-Process-Object path. The vector space concept is then constructed on these layers, forming an even higher layer of abstraction and as the vector space schema develops, at each stage the previous layer is re-organised as increasing coordination and coherence across the objects and relationships develops. The vector subspace concept is built upon this schema – students will not be able to see the connections between a vector space and vector subspace if they have not developed the vector space schema up to at least an Inter level.

## Methodology

This study was conducted with 73 underqualified mathematics teachers who were enrolled in a part-time in-service course at a Zimbabwean university that was designed to upgrade them. The design of the program was such that the teachers would complete the equivalent of an undergraduate three-year degree program. However, the lectures were offered in two intensive block sessions for each

semester and held from 8 Am to 6 Pm every day. The participant teachers have already taken a first course in matrix algebra, a course in mathematical discourse and structures together with two courses in calculus. The second course in linear algebra (during which they participated in the study) includes the concepts of vector spaces, linear independence, linear transformation and diagonalization, eigenvalues and eigenvectors. The research question that underpins this study is: *What does an APOS perspective suggest about the conceptions of vector subspace concepts held by 73 in-service mathematics teachers as revealed in their written responses to two tasks?*

The data was collected from the teachers' written responses to an activity sheet consisting of nine items which were intended to probe their understanding of vector spaces and vector sub-spaces. In this short paper, we focus on two tasks which were set within the vector space of  $2 \times 2$  matrices. These appear below.

Item	Comments
1. Let $\mathbf{V}$ be the vector space over of all $2 \times 2$ matrices over the real field $\mathbb{R}$ . Show that $\mathbf{W}$ is not a subspace of $\mathbf{V}$ , where $\mathbf{W}$ is the set of $2 \times 2$ matrices which have a zero determinant.	For this, teachers were expected to find a counter-example to show that the set $\mathbf{W}$ is not closed under vector addition.
2. Show that the set of all $M_{2 \times 2}$ matrices of the form $\begin{bmatrix} a & 0 \\ 0 & b \end{bmatrix}$ is a vector space.	For this, teachers could argue that since $M_{2 \times 2}$ is already a vector space, then it was only required to show that the given subset formed a vector subspace of $M_{2 \times 2}$ or, they could show that the eight axioms for a vector space were satisfied.

**Table 1: Research Tasks**

## Results and discussion

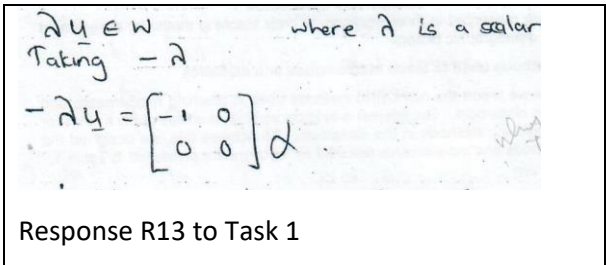

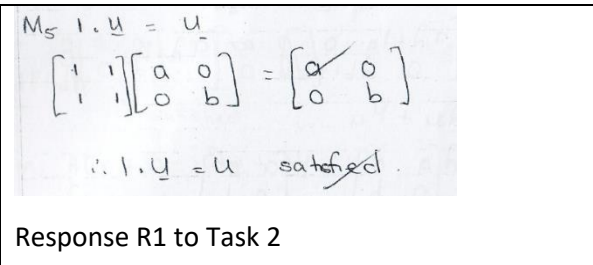

The teachers' responses were numbered from one to 73, where the order held no significance, for example, R11 is the response of Teacher number 11 on the list. We found that the teachers displayed different levels of engagement with the vector space concept. On the one hand some teachers held extremely limited conceptions of binary operations and of set that were not even at Action levels, while on the other hand some teachers had developed strong enough conceptions of vector space schema at an Inter level. The details of some of these levels of engagement are described now.

### *Binary Operation Layer*

The teachers' responses to the two tasks, suggested that the teachers were reasoning at various levels about binary operations, ranging from those who did not show evidence of even Action-level conceptions, while some displayed Object-level conceptions. Responses which illustrate different levels of reasoning are discussed below.

### Not yet at Action levels

It was clear that some teachers had not developed an Action conception of binary operations, as illustrated by the responses of R13 to Task 1 and that of R1 in Task 2. The response by R13 below shows that the teacher has not been able to carry out the Action of scalar multiplication because he has been sidetracked by thinking about the sign of the scalar.

 <p>Response R13 to Task 1</p>	 <p>Response R1 to Task 2</p>
---	---

**Figure 1: Responses suggesting action level conceptions of the binary operation have not developed**

The response R1 showed that the teacher was not clear about what “1” in the axiom referred to in the scalar multiplication  $1.u$  and took it as the “identity” matrix, consisting of 1’s in all the entries. The teacher then proceeded to carry out a pairwise multiplication of the corresponding elements in the two matrices. This is shown in the response of R1 in Figure 3.

### Process- level engagement with the binary operations

Some teachers’ responses suggested that they were able to engage in Process- level reasoning with the binary operations. However, for Task 2, if they had not developed an Object-level conception they were unable to apply the axioms correctly to the binary operations, as illustrated in Figure 2 below.

	
---	--

**Figure 2: Response R11 working with scalar multiplication and R12 showing confusion about closure**

In Figure 2, R11 is trying to show the associativity property of the operation of scalar multiplication  $(\lambda\mu)v = \lambda(\mu v)$ . The teacher is able to multiply the scalar into the vector ( $2 \times 2$  matrix) without any problems, suggesting that she has developed a Process conception of the binary operation of scalar multiplication. However, her expression on the left hand side of the first line does not have any brackets. This indicates that the teacher has problems with distinguishing between Objects arising from the different binary operations  $((\lambda\mu)v$  as opposed to  $\lambda(\mu v)$ . This suggests that the teacher has

not yet developed the necessary Object- level conception of the binary operation of scalar multiplication.

Similarly some teachers showed evidence of Process-level reasoning about the binary operation of addition but this was not sufficient to enable them to respond correctly to Task 1, which required them to show that the closure condition was not satisfied as in the case of R12 which also appears in Figure 2.

The response R12, shows firstly that the teacher has considered a particular type of  $2 \times 2$  matrices, that has identical entries. These matrices belong to the given set, because their determinants are zero. The teacher has done the vector addition of the two matrix elements, but was unable to show that the set was not closed under the binary operation. The sum of the matrices does satisfy the condition of having a zero determinant. Although he is able to reason at a Process-level about the binary operation of vector addition of  $2 \times 2$  matrices, the teacher was confused about what he needed to do, with the result of the addition (sum). He seemed to be trying to show that the sum should be equal to the identity matrix. This shows that he is unable to work with the sum of the vectors as an Object.

### ***Set Layer***

Similar to the binary operations layer, teachers' responses to the two tasks, showed reasoning at various levels in the Set layer. Examples of responses which illustrate this are discussed below.

#### *Not yet at Action levels*

Many teachers were not clear about what the elements of the subset of Task 1 was. One teacher (R17) used a general  $2 \times 2$  matrix,  $U$ , with variable entries and the zero matrix and tried to show that the closure condition was not satisfied as shown in Figure 3. The teacher has assumed that the matrix  $U$  belonged to the set  $W$ . This suggests that the teacher has not developed an Action conception of the subset  $W$ , of all  $2 \times 2$  matrices which have a zero determinant.

$$\text{i) } 0 \in V \quad \text{Axiom 1 holds}$$

$$\text{ii) let } u = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \quad \text{and } w = \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix}$$

$$\quad \quad \quad \text{2x2 matrix} \quad \quad \quad \text{mat. w 0 determinant}$$

$$\therefore u + w = \begin{pmatrix} a & b \\ c & d \end{pmatrix} + \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix} = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \quad \text{Axiom 2 holds on addition closure}$$

**Figure 3: Response R17, unable to identify non-zero elements of the given Set**

#### *Process- level reasoning*

Some teachers showed that they were able to recognize whether elements belonged to the set of  $2 \times 2$  matrices with zero determinants by considering the condition which characterized the set. One teacher (R6) considered a matrix with elements 1, 2, 3 and 4 and showed that the determinant of the matrix is not equal to zero as shown in Figure 4. That is, he identified a  $2 \times 2$  matrix which did not belong to the given set. This shows that he can work out that the element does not belong to  $W$ .

suggesting that he has developed a Process conception of the Set of all  $2 \times 2$  matrices which have a zero determinant, however he could not prove that the set  $\mathbf{W}$  was not a subspace.

Handwritten work showing a counterexample for a set  $\mathbf{W}$  of  $2 \times 2$  matrices with zero determinant. The student defines  $u = \begin{pmatrix} 1 & 2 \\ 3 & 4 \end{pmatrix} \notin \mathbf{W}$  and calculates the determinant:  $\text{since } 4 - 6 = -2 \neq 0$ . An arrow points from the calculation to the conclusion that  $u$  is not in  $\mathbf{W}$ .

**Figure 4: Response R6 considering an example of a  $2 \times 2$  matrix which did not belong to the given set.**

### *Indications of Inter level conceptions of vector space schema*

There were six teachers whose responses suggest that they have may developed an Inter level conception of the vector space schema. R3, for example, considered two  $2 \times 2$  matrices  $\mathbf{x}$ , and  $\mathbf{y}$  where  $\mathbf{x}$  had 0's in the first column and 1 in the first row of the second column, while  $\mathbf{y}$  had had 1's in the first column and 0's in the second column. The sum  $(\mathbf{x} + \mathbf{y})$  was therefore a  $2 \times 2$  matrix with three entries being 1. So the determinant was 1 and hence did not satisfy the zero- determinant condition. The proof involved generating a counter-example of two elements and then showing that the sum did not belong to  $\mathbf{W}$ , hence implying that  $\mathbf{W}$  was not closed under the binary operation of vector addition. This argument suggests that the student has developed Object-level conception of both binary operation as well as Object-level conception of the set of  $2 \times 2$  matrices with zero determinants set and the relations between these are perceived. Being able to show that the set  $\mathbf{W}$  did not satisfy the conditions for being a subspace of the vector space  $\mathbf{V}$ , suggests that these teachers have developed Inter level conceptions of the vector space concepts. These teachers also presented appropriate responses to Task 2.

## **Conclusion**

The use of APOS theory suggests that most of the teachers have not developed the necessary mental constructions that would enable them to reason about the properties of vector subspaces, which requires an Inter level conception of vector space schema. The study showed that for many teachers, their conceptions of the prerequisite schemas of set and binary operations hampered them from developing the vector space schema at an Inter level. Most teachers showed that they were able to generate the vector addition of two matrices, in their responses to Task 1. This suggests that they had developed a Process conception of the binary operation of vector addition using  $2 \times 2$  matrices. However, to show that the set was not closed under the binary operation, the teachers needed to have encapsulated the process of vector addition into an Object

whose properties they could analyse further. Some teachers had not developed even Action level conceptions of the binary operations. Many teachers struggled with the basics such as trying to identify the elements of the subset and were unable to reason about the kind of elements that produced a zero determinant. These teachers had basic problems with working with the set itself of matrices. These struggles indicate that their conceptions of the set of  $2 \times 2$  matrices with zero determinants had not progressed past an Action level so they did not have access to the sophisticated Object-level reasoning about properties of  $2 \times 2$  matrix with zero determinants. It is however important to note that the classification is based on written responses and if interviews

were used, the inferences about their levels of reasoning may differ somewhat depending on how the teachers' responded to questions about their reasoning.

Unlike simpler concepts which require coordination between few Objects and Schema, developing a robust understanding of vector subspace is dependent on a sufficiently strong conception of the various layers underlying the concept. Each of these layers is built upon previous ones and becomes increasingly abstract, requiring the coordination and connection between the various objects and relations. Hence very few teachers were able to cope with both tasks. For the teachers to develop the insight that was necessary, they needed to have access to Object-level conceptions of the set (of  $2 \times 2$  matrices with zero determinants as well as Object-level conceptions of both binary operations. It is therefore no surprise that only six teachers seemed to be able to cope with the abstraction required to present proofs about why a subset did not form a vector subspace of the vector space.

*This article presents a case in which a pair of middle-school students attempts to make sense of a previously obtained by them position formula for a particular numerical sequence. The exploration of the sequence occurred in the context of two-month-long student research project. The data were collected from the students' drafts, audiotaped meetings of the students with the teacher and a follow-up interview. The data analysis was aimed at identification and characterization of events and algebraic activities in which the students were engaged while making sense of the formula. We found that the students' conviction, by the end of the project, that the formula "makes sense" emerged when they justified the formula, checked its generality, discovered a geometry mechanism behind it, and found that it came to cohere with additional formulas. The findings are summarized as a suggestion for a four-component decomposition of algebraic sense making.*

*Keywords: Algebraic sense-making, problem-solving, project-based learning, integer sequences.*

## Introduction

Sense making has long been a focal concern of the mathematics education research community (e.g., Kieran, 2007; NCTM, 2009). NCTM (2009) recognised sense making as a means to know mathematics as well as an important outcome of mathematics instruction. To review, NCTM (2009) refers to *sense making* in mathematics “as developing understanding of a situation, context, or concept by connecting it with existing knowledge” (p. 4). Nevertheless, NCTM (2009), as well as many additional mathematics education publications, is rather inexplicit as to what sense making comprises of and how it occurs. Moreover, it has been broadly acknowledged (e.g., Schoenfeld, 2013) that empirically-based knowledge about the processes involved in sense making, as well as knowledge about the processes involved in learning through mathematical problem solving, is insufficient.

The case presented in this article occurred with two 9<sup>th</sup> graders, Ron and Arik (pseudonyms) who participated in the Open-Ended Mathematical Problems project, which was conducted by the authors (an abridged version of Palatnik and Koichu, 2017). The initial part of Ron and Arik's project lasted for three weeks and resulted in an insight solution to the problem of finding a position formula for a particular sequence. This part is analysed elsewhere (Palatnik & Koichu, 2015). The insight gained was celebrated as an important highlight of the project. The students told us, however, that they found the formula “by chance” and that it did not make sense for them. As a result, making sense of the obtained formula became an explicitly chosen goal and the main theme of the second part of the students' project. This part had lasted for four weeks and ended when the students succeeded, in quite an idiosyncratic way, to make sense of the formula.

The goal of our study was to discern the activities and processes involved in the sense making effort. Specifically, we pursued the following research questions:

In which events and algebraic activities were the students engaged while attempting to make sense of a formula?

What were some of the processes involved in the students' explicitly expressed conviction, by the end of the exploration, that the formula "makes sense"?

## Theoretical background

In empirical studies, the notion of sense making frequently denotes ways by which learners of mathematics act upon a particular entity in the context of particular mathematical activity. The expression "to make sense of..." is attributed in different studies to such entities as proofs, instructional devices, concepts, solution methods and problem situations (e.g., Smith, 2006; Rojano, Filloy, & Puig, 2014).

The idea of algebra as an activity was elaborated by Kieran (1996, 2007). Kieran identifies three types of activities in school algebra: *generational*, *transformational*, and *global/meta-level* activities, and argues that each type has special affordances to meaning construction. The *generational activity* involves the forming of the objects of algebra (e.g., algebraic expressions or formulas) including objects expressing generality arising from geometric patterns or numerical sequences. The *transformational activity* includes various types of algebraic manipulations. Transformational activity can involve meaning construction for properties and axioms on which the manipulations rely. A related point is highlighted by Hoch and Dreyfus (2006), who proposed the notion of *structure sense*, which is related to algebraic manipulations and aspects of *symbol sense* (Arcavi, 2005) in relation to *friendliness* with symbols as tools, an ability to switch between attachment and detachment of meaning, and an examination of the meaning of symbols. Finally, Kieran (2007) argues that meaning construction is associated with *global/meta-level mathematical activities* (e.g., problem solving, working with generalizable patterns) in a sense that "these activities provide the context, sense of purpose, and motivation for engaging in the previously described generational and transformation activities" (p. 714). It is essential for the forthcoming analysis that when the learners are engaged in a global/meta-level activity, they can carry it out in a variety of ways, and the decision to use the algebraic apparatus arises as learners' choice.

Treatment of sense making as an inseparable part of mathematical thinking makes the MGA model of creating mathematical abstractions (Mason, 1989) particularly important for our study. The main operational categories of the model are Manipulating, Getting-a-sense-of, Articulating (hence MGA). The MGA model elaborates on the processes of creating abstraction as a helix, in which each cycle includes its own, local, sense-making act. Briefly, the model presumes that manipulating familiar mathematical objects (M) leads to the formation of a sense of generality or regularity based on properties of these objects (G), and then to the articulation of that general property or regularity (A), which in turn forms new objects for further manipulations. Mason (1989) suggested that the driving force behind the process of creating abstractions is the gap between expected and actual results of manipulations.

To summarize, in our study we adapt NCTM's (2009) perspective on sense making, and elaborate on it in an algebraic context. Our theoretical framework is built upon the idea of algebra as an activity (Kieran, 1996, 2007) and on analytical apparatus of Mason's (1989) model of mathematical thinking known as Manipulating – Getting-a-sense-of – Articulating (MGA).

## Method

### Learning environment, participants and the mathematical context

The Open-ended Mathematical Problems project, in the context of which the case of Ron and Arik took place, is being conducted, since 2010, in 9<sup>th</sup> grade classes for mathematically promising students. The learning goal of the project is to create for students a long-term opportunity for developing algebraic reasoning in the context of numerical sequences. It is of note that 9<sup>th</sup> graders in Israel, as a rule, do not possess any systematic knowledge of sequences; this topic is taught in the 10<sup>th</sup> grade.

The project is designed in accordance with the principles of the Project-Based Learning (PBL) instructional approach (e.g., Blumenfeld et al., 1991). Specifically, the organizational framework of the project is as follows. At the beginning of a yearly cycle of the project, a class is exposed to 8-10 challenging problems. The students choose one problem and work on it in teams of two or three. They work on the problem at home and during their enrichment classes. Weekly 20-minute meetings of each team with the instructor (the first author) take place during the enrichment classes. When the initial problem is solved, students are encouraged to pose and solve follow-up problems. At the end of the project, all teams present their results to their peers. Then 4-6 teams, chosen by their classmates, present their work at a workshop at the Technion – Israel Institute of Technology, attended by academic audience (for more details see Palatnik, 2016).

Ron and Arik chose to pursue the Pizza Problem (Figure 1) which is a variation of the problem of partitioning the plane by  $n$  lines (e.g., Pólya, 1954).

Every straight cut divides a pizza into two separate pieces. What is the largest number of pieces that can be obtained by  $n$  straight cuts?

A. Solve for  $n = 1, 2, 3, 4, 5, 6$ .

B. Find a recursive formula for the  $n^{\text{th}}$  term of the sequence.

C. Find a position formula for the  $n^{\text{th}}$  term of the sequence.

**Figure 1: The Pizza Problem**

Using Kieran's (2007) terminology, we expected the PBL environment and the Pizza Problem in particular to afford students to be engaged with generational and transformational activities in the context of a global/meta-level activity. In this way, the students were provided with opportunities for developing algebraic sense-making and we – with an opportunity to study their sense-making effort.

### Data sources and analysis

We audiotaped and transcribed protocols of the weekly meetings with Ron and Arik (eight 20-minute meetings), collected written reports and authentic drafts that the students prepared for and updated during the meetings (more than 40 pages) and interviewed the students by the end of the project. These data were used to create a description of the students' exploration and for dividing it into events.

In accordance with the presented above methodological principles for exploring sense making, we discerned the activities the students chose to be engaged in: proving, generalizing, pattern-seeking,

and question-generating. We also applied the MGA model to trace mathematical objects manipulated by the students in a sequence of activities potentially contributing to sense-making.

### Findings: Ron and Arik make sense of the obtained formula

We present here four main events that occurred during students' sense-making pursuit.

#### Event 1: Choosing new goals

The following conversation took place just after the students presented their solution of the Pizza Problem to the instructor:

Instructor: Now you have a lot of work to do, and this is great. First of all, you see that the formula works. Now we have to think why it works, and try proving that it works.

Ron (to Arik): Write it down. "Why it works, and prove that it works" (laughs), it is interesting!

Ron accepted instructor's suggestion. In his words: "When we have a formula, but don't know its meaning, it is not interesting. If we knew how the formula is constructed, we would know it 100%. We got it by chance. So we do not know what it means." In addition, both students proposed to explore a more general problem, that of plane partitioning (see Figure 2).

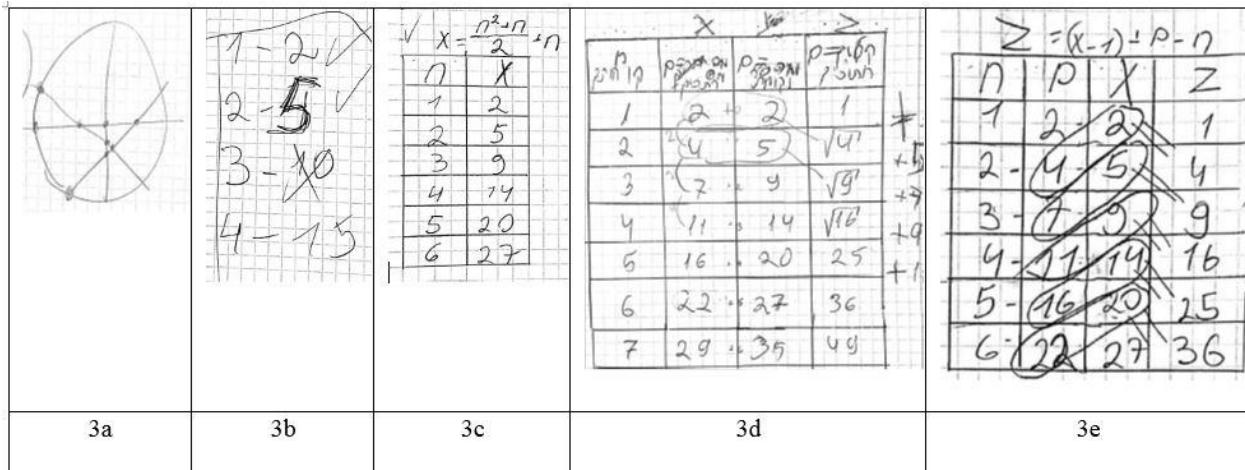

**Figure 2: Division of the plane: there are three closed (hatched) and eight open pieces**

The students also suggested additional objects to explore: the points of intersection of the cutting lines with and within a circle representing a pizza and the number of segments on the cutting lines.

#### Event 2: Simultaneous exploration of several sequences and first manipulation with a formula

Having chosen the above goals, the students started making sketches and counting: segments within the circle, closed and open parts of the plane and points of intersection of the cutting lines, for different numbers of lines (see Figure 3a-c). As a by-product, the students noticed that the sum of the first  $n$  odd numbers also equals  $n^2$ . They also began exploring the connections between different sequences (see Figure 3d-3e). In particular, Ron noticed that the differences between the corresponding terms of the sequences form a sequence 0, 1, 2, 3... (see columns X,Y at Figure 3d).

**Figure 3: The strategy employed in Events 1 and 2**

To obtain an explicit formula for the sequence 2, 5, 9, 14 ... (the numbers of intersections of the cutting lines with and within the circle), Ron *adjusted* the formula  $P_n = \frac{n^2 + n}{2} + 1$  into the formula  $X = \frac{n^2 + n}{2} + n$  (Figure 3c) in the following way: “I thought it would be like the previous formula, but it did not fit. So I got rid of 1 and added  $n$  [to the right side of the formula], and it was right.”

### Event 3: Producing an explanation of why the target formulas worked

The wish to understand why the formula returns the maximum number of pieces was a repeated theme in weekly meetings with the instructor. The students eventually answered this query in the following way. After exploring of new drawings Ron and Arik realized that the maximal number of pieces is obtained when a new cutting line crosses *all* the previous lines in new points. As a result, the students concluded that a new cutting line added  $n$  new intersection points to the existing configuration of lines. For the students, it was an explanation of why the formula  $X = \frac{n^2 + n}{2} + n$  returned the *maximum* number of the intersection points. They further asserted that this idea also explained, for them, why the target formula  $P_n = \frac{n^2 + n}{2} + 1$  returns the *maximum* number of pieces.

### Event 4: “Proving” the target formula

As mentioned, the need to prove the correctness of the formula for the Pizza Problem was an additional driving force for the students. First, Ron suggested: “We thought of a way to prove it [the position formula]...[in order to do so, we wanted] to connect all the formulas we had, every table we’ve made... may be it will give us the formula, then we will know that it is a true formula indeed. Then we’d have a proof”. Ron and Arik built upon the following inference: for any number of cuts, the sum of the number of open and closed pieces (see Figure 2) equals the overall number of pieces into which a plane is divided. They explored the sequences for open and closed pieces. The number of open pieces for  $n$  cuts,  $2n$ , was easy for them to find and explain: adding a new cutting line adds exactly two open pieces to the drawing. For the closed pieces the students empirically (i.e., by counting on the drawings) obtained a sequence 0, 0, 1, 3, 6 for 1, 2, 3, 4 and 5 cuts, respectively. They perceived it as “quite close” to the target sequence (2, 4, 7, 11, 16...) and began manipulating

the target formula ( $P_n = \frac{n^2 + n}{2} + 1$ ) in a way similar to *adjustment* in Event 2. Eventually Ron and Arik obtained the correct expression  $\frac{(n-2)^2 + n}{2} - 1$ . The last piece of the puzzle came when Ron and Arik and their classmate with whom they consulted devised and realized the following plan. Since the formula  $P_n = \frac{n^2 + n}{2} + 1$  represents the total numbers of pieces and since Ron and Arik have obtained the formulas for the numbers of closed and open pieces, the three formulas should match. After several unsuccessful attempts, Ron and Arik implemented this idea and algebraically connected the three formulas. In their final presentation, they showed a slide with the following transformations:

$$\frac{(n-2)^2 + n}{2} - 1 + 2n = \frac{n^2 - 4n + 4 + n - 2 + 4n}{2} = \frac{n^2 + n + 2}{2}; \quad \frac{n \cdot (n+1)}{2} + 1 = \frac{n^2 + n + 2}{2}. \quad \text{This and}$$

validation of all three formulas by means of Excel tables were presented as “the proof” of the target formula, and the formula itself was treated as “making sense” by the students.

## Discussion

The four-weeks-long exploration of two 9<sup>th</sup> grade students working on a particular project has been presented. The answer to the first research question (about events and algebraic activities in which the students were engaged while attempting to make sense of the previously obtained position formula) straightforwardly follows from the above exposition. Briefly, the students were engaged in generational and transformational activities in the context of the global/meta-level activities of explaining to themselves why the formula worked and of proving the formula. It is of note that Ron and Arik’s persistence to make sense of their formula is unusual. We suggest two circumstances contributing to the emergence of the students’ self-imposed sense-making goal. First, the students’ activities were organized and driven by their interest to a particular mathematical phenomenon and not merely to generation of some patterns (cf. Hewitt, 1992, for train spotters metaphor). Second circumstance is the organizational setting of the project, which was in accordance with project-based learning instructional approach (Blumenfeld et al., 1991). In such an environment the students had a chance to get used to the long-term, open-ended explorations, to the high level of expectations and to having room and time to spend with a problem.

Our second research question concerned the processes involved in student sense making. To answer the query “why the formula works” the students examined *the geometric mechanism* behind the formula. In the course of generational activity the students experimented with concrete drawings (i.e., drawings with 4-6 cutting lines), which apparently served as a visual tool to reveal a generic process that occurs when a line is added to a system of  $n$  existing lines. Accordingly, the multi-stage process of abstracting, at each stage of which an MGA cycle occurred, seems to be the central process underlying the why-part of the students’ sense-making effort.

The query “how to prove the formula” turned to be the thorniest part of the project. The students addressed this query when they succeeded to show how the target formula came to *cohere* with two geometrically related formulas. These formulas were obtained by means of exploration of the connections between the sequences chosen by students. The connections were found in the process that featured counting on the drawings, pattern-sniffing in the tables and manipulating the previously obtained formulas by adjusting them. Eventually, the target formula was inserted in a cloud of related formulas, which did not exist when the students began the sense-making pursuit.

Thus, the process of generating a cloud of formulas and checking it for coherence seems to be an important process in the proving part of the students' sense-making effort (cf. Rohano, Filloy & Puig, 2014, for sense making by connection of a new mathematical text to a system of texts). It is of note that the coherence was achieved not only among various objects, but also by means of a coherent exploration strategy.

As argued, Ron and Arik constructed meaning of the target formula in a sense-making process consisting of sequence of generational and transformational algebraic activities in the overarching context of global, meta-level activity, long-term problem solving. In this sense-making process, the students: (1) formulated and justified claims; (2) made generalizations, (3) found the mechanisms behind the algebraic objects (i.e., answered why-questions); and (4) established coherence among the explored objects. We now take the liberty of formulating this summary as a proposal for a four-component decomposition of sense making (see Figure 4).

**Figure 4: Four aspects of an algebraic sense making through algebraic activities**

The aspects of *generalizing*, *justifying* and *search for mechanism* in sense making are in line with the main attributes of symbol sense (Arcavi, 2005) as well as findings about the role of generalizing and justifying in meaning construction (e.g., Lannin, 2005; Radford, 2010). However, *establishing coherence* has not yet been considered as part of sense making.

The four-component decomposition elaborates NCTM's (2009) definition of sense making in the following way. First, it presents sense making as a conjunction of processes. Second, it highlights the potential of algebraic activities to provide students with means to make sense of algebraic objects.

<sup>1</sup>Aristotle University of Thessaloniki, Greece; [ypapadop@eled.auth.gr](mailto:ypapadop@eled.auth.gr)

<sup>2</sup>Aristotle University of Thessaloniki, Greece; [nafspats@eled.auth.gr](mailto:nafspats@eled.auth.gr)

*In this paper, the contribution of the use of the “Father Woodland” learning environment in Grade-3 students’ algebraic thinking is examined. Four types of thinking were identified indicating a progressive movement towards the use of symbolic language that seems to have a rather developmental character. In their solutions the students induced rules for solving equations that will later be introduced formally to them.*

*Keywords: Early algebraic thinking, puzzle-like environments.*

## **Introduction**

Given the central position of algebra in the secondary curriculum which led to a separation between arithmetic and algebra with the first being the main focus of elementary mathematics curriculum, mathematics educators try to cope with the challenge of managing the transition from arithmetic to symbolic algebra. Numerous researchers admit that this separation deprives children of powerful schemes of thinking in the early grades and makes it more difficult to learn algebra in the later years (e.g., Kieran, 2007). One way to address this issue might be to study the impact of certain learning environments in the students’ development of algebraic thinking. Papadopoulos, Kindini and Tsakalaki (2016) working with a mobile puzzle environment found that sixth graders exhibit a progressive movement towards algebraic thinking. In this context, we try to explore the potential contribution of another specific learning environment called ‘Father Woodland’ in young students’ algebraic thinking that would allow us to identify certain steps in this movement from arithmetic to algebra. This is based on two of the algebra goals specified by NCTM (2000) standards, i.e., (i) represent and analyze mathematical situations and structures using algebraic symbols, and (ii) use mathematical models to represent and understand quantitative relationships. Therefore, we try to examine whether this environment facilitates the achievement of these goals through the identification of the types of thinking that the students followed in order to cope with the given tasks.

## **Early algebraic thinking and ‘Father Woodland’ environment.**

Cai and Knuth (2011) do not limit algebraic thinking in earlier grades to simply mastering arithmetic and computational fluency but it goes deeper in identifying the underlying structure of mathematics which includes the development of particular ways of thinking, analysis of relationships between quantities, noticing structure, generalization, problem solving, justifying, proving and predicting. Cai et al. (2005), in a cross-cultural comparative study talk about multiple representations (pictures, diagrams, tables, graphs, and equations) that are used to represent functional relationships between two quantities and more specifically about ‘pictorial equations’ used to represent quantitative relationships providing thus a means for developing students’ algebraic ideas. This raises the necessity to make the distinction between the external and internal representations in the sense of considering at a minimum configurations of symbols or objects external to the individual learner or

problem solver (i.e., concrete materials, pictures/diagrams, spoken words, written symbols) that can be described mathematically and configurations internal to the individual (i.e., mental models and cognitive representations of the mathematical ideas underlying the external representations) respectively (Goldin, 2002). Such internal representations are inferred from the way the students express their aspects of the process of mathematical thinking in their written responses. It seems that certain learning environments can be in favor of introducing young learners to these aspects of algebraic thinking (Papadopoulos et al., 2016). In the current study a specific learning environment has been chosen. It is called ‘Father Woodland’ and is about a Czech fairy-tale figure owning a farm who organizes tug-of-war games among the animals living in the farm (Hejný, Jirotková, & Kratochvílová, 2006). The weakest animal is the mouse. Two mice are as strong as a cat, a cat and a mouse equal a goose and a goose and a mouse equal a dog (Fig. 1). The strength of each animal is represented by a picture and an icon (symbol) and the students are asked mainly to decide between two groups the stronger one or to add some animals to the weaker group in order to create two equivalent groups, or to reveal the identity of hidden animals so as to obtain equity.

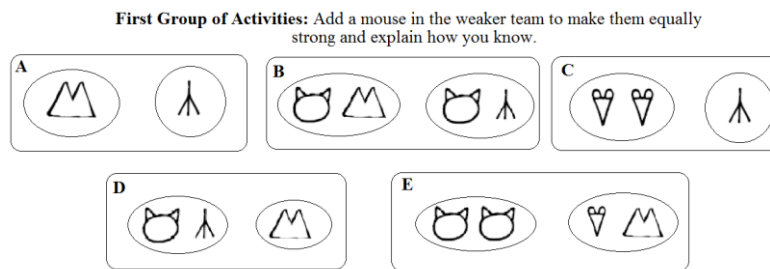

**Figure 1: Equivalences in the Father Woodland environment**

It is a rich environment. Hejny and his colleagues use it in a series of textbooks they produced. The relevant tasks within these textbooks are connected with the development -among others- of an early number sense, pre-concept of divisibility, the lowest common multiple and greatest common divisor as well as the solving of equations. Hejný, et al. (2006) used this environment with Grade 1-3 students focusing on how the environment facilitated the identification and acceptance of the association between animals and quantities. Marchini and Back (2010), used also a modified version of the environment to fit in the Italian schools and worked with Grade-1 students focusing on how the variety of “ways for representing the same mathematical concept together with *treatment* inside a register and *conversion* between registers facilitate pupils’ understanding and the construction of concepts” (p. 55). In this study we focus on the use of this environment as a way to smooth the transition from arithmetic to algebra (in the sense of using pictorial equations as a means or developing algebraic ideas, see Cai et al., 2005) by considering the various types of students’ thinking that would show a progressive movement towards algebraic thinking.

## Design of the study

Seventy 3<sup>rd</sup> graders (8-9 years old) participated in the study. They were the total population of three classes from two primary schools and they represent a sample of an ordinary Greek primary school. They had no previous experience working with this kind of environments and they had not been taught any of the basic concepts of algebra such as equations or variables. When the students were introduced to the ‘Father Woodland’ environment, each tug-of-war game was presented using both the pictorial and symbolic representations of the animals. The whole study (part of a broader one) lasted five weeks. The students were initially introduced to ‘Father Woodland’ and then on a regular basis they were given tasks to solve individually. The whole project took part in parallel to the normal

teaching and was not integrated in the content of their math lessons. This paper focuses on the first 10 tasks due to the limited number of pages. There are 3 collections of tasks. In the first, there were two groups of animals in each task and the students were asked to add a mouse to the weaker group in order to make both groups equivalent (Fig. 2). This demands comparison and relational thinking connected to the notion of equality as an equivalence. In the second, the tug-of-war game took place but one (or some) of the animals wore a mask. The students were invited to find the animal(s) behind the mask (Fig. 3, left and middle). The aim was to exploit relational thinking in the form of using alternative ways for representing the unknown quantity. Finally, in the third, the students were asked to create two equally strong teams using any combination of the farm animals (Fig. 3, right). The aim was to see whether the students exploit the experience gained before and how intuitive mathematical ideas are embedded in their creations. For each task, the students were asked to explain their answer in a separate textbox. During the study, no feedback was given to the students about their answers. The students' worksheets constituted the data for this study. These data were examined in order to identify evidence of early algebraic thinking and possible formal mathematical concepts, which are informally used in the students' answers. In the context of qualitative content analysis, inductive category development was used to organize the categories.

**Figure 2: The first group of activities**

**Figure 3: The second (left, middle) and the third (right) group of activities**

## Results and discussion

After the data examination, the answers were categorized in four types. The criteria for this categorization were the ways students chose to express the underlying structure in each task (i.e., using pictures, words or symbols), the relationships among the given quantities (i.e., using the given or new (invented) relationships), and the mathematical information contained within the pictorial representation (i.e., identifying a basic unit, substituting animals with their equivalents, adding/subtracting the same quantity in both sides, etc.). The four types are: (i) using pictorial language, (ii) using words to express relationships, (iii) combining words and symbolic representations and (iv) using 'symbolic' language to express relationships. Obviously not all the

students applied all the types. This is why it was decided to choose a proper sample of students to show the diversity of the approaches taken.

### Type 1 – Using pictorial language

This type refers to the students who preferred drawing pictures in detail rather than using a symbolic representation (Task-E, Fig. 4). The answer is correct. The missing mouse must join the group on the left to get two equal teams but the reasoning is weak since it is limited to merely transfer the ‘abstract’ information into a more ‘realistic’ version and it lacks an explicit explanation of the ‘underlying’ thought. It seems that the student fails to shift the focus to the existing relationships between the values of the participating animals.

Figure 4: Use of drawings

### Type 2 – Using words to express relationships

This type was used by the majority of the students and it proved more convenient for most of them to express their solution of the problem. Actually, in this type, the students made a step forward by trying to use words for expressing relationships among the quantities as it can be seen in the next two examples. This choice in many of the cases was described by the students in detail revealing thus their line of thought. In Task-J, one student created two equivalent groups by placing 5 dogs on the left and 20 mice on the right (Fig. 5). His explanation was: “*I thought that 5 dogs are as strong as 5 geese and 5 mice. But, 5 geese = 5 mice and 5 cats and 5 cats are as strong as 10 mice. So 20 mice*”.

Figure 5: Use of mouse as the basic unit

The student exploited all the default information given by the pictures in Figure 1, e.g.,  $1d(og)=1g(oose)+1m(ouse)$ ,  $1g(oose)=1c(at)+1m(ouse)$ , and  $1c(at)=2m(ice)$ . Then, the whole process can be presented on a more formal way as  $1d=1g+1m \Rightarrow 5d=5(g+m)$  [*multiply both parts by the same number*]  $\Rightarrow 5d=5g+5m$  [*distributive property*]  $\Rightarrow 5d=5(c+m)+5m$  [*substitute with equivalent*]  $\Rightarrow 5d=5c+5m+5m \Rightarrow 5d=5 \times 2m$  [*substitute with equivalent*]  $+10m \Rightarrow 5d=10m+10m \Rightarrow 5d=20m$ . It must be said that this is not explicitly outlined by the child. But this enables us to identify in the student’s explanation the seeds of the mathematical reasoning described above. In the same way we will try to see the possible formal way of expressing the students’ answers in the remaining part of the paper. Actually, we make inferences about students’ internal representations on the basis of their production of external representations (Goldin & Shteingold, 2001).

The second example concerns Task-H which asked the students to identify the animal hidden behind the mask. The student's answer was (Fig. 6, left): "There is a cat hiding behind the mask. Because, a mouse and a dog are as strong as a cat and two mice. I figured it out because a mouse and a dog are as strong as 5 mice so behind the mask is a cat since 2 cats and 1 mouse are as strong as 5 mice too".

The student's starting point was the right part of the equation and she chose the mouse as the building block to replace all the involved animals. It is necessary to mention here that the students did not restrict themselves on the given relationships that were given during the first session (Fig. 1). They were able, during the next sessions, to identify new relationships based on the given ones. This student made use of one of these invented relationships by claiming implicitly that a dog has the same strength with 4 mice. This claim results to the total amount of 5 mice in the right part. Given that a cat has the same strength with 2 mice, it means that there are 3 mice in the left part of the equation plus the hidden animal. Two mice are needed to obtain equality; therefore, a cat must be placed behind the mask.

**Figure 6: Use of words (left) and combination of symbols and words (right) to explain relationships**

If we translate the reasoning of the student into its formal version, considering  $x$  the unknown, we obtain the following series of equations.  $x + c + m = m + d \xrightarrow{d=4m} x + c + m = 5m$  [substitute with equivalent]  $\xrightarrow{c=2m} x + 3m = 5m$  [substitute with equivalent]  $\Rightarrow x = 2m$  [subtract the same amount from both sides]  $\xrightarrow{c=2m} x = c$  [substitute with equivalent]

The strategy that led to successful solution here was: (i) choose the basic unit (e.g., the mouse), (ii) translate the picture to equation, (iii) substitute the dog by its equivalent number of mice and execute the operation, (iv) substitute the cat by its equivalent number of mice and execute the operation, (iv) find the unknown ( $x$ ).

### Type 3 – Combining words and symbolic language

This type starts -as a first step towards symbolic language- to combine words and symbols to show relationships between the participating animals. This is one answer for Task-I: "I figured it out because 1 cat becomes (equals) 2 mice plus 2 mice = 4 mice. So there is 1 mouse hiding behind the mask".

The student in the first half of her answer used the word 'becomes' to denote the equality between cat and mice (Fig. 6, right). But, in the second half she used the sign of '=' to denote again the relationship between mice and geese (left part) and dogs (right part). Firstly, she substituted the cat ( $c$ ) with 2 mice ( $m$ ). Now, the left part consists of two identical sub-groups (a goose and a mouse per subgroup) which if substituted by their equivalence in terms of dogs reveal the identity of the unknown. So, starting from the left part:  $2g + c = x + d \xrightarrow{c=2m} 2g + 2m = x + d$  [substitute with equivalent]  $\Rightarrow 2(g + m) = x + d$  [distributive property]  $\xrightarrow{g+m=d} 2d =$

$x + d[\text{substitute with equivalent}] \Rightarrow x = d [\text{subtract the same quantity}]$ . The knowledge that 2 mice plus 2 geese is the same as 2 dogs -which is based on the given relationship that a mouse plus a goose is the same as a dog- reveals an implicit understanding of the above mentioned distributive property.

#### Type 4 – Using symbolic language to express relationships

The last type used by the students abandons the use of words and the reasoning is mainly symbolic. The first example is an answer from Task-F dealing with the animal behind the mask. The student started with the left group, using a symbolic expression to show its substitution by a dog (

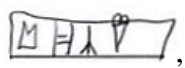

). Then, based on this expression she wrote another one to show the solution (  , see Fig.7 left). The first claim of the student seems arbitrary but if seen carefully it makes use of known relationships in order to obtain new ones. The left group represents the sentence  $m+m+c$ . Given that  $m+c=g$  (oose) the sentence becomes  $m+g$  which, according to the given relationships, equals with a dog. Then, it is obvious that what is needed in the right part of the equation is a mouse.

Figure 7: Usage of symbolic representations (left and right)

The second example shows a solution for Task-C. This solution is considered more elaborated since the student made use of the sign of the required operation to show the equivalence. This is indicative of understanding both the operation that takes place and the correct use of the sign of this operation. The missing animal is the mouse that must join the left group to get equality (Fig. 7, right). The sum of the strength of the three mice equals the strength of the goose. Again, this is a relation different than the given ones and it is important that so young students exhibit this ability, to use and combine given situations in order to get new ones. So, it is interesting to follow the thought of the student. Two mice equal with a cat. Then, a cat and a mouse have the same strength with a goose. Consequently (transitivity) three mice are equivalent with a goose. Expressing relationships using this symbolic language to solve a problem constitutes an important step towards the development of algebraic thinking. Besides, all the answers show an explicit focus of the students to the underlying structure of each equivalence in order to reach a solution.

It is interesting to examine now the findings of this study in the light of a previous one. Papadopoulos et al. (2016) in their study based on the use of mobile puzzles with 6<sup>th</sup> graders, distinguished mainly four types of students' thinking (translating the picture to equality expressions, using words to show the relationship, using symbolic language to show the relationship, and combination of more than one of the previous types). This means that there is a match between the types of thinking in these two studies and this strengthens the possible positive contribution of puzzle-like learning

environments to the development of young students' algebraic thinking. The feeling from the first study (no numerical data available) was that the order of these types is rather developmental in the sense that types 3 and 4 are more advanced (and thus less frequent), and are met at the end of the project (an indication that they are connected with the accumulated experience). One could attribute this finding to the teachers' appreciation of the symbolic answers instead of textual ones. However, this is not the case, since the teachers were not involved in the project and in the meanwhile the students did not receive any feedback about their answers.

	Type-1	Type-2	Type-3	Type-4
Tasks A-E	5 (1.6%)	253 (83%)	14 (4.6%)	33 (10.8%)
Tasks F-I	8 (3.74%)	157 (73.36%)	24 (11.22%)	25 (11.68%)
Task J	2 (2.94%)	56 (82.35%)	8 (11.77%)	2 (2.94%)

**Table 1: Frequency of Types 1-4**

In this study an effort was made to get arithmetical evidence that would shed light on this issue. Table-1 confirms that Types 3 and 4 are indeed the less frequent ones. The low frequency of Type-1 was expected since the pictorial language was already included in the statement of the tasks.

Table-2 presents the distribution of the last two types across the range of the tasks. As it can be seen to a great extent the number of instance for each Type is increased as we move towards the last tasks indicating that these types are connected with the accumulated experience.

	Task-A	Task-B	Task-C	Task-D	Task-E	Task-F	Task-G	Task-H
Type-3	3	2	4	3	3	7	7	7
Type-4	5	6	3	8	10	8	8	8

**Table 2: Distribution of Types 3-4 across tasks**

## Conclusions

The findings of our research indicate that the 'Father Woodland' environment might contribute to the development of students' algebraic thinking. The four types of thinking mirror the rules induced by the students in order to solve the posed problems. Starting from certain external representations of equality sentences the students made an attempt to express their internal representations through the shift from pictorial to symbolic language. Obviously, this is not all that matters with the development of algebraic thinking with young children. However, it cannot be considered trivial. The students had to add or remove the same animal (quantity) from both sides, to substitute certain animals with their equivalence, isolate the unknown animal (variable) trying to maintain the same strength between both groups of animals applying at the same time the distributive law or transitivity. Despite that lack of explicit knowledge about operations and relations hinders a good approach to algebra (Gerhard, 2013), it seemed that there were instances of an implicit knowledge of certain rules for solving equations which will be later introduced formally to the students. However, it still remains to answer questions like: In what way the transition from the animal symbols back to the arithmetical or algebraic equations will be possible? Additionally, the findings support the developmental character of these types of thinking when the students use puzzle-like learning environments aiming to support

algebraic thinking. However, this does not mean that some students did not occasionally move backwards to previous types of thinking. This is in itself a significant finding we aim to explore further since the relatively small number of participants does not allow to generalize our findings.

*This paper provides insight in the process of developing a comprehensive and concise summary of the most prominent aspects of proficiency in elementary algebra at the end of secondary grade. It will serve as a theoretical frame of reference for devising or validating instruments for diagnosing the mastery of elementary algebra at the transit from school to university. A first draft had been based on literature, which then was presented to experts for further evaluation. The model now comprises ten aspects of proficiency which are allocated into a table of two dimensions, one referring to elements of algebraic language, the other referring to the cognitive actions performed on them.*

**Keywords:** Elementary algebra, basic skills, secondary school mathematics, STEM Education.

## Introduction

For being successful in subjects from science, technology, engineering or mathematics at high school or university (STEM), a good mastery of formal algebra is indispensable. But what is a good mastery of algebra, and how does it show? To provide a theoretical base for devising an instrument for diagnosis, we have been working on a comprehensive yet concise overview of the important aspects of proficiency in elementary algebra as it has been covered by relevant research. For this, the model is meant to be summative, i.e. it contains aspects of proficiency that are expected by the end of secondary school. And, when referring to elementary algebra we mean symbolic algebra as it appears at the end of secondary school. A first draft of the overview was based on relevant literature from national and international publications, which was then presented to experts for validation. In the following we will first give a short report on the main outcomes of the literature review of the first stage, after that we will present the main outcomes of the expert survey. This paper's main part then contains a detailed description of the present state of our model.

## Model development

### First draft based on literature

The aim of this first stage of model development was to give a structured compilation of the important aspects of proficiency in elementary formal algebra as it is present in research publications of nearly 40 years, starting with Küchemann's paper on children's understanding of variables (1978). A loose series of unconnected aspects would not be of much help where a concise summary is needed. So we decided to build categories from the various aspects found in literature, based on two a-priori dimensions that served as a first theoretical frame for categorization: It starts with listing all relevant mathematical objects of the domain in question, which here are variables and expressions as elements of the algebraic language. The second dimension focusses on the mental and real activities associated with these objects that all represent some stage of "making

sense of algebra” (Arcavi, 1994). Arcavi’s approach to describing what is meant by understanding algebra seemed a suitable frame, or better: attitude for collecting and arranging research findings from the past years. “Symbol sense” is, in his own words, “a complex and multifaceted 'feel' for symbols” (Arcavi, 1994, p.31) which invites to searching for aspects of quickly grasping a situation where symbolic algebra is involved. Hence the second of the two dimensions of our model comprises a range of various activities that in some way “make sense” of variables and expressions, ranging from stating correct manipulation rules and identifying expression to which these rules can be applied to modeling realistic situations by means of algebra.

		making sense of...			
...elements of algebra		reciting	manipulating	structuring	innermath. interpreting
variable	no meaningful aspects			(4) interpret variables	
parameter				(6) identify parameters (among variables)	
term	(1) formulate rules for manipulating expressions	(2) manipulate expression by applying given rules	(3) identify expression type	(7) formulate equation	
equation			(4) immediately identify equivalence	(8) switch between representations	(9) switch between expression and realistic situation
				(10) interpret equation signs	

**Table 1: Literature based draft of important aspects of proficiency in elementary algebra**

This first draft resulted in formulating ten aspects of proficiency, arranged in a tableau along the two dimensions (table 1) introduced above. Here, these ten aspects were defined as single elementary “blocks” of which more complex activities could be constructed by combination. For example, combining three abilities which we then called “(1) formulate rules for manipulating expressions”, “(2) identify expression type” and “(3) manipulate expression by applying rules” would sum up to what is generally meant by the ability to manipulate algebraic expressions correctly. While this approach seemed sensible for a detailed diagnosis, it proved to be unhandy in discussions even between experts as the following sections shows.

### Expert survey

For validating the results of the literature review an expert survey was conducted. By choosing the experts we focused on professors and seminar teachers of mathematics education in German speaking areas who published primarily about teaching and learning elementary algebra within recent years. Twenty-four colleagues were contacted via e-mail, one of them declined but recommended a colleague as a substitute who, after checking our requirements, was contacted too. All experts were asked to complete an online-questionnaire which was implemented in the free online-tool SoSci Survey ([www.soscisurvey.de](http://www.soscisurvey.de)). The experts were expected to comment on two fields: firstly, on the contents and the structure of the model, while each of the ten aspects was illustrated by one exemplary task, and, secondly, on a battery of additional 48 items that was devised to operationalize the ten aspects. Because giving feedback on all 48 items would have taken too much time we created 6 different versions of the online-questionnaire and reduced the extent of each version by an overlapping multi-matrix-design (cf. Zendler, Vogel & Spannagel, 2013). All in

all, an expert had to view 22 or 23 tasks. Since the response rate was 50%, each task was processed and judged by an average of about 6 randomly assigned experts.

In the first section of the survey the experts were presented an interactive version of Table 1 where explanations of the entries were shown together with exemplary tasks in a pop-up window. Here, they were asked to familiarize themselves with the table entries and explanations while making notes on which aspects they thought needed to be reworked or were unessential for basic mastery of algebra, or which aspects were missing in their view. There also was place for free comments on the model as a whole. In the second section of the survey the experts were asked to assign each of the 22 or 23 task assigned to them to three of the ten aspects of the model and comment on their decision. Here, a smaller version of the interactive table was present with each assignment question. By combining assignment questions and open question types the question format can be considered as being half-open. This type of questions is suitable for experts who are considered to have a differentiated self-awareness, expressiveness, motivation and fidelity (cf. Gerl & Pehl, 1983). The open question format is to be seen as the qualitative part of the online-questionnaire which complies with a written survey in sense of an expert interview (Bogner, Littig, & Menz, 2002). Qualitative methods are especially suitable for purposes of theory-based exploration (cf. Bortz & Döring, 2006). In the following we focus on the results of this qualitative part of the survey.

### **Data analysis and results of the expert survey**

The aim of the expert survey was to validate the first, literature based draft of the model. For data-reduction by clustering analogous comments we followed an open-ended approach to qualitative evaluation as provided by Grounded Theory (Corbin & Strauss, 1990) along these four steps: (1st) All comments from the open question parts of the survey were rephrased by the authors into single conclusive statements about the model or a task. (2nd) All these statements were pasted into the free digital mindmap programm xmind ([www.xmind.com](http://www.xmind.com)) where, for each expert, they were arranged in the order as they appeared in the survey. (3rd) Categorisation took place first with the aim of clustering comments of analogous content – now renamed as “contributions to model revision” and then, (4th), with the aim of categorizing these contributions according to how each of them would contribute to modifying the model or the test battery.

Since many of the statements – though sometimes commenting on single items of the battery – were of a general kind, the process of categorizing eventually detached from the original structure of the questionnaire, so that the following four categories emerged: (a) contributions to clarifying the theoretical frame of the model, (b) contributions to restructuring the model, (c) contributions to reformulating definitions or exemplary tasks of single aspects of the model, (d) contributions to reformulating or deleting a task from the test battery. Among the contributions assigned to category (a), some experts asked how the various aspects of “making sense of algebra” relate to existing models of mathematical understanding. Other experts expressed their uncertainty of how our model relates functions. And other experts were missing activities of preformal algebra. Among the contributions assigned to category (b), one expert pointed out that the activities of transforming or interpreting algebraic expression would imply the activity to identify the structure of an expression so that “structuring” needs to be given a more prominent role in our model’s layout. Some experts mentioned “substituting” as one of the central activities in doing algebra. Additionally, from their task assignments it became apparent, that many experts were misinterpreting the elementary activity

“to transform with given rules” from our first draft as meaning “being able to manipulate expressions correctly” regardless whether a rule is given or not. This contribution also was assigned to category (c), as it would not only lead to introducing a new aspect but to reformulating existing elementary activities too. There were also further contributions to reformulating definitions or exemplary tasks, and to reformulating or deleting tasks from the test battery.

## The revised model

For model revision, the authors discussed each contribution as to whether to incorporate it and how. Among contributions that were accepted was that the activity of structuring needed a more prominent position within the model. Here we followed recent findings of Rüede (2015) as to which structuring can be understood as an activity of making sense of an expression by identifying relations between parts. Relations are identified by substitution, i.e. parts of an expression are seen as entities that can be related to each other. Thus the activity of “substituting” was accepted as part of the central activity of structuring. Together with Musgrave's et al. (2015) definition of substitution and Kieran's (1989) distinction between systemic and surface structure it helps to refine activities of recognising the applicability of transformation rules or the operational ordering of an expression. Now, these two activities cover the activity of substituting which, from a cognitive perspective, means to construe parts of an expression as meaningful entities, esp. to replace variables and terms by other variables or terms in writing or in thought.

...elements of algebra	making sense of...	knowing	acting			
			transforming	structuring	interpreting	
variables incl. parameters		no meaningful aspects		(3) to recognize the applicabilty of transfor- mation rules	(4) to recognize the operational ordering	(7) to interpret variables and parameters
	expressions and equations	(1) to specify transformation rules or terminology	(2) to transform following given rules	(5) to compute or to compare		(8) to switch between expressions and inner- mathemati- cal situati- ons
		(6) to transform (efficiently)				(9) to switch between ex- pressions and tables or graphs

**Table 2: A concise summary of the important aspects of proficiency in elementary algebra**

Further amendments were applied to the model so that Table 2 now shows its present state. In the following each table entry is explained in detail.

### Elements of algebra

- Variables including parameters: Variables are signs that represent numbers or quantities. Parameters are variables that vary over sets of values of other variables (Veränderliche vs. Einzelzahl: Malle, 1993, variable vs. metavariable: Drijvers, 2001, values taken by a variable: Bardini et al., 2005). This discrimination arises from the context of the task.

- Expressions and equations: Algebraic expressions are compositions of variables and arithmetic operation signs. When a variable is viewed as representing a range of number values or quantities (variable object: Schoenfeld & Arcavi, 1988; Bereichsaspekt: Malle, 1993) the value of the expression is interpreted as a function of this variable (Malle, 1993; Heid, 1996). Equations are expressions where two terms are compared with regard to their values, symbolized by an equation sign. An equation differs from a computation or transformation of a term in that it is used in a relational sense (notion of equivalence: Kieran, 1981; operational vs. relational view: Baroody & Ginsburg, 1983; Zuweisungs- vs. Vergleichszeichen: Malle, 1993).

### **Making sense of elements of algebra**

- Knowing and acting: a first level of differentiation that differs between declarative knowledge about rules and various forms of “making sense” of algebraic objects. The latter is further differentiated into transformational and generational types of activities following Kieran (2004). Kieran’s third class of “meta-level” type of activities has been omitted as it describes a higher level of mastery that is not considered being a part of basic mastery.
- It seemed appropriate to formulate within the range of Kieran’s (2004) transformational and generational types of activities three central activities: Transforming (to transform an algebraic expression into an equivalent expression of different structure (transformational equivalence: Musgrave et al., 2015; treatment: Duval, 2006)), structuring (to transform or interpret an algebraic expression while maintaining its structure (substitutional equivalence: Musgrave et al., 2015, Rüede 2015)) and interpreting (to describe a non-algebraic situation by formal algebra and vice versa (conversion: Duval, 2006)). Among these, structuring takes on a fundamental role. It describes an activity of recognizing the structure of a present expression or formulating an expression that is structurally equivalent to relations between quantities in a given situation.

### **Ten aspects of proficiency in elementary algebra**

- (1) “To specify transformation rules or terminology” – Important technical terms for expressions and rules for manipulating expressions or equations are identified or specified, e.g. names for classes of terms or equations, or rules for simplifying expressions, binomial rules, rules for solving quadratic equations, etc.
- (2) “To transform by following given rules” – Expressions and equations are transformed into equivalent expressions or equations by applying given rules (manipulation skills: Hoch & Dreyfus, 2006).
- (3) “To recognize applicability of transformation rules” – An expression is identified as a representative of a class of structurally equivalent expressions and transformation rules that are associated with this class. This is done by, mentally or explicitly, substituting variables or terms by terms or variables (systemic structure: Kieran, 1989; structure sense: Hoch & Dreyfus, 2006)
- (4) “To recognize the operational ordering” – The logical ordering of the operations within an expression is recognized. This is done by, mentally or explicitly, substituting terms by variables (surface structure, Kieran, 1989; Rechenschema: Vollrath & Weigand, 2006; Rechenhandlung: Malle, 1993)

- (5) “To compute or to compare” – An expression with an equation sign is interpreted in an operational or a relational sense, as it is appropriate in the context (Malle, 1993; operational vs. relational view: Baroody & Ginsburg, 1983; Knuth et al., 2006).
- (6) “To transform (efficiently)” – Expressions and equations are being transformed into equivalent expressions or equations (2,4), by activating existing knowledge about transformation rules (1) which are identified as applicable to the present problem (3). Also, two expressions or equations are identified as being equivalent „on the spot“ without applying rules explicitly (algebraic expectation, Pierce & Stacey, 2001). A transformation is „efficient“ if, among various rules of transformation that are applicable, one is chosen that allows relatively few steps and few computations (strategic flexibility: Rittle-Johnson & Star, 2009; structural relations of second order: Rüede 2015, cp. Malle 1993).
- (7) “To interpret variables and parameters” – Variable signs are interpreted or used as representations of numbers (Einsetzungs-, Gegenstandsaspekt: Malle, 1993; Küchemann, 1978). Within given contexts, appropriate variables are identified or used as parameters.
- (8) “To switch between expressions and innermathematical situations” – A non-algebraic but innermathematical situation (e.g. dot patterns or geometric configurations) is described by a term or an equation, and vice versa (Bauplan: Vollrath & Weigand, 2006).
- (9) “To switch between expressions and tables or graphs” – An expression or equation is translated to a value table or a graph, and vice versa (McGregor & Stacey, 1995), e.g. when viewed as a function (Duval, 2006; Nitsch, 2015), or for solving an equation (Arcavi, 1994).
- (10) “To switch between expressions and real situations” – An expression or equation is translated to a realistic situation, and vice versa (McGregor & Stacey, 1995; Heid, 1996), e.g. when viewed as a function (Nitsch, 2015). This activity involves a higher gradient of abstraction than activities (7,8,9) that results from the need to replace the concrete mental model of the given real situation by an abstract mental model before formulating an expression (Malle, 1993).

## Summary and outlook

In its present state, the model intends to be a concise summary of aspects of proficiency in elementary algebra, based on relevant literature and a survey of maths educators from the German speaking community. It represents a normative view on what ideal schooling can provide at the end of secondary grade, thus serving as a theoretical base for devising instruments for a summative and differentiated diagnosis of proficiency in elementary algebra at the transition from school to university. The model does not cover all aspects of school needs to consider, but it is restricted to

- symbolic algebra, not generic: at the end of secondary school maths, an individual's proficiency in algebra must have reached a stage of being competent with symbolic representations of indeterminate number values and quantities and relations between them,
- a summative view, not formative: the model is meant to comprise all aspects of proficiency at the end of secondary school maths, not while they are being taught,

- algebra, but not functions: a model about algebraic proficiency cannot cover all aspects of the concept of function, but does cover some which are only present in the form of a functional interpretation of an algebraic expression.

Additionally, based on this frame of reference, a test battery is presently being prepared for large scale application. While the model helps to devise tasks that cover most important aspects of proficiency in elementary algebra, the data raised from applying the battery will be used to generate an empirical cognitive model that adds to the theoretical normative view of the present one.

# Functional thinking and generalisation in third year of primary school

Eder Pinto and María C. Cañadas

University of Granada, Spain

[epinto@correo.ugr.es](mailto:epinto@correo.ugr.es) / [mconsu@ugr.es](mailto:mconsu@ugr.es)

*This paper focuses on functional thinking as an approximation to algebraic thinking in third-year primary-school students. It describes a study with a class group of 24 Spanish pupils displaying functional thinking to solve a contextualised problem, identifying the type of functional relationships distinguished by these students and the ability to generalise observed in some of them. It contains an analysis of the information collected in one questionnaire, which is part of a teaching experiment. The students distinguished two types of functional relationships, correspondence and covariation, predominantly the former. Three students generalised as well.*

*Keywords: Algebraic thinking, generalisation, functional relationship, functional thinking.*

## Introduction

The idea of introducing algebraic notions in the elementary and even in the pre-school curriculum began to gain acceptance in the early nineteen nineties, when the emphasis was on what students were able to learn (Kaput, 2008). That led to the early algebra proposal, which seeks to further and enhance algebraic thinking among the younger pupils through approximations by working on classroom algebra-associated elements intended to help secondary school students perform the tasks expected of them. Generalisation lies at the heart of algebraic thinking: arithmetic operations can be viewed as functions and algebraic symbolism supports such thinking (Blanton, Levi, Crites, & Dougherty, 2011).

Functional thinking is a type of algebraic thinking, which is focussed on functions, regarded as the relationship between two co-varying quantities. The growing research interest in this type of thinking is attributable to its many advantages as an introduction to algebra (Blanton & Kaput, 2011).

Studies on functional thinking address different aspects. Some of the foremost include: (a) functional relationships drawn by students (Cañadas & Morales, 2016), (b) patterns and generalisation (Brizuela & Lara-Roth, 2002), and (c) representational strategies and systems (Carraher & Schliemann, 2007).

This paper addresses a topic not covered by previous studies concerning the different types of functional relationships identified by third year primary school students (hereafter, P3). The objectives pursued are: (a) to identify P3 pupils exhibiting functional thinking, (b) to describe the generalisation observed, and (c) to describe the functional relationships identified by students who generalise.

## Functional thinking and functional relationships

Consensus has yet to be reached around the definition of algebraic thinking (Cañadas, Dooley, Hodgen, & Oldenburg, 2012). Algebraic thinking is regarded as an educational objective that affords, for instance, opportunities: (a) to generalise; and (b) to enable students to use symbols to

represent ideas, which helps them solve problems, communicate and justify their ideas (Kaput, 2008).

Functional thinking is regarded as a cognitive activity “that focuses on the relationship between two (or more) varying quantities, specifically the kinds of thinking that lead from specific relationship (individual incidences) to generalisations of that relationship across instances” (Smith, 2008, p. 143). Such thinking involves the construction, description and reasoning with and about functions and includes generalizing about inter-related variables (Blanton, 2008).

Based on the functional relationships established from a mathematical perspective, Smith (2008) proposed three types of approximation for working with functions: (a) recurrence, which entail finding the variation or pattern of variation in a series of values for a variable in a way such that a specific value can be obtained based on the preceding value or values; (b) correspondence, and (c) covariation. We particularly focus on the correspondence and covariation relationships because the recurrence does not involve values of more than one variable. Correspondence, stresses the relationship between the pairs  $(a, f(a))$  for the variable; and covariation focuses on how a change in the values of one variable entails a change in the values of another. We show an example of these two functional relationships in Figure 1.

*Correspondence.* “The focus would be on the relation between  $x$  and  $y$ , which might be described as twice  $x$  plus six, or algebraically as:  $2x + 6$ ”.

Variation between two quantities	
$x$	$y$
1	8
2	10
3	12
...	...

*Covariation.* “The focus is on corresponding changes in the individual variable”. Example, in the table 1, when  $x$  increases by 1,  $y$  increases by 2.

**Figure 1. Example of functional relationship (Smith, 2008, p. 146-147)**

These relationships not only concern the generalization as the representations of the general relationship, they can also refer to the pattern observed in particular cases of the two variables. In recent studies, Blanton, Brizuela, Murphy, Sawrey, and Newman-Owens (2015), and Stephens, Fonger, Knuth, Strachota, and Isler (2016) described the types of functional relationships and the levels of sophistication with which subjects think about such relationships. One indicator for establishing such levels is the kind of functional relationship. Some findings showed that students in the early years evolve from the ability to establish recurrent relationships, the most basic area worked with, primarily in pre-school and early primary education, to the understanding of correspondence and covariation. Cañadas & Morales (2016) observed correspondence and covariation relationships in P1 pupils. These pupils’ replies showed no evidence of the recurrence relationship. Moreover, as pupils generalise, correspondence and covariation relationship were observed more frequently, particularly the former.

## Generalisation

Generalisation is one of the core processes in algebra (Kaput, 2008). All pupils can generalise and abstract from specifics, for this activity is “entirely natural, pleasurable, and part of human sense-making” (Mason, Graham, & Johnston-Wilder, 2005, p. 2). Generalisation is said to have been attained when a statement is made that applies to all the instances in a given class.

Although algebraic symbolism is the characteristic representation for algebra, there are other ways of representing the generalization, specially when concerns elementary students. Carraher, Martinez, & Schliemann (2008) focused on third year primary school students’ generalization and how they express it. These students generalise functional relationships (correspondence and covariation). The authors highlight that students should learn to generalise solving mathematical problems that allow them to look for and observe patterns, relationships, and structures. In this way, students have the possibility to get new informations and reflect about the generalisations produces by themselves and their partners.

## Method

This study forms part of a broader teaching experiment focusing on Spanish P3 students’ functional thinking. The contextualised problem posed in each session involved a linear function. The fourth and last session is discussed hereunder.

### Subjects and data collection

The subjects were 24 P3 pupils (8-9 years old), intentionally selected on the grounds of school and teacher availability. These students had not worked with problems involving functional relationships prior to the study, except in the first three sessions of the same project in which they were introduced to problems involving two linear functions:  $f(x)=x+5$  and  $f(x)=x+3$ . All the sessions were guided by a teacher-researcher.

In the first part of the session, we introduced the tiles problem<sup>1</sup> to the students, asking them questions concerning particular cases, in order to assure that they understand the situation and the questions. In this problem, the function involved is  $f(x)=2x+6$ . This paper focuses on the results from a written questionnaire that had to be answered individually in connection with the problem posed. The way in which the problem was posed and questions used are presented in Figure 2. In questions Q1, Q2, Q3, Q4.A and Q4.B pupils were asked about specific non-consecutive cases, whilst the fifth (Q5) asked the pupils to generalise the relationship between the dependent and independent variables (white and grey tiles, respectively). The students were furnished with manipulative material: white and grey paper tiles.

---

<sup>1</sup> The well-known tiles problem used here has been applied by a number of researchers in the context of classroom algebra (e.g., Küchemann, 1981).

A school wants to renovate the ground of all its corridors because it is already very damaged. The management team decides to pave the corridor with white tiles and grey tiles. All tiles are squares and have the same size. The tiles are being placed in each corridor so that you can see in the picture below.

The school ask a company for renovating the different corridors of the school. We ask you to help the workers to answer some questions that they need to answer for their work.

Q1. How many grey tiles are needed for the floor of a corridor in which 5 white tiles are placed? How do you know that?

Q2. Some corridors are longer than others. Therefore, the workers need different number of tiles for each corridor. How many grey tiles are needed for a floor corridor in which 8 white tiles are placed? How do you know that?

Q3. How many grey tiles are needed for a floor corridor in which 10 white tiles are placed? How do you know that?

Q4A. How many grey tiles are needed for a corridor floor in which 100 white tiles are placed? How do you know that?

Q4B. Now, do it in a different way and explain it below.

Q5. The workers always place the white tiles and then the grey tiles first. How do you know how many grey tiles you need if you have already placed the white tiles?

**Figure 2. Tiles problem**

### Analytical categories and data analysis

Following our research objectives, we used information from the theoretical framework and previous studies to design the categories used in data analysis. Moreover, we were aware of possible modifications needed as long as we performed a preliminary data analysis in order to adapt them to our specific data. Two categories were established: (a) functional relationships, and (b) generalisation. Finally both categories were related because the generalisation involved at least one of the functional relationships.

The category of functional relationship covered the type of functional relationships identified by the pupils: (a) correspondence, and (b) covariation. Functional thinking was deemed to be present in pupils' replies when at least one functional relationship was drawn in at least two of the questions posed. This criterion pursued to avoid those students who used a computation strategy but not necessarily a relationship between variables.

The second category dealt with the presence or absence of generalisation and how it was reached and expressed in any of the five questions posed. More specifically, it focused on the students' replies to Q5 (regarding generalisation), because is the only question in which students generalised.

### Results and discussion

The 24 pupils' written responses to the questionnaires were analysed. All the students answered the first three questions, 23 the fourth one, and 16 the fifth one (generalisation). Those findings were

interpreted to mean that more students answered the first four questions because they involved specific, non-consecutive instances and small numbers. Similarly, the high rate of blank answers to Q5 was conjectured to be due to the complexity involved in generalizing the functional relationship.

The findings set out below are organised in keeping with the objectives pursued. The students are referred to with the letter S followed by a number, from 1 to 24.

### Functional relationships

Eleven students exhibited functional thinking, identifying a functional relationship in at least two of the questions asked. The other 13 students, in contrast, did not.

Among the students exhibiting functional thinking, seven students distinguished only correspondence relationships in their replies, and four identified both functional relationships (correspondence and covariation).

A representative example of students who used only the correspondence relationship is S22. We show this student's responses to the first four questions in Figure 3.

Q1	$4 + 7 + 2 = 16$
Q2	$10 + 10 + 2 = 22$
Q3	$12 + 12 + 2 = 26$
Q4.A	$102 + 102 + 2 = 206$

**Figure 3. S22's responses**

For instance, in Q4.A, he took the number of white tiles (100) and added 2 ( $100 + 2$ ). Then he found the number of grey tiles needed for the bottom and top rows by adding 102 twice ( $102 + 102$ ). Lastly, he added 2, the ones on the right and left of the white tiles ( $102 + 102 + 2$ ). He used that same functional relationship for 5, 8 and 10 white tiles in Q1, Q2, and Q3, respectively. In all three cases, this student related pairs of values ( $a, f(a)$ ) to the  $a$  values in each specific case and established a relationship with the number of grey tiles: 16, 22 and 26, respectively.

Four pupils identified two functional relationships in their answers to the questions on the questionnaire: correspondence and covariation. None of the students recognised more than one functional relationship in their answers to a given question.

S3 is a student who identified correspondence and covariation relationships. In Q2, she answered that 22 grey tiles are necessary for 8 white tiles, using a counting strategy. In Q3, S3 answered, "if 8 [white tiles] need 20 [grey tiles], there are  $20 + 2 = 22$ ". Although this answer is wrong, she used the previous response to work on (adding two to the previous response). We observe that the student focused on the variation between the number of white tiles (between 8 and 10, there is an increase of 2 white tiles) in order to calculate the number of grey tiles, considering that such increase is also 2. Therefore, she focused on how variation in values of the number of white tiles influence in a variation in values of grey tiles, which is the notion of covariation relationship.

## Generalisation

We find generalization evidence in Q5. In previous questions, students referred to the relationship between variables through particular cases involved.

Three of the 11 pupils who exhibited functional thinking showed the generalisation in their replies to Q5. One of them, S9, generalised appropriately to the problem posed. In contrast, the other two students —S11 and S22— generalised incorrectly. In what follows, we present examples of the students who generalized, describing when they got it and what kind of relationship generalised.

S9 used a numerical representation to calculate the number of grey tiles in the first four questions. In Q5, he stated “you double the number white tiles and then you add 6”. He used different representation to the verbal one in other questions. This fact evidences the importance of the verbal representation in the development of functional thinking in the same way as Kieran, Pang, Schifter, and Fong Ng (2016) noted. Student S9 generalised the correspondence relationship that he also identified in questions concerning particular cases.

S11 found a correspondence relationship in the questions concerning particular cases. In his reply to Q5 he noted: “if there are 50 tiles, then I add  $50+50$  and then the ones on the sides,  $3+3$ , 106 in all”. The student used a particular case to answer the question but he evidenced that he recognised the fixed number of grey tiles ( $3+3$ ). This fact shows generalization at an initial stage: although his answer is not complete, he is approaching to the generalization of the relationship because he identified the function constant (6). S11 used different relationships to determine the number of grey tiles in Q2, Q3, and Q4, focussing on a correspondence relationship between the variables involved. He “generalise” the correspondence relationship in Q5.

S22’s reply illustrates another way to generalise in Q5: “add 6”. This generalisation was incomplete, for she recognised the number of grey tiles that remains constant (left and right sides), but not the number on the top and bottom rows, even though in the preceding questions she distinguished the pattern for determining the number of grey tiles given a certain number of white tiles (see Figure 1). Moreover, S22 used the correspondence relationships to answer the first four questions (see Figure 3). On the contrary, this student used a co-variation relationship in Q5 because he identified the necessity of adding 6 to calculate the number of grey tiles given any number of white tiles.

## Conclusion

The students exhibiting functional thinking (those recognizing at least one functional relationship in at least two questions) could be detected on the grounds of the relationships they identified.

The correspondence was the functional relationship predominantly observed in the students’ answers, followed by covariation. This holds particular significance, specifically by: the pupils’ age, the specific demands of the tiles problem and the functional relationships distinguished. The prevalence of the correspondence relationship in the first four questions, which involved familiar specific cases, seemed to be connected with the pupils’ broader experience with areas such as numerical patterns. Additionally, we conjecture that this functional relationship could be induced by the problem context because each particular case involved in one question is not connected with other particular cases.

Covariation was observed in Q5, which sought to induce the pupils to express the general relationship between the variables involved; the preceding questions could be answered with no need to generalise.

According to Blanton, Brizuela, Gardiner, Sawrey, and Newman-Owens (2015), functional thinking involves (among others) drawing general patterns from relationships between quantities that co-vary and representing and justifying such relationships in different ways with a number of representational systems. The results of their study are supplemented by the present findings, further to which P3 pupils naturally (for they had not worked on this area in the classroom) identified more than mere recurrence, establishing relationships (correspondence and covariance) involving the values of both variables. Whilst influenced by the type of problem, these P3 students were found to be able to distinguish correspondence and covariation relationships, even though they were not always able to recognise a general pattern.

In a future line of research the way generalisation is expressed will be studied in greater depth, along with pupils' arguments and explanations. Student interviews are regarded as a suitable tool for obtaining a fuller description of how inter-variable relationships are expressed.

# Didactic transposition in school algebra: The case of writing equations of parallel and perpendicular lines

Valentina Postelnicu

Texas A &M University-Corpus Christi, USA; [Valentina.Postelnicu@tamucc.edu](mailto:Valentina.Postelnicu@tamucc.edu)

*A study was conducted with a high school teacher and her 58 Algebra I students, with the purpose of gaining insight into students' difficulties with writing equations of parallel and perpendicular lines. Chevallard's theory of didactic transposition was employed in order to account for the relativity of the mathematical knowledge with respect to the institutions where the knowledge was created. During the process of didactic transposition, the mathematical knowledge lost its essential feature, the proof, with dramatic consequences for the school algebra curriculum. What remained to be taught and learned was how to execute tasks. As predicted by mathematicians, this utilitarian view of the curriculum affected the actual process of teaching and learning by focusing on executing basic tasks, and resulted in teachers and students having difficulty executing those tasks.*

*Keywords: Didactic transposition, school algebra, writing equations of lines.*

## Introduction

Students' difficulties with aspects of linear functions, like the rate of change, slope, y-intercept, or writing equations of parallel lines have been studied in the United States by many researchers, among them the group from Berkeley led by Schoenfeld (Schoenfeld, Smith, & Arcavi, 1993). In spite of a wealth of research, the issue of students' difficulties with linear functions has remained relevant (Postelnicu, 2013). The study reported here has the purpose to account for the students' difficulties with writing equations of parallel and perpendicular lines, and to advance a plausible explanation on the persistence of students' difficulties. We propose another way to look at this issue, by paying attention to the difference between the mathematics as a body of knowledge (scholarly mathematics created by mathematicians) and mathematics as a subject matter to be taught and learned (school mathematics created by textbook authors or taught by teachers) (Bosch & Gascón, 2006).

## About the theory of didactic transposition

For this study we employ Chevallard's theory of didactic transposition because it takes into account both the mathematics as a scholarly body of knowledge and as a subject to be taught and learned. By *didactic transposition* of knowledge, we mean "the transition from knowledge regarded as a tool to be put to use to knowledge as something to be taught and learnt" (Chevallard, 1988). As pointed out by Bosch and Gascón (2006), when studying any didactic problem, like the teaching and learning of writing equations of parallel and perpendicular lines, we must account for all the steps of the process of didactic transposition:

i) from scholarly knowledge created by mathematicians (e.g., analytic geometry) to school mathematics written by textbook authors (e.g., high school textbooks); ii) from textbook knowledge (e.g., Algebra I textbook written by Larson et al., 2007) to school mathematics taught by teachers in classrooms (e.g., the mathematics taught by the teacher in the study reported here); and iii) from school mathematics taught by the teacher in this study to mathematics learned by her students.

Each society and institution has a certain way of creating mathematical knowledge and using it, thus bringing to life a *praxeology*, “an organized way of doing and thinking contrived within a given society” (Chevallard, 2006). A praxeology is composed of *praxis* and *logos*, each with two components (Bosch & Gascón, 2014):

- i) *praxis* - **tasks**/problems that can be solved employing a certain **technique** (“ways of doing”/executing the tasks/solving the problems), and
- ii) *logos*- **technology** (the discourse of the technique, justifies the technique), and **theory** (general discourse or abstract set of constructs and arguments, justifies the technology).

A praxeology can be “*point praxeology*” with only one type of task, “*local praxeology*” with a set of tasks sharing a technological discourse, and “*regional praxeology*” with all the point and local praxeologies sharing a theory (Bosch & Gascón, 2014). For example, a point praxeology may contain only the task of sketching a “quick” graph of a line with an equation written in slope-intercept form. A local praxeology may contain all the tasks requiring writing equations of lines given certain conditions, including tasks like Tasks 1 and 2 given to students by the teacher from our study:

**Task 1:** Sketch the graph of the line that is parallel to  $y = \frac{1}{2}x - 3$  and goes through  $(2, -1)$ .

**Task 2:** Sketch the graph of the line that is perpendicular to  $y = \frac{3}{4}x - 2$  and goes through the point  $(2, -6)$ . What is the equation of the new line you created?

Tasks 1 and 2 have the same target knowledge, an algorithm for solving the class of problems that require the writing of the equation of a line passing through a given point and parallel or perpendicular to a given line. Such tasks are similar to those proposed in the textbook used by the participants in this study. The technique used to execute Task 1 may employ algorithms like the one used by the teacher in this study:

1. Draw a Cartesian systems of coordinates and plot the given point  $(2, -1)$ .
2. Identify the slope of the line parallel with the given line,  $m = \frac{1}{2}$ .
3. Use a “quick graph” to obtain a second point on the line (from the point  $(2, -1)$  move 1 unit up and 2 units to the right, and obtain and plot the point  $(4, 0)$ ).
4. Draw the line passing through the given point  $(2, -1)$  and the newly found point  $(4, 0)$ .

Part of the technological discourse for this local praxeology may include the justification for the fact that the second point  $(4, 0)$  obtained in the way described above is indeed situated on the line with the slope  $m = \frac{1}{2}$  and passing through  $(2, -1)$ , or the justification that the line parallel to the line  $y = \frac{1}{2}x - 3$  has the same slope,  $m = \frac{1}{2}$ . A theoretical justification of the fact that parallel lines have the same slope and, conversely (i.e., a theorem and its proof in analytic geometry, based on similarity of triangles) may belong to a regional praxeology.

## Method

Participants in this study were an Algebra 1 teacher from a public high school in the United States and her 58 students who agreed to participate in this study. The teacher had a Bachelor degree in Mathematics and five years of teaching experience. Classroom observations (Erickson, 1985) were conducted by the researcher/author of this paper for all six Algebra 1 classes of 50 minutes each, taught by the participating teacher, during the same day of school. The researcher took notes referring to the way the teacher and her students interacted with the mathematical content of the tasks. The teacher taught the same lesson, about writing equations of parallel and perpendicular lines, to each of her classes. Prior to the day of observation, the teacher introduced to her students the equation of a line in slope-intercept form and point-slope form, and the notions of parallel and perpendicular lines. The teacher started each lesson with Task 1 (described above), discussed it with her students, and then administered Task 2 (described above). Two raters scored students' answers to Task 2 ("1" for correct answer, and "0" for incorrect or incomplete answer). Using techniques from grounded theory (Strauss & Corbin, 1998), students' algorithms were split into two categories, algorithms with a graphical approach (teacher's approach, described in the section referring to the theory of didactic transposition, and in the section referring to teacher knowledge), or algorithms with an algebraic approach (textbook approach, described in the section referring to textbook knowledge). The inter-rater agreement (Cohen, 1960) was very high,  $k = .92$  ( $p < .001$ ), 95 % CI [.83, .98].

## Analysis and results

Figure 1, below, is adapted from Bosch & Gascón (2006) and illustrates the steps of the process of didactic transposition specific to the study presented in this paper.

**Figure 1. The process of didactic transposition**

We will describe each of the types of knowledge/praxeologies in Figure 1, starting from the scholarly knowledge, in the direction of the arrows. Worth mentioning, in determining the regional, local or point praxeologies, one starts from the task and what the task entails, in our case writing linear equations of parallel or perpendicular lines to a given line, and passing through a given point.

### Scholarly knowledge/Regional praxeology

As can be seen in Figure 1, we chose analytic geometry as our regional praxeology. Given the space constraints, we refer here only to perpendicular lines. When writing equations of perpendicular lines, we use the following **theorem**:

Two nonvertical, nonhorizontal lines  $l_1, l_2$  with slopes  $m_1$  and  $m_2$  are perpendicular if and only if  $m_1 m_2 = -1$  (Kay, 2001, p. 303).

Worth mentioning, the proof chosen for the above theorem is specific to the participants' institutionalized knowledge. Our regional praxeology/theory contains all the axioms, definitions, theorems and their proofs needed to prove the above theorem. An example of a path through the theory is given by Kay (2001) in his textbook, *College Geometry*, where he starts constructing the geometry with the foundations of absolute geometry (points, lines, segments, angles, triangles, quadrilaterals, circles), and continues with the Euclidean geometry (trigonometry, coordinates, vectors). This path of knowledge includes the definition of a right angle, the definition of perpendicular lines, the Pythagorean theorem and its converse together with its proof based on similarity of triangles, and the distance formula between two points, given their coordinates. Within this regional praxeology, “a right angle is any angle having measure  $90^\circ$ ” and “two (distinct) lines  $l_1, l_2$  are perpendicular if and only if  $l_1, l_2$  contain the sides of a right angle” (Kay, 2001, p. 97). A proof of the theorem stated above is simple (see Figure 2).

**Figure 2. Perpendicular lines and their slopes**

As can be seen in Figure 2, the system of coordinates has been specially chosen, without loss of generality, so that its origin,  $O$ , coincides with the point of intersection of the two lines,  $l_1$  (with slope  $m_1$ , containing the segment  $OA$ , with  $A$  chosen such that its  $x$ -coordinate,  $x_A = 1$ ) and  $l_2$  (with slope  $m_2$ , containing the segment  $OB$  with  $B$  chosen such that its  $x$ -coordinate,  $x_B = 1$ ). The line  $l_1$  passes through  $O(0,0)$  and has the slope  $m_1$ , hence all its points  $(x, y)$  satisfy the equation  $y = m_1x$ . Similarly, all the points  $(x, y)$  situated on  $l_2$  satisfy the equation  $y = m_2x$ . As such, the points  $A$  and  $B$  have the coordinates:  $A(1, m_1)$  and  $B(1, m_2)$ , respectively. To prove the direct implication of the theorem, we assume that the lines are perpendicular therefore they contain the sides of a right angle, hence the triangle  $AOB$  is right, and according to the Pythagorean theorem we have  $OA^2 + OB^2 = AB^2$ . Using the distance formula to calculate  $OA$ ,  $OB$ , and  $AB$  function of their coordinates, we obtain  $m_1^2 + 1 + m_2^2 + 1 = (m_2 - m_1)^2$  and after we simplify, we have  $m_1m_2 = -1$ . Conversely, if  $m_1m_2 = -1$ , then  $m_1^2 + 1 + m_2^2 + 1 = (m_2 - m_1)^2$ , therefore  $OA^2 + OB^2 = AB^2$ . Using the converse of the Pythagorean theorem, it follows that the triangle  $AOB$  is right, hence the lines  $l_1$  and  $l_2$  containing its legs,  $OA$  and  $OB$ , respectively, are perpendicular.

The observation that any vertical line with the equation  $x = a$  is perpendicular to any horizontal line with the equation  $y = b$  takes care of the exception stated in the theorem (“nonvertical, nonhorizontal lines”).

### Textbook knowledge/ Local praxeology

In the United States, the Algebra 1 course, usually taught in the first year of high school, contains topics like linear equations with one and two variables, linear functions, linear inequalities, systems of linear equations, quadratic equations and functions, and introductions to polynomials, exponential equations and functions. For historical reasons (Kilpatrick & Izsák, 2008), the American students take the Algebra 1 course before Geometry, thus they learn about the slope of a line, or slopes of parallel and perpendicular lines before learning about similarity or how to prove the Pythagorean theorem. As such, there is no expectation for justifications or proofs for the “key facts” stated in Algebra 1 textbooks. The textbook knowledge for this study comes from the Algebra 1 textbook used by the participants’ school district (Larson et al., 2007). The lesson referring to the writing of parallel and perpendicular lines offers some techniques and the technological discourse to justify the techniques (e.g., definition of perpendicular lines and a “key concept” without proof - the theorem referring to the slopes of perpendicular lines):

**PERPENDICULAR LINES.** Two lines in the same plane are perpendicular if they intersect to form a right angle. Horizontal and vertical lines are perpendicular to each other.

**KEY CONCEPT.** If two nonvertical lines in the same plane have slopes that are negative reciprocals, then the lines are perpendicular. If two nonvertical lines in the same plane are perpendicular, then the slopes are negative reciprocals (Larson et al., 2007, p. 320).

A similar definition and a similar theorem about parallel lines precede the definition and theorem about perpendicular lines. The technique/algorithm described in the textbook (Larson et al., 2007, pp. 319-321) for executing tasks similar to Task 1 and 2 has an algebraic approach (Knuth, 2000):

1. Identify the slope  $m$  of the new line based on the “key concepts” referring to the slopes of parallel or perpendicular lines (parallel lines have the same slope, perpendicular lines have slopes negative reciprocals).
2. Use the slope-intercept form of an equation  $y = mx + b$ , the newly found slope  $m$ , and the given point  $(x_1, y_1)$  to find  $b$  (the y-intercept).
3. Write the equation of the newly found line  $y = mx + b$ .

### Teacher knowledge/Local praxeology

We continue describing Figure 1 with teacher knowledge, as observed. After discussions with her students, the teacher executed Task 1 using the algorithm with the graphical approach described above, in the section about the theory of didactic transposition. She drew a system of coordinates, plotted the point  $(2, -1)$ , identified the slope of the parallel line  $m = \frac{1}{2}$  and used it to obtain the second point  $(4, 0)$  (from  $(2, -1)$  moved 1 unit up and 2 units to the right), and drew the line connecting the points  $(2, -1)$  and  $(4, 0)$ . To check the execution of Task 1, the teacher proposed to her students to graph the first line  $y = \frac{1}{2}x - 3$  as well, on the same system of coordinates like the newly obtained line, and make a judgment regarding their parallelism, based on visual inspection. When one of the students proposed a technique with an algebraic approach for Task 1, the teacher allowed the student to carry it out, but then she asked the class for another way to execute Task 1, and led the students to use her graphical approach technique. Part of the observed technological

discourse for the teacher's local praxeology also included the definitions of parallel lines ("lines that do not meet") and perpendicular lines ("two lines in a plane that intersect at a  $90^\circ$  angle"), and the "key concepts" that parallel lines have the same slope and perpendicular lines have the slopes opposite reciprocals. In short, the teacher's local praxeology, as observed, consisted of some basic tasks, a technique with a graphical approach, and some of the technological discourse necessary to justify the technique. In the teacher's view, as expressed during the class discussions, Tasks 1 and 2 were part of the same class of problems, requiring the same technique, and Task 2 could be approached in the same way as she approached Task 1, i.e., graphically.

### Student knowledge/Point praxeologies

Executing Task 2 with the algorithm from the textbook implies: i) identify the slope of the perpendicular line,  $m = -\frac{4}{3}$ ; ii) substitute  $(2, -6)$  and  $m = -\frac{4}{3}$  in  $y = mx + b$ , and determine  $b$  from  $-6 = -\frac{4}{3}(2) + b$ ; iii) write the equation of the newly found line  $y = -\frac{4}{3}x - \frac{10}{3}$ . Only two students (3.4 %) of those 58 participating in the study executed Task 2 successfully, and both employed the technique with an algebraic approach described in their textbook. About one out of five students (20.6 %) tried to solve the problem employing the technique with the graphical approach used by the teacher – they determined the slope of the perpendicular line,  $m = -\frac{4}{3}$ , started from the given point  $(2, -6)$  and used the "quick graph" technique to obtain the second point on the line, then drew the line connecting those two points and determined incorrectly, by visual inspection, the value of the y-intercept of the newly created line, and finally wrote the equation of the line (see Figure 3).

Sketch the graph of the line that is perpendicular to  $y = \frac{3}{4}x - 2$  and goes through the point  $(2, -6)$ .

What is the equation of the new line you created?

$$y = -\frac{4}{3}x - 2$$

**Figure 3. Example of student work – Task 2**

It can be seen in Figure 3 that the student incorrectly determined the y-intercept of the newly created line as  $-2$ , while the correct value is  $-\frac{10}{3}$ , a value hard to determine with the graphical approach. Moreover, the student tried to check/evaluate her work, and graphed the original line together with the newly created line and it seems that she was satisfied with her visual inspection of the perpendicularity of those two lines she graphed. The rest of the students (76 %) tried to use a graphical approach (strongly suggested by the teacher's approach and the presence of the grid), but could not identify the slope of the perpendicular line, or determine the y-intercept. When writing the equation of the perpendicular line, students tried to substitute the point  $(2, -6)$  or its coordinates in

the slope-intercept form equation of a line  $y = mx + b$ , irrespective of their graphical representations or the meanings of the coordinates of the point, slope of the line, and y-intercept of the line. They obtained equations, like “ $y = -\frac{4}{3}x + (2, -6)$ ”, “ $y = -\frac{6}{2}x - 2$ ,” or “ $y = 2x - 6$ ,” showing a great disconnect with the technique required to execute Task 2. As observed from their written assignments, the students’ praxeologies were point praxeologies with only one task and technique (successful or not), without any justification of the technique.

## Discussion

The scholarly knowledge constructed from axioms, definitions, and rigorously proven theorems has been replaced by other definitions and axiom-like “key concepts” considered true without proof. In our case, the theorem regarding the slopes of perpendicular lines and its proof has been replaced by a “key concept” without proof, and several “solved examples” presenting the technique for executing basic tasks. What remained to be taught and learned was how to execute basic tasks. The change was dramatic from scholarly mathematics to textbook knowledge, since mathematics was stripped of its essential feature – the proof. The mathematicians warned that this dramatic change in our curriculum would lead to generations of teachers and students with increasing difficulty executing tasks requiring more than one step (Wu, 1997). The textbook knowledge shrank to teacher knowledge, but remained the same in nature, i.e., a set of tasks, techniques, and justifications for techniques. As observed, the teacher from this study used only basic tasks that were similar with the examples solved in the textbook, employed only the graphical approach, and supported her technique with some justifications. The teacher may have favored those tasks and techniques for various reasons like, the end-of-course exams contained mainly basic tasks for which the techniques were appropriate, her students’ weak competency with symbolic manipulations, and time constraints. The technique with a graphical approach imposed by the teacher in this study was inadequate for Task 2. Almost all the students (96.6 %) relied on the teacher’s knowledge – a subset of the textbook knowledge. The students failed to connect the graphical and symbolic representations of points and lines, and the techniques necessary to carry out Task 2. As predicted by mathematicians (Wu, 1997), the students had difficulty executing tasks with more than one step.

The observed *logos* from the local praxeologies (textbook and teacher knowledge) contained only the technological discourse. There was no observed *logos* in the case of point praxeologies (student knowledge). Without theory based on proof, the knowledge advancement can only be obtained by learning to execute new tasks with new techniques that are not necessarily connected to old ones. As seen in our study, this type of knowledge advancement did not lead to teacher’s or students’ success.

# Students' and teachers' mental solving of algebraic equations: From differences to challenges

Jérôme Proulx, Marie-Line Lavallée-Lamarche, & Karl-Philippe Tremblay

Université du Québec à Montréal, Canada; [proulx.jerome@uqam.ca](mailto:proulx.jerome@uqam.ca)

*This paper presents students' and teachers' strategies for mentally solving algebraic equations. The enactivist notions of problem-posing offer conceptual grounds to engage in analysis of students' and teachers' strategies, and in their comparisons, leading to the exploration of differences in the nature and origin between the solving processes of students and those of teachers. Final remarks reflect on the potential of being sensitized to the nature of these differences in solving processes.*

*Keywords: Algebraic equations, mental mathematics, problem-solving.*

## Introduction

This paper is in continuity with the one presented at CERME-8 in WG3 about the mental solving of algebraic equations (Proulx, 2013a). Work has been conducted with secondary-level students and with teachers on mentally solving algebraic equations of the form  $Ax+B=C$ ,  $Ax+B=Cx+D$ ,  $Ax/B=C/D$  without paper and pencil or any other material aid. The main research objective is to gain better understandings of the nature of the strategies developed when solving these algebraic equations mentally. From our analysis, students' and teachers' ways of solving highlight significant differences to which it is worth paying attention in terms of their meaning and nature as well as the issues that they raise about the teaching and learning of algebraic equation-solving. This paper reports on analyses of the strategies developed by students and teachers for similar if not identical algebraic equations, and grounds it in a discussion of the nature of solving processes.

## Solving processes in mental mathematics: Emergence and problem-posing

As mentioned in Proulx (2013a), recent work in mental mathematics points to a continued need for investigating and conceptualizing how students develop mental mathematics strategies. Researchers have begun criticizing the notion that students “choose” from a toolbox of predetermined strategies to solve problems in mental mathematics. Threlfall (2002), for example, insists rather on the organic emergence and contingency of strategies in relation to the tasks *and* the solver (e.g., what s/he understands, prefers, knows, experienced, is confident with; see Butlen & Peizard, 1992). This view is aligned with Lave's (1988) situated cognition perspective that conceives of mental strategies as flexible emergent responses, adapted and linked to specific contexts and situations.

In mathematics education, the enactivist theory of cognition has been concerned with issues of emergence, adaptation and contingency of learners' mathematical activity (e.g., Maturana & Varela, 1992; Varela, Thompson, & Rosch, 1991). In particular, Varela's (1996) distinction between problem-posing and problem-solving offers insights for conceptualizing the generation of strategies. For Varela, problem-solving implies an understanding that problems are already in the world, lying “out there” waiting to be solved independent of us. He explains, in contrast, that we specify – we pose moment by moment – the problems that we encounter through the meanings we make of the world. We do not “choose” or “take” problems as if they were lying out there objectively and independent of our actions: we bring them forth. In short, for Varela, we *pose* our problems.

This perspective underlines Simmt's (2000) argument that it is not tasks that are given to solvers, but rather prompts that are taken up by solvers, who by posing them in a specific mathematical context create tasks with them. Prompts become tasks when solvers engage with them, when they pose them as tasks. Hence solvers make the prompt a multiplication task, a ratio task, a function task, an algebra task, and so forth, and solve it in relation to this posing. And, this posed task is not static or fixed once and for all, because the posing triggers a solving process that in turn transforms the posed task in an ongoing and dynamic process. It is with/in this process that the task emerges, organically, constantly becoming, being re-solved and re-posed (see Proulx, 2013b). By way of an example of this interaction between the posing and the solving, here is a strategy taken from a study on mental calculations (Proulx et al., 2014). To solve  $741-75$ , one solver explained:

- (a)  $741 - 75$  is like  $700 - 75 + 41$ .
- (b)  $700 - 75$  is like having 7 dollars and subtracting 3 quarters. I am left with \$6.25.
- (c) 6.25 is six-twenty-five, so I add 41 to 625. I do  $5+1$  is 6,  $4+2$  is 6, and I have 600, so 666.

When  $741-75$  was given, the first step was to find a way of solving, of entering, of posing it as a task. This prompt was then posed as a decomposition task, leading the solver to decompose 741 in 700 and 41, in order to subtract 75 from 700. This decomposition produced in return a new prompt for the solver, that is, to solve  $700-75$ , which was posed as a monetary task (7 dollars minus 75 cents). This other solving step led to another prompt,  $625+41$ , which the solver posed anew as a decomposition task of each digit in each number in relation to their position (hundreds, tens, units) and its successive addition. Hence each solving step led to the posing of a task to solve, necessitating a way of entering into it, continuing to solve it, etc., producing an entire solution path.

*A posteriori*, in light of this entire solution path, one can assert the presence of a strategy, but this is an assertion after the fact because all this unfolds one step at a time when advancing in the solving of the posed task. Interacting with the prompt, engaging in the task, is to take a step and another, and these steps emerge in the solution path. All this happens in continuity, step by step, with each step leading to another posing of the task, to another solving process contingent on and emerging from previous steps, leading in return to another posed task, leading to another step, etc.

[E]ach solution 'method' is in a sense unique to that case, and is invented in the context of the particular calculation – although clearly influenced by experience. It is not learned as a general approach and then applied to particular cases. [...] The 'strategy' (in the holistic sense of the entire solution path) is not decided, it emerges. (Threlfall, 2002, p. 42)

The entire solution path, or strategy in Threlfall's sense<sup>1</sup>, is not predetermined, but generated for solving, emerging from the interaction with the prompt. Thus the solver *transforms* the prompt as a mathematical task generating a strategy for the posed task for solving it. It is this dynamic entry on strategies, on solution paths, that characterizes the conception that grounds the analysis of solving processes in this study, that is, of students' and teachers' strategies for solving algebraic equations.

---

<sup>1</sup> It is in Threlfall's sense that the expression *strategy* is used in this paper, that is, not as a fixed and reified entity, but as the *entire solution path*, in its totality and dynamic nature as it unfolds through the diverse *solving steps*.

## Solving algebraic equations without paper and pencil

The context in which the mental mathematics sessions are conducted is simple. A group of solvers, students or teachers, sit at their table without any paper or pencil and attempt to solve the prompts given. The organization takes the following structure: (1) an equation is offered in writing on the board; (2) solvers have 15-20 seconds to solve the equation mentally (without paper-and-pencil or material aid); (3) at the signal, strategies are shared orally and explained to the group.

The data collected come from the strategies explained orally by solvers, taken in note form by at least two research assistants (RAs). These notes are refined with on-the-spot discussions between the research team members (PI and RAs) following data-collection sessions, to produce a report on the various solution paths developed by participants. In this report, each strategy is given a name that describes it for matters of classification (descriptive level of analysis). With these descriptions, various analyses are conducted, depending on the purpose aimed for (meaning making engaged with, nature of strategies produced, difference with paper and pencil, etc.). In this case, as explained in the introduction, the analysis of strategies is conducted with the precise intention of establishing comparisons between students' and teachers' solving processes. Thus the analysis in this paper is not conducted for/on the strategies themselves, but mostly to establish this comparison ground between the solution paths being laid down by students and by teachers.

### Students' posed tasks and solution paths

Work was conducted in two Grade-8 classrooms with about 30 students for 75-minute periods. In each classroom, the same five equations were given. The two used in the analysis are "Solve for  $x$  the equation  $2x+3=5$ " and "Solve for  $x$  the equation  $\frac{2}{5}x=\frac{1}{2}$ "; the solution paths emerging for these

are illustrative of the solving processes developed by students. As such, the analysis is not focused on the occurrences of strategies, but on the nature of the solving processes and the functionality and meaning of the strategies developed. For this, strategies in both classrooms are grouped to offer and set up comparative grounds with teachers' solving processes.

For "Solve for  $x$  the equation  $2x+3=5$ ", students produced the following:

*Inversing operations.* One student explained that he did "minus 3" on the right side of the equality to obtain  $2x=2$ , which directly gave  $x=1$  (without needing to divide by 2).

*Balancing.* One student explained having done the same actions on both sides of the equality, thus subtracting 3 on both sides to obtain  $2x=2$  and then dividing by 2 on both sides to get  $x=1$ .

*Direct reading.* Some students explained that with  $2x+3=5$  he knew right away that  $x$  must equal 1, because  $2+3=5$ . Another explained having first taken the  $x$  out of the equation, leaving  $2+3=5$ . So, when 2 was multiplied by  $x$ , it has to remain a value of 2 to fit in the equation, so  $x$  needed to be 1. Another student explained that this meant that  $x=0$ , because in  $2+3=5$  the  $x$  is unnecessary.

For "Solve for  $x$  the equation  $\frac{2}{5}x=\frac{1}{2}$ ", students produced the following:

*Transforming in equivalent fractions and decimals.* One student explained having transformed  $\frac{1}{2}$  in  $\frac{10}{20}$  to make the  $\frac{1}{2}$  divided by  $\frac{2}{5}$  simpler, then repeating the same thing for  $\frac{2}{5}$  to obtain  $\frac{20}{50}x=\frac{10}{20}$ . He explained that this is equivalent to  $0.4x=0.5$  and thus the response is  $x=0.5/0.4$ .

*Inversing and transforming in decimals.* One student explained inversing the equation to  $\frac{5}{2}x = 2$ .

He then transformed in decimals to obtain  $2.5x=2$ , and dividing by 2 got  $1.25x=1$  so that  $x=1.25$ .

*Cross multiplying.* After making the equation  $\frac{2x}{5} = \frac{1}{2}$ , the student explained having cross multiplied, where 5 times  $\frac{1}{2}$  gave  $2x= 2.5$  and thus  $x=1.25$ .

*Halving.* One student explained that half of 5 is 2.5, and because one looks for  $\frac{1}{2}$ , so  $x$  is 1.25.

*Finding a scalar.* One student explained looking for the value of  $x$  that made  $2/5$  equal  $\frac{1}{2}$ . Placing fractions over 10, he explained that  $x$  is 1.25 because 4 times 1.25 is 5 and  $5/10=\frac{1}{2}$ .

*Finding common denominator and adding.* The student explained having placed fractions over 10, obtaining  $\frac{4}{10}x = \frac{5}{10}$ . Subtracting  $4/10$  and  $5/10$  gave  $-1/10$ , so then  $x$  is worth  $1/10$ .

All these solution paths, and their underlying solving steps, are not necessarily “adequate” or “standard”, but illustrate an emergent solving process geared toward finding a value for  $x$  that satisfies the equality. Through these examples of solution paths emerges a diversity of solving steps, of entries for solving. As explained in Proulx (2013c), the “mental” dimension provokes the search for an entry point, a way of posing the prompt, of getting in, of making a step. The solving context is thus created by the solver, producing an adapted way of entering into the problem. This diversity, which is translated in a variety of solution paths for solving the “same” equation, transforms that “same” equation, which is differently contextualized or posed differently from one solver to the next as each develops his/her own ways of posing and solving. The diversity of solution paths illustrates well how the various ways of posing the task led to varied ways of solving by solvers, hence diverse strategies or solution paths. In other words, the “same” equation gives rise to the emergence of a variety of posing, which leads to the development of a variety of strategies.

### Teachers’ posed tasks and solution paths

The work with the group of 20 secondary-level teachers was conducted during a day-long session, where the solving of algebraic equations was carried out in the first half of the day. Similar equations given to students, even identical ones, were given to teachers to solve (about 10).

In general, most if not all teachers’ strategies can be described as efficient and errorless for solving the algebraic equations, e.g., through balancing strategies and isolating  $x$ . However, at specific moments during the sessions, some strategies of a more arithmetical nature were proposed. For example, some teachers explained having done what they described as “recovering”, where, e.g., for “Solve for  $x$  the equation  $x^2 - 4 = -3$ ”, one teacher explained:

[Hiding  $x^2$  with his hand] I look for the number which, when subtracted 4, gives  $-3$ . I know it is 1. So then, what number squared gives 1? It is  $\pm 1$ .

This solution path is similar to “inversing” methods discussed in Filloy and Rojano (1989), or Nathan and Koedinger’s (2000) unwinding, where operations are undone to obtain a value for  $x$ . As Filloy and Rojano explain, in order to solve an algebraic equation this way “[i]t is not necessary to operate on or with the unknown” (p. 20), because it comes back to an arithmetical context of operating on numbers. However, these arithmetic strategies were occasional for teachers. For example, for “Solve for  $x$  the equation  $\frac{2}{5}x = \frac{1}{2}$ ”, teachers produced the following:

*Equating middle and extreme products.* One teacher explained having acted like with ratios, multiplying middle and extreme terms together, obtaining  $4x=5$ , hence  $x=5/4$ .

*Multiplying by the inverse.* One teacher explained having divided by  $2/5$  on each side of the equality, leading to multiply by  $5/2$  to get the same answer, giving  $x=5/4$ .

*Isolating  $x$  in two steps.* One teacher explained having multiplied by 5 on each side of the equality, obtaining  $2x=5/2$ , and then dividing all by 2 to obtain  $x=5/4$ .

Following these solution paths, one teacher offered another entry:

*Simplifying the equation.* The teacher explained having aimed to get rid of  $\frac{1}{2}$  by multiplying the entire equation by 2, giving “4 fifths of  $x$  equals 1”. He then multiplied by  $5/4$  to find  $x$ .

Here the teacher simplifies the equation, eliminating the  $\frac{1}{2}$ , in order to find the value of  $x$  through multiplying by the inverse coefficient. Numerous teachers were intrigued by this solution path and questioned the teacher about it. He explained that his intention was to get rid of  $\frac{1}{2}$  to obtain “1 on one side” of the equation and because “multiplying by 2 is easy here”. Asked about the numbers present in the equation, he also explained that it was not clear for him if other numbers like  $3/2$  or  $1/6$  would have led him toward similar solving steps and that it was the presence of  $\frac{1}{2}$  that triggered his activity. This is thus an example of a local strategy, affected by the concrete “data” in the equation: the solving steps are produced on the spot for this equation and not as a general strategy applicable to all cases (as well as not being a strategy for isolating  $x$ , but about simplifying  $\frac{1}{2}$ ). The entry in the solving is done locally with the  $\frac{1}{2}$ , the task is posed as one implying a  $\frac{1}{2}$ , and not by the equation taken in its totality independent of its concrete values as could be the case in a cross-multiplying product. Although local, this strategy underlines an entry directly grounded in the data of the equation. The teacher simplifies this equation by doubling  $\frac{1}{2}$ , because it was “simple” to do so, and then solves it. However, this kind of solution path diverges from most of the strategies that teachers have produced.

Whereas in students one sees more local solving steps of this sort, directly sensitive to the data in the equation to solve, the strategies developed by teachers appear more decontextualized and general, less centered on the direct data of the equation. In short, faced with the same prompts, teachers posed problems different from those posed by students. This difference between teachers and students is well reflected in a comment made, after sharing the “doubling the  $\frac{1}{2}$ ” strategy, by one of the teachers about what he perceived as the optimal strategy to solve this equation:

In Grade-8 the winning strategy is really the ratio one [multiplying extreme and middle values]. We work at it so much with them and I encourage them to use it in front of these sorts of equations. [...] I am not against the other strategies, but with my students [waiving his hand in discouragement], I am not sure that it would come out much, especially if we ask them to solve without paper calculations. In mental mathematics it is not obvious, whereas with ratios I think that 2 times  $2x$  gives  $4x$ , and 1 times 5 gives 5, and  $4x$  over 5 they know afterwards that they have to divide by 4, these are rules of transformation of the equations.

This comment on the winning strategy and students’ (un)ease, supported by the other teachers, contrasts with the students’ solution paths displayed above. Shortly afterwards, this prompt was given to teachers: “Find the value of  $2t$  in  $3(2t)+6=18$ ”, for which they produced three strategies:

*Balancing.* One teacher subtracted 6 on each side of the equation, obtaining  $3(2t)=12$ , and then dividing by 3 on each side to obtain  $2t=4$ .

*Undoing of operations.* One teacher explained having done the opposite operation, by subtracting 6 from 18 and then dividing it by 3.

*Recovering.* One teacher explained hiding  $2t$  to find the number which when added 6 is worth 18. This number is 12. Then he asks which number multiplied by 3 gives 12. This number is 4.

Here again, this recovering strategy provoked questions from teachers, not stemming from misunderstanding but mostly from curiosity about having used this kind of strategy to solve the equation. One teacher explained that even if he himself solves algebraic equations in a variety of ways, he does not teach this variety to his students because he considers it important to proceed step by step in a structured and linear fashion for each side of the equality: something with which other teachers strongly agreed. However, after this comment, another teacher raised the following:

I have a question. I would show it like that to my students [step by step, operating on each side of the equation in the same manner]. However, as a secondary student I was never shown this “balancing” way. It is one of my colleagues who told me “Listen, I teach it like that”. Then, when I taught Grade-7, I started doing this “you do the inverse operation, bing, bang”. And I wonder if it has not become an automatism. Is it because we always do it like that, that students themselves begin doing it also rapidly? Is it OK if they do so, or do they need to continue with their personal strategies? [...] Should we encourage varieties of strategies in students?

This comment is reminiscent of Freudenthal’s (1983) one about automatism in teaching:

I have observed, not only with other people but also with myself [...] that sources of insight can be clogged by automatisms. One finally masters an activity so perfectly that the question of how and why [students don’t understand them] is not asked anymore, cannot be asked anymore and is not even understood anymore as a meaningful and relevant question. (p. 469)

What Freudenthal underlines as much as the teacher is not about misunderstandings of non-usual solution paths, but about well-ingrained habits of solving that (1) prevent one from stepping outside them, and (2) question the relevance of alternate solution paths for solving equations. The teacher’s question is about this, that is, the relevance or legitimacy of alternate solution paths: Should they be taught? Should they be accepted? These questions sensitize one to the variations in ways of solving, but also to the challenges that this raises for teaching-learning situations.

## **Discussion and reflections on algebraic equation solving processes**

In what ways do these differences in solution paths raise challenges? The discontinuity, the distances between the various strategies developed by students and teachers are without any doubt important sources of challenges for the teaching-learning of algebraic equation solving. One way of addressing these questions is to probe the solving processes as much in students as in teachers. How can this variety be explained, as well as the differences in solution paths of teachers and students?

If we take into account Threlfall’s (2002) views, we can consider that the nature of what emerges for the student is quite different from what emerges for a teacher. A student’s experience is quite different from that of a teacher. For the teacher, one has the impression that some earlier

experiences intensely orient future ways of solving. The teacher's comments above, as well as Freudenthal's, insist on the challenge of stepping out of the frame pretraced by earlier repetitive experiences of teaching the solving of algebraic equations along specific solution paths. Faced with having to teach students and make them learn, teachers make choices that in turn orient the nature of their own mathematical experiences of this specific mathematics thematic. By insisting on some solution paths seen as fruitful for students to solve equations, these solution paths in turn orient teachers' solving processes; a phenomenon that the above expression *automatism* describes well.

It is this experience that plays a major role for teachers. When facing the "same" equations, teachers and students pose quite different tasks. Although all solving steps leading to what are seen as different strategies arise from the posing of different problems by different persons when interacting with the prompt, the solving steps do not share the same origins. Teachers are expert solvers in the sense of what could be called an "overspecialization". They can perceive these equations through the same algebraic lens, steering almost all equations to the same kind of task, posing them as the same tasks. Students are not non-experts, but have, however, not yet lived the same repetitive experiences that cause this overspecialisation. Think of the riverbed metaphor: teachers' riverbed is well dug, quite specialized, and the river runs through it comfortably. That of students looks much more like a stream that deviates at the least change in scenery, but this does not prevent it from unfolding (sometimes in the same place, sometimes elsewhere, unpredicted but adequate, or not).

### **Final remarks: On differences and challenges**

Despite its efficiency in solving, teachers' overspecialisation limits the variety of problems that they pose, being less sensitive to variations (in numbers, unknowns, operations, etc.). This makes it difficult for them to act differently, as one of the teacher expressed, but also to appreciate the variety of students' solution paths; a variety that teachers themselves no longer experience much in their day-to-day mathematics teaching (a situation that also leads to question the validity of these solution paths). These different poses provoke a distance between solution paths in students and in teachers. The challenge for the teaching and learning of algebraic equation-solving can then be seen in teachers' overspecialization – which implicitly imposes a particular pose of the task and thus the strategy – which brings about a distance with students' solution paths. Also, this overspecialisation seems to be generated by the belief that a specifically guided and structured experience of solving will be helpful to students: teachers believe, as expressed above, that students need these structured and specific experiences. This belief may be an important source of reflection, because the challenge of this overspecialisation points to the necessity of not discarding the less common or local solution paths, but of developing a sensitivity toward them and toward the role played by this overspecialisation or these automatisms.

This resonates with Anghileri's (2001) literature review on mental calculations, pointing to students locally tailored strategies, linked to their understanding of problems. However, she explains that these strategies do not last because they are often substituted by standard algorithms taught in classrooms, where students attempt to conform to what happens in everyday mathematics lessons. Anghileri adds that this situation is complex, because without negating the power of standard algorithms for solving, they conflict, provoke a "distance", in the development of students' aptitudes in problem-solving. For her, this amounts to a matter of intentions:

The emphasis in teaching arithmetic has changed from preparation of *disciplined human calculators* to developing children's abilities as *flexible problem solvers*. This change in emphasis requires new approaches in teaching that will develop children confidence in their own methods rather than replicating taught procedures, and that will enable them to understand the methods used by others (Anghileri, 2001, p. 79).

The transition toward flexible problem-solvers represents an invitation to think about algebraic teaching and learning, an invitation directly aligned with the above argument on the importance of developing sensitivities about distances between teachers and students' algebraic solving processes.

*Understanding of equality and solving equations are some of the big ideas in algebra. They have been in focus in early algebra research for some decades and in many countries it is now usual to work with equalities and solving equations using informal methods from early school years. However, it is not clear how the transition to formal methods of equation solving could be conducted in order to maintain students' interest and enhance their algebraic understanding. We shed light on the issue by reporting on what happens when three teachers introduce equation solving with formal methods in Grade 6 (age of 12) in Finland. We especially consider how the introduction could support students' development of an algebraic understanding of equality and their engagement in more formal mathematics.*

*Keywords: Equations, primary school mathematics, equality, algebra.*

## Introduction

Learning to solve linear equations in a more formal manner may be a critical moment in a student's school mathematical experiences. The student is perhaps able to figure out the missing value in an equation with one unknown written as an open number sentence, for instance solving  $x - 10 = 15$  by arguing 'for  $x$  minus 10 to become 15, then  $x$  has to be 25 because when 10 is taken away from 25 the answer is 15'. But the student does not understand how and why the standard algorithm works for solving the very same equation, that is, looking at the equation  $x - 10 = 15$  as equivalent to the equation  $x - 10 + 10 = 15 + 10$  and equivalent to the equation  $x = 25$ . This particular situation is shown to be associated with how the student understands equality (Kieran, 1981; Knuth, et. al., 2006, 2011; Vieira, Gimenez & Palhares, 2013). In arithmetic it is often enough to understand the equal sign as an operator, as a do something -signal (Kieran, 1981). In algebra, however, the student should understand equality between two expressions as an equivalence relation that does not change. Such algebraic understanding may not be supported if the student is taught to solve equations by memorized procedures as 'move terms from one side to the other side of the equal sign and change the corresponding signs' or 'do the same thing on both sides'. Successful equation solving is connected to a relational meaning of the equal sign, and understanding the notion of equation as a statement about an equivalence structure (Knuth, et. al., 2006, 2011; Stacey & MacGregor, 2000).

Scholars have only recently started to theorize about possible learning progressions with respect to algebra in different school years (Cai & Knuth, 2011). Although students may be taught to consider the equal sign as a relation by working with equivalent expressions and by solving simple equations with informal methods already in early school years, it is not sure that they can operationalize the

meaning of their experiences when moving to more formal methods of equation solving in later school years. In Finland, Grade 6 teachers are expected to focus on a progression from equation solving by informal methods to equation solving by more formal methods. The general aim of this paper is to shed light on this progression by analyzing how students in three Grade 6 classrooms in Finland are introduced to solving linear equations with one unknown.

## Learning to solve linear equations

A distinction can be made between an arithmetical and an algebraic notion of equality and a corresponding difference in arithmetical and algebraic understanding. Following Filloy and Rojano (1986) and Vlassis (2002), if the unknown in a linear equation appears only on one side of the equal sign, e.g.  $x + 5 = 8$ ,  $13x = 39$ ,  $6(x + 3) = 48$ , the student has less need to operate on or with the unknown, or to deal with the equivalence structure of the expressions on both sides of the equal sign. For equations of this arithmetical type the student probably manages to find the value of the unknown by applying known number facts or inverse operations. When the unknown appears on both sides of the equal sign arithmetical understanding is however no longer enough. Neither is arithmetical understanding enough in the abstract type of arithmetical equations where certain algebraic manipulations are needed, for example, because of the presence of negative integers (e.g.  $2 - x = 7$ ) or several occurrences of the unknown (e.g.  $6x + 5 - 7x = 27$ ) (see Vlassis, 2002, p. 351). When solving such more abstract equations the student who has an algebraic understanding of equality first of all acknowledges that the expressions on both sides of the equal sign are representing equal values, next that the solving process involves mathematical actions, which preserve this balance and produce equivalent equations. Vlassis (2002) noted that concrete representations of equalities, like the two pan balance model, might act as good tools for developing students understanding of equality, but Vlassis also pointed at their limitations. For example, the balance model cannot represent the negatives in an equation. More generally, a true algebraic understanding of equation solving implies that the student considers the equation as representing a problem situation, and starts to understand the equation as an equivalence structure maintained by the operations one has to apply on both sides to solve for the unknown.

If a real-life problem is used as a tool to introduce students to solving equations and the unknown is solved for through the syntax of algebra, the student needs to refrain from an arithmetical understanding of the solution to the problem. This situation may be at odds with the student's knowledge and intuitions about arithmetic because the meaning of the equal sign changes from announcing a result to stating an equivalence relation (e.g. Carraher, Schliemann, Brizuela & Earnest 2006). Furthermore, an algebraic interpretation of the solution to the real-life problem implies that the student should be able to refrain from immediately attributing a concrete meaning to the letter appearing in the corresponding equation. Instead the student should understand the letter as an unknown number, the value of which is not significant at the moment the equivalence relation is set up and manipulated (Vlassis, 2002).

Although the equal sign ( $=$ ) is focused together with minor than ( $<$ ) and major than ( $>$ ) signs already from Grade 1 in order to enhance students' understanding of equality, primary school students in Finland most often use the equal sign in their mathematical practices in order to show the result of an arithmetic problem. It is also usual to concretize the simple equations appearing in primary

school with a balance model and encourage students to solve equations with testing, using inverse operations and other informal methods.

## Methodology

The material was gathered in the spring 2012 from three Grade 6 classrooms in the Swedish-speaking community of Finland as part of the international VIDEOMAT-study (see Kilhamn & Røj-Lindberg, 2013). Four consecutive lessons on equation solving, and a fifth lesson on problem solving were video-taped and imported into Transana, an open source transcription and analysis software for audio and video data ([www.transana.org](http://www.transana.org)). The teachers answered a few clarifying questions immediately after each lesson and participated in formal interviews after the last (fifth) videotaped lesson. The teachers Anna, Bror and Cecilia have a similar educational background as certified generalist teachers and Masters of Pedagogy. At the time of the study their teaching experience varied from Bror's five years to Cecilia's seven and Anna's 15 years of experience. They used the same textbook and teacher guide. In this paper we report on a close attention to what happened during the first videotaped lesson when the three teachers introduced solving linear equations in one unknown with formal methods. We especially considered how the introduction might have supported students' development of an algebraic understanding of equality. First we briefly present the characteristics of all three teachers' introductions to solving equations and continue by presenting the case of Anna.

## Three entries to equation solving

In line with the Grade 6 textbook all three teachers introduced equation solving with one-step equations where the unknown appeared once on the left side and with an integer on the right side.

Cecilia started from a strong emphasis on the equal sign as stating an equivalence relation. Her aim was to help students unlearn their earlier use of the equal sign to represent a string of calculations. She focused on the equal sign as representing equivalence in several ways: by discussing its meaning explicitly with her students, by referring to a solution a student had made in the test, and by representing both inequality and equality with a balance scale. These situations were familiar to the students, who also participated in the corresponding discussions in seemingly relevant ways. However she did not utilize the balance scale analogy to support the emergence of algebraic understanding of equation solving. The first lesson her students solved only equations of the addition type, e.g.  $x + 8 = 15$ , by subtracting, in this case  $x = 15 - 8$ , without any further discussion related to a structural meaning of the equal sign.

Bror started from four uncomplicated real-world situations that the students solved mentally by stating the answer. The first one was "There are seven fruits in a basket altogether. And four of the fruits are apples, the rest are pears, followed by the question: How many pears are there in the basket?" Each situation was then represented with an equation, e.g.  $7 + x = 12$ , solved and checked with arithmetical means like in Cecilia's classroom. Next Bror did a rapid switch in his teaching to an algebraic interpretation of why the subtraction  $12 - 7$  in the solution can be thought of as 'the number 7 is moved to the right side of the equal sign and the corresponding sign is changed'. However, the students' activity showed no explicit signs of an emerging algebraic understanding of equality. In their verbal answers students continued to refer to the equal sign as a do something –

signal, and in their notebooks they applied inverse operations to find the value of the unknown for all equations.

The third teacher, Anna, started in a similar way as Cecilia and focused on the equal sign as stating an equivalence relation, however in a more formal manner. Anna started from defining an equation as equal expressions. She then did a quick transition to the algebraic approach of ‘doing the same thing on both sides’ to maintain equality and find the value of the unknown. Her message to the students was clear: you must isolate the unknown number step by step by operating on both sides of the equation.

Here we present episodes from the first lesson in Anna’s classroom. The episodes show how the pattern of communication funneled the students (Wood, 1998) into memorizing ‘do the same thing on both sides’ rather than focusing on why this strategy works.

### **We have to do the same thing on both sides**

Anna opens her lesson by writing an open number sentence,  $4 + \_ = 9$ , on the white board. The students give the value of the open number, and they name the object an equation. Anna reads the following aloud from the white board and then fills the placeholder in  $4 + \_ = 9$  with the letter  $x$ .

Anna: An equation is an equality relation between two mathematical expressions, which are called left side and right side. It includes one or more unknown numbers. If there is one unknown number, you normally use the letter  $x$ .

Next, Anna continues to read aloud: “An equation is an equality relation between two sides. The two sides are separated by an equal sign”. She illustrates the statement with an arithmetical equality,  $4 + 2 = 7 - 1$ ,  $6 = 6$ , and with the equation  $4 + x = 9$  where she emphasizes that both sides of the equation must be equal. The students are asked to solve for two open number sentences and she stresses that the placeholder for an unknown can be replaced by the letters  $x$ ,  $y$  or  $z$ . All the equations she has shown to her students so far include only one number on the right side, except for the arithmetical equality she used to indicate a new understanding of equality: the equal sign as a signal of an equivalence structure.

Before the start of the following episode Anna refers to solving equations as a stepwise mathematical strategy. She writes  $x + 12 = 18$  on the white board. By stating, “we know that  $x$  should be six” she then indicates that the students’ attention should not be on finding the value of the unknown. She then starts funneling her students to discover “how to do it”: how to preserve the equality while simultaneously finding the value of the unknown.

Anna: If I have an equal sign in the middle, then I aim at having  $x$  alone on the left side (...) But now I have plus twelve there, what do you think, the way of thinking, how can I get this plus twelve away from there? I want to have  $x$  alone on the left side of the equal sign. How can I get it away? Janne.

Janne’s answer “eighteen minus twelve” shows that he attends to finding the value of the unknown. Anna’s attention is however on the mathematical actions to preserve the equality and she does not develop his answer any further. She repeats the question “How can I make plus twelve to zero?” several times, but does not get the answer she wants. She then gives the students a hint by drawing a

minus sign after 12 on the left side of the equation. When she starts getting answers she accepts, the funneling accelerates and ends by her statement “I have shown how it actually goes step by step”.

Anna: How shall I get plus twelve to zero? I helped you a little bit on the way. Nelli.

Nelli: Minus twelve.

Anna: Minus twelve. But twelve minus twelve is zero, isn't it. But now the matter here, when I do something on the left side so what do you think I should do on the right side? Tor.

Tor: Take away from there, that twelve.

Anna: Exactly. I have to do the same thing here, now I have got eighteen, what should I also do then, here, on the right side? Well, now, Mimmi.

Mimmi: Minus eighteen.

Anna: No, not minus eighteen, the same thing as on the left side. Mimmi.

Mimmi: Minus twelve.

Anna: Minus twelve. Well let's check, x, twelve minus twelve is zero, so then, now I've got x on the left side, eighteen minus twelve is (...) Quickly Mimmi.

Mimmi: Six.

Anna: Six. Now I have, stepwise, through mathematical steps, done this equation. You could quickly see that it must be six. You could do it just like that. But now I have shown how it actually goes step by step. I want to have x alone on the left side, so that I get what x equals to. And then, I just have to look what I have on that side, what I need to do. In this case, I had plus twelve, then I have to take minus twelve so that it becomes zero. But when I do something on the left side, I also have to do the same thing on the right side. Do you understand? Did you follow?

Immediately after the previous episode, Anna and her students started solving the equation  $y - 6 = 11$ . The “mathematical steps” are repeated and it becomes clear that some students, as Janne, now know that “to do the same on both sides” is the name of the game the teacher wants to hear.

Anna: Quickly, I know you know the answer. But we shall think about the mathematical steps. What do I want, I'll put the equal sign here, what do I want to have alone on this side of the equation? What am I aiming at? (Suggestions from students: x and y) Y, okay, I've got y there. But it is not ready yet. I've got the minus six, what shall I do then, what do I want to do then? Now I've got minus six. Karin

Karin: You want to make it zero.

As Anna then continues by asking how she can get a zero out of  $y - 6$  she gets the answer “plus six” from both Karin and Janne. But she is not yet satisfied.

Anna: Plus six. Okay. And then on the right side I have eleven. Are we ready with it or shall I still do something? /.../ Why Janne, plus six there too?

- Janne: We have to do the same thing on both sides.
- Anna: The same thing on the left and right sides. What I do on the left side, the same thing on the right side, or on the right and left sides. It's plus six, now, because I had minus six. Okay. Then I have got y. Those two cancel each other out. Then I've got y there. And what will be on the right side? Vanja.
- Vanja: Seventeen
- Anna: Seventeen. And I know that you could have been able, you could find it already in a few seconds, but now we did the mathematical steps, again. Are you following? [SS: Yeah, yeah.] Beginning to understand this, although these are easy numbers /.../ Now you have solved equations, easy equations. Later, there will be a little bit harder ones, but now we'll begin with these.

When Anna starts teaching the steps of solving the equation  $x + 12 = 18$  in the first episode, the students do not contribute with the answers she seems to expect. After receiving a hint from Anna in the form a minus sign,  $x + 12 -$ , Nelli gives the expected answer, “minus twelve”. In the second episode we can notice how the students and Anna use the same wordings as when solving the equation  $x + 12 = 18$  in the first episode. Earlier Anna stated her expectation very clearly when she said “I want to have x alone on the left side of the equal sign” and she repeats the question “How shall I get plus twelve to zero?” many times. Now her expectation is reformulated as questions, “What do I want to have alone on this side of the equation?” followed by “What do I want to do then? Now I've got minus six”, and the student Karin finally gives Anna the expected answer “You want to make it zero”.

In her summary in the first episode Anna reminded the students “when I do something on the left side, I also have to do the same thing on the right side”. In the second episode the student Janne repeats her words in his answer “We have to do the same thing on both sides” and Anna confirms that he remembers correctly by saying “The same thing on the left and right sides. What I do on the left side, the same thing on the right side, or on the right and left sides”. Anna's discussion with her students focused strongly on memorizing the procedure she called the “mathematical steps” and, hence, did not serve well in supporting their development of an algebraic understanding of equality. Moreover, solving the equation by algebraic means, and with an algebraic interpretation of equality, was of no use to the students who already knew the value of the unknown x. Nevertheless they tried to fulfill Anna's expectations and answer her questions.

## Discussion

The three teachers in this study took some initiative in leading their students forward, from an arithmetical to an algebraic understanding of equality, but none of the teachers confronted the students with situations where mathematically more powerful approaches were needed than those students were already familiar with. Cecilia emphasized the need of understanding the structural meaning of the equal sign. Bror and Anna focused the strategy of doing the same thing to both sides of the equation. It seems, however, that neither the teachers nor the authors of the Grade 6 textbook were aware of the underlying conceptual differences between solving equations within an arithmetical understanding of equality and, on the other hand, within an algebraic understanding.

The students had encountered missing value problems in the textbooks every now and then from Grade 1 onwards. They were familiar with the logic of that type of tasks. However, in the videotaped lessons the students did not have any real need to adopt algebraic ways of thinking about equality. For instance, one can wonder whether the students in Bror's classroom were motivated at all to make sense of the uncomplicated real-life situations with a new complicated way of thinking as the solutions to the problems were obtained more economically by arithmetical means. At best, solving equations by adding or subtracting the same term from both sides of an equation was used by students as a memorized procedure and applied for one particular type of equation, only. The students did not need an algebraic understanding of the equal sign to solve neither the real-life problems nor the equations, and the book did not explicitly expect students to expand their mathematical knowing into operating with or on the unknown (cf. Filloy & Rojano, 1986).

Balacheff (2001) recommends that students should experience a clear rupture between arithmetic and algebra. The rupture might be a strong emphasis of the newness of a situation, for instance to give more complex equations to students to be solved by including numbers beyond students' arithmetic capacity and hereby support a need for an algebraic approach. Another way forward could be an algebraic use of numbers (Blanton & Kaput, 2003), for instance to investigate series of arithmetic tasks with a pattern, and support the students to express and justify the pattern. In many cases an algebraic sense of equality can be developed from just small changes and extensions in the types of tasks and questions textbooks or teachers present to students, and by encouraging discussions. The students' arithmetical understanding of the equal sign can be confronted in versatile problem situations where a structural meaning of the equal sign is in focus whilst the situations are represented and made sense of within an algebraic syntax. In Anna's classroom, for instance, the students general thinking about numbers, and hereby their emerging algebraic sense of equality, could have been supported in several ways (cf. Blanton & Kaput, 2003; Carraher et al., 2006). A focus on transforming the arithmetical equality  $4 + 2 = 7 - 1$  into equivalent expressions like  $4 + 1 = 7 - 2$  or  $14 + 2 = 10 + 7 - 1$  at the start of the lesson, as well as on the simple questions "How do you know that the procedure 'doing the same on both sides' is true and does the procedure *always* work?" could probably have promoted an algebraic understanding of equality by means of students' own justifications of the transformations and the procedure. Moreover, the funneling effect we saw in Anna's classroom could have been avoided (cf. Wood, 1998).

*The term “multiple referents” (MR) is used to describe the error of using the same letter to refer to two different quantities when translating word problems to equations. MR can be related to the presence in the statement of what are termed indexical expressions so that the presence of indexical expressions in statements may be associated with a greater number of MRs. In this paper we analyse students’ performances when solving word problems algebraically with the aim of determining the causes of this kind of error. Results from this research indicate that there is not an unique factor that accounts for the commission of MRs. At least the error may be associated either with the tendency for students to use personal idiosyncratic sign systems when translating from the natural language to the algebraic language or with the construction of a wrong problem model.*

## Introduction

The relevance and utility of solving word problems is widely accepted by the educative community as an issue interesting by itself and as medium to develop general skills applicable to everyday life and other academic subjects. Actually, its relevance is reflected in many research agendas on educational mathematics (e.g., Kieran (2006) or Mason, Graham & Johnston-Wilder (2005)).

In the mathematical activity in general and in problem solving in particular, it becomes essential the internal and external representation of the mathematical ideas, in such a way that different registers are simultaneously combined. As word problems are enounced in natural language, the role of this register is a determinant factor in the task difficulty and, indeed, a correlation between reading comprehension and mathematical ability exists (e.g., Capraro, Capraro, & Rupley, 2012). In this regard, the influence of syntactic (e.g., Abedi & Lord, 2001) and semantic (e.g., Riley, Greeno, & Heller, 1983) variables has been studied. In the algebraic solving, another register that necessarily arises is the symbolic one, which works differently than the natural language. For instance, in the algebraic language there is a univocal correspondence between expressions and symbolised quantities, whereas it does not happen in the natural language, where the same name can be given to different objects (Filloy, Rojano, & Puig, 2008). This fact may cause errors when solving word problems algebraically. Without prejudice of the usefulness of other methods, the algebraic resolution constitutes a useful tool that can expand the potential of the subjects as problem solvers.

## Theoretical framework

The Cartesian Method describes the process of obtaining and solving the equation (or equations) that represents the situation depicted in a problem statement (Filloy et al., 2008; Polya, 1981). This process implies a cyclical process of sense production. In order to explain it, we use the notions of Textual Space and Text (Filloy et al., 2008). The Textual Space encompasses the semantic content communicated by the linguistic structure of the text in the explicit context to which it refers. The Text is the result of a personal re-elaboration of the Textual Space carried out by the subject, by means of which he/she gives sense to these semantic content. The resulting Text becomes the Textual Space of a new reading and so on. In a global way, the Cartesian Method requires a transformation from the original Textual Space expressed in natural language to a Text expressed with one equation (or a system of equations). The first step is an analytical reading of the statement (Filloy et al., 2008), which involves a reading/transformation process where the solver extracts the set of quantities and arithmetical relationships among them from the original Textual Space. Hence, its result may be interpreted as the identification of the problem model in the terminology of Nathan, Kintsch and Young (1992). By way of example, let us consider the problem P2 of Table 1. If we use the letter  $x$ , to represent the son's age at present, and  $y$  for the father's age at present, then the problem model can be expressed, for example, by means of the system  $y = 2x$ ;  $y - 17 = 3(x - 17)$ . The resolution of the system provides the solution  $x = 34$ ,  $y = 68$ .

However, a solver can eventually perform this process in successive cycles of transformation from Text to Textual Space, and use several registers in order to externally represent it. Since many non-linguistic signs are commonly used, we adopt a semiotic perspective and consider the notion of Mathematical Sign System (MSS) in the sense of Radford (2000). In this way, we account for the construction and use of idiosyncratic MSS ( $MSS_{Idi}$ ), specific for each individual, with its own syntactic features and ways of assigning meaning to symbols. Such  $MSS_{Idi}$  are used as intermediate registers when the student attempts to translate a Textual Space stated entirely in natural language ( $MSS_{Nat}$ ), and to produce a Text expressed in algebraic language ( $MSS_{Alg}$ ).

Regarding the change of MSS, we follow the approach of Duval (2006) and use the term conversion to name the change of semiotic representation register where the signifier is located, but without modifying the represented meaning. Such conversion can be congruent or non-congruent, depending on whether the syntactic structure and/or semantic segmentation are the same or not in the source and in the image representations. In this paper, we focus our attention to one kind of linguistic expressions called indexical expressions. These are expression whose meaning may shift depending on the context. They are common in  $MSS_{Nat}$  (e.g., “here”, “today”, or “somebody's age” at different temporal moments). However, in  $MSS_{Alg}$  the designation of quantities is functional and indexical expressions do not exist. Hence, if the statement of a word problem contains an indexical expression, then the conversion to equations is necessarily non-congruent. In this paper we study the phenomenon consisting on the violation of such functional designation. We will refer to it as use of multiple or shifting referents for the unknown (MR), following the terminology of Stacey and MacGregor (1997, 2000). Although MR is valid in  $MSS_{Nat}$  or certain  $MSS_{Idi}$ , it represents an error in the context of  $MSS_{Alg}$ . In the present work we use a family of word problems known as age problems, and where indexical expressions arise naturally. Specifically, they are used to express that the age of the characters evolve over time (Table 1). As Stacey and MacGregor (2000)

reported, the MR may appear due to distinct causes: “i”) the letter refers to different quantities in one equation or within a system of equations; ii) the letter refers to different quantities at different stages (ages); and, iii) the letter is a general label for any unknown quantity or a combination of quantities” (p. 10). It should be noted, however, that we follow the Radford (2000) semiotic approach, where signs are seen as tools of the mind to perform actions in a particular context, so they must be studied in terms of the practice they mediate. In this sense, the tasks we propose in this work are essentially different from that of Stacey and MacGregor (1997, 2000), because we require the students to pose an equation (or equations) but not to solve it. The latter is relevant because, as Stacey and MacGregor (1997, 2000), or Radford (2000) have pointed out, it is usual that, when a solution is required, the meaning students give to letters has an arithmetic resemblance. The task we propose focuses on the conversion from the natural language to the algebraic language. As a consequence, in concordance with Radford’s (2000) approach, the idiosyncratic semiotic registers that might potentially emerge would be different from those of Stacey and MacGregor (1997, 2000).

Another key aspect that must be taken into consideration is the moment, specific mathematical activity or step of the Cartesian Method where the MR has its origin. In particular, if a solver did not build a problem model correctly and two different quantities are erroneously considered as equals, then an MR would be committed although the subsequent steps were done correctly. On the other hand, even though a correct problem model was identified during the analytical reading, an MR can happen due to conversion errors when posing equations. A lack of command of  $MSS_{Alg}$  or coordination between distinct MSS (especially between  $MSS_{Nat}$  or  $MSS_{Idi}$  and  $MSS_{Alg}$ .) may cause MRs. The ideas exposed above seem to point out the existence of various sources of MRs and that MRs may be due to different causes for each person, this being relevant in order to design a didactic intervention. Note also that the error by MR during the application of the Cartesian Method has a conceptual nature, because it relies on the unawareness about the way meaning is given in the  $MSS_{Alg}$  and the  $MSS_{Idi}$ . This may reduce the potentiality of the  $MSS_{Idi}$  as a tool, and obstruct the progress in the use of the algebraic method.

## Research aims and research methodology

The aim of this work is to search for and to document possible sources of MR when solving word problems using the Cartesian Method. Subsequently, we pay special attention to determine in each case whether the MR arises due to the inability to build a correct problem model or due to a lack of command to perform conversions between different MSSs. Regarding to the last possibility, we also study the emergence of  $MSS_{Idi}$ s during the conversion process from  $MSS_{Nat}$  to  $MSS_{Alg}$ .

## Participants

The sample consists of 54 students (15-16 years) in their fourth grade of secondary school (in a modality oriented to a subsequent BScs) in three Spanish Public High Schools. According to the Spanish curriculum, they were familiar with the Cartesian Method, having used it over the two previous years.

## Materials and procedures

This work consists of two phases: a written phase and a case study, although in this paper we will exclusively focus on a qualitative study of students’ written productions from the written phase.

Prior to that, we carried a pilot study with 36 participants, aimed to calibrate the difficulty of the problems and the time required to complete them. In addition, based on the pilot study, we stipulated a series of criteria to code the students' productions.

In the written phase we used a questionnaire consisting of six age problems but in this manuscript we only employ students' resolution of three problems from the whole collection (Table 1). All the problems were versions from others in textbooks corresponding to two previous grades (13-14 years old). The statements were entirely expressed in  $MSS_{Nat}$  and they all contained indexical expressions. The written test was conducted in the students' usual classroom. Each statement was shown on a screen at the front of the classroom for three minutes. The participants were given explicit instructions prior to beginning the test. They must try to pose the equation (or equation) that leads to the solution of each problem but solving it was, however, not mandatory. We focus on the raising conflict due to the structural differences in MSSs. In order to stress these differences and also to delimit the study, we turn to the indexical expressions.

Students' productions were analyzed on the basis of the above developed theoretical framework, taking into especial consideration the ideas contained in Duval (2006), Filloy et al. (2008), Radford (2000) and Stacey and MacGregor (2000).

P1	One sister is 3 years older than the other sister, and their father is 43. In 7 years time the father's age will be twice the sum of the sisters' ages. How old is each sister?
P2	A father is twice the age of his son. Seventeen years ago, the father was three times the age of his son. How old is each one?
P3	Eight years ago Ana's age was four times Maria's age. In 12 years time Ana's age will be only twice Maria's age. Find the age of each one.

**Table 1: Problems from the written test**

## Results

In the example shown in Figure 1 the student performs some cycles from Textual Space to Text and represents a Text in a  $MSS_{Idi}$ , which is less abstract than the  $MSS_{Alg}$ . It consists of a table with two columns separated by a straight line, and also a system with two equations. In each column of the table the relations between the ages of the characters at a particular temporal moment are correctly represented. The letter  $x$  stands for Maria's age in both temporal moments, and its value evolves automatically when switching between columns. This means that indexical expressions are valid in this  $MSS_{Idi}$ , so it shares some features with the  $MSS_{Nat}$ . A spatial reorganization takes place, but, at a deeper structural level, there is not a discontinuity between the rules of both systems regarding the acceptance of indexical expressions. Here we interpret that the subject's analytical reading produces a correct problem model, and that it is correctly represented within the frame of her/his  $MSS_{Idi}$ . The subject properly coordinates both MSSs, performing a correct conversion from  $MSS_{Nat}$  to  $MSS_{Idi}$ . However, when posing the system of equations the student produces an MR because the letter  $x$  stands for the age of both problem characters. In this case we interpret that the MR takes place in subsequent cycles due to a lack of command of the  $MSS_{Alg}$  and/or a deficient coordination between her/his  $MSS_{Idi}$  and the  $MSS_{Alg}$ . Indeed, the error may be a consequence of the student's

lack of awareness of the structural differences between her/his  $MSS_{Idi}$  and the  $MSS_{Alg}$  regarding the validity of indexical expressions.

problema: 7A - Ana y María

-8 años	+12 años
Ana: $4x$	Ana: <del><math>2x</math></del> $2x$
María: $x$	María: $x$

$$\begin{cases} 4x - 8 = x - 8 \\ 2x + 12 = x + 12 \end{cases}$$

**Figure 1: Student's resolution of the problem P3 ("años" means "years")**

Hijo =  $x$

Padre =  $2x$

$2x = x$

$2x - 17 = 3x - 17$

**Figure 2: Student's resolution of the problem P2**  
 ("Hijo" and "Padre" mean "Son" and "Father", respectively)

Figure 2 shows another student's performance in which we interpret that a correct problem model has been built and again the MR seems to be caused by a lack of ability to use the  $MSS_{Alg}$  in subsequent steps of the Cartesian Method. The first equation seems to indicate an overlapping between  $MSS_{Alg}$  and the student's  $MSS_{Idi}$ . Indeed, the letter  $x$  does not stand for the actual age of one character, but as a general label that refers to any unknown quantity. Actually, one of the possible causes of MR suggested by Stacey and MacGregor (2000). In addition to that, in light of the first equation, we interpret that the meaning and interpretation of the equals sign in this  $MSS_{Idi}$  differs from those in the  $MSS_{Alg}$ . The subject uses symbols from the  $MSS_{Alg}$ , but the way of giving meaning to them is completely wrong in the frame of the  $MSS_{Alg}$ . Finally, the second equation seems to reveal that the student has difficulties related to the syntactic rules of  $MSS_{Alg}$  because he/she does not perceive the necessity of using brackets.

padre - 43

1ª her. -  $3x$

2ª her. -  $x$

~~$2(3x + x) = 43$~~

$2(3x + x) = 43$

**Figure 3: Student's resolution of the problem P1**  
 ("hermanas" and "padre" mean "sisters" and "father", respectively)

Unlike in previous examples, in the case shown in Figure 3 the student does not identify a correct problem model since the passage of time is not considered for any character. In addition to that, the additive relation between the siblings' ages is wrongly symbolised because a multiplicative relation is used. Regarding the multiplicative relation that should link the future ages of the three characters, the student seems to use the actual ages instead of the future ages. From a conservative view it may be argued that the letter  $x$  could refer to one quantity at different times (e.g., the current and the future ages of one sister). However, the use of the known quantity father's current age in the equation reveals the existence of an incorrect problem model. Here, the MR already arises during the analytical reading, because it seems that the student does not perceive the necessity to involve in its model two different quantities for each character (one referring to the current time and another to the future).

## Conclusions

Personal idiosyncratic representations are usually thought to be helpful to students in order to understand and solve problems. It is commonly accepted that these representations can work as a bridge to more formal systems, as is the algebraic language. However, as Weinberg, Dresen and Slater (2016) suggest, the differences between such idiosyncratic systems and institutional semiotic systems can be also a source of conflict. In particular, these authors claim that the way in which such systems differ may greatly influence the students' mathematical activity. In this paper we report and analyse an example (Figure 1) where the student firstly represents a problem model in an idiosyncratic system that contains algebraic symbols but structurally different to the algebraic language, and only following this, a system of equations is posed.

This and other examples of students' outputs reported in this work provide evidences of the tendency to manage algebraic symbols according to a set of personal rules that are not coherent with those of the algebraic language. Indeed, the analysis of such outputs allow us to affirm that some of the characteristics of these idiosyncratic semiotic systems are more close to the natural language rather than the algebraic register. This fact is not trivial and can lead to the commission of errors when mathematical relationships are translated between different mathematical sign systems. But such translation has to be unavoidably performed during the algebraic solving of word problems. Thus, a semiotic perspective on the students' performances makes possible to locate possible sources of the error consisting on using multiple referents for the unknown (MR). Specifically, the examples presented in this paper strongly support the fact that the commission of MR may be due to quite some different factors. On the one hand, an erroneous understanding of the problem may lead to the construction of a wrong problem model, what in turn would lead to commit a MR. In this case, however, the error is not necessarily related to the students' ability to use the algebraic language. Instead, difficulties seem to emerge when conceptualising the arithmetical relations expressed in the statement in natural language.

On the other hand, we provide examples that show how the appearance of MR can be a consequence of students' misunderstandings and overlapping between the structural semantic and syntactic rules of natural language, idiosyncratic systems, and algebraic language. In some cases, the student build a correct problem model but represent it using an idiosyncratic sign system that shares important features with natural language (e.g., indexical expressions are valid in both systems). Since these idiosyncratic sign systems employ algebraic symbols but do not obey the

same rules than this language, the MR may appear due to the incongruity between both mathematical sign systems. In other examples, similar causes prompt errors when the student directly translates from natural language to algebraic language. From a didactic point of view the different nature of MRs is transcendent because teachers need to know the sources of the MR for a particular student in order to design an appropriate remedial instruction.

# Key ideas as guiding principles to support algebraic thinking in German primary schools

Anna Susanne Steinweg

University of Bamberg, Germany; [anna.steinweg@uni-bamberg.de](mailto:anna.steinweg@uni-bamberg.de)

*German mathematics teaching-units in primary school lack explicit algebra learning environments; however, the topics which are taught address algebraic thinking if seen from a new perspective. Teachers and children are mostly unaware of the algebraic potentials of tasks –especially in the scope of the content area patterns and structures. The project presented here submits a suggestion of algebraic key ideas as guiding principles to rethink ‘arithmetical’ topics and to design learning environments on algebraic thinking. Additionally, effects of implementing and evaluating such tasks are illustrated by one example.*

*Keywords: Algebraic thinking, awareness, key ideas, patterns and structures, properties.*

## Introduction

The approach presented here is worked out for the particular situation in German primary schools and accordingly addresses one of the borderlines in the scope of algebraic thinking pointed out by Hodgen, Oldenburg, Postelnicu, & Strømskag (2015), i.e. “differences between teaching cultures in different countries (and within countries) are enormous and restrict generality of results very much” (p. 386). In German primary school algebraic topics have no tradition and still no explicit place in curricula, textbooks, and teaching-units on the one hand (KMK, 2004). On the other hand, recent research on early algebra or algebraic thinking is emerging (e.g. Akinwunmi, 2012; Gerhard, 2013). Furthermore, the daily classroom interaction and common teachers’ beliefs reveal bright opportunities for early algebra (e.g. Krauthausen & Scherer, 2007). Yet, implementing promising approaches and algebraic tasks in daily school life still is a great issue.

The main aim of the project is making algebraic learning chances possible for children. Opportunities to get to know algebraic ideas and ways of algebraic thinking depend on tasks presented in the classroom. These tasks are offered by teachers. Hence, the focus has to be on tasks and on teachers’ awareness of the potential of these tasks. In so doing early algebra can be supported via a detour that influences classroom interaction and therefore children’s awareness and abilities.

## Theoretical framework

### Algebraic thinking and core areas

Algebraic thinking is assigned to special thinking habits. Current research identifies mainly four algebraic thinking practices, which lay in generalising, representing (incl. symbol use), justifying, and, reasoning with generalisations or relations (e.g. Kaput, 2008; Kieran, Pang, Schifter, & Ng, 2016; Blanton, Stephens, Knuth, Gardiner, Isler, & Kim, 2015). The focus of attention needs to shift from numerical solutions to mathematical structures behind the given patterns or equations. This shift allows seeing the generality as reification (Sfard, 1991) and therefore creating new objects (Mason, 1989). “By attending to relations and fundamental properties of arithmetic operations (what we call relational thinking) rather than focusing exclusively on procedures for calculating answers” (Carpenter, Levi, Franke, & Zeringue, 2005, p. 53) procedural thinking is not erased but expanded.

Algebraic thinking as conceptual (Tall & Gray, 2001), relational or structural thinking can be applied to various topics or as Sfard puts it, “any mathematical activity may be seen as an intricate interplay between the operational and the structural versions of the same mathematical ideas” (Sfard, 1991, p. 27). Although in most of the research studies certain topics are outlined to be particularly relevant for algebraic thinking, different content-orientated registers identifying the strands or core areas of algebra can be found in many of them (Table 1).

		pattern and formulas	patterns	patterns (& structures)
generalised arithmetic	generalised arithmetic	restrictions	arithmetical structures	property structures
	equations			equivalence structures
functional thinking	functional thinking	functions	relations	functional structures
	proportional reasoning			
application of modelling languages	variable	symbolic language		
Kaput 2008	Blanton et al. 2015	Drijvers, Goddijn & Kindt 2011	Kieran et al. 2016	Steinweg 2016

**Table 1: Algebraic strands and core areas**

These lists overlap in various topics as shown in the re-assigned order in Table 1. The core areas therefore are more or less universally acknowledged and differences can be identified in details only. For instance, some authors differentiate between generalised arithmetic and equations whilst others exclude patterns or list symbolic language (variables) within its own section. My suggestion (Table 1 rightmost column) and basis of this paper takes into account the current situation in Germany, because it “is important to indicate that any curriculum has a complex relationship to what actually occurs in classrooms” (Cai et al., 2005, p. 14). The German primary curriculum includes no algebra area, even though a single door for the implementation of algebraic thinking opens up. This possible link is the content area ‘patterns and structures’, which is given in the national standards (KMK, 2004). Moreover, patterns and structure can be regarded as generic field for the different algebraic topic strands (Drijvers et al., 2011).

Owing to these two reasons my own suggestion stresses the terms patterns and structures. In the following paragraph these terms are theoretically analysed in more depth.

### **Patterns and structures**

Often mathematics itself is described as the science of patterns (Devlin, 1997). In this view, all mathematical theories arise from patterns spotted. Even axioms characterise patterns to build on. Not surprisingly, teaching and learning about patterns and structures is not a special topic but is fundamental for all mathematics lessons:

Pattern is less a topic of mathematics than a defining quality of mathematics itself. Mathematics ‘makes sense’ because its patterns allow us to generalize our understanding from one situation to another. Children who expect mathematics to ‘makes sense’ *look* for patterns. (Brownell, Chen, & Ginet, 2014, p. 84)

Becoming aware of patterns allows us to see sense in mathematics and to appreciate its beauty. This awareness is at least twofold. On the one hand, seeking patterns can be classified as meta-cognitive, on the other hand, there is a cognitive component of awareness which is characterised by “knowledge of structure” (Mulligan & Mitchelmore, 2009, p. 38).

*Patterns* can be described as “any predictable regularity, usually involving numerical, spatial or logical relationships” (Mulligan & Mitchelmore, 2009, p. 34). Constructing a pattern of numbers or shapes by making up a rule or a certain operative variation (Wittmann, 1985) of a given number or task is an individual creative process. If, for instance, the pattern of a number sequences is creatively made up, the regularity then is fixed and can be used, continued, and described (Steinweg, 2001).

In the approach presented here *structure* is understood as mathematical structure and not as a category system to describe the individual pattern awareness of children (Rivera, 2013). Mason, Stephens & Watson (2009) recommend “to think of structure in terms of an agreed list of properties which are taken as axioms and from which other properties can be deduced” (p. 10). They point out the difference between the spotting of (singular) relations and the use of the given example as paradigmatic for certain properties of a general structure (Mason et al., 2009). Thus, detecting structures, in contrast to patterns, requires mathematical knowledge about objects and operations. The relation between mathematical objects is essentially determined by mathematical structures (Wittmann & Müller, 2007). Awareness of structures often suffers from the fact that structures are mentioned only briefly and only formulated in rules, like  $a+b=b+a$ , in mathematics lessons. Unfortunately, these condensed statements are not an appropriate tool to become aware of the logical structures and properties of mathematical objects and relations which are fundamental for mathematics. In summary structure is the crucial term in the twosome patterns and structures. The approach described in this paper therefore puts emphasise on structure, and mentions structure purposefully in each key idea in order to call attention to it.

### **Algebraic key ideas – a suggestion**

The key ideas outlined in the approach presented here focus on (1) patterns (& structures), (2) property structures, (3) equivalence structures, and (4) functional structures (Steinweg, 2016). The first idea differentiates between patterns and structures. Patterns are not a priori structures but may eventually generate products following mathematical properties and relations. Hence, the expression ‘structures’ is given in brackets to indicate this substantial difference. The second key idea lies in the properties of numbers and operations: Numbers can be divided into odd and even, divisibility can be explored, etc. Daily used –supposedly arithmetical– operations follow structures because of their properties (commutativity, associativity, distributivity). One example of this key idea is presented below. The third key idea holds learning opportunities in evaluating, preserving or construing equivalence in given correct or incorrect equations by sorting terms, etc. The main issue here is to overcome the urge to calculate the given terms and to solely compare the results but to focus on the relation of given numbers, sums, differences, products, or quotients (Kieran, 1981; Steinweg, 2006). This key idea goes hand in hand with the currently commonly used and fostered individual strategies in arithmetic, which can be found in Germany (also cf. Mason et al., 2009). The last key idea sums up learning environments on functional structures, (i.e. mainly proportional), relations, and co-variation aspects. One example is a task called ‘number & partner number’

(Akinwunmi, 2012). The structural relationship can be described by a rule (functional term) which assigns a partner number to each given number.

As mentioned above, the key ideas presented here are ordered by mathematical core areas and put emphasis on structures as one of many feasible approaches. Sufficient knowledge of mathematical structures is crucial for both teachers and children. Only well trained teachers are able to understand the mathematical structures and to make them accessible for children. One possible strategy to get access to mathematical structures lies in implementing especially designed tasks which enable children to explore, use, describe, and even prove mathematical structures (Steinweg, 2001).

## Methodology

In the research project learning environments suitable for the four key ideas outlined above are designed (Wittmann, 1995) and evaluated in order to uncover the algebraic potential of common tasks and to give tangible examples in the algebraic core areas within the field patterns and structures. Each learning environment includes various tasks in a booklet to be handed out to the children and information for teachers in a teacher's guide (Steinweg, 2013). The teachers participated in an introductory meeting in which the tasks and possible teaching arrangements – given in the guidelines– were discussed. They committed themselves to implement all of the tasks in daily classroom work with the intensity and depth of the use of the learning environments being in their hands. This means that there was no specific focus on the child-teacher-interaction while working on the tasks –with the exception of some mathematics lessons randomly visited by the author. The research therefore focusses on the question: *Does the implementation of the designed tasks show any effects on children's algebraic competencies?* Six German primary school classes with 144 children from 2<sup>nd</sup> to 4<sup>th</sup> grade (on average 7- to 9-year-olds) participated in the project.

## Research results on the example of distributivity

This paper exemplarily illustrates the research idea on distributivity as one element of the key idea 'property structures'. The main challenge is to see the structure of equations and terms in a meta-perspective way. For instance in the term  $2 \cdot 8 + 5 \cdot 8$  children have to spot the specific 'internal semantic' (Kieran, 2006, p. 32). Only if the equal factor is identified as an important component in the products can the 'variable' factors be summed up. The two products have to be identified as objects in a sum and then the two different factors can be added to create a new product ( $7 \cdot 8$ ). The additive combination of products and the decomposing of products into a sum of two products with one equal factor in each case seems a tough challenge for the children. The shift of attention to elements of the equation as objects and to identify the mathematical structure is essential for algebraic thinking. Most likely, the children participating in the project had already experienced derive-and-combine-strategies solving multiplication tasks in class. The actual approach to the multiplication tables in German mathematics in primary school is peculiar. There is no longer 'doing tables' but working on core tasks (e.g. doubles, times 5, times 10) and derive-and-combine-strategies to solve other multiplications. Only core tasks should be known by heart as facts (sometimes known as 'helping facts' in Anglo-Saxon literature). Unfortunately, an arithmetical perspective –calculate terms to determine the specific result– is normally supported by teachers in primary mathematics. The out of the common change of perception of the structure of equations is

therefore challenging. Only by a shift of attention can the structure of the maths behind the equation, i.e. distributivity, be recognised.

The tasks implemented in the project try to support the identification of structure. For instance columns of variations of one equation are given to allow focussing on both the constant and the changing elements, like  $3 \cdot 2 + 6 \cdot 2 = \dots \cdot 2$ ,  $3 \cdot 3 + 6 \cdot 3 = \dots \cdot 3$ ,  $3 \cdot 4 + 6 \cdot 4 = \dots \cdot 4$ , etc. Alongside tasks in symbolic representations, rectangle areas as representation for multiplications (length by width) can be used as well. If rectangles are accepted as multiplication representation, manipulating these rectangles by cutting and re-interpreting the two part-rectangles as multiplications can be the next step to explore and understand distributivity. The children were given one example and then asked to find three more possibilities to decompose the product  $7 \cdot 5$  (Figure 1). Such rectangles can be provided by the teachers as representations on worksheets or ‘actively’ made up by the children by cutting out sections of grid paper. As an instance of possible developments in algebraic thinking by simply working on the tasks Philipp’s solution of one exemplary task of one worksheet given in the booklet is interpreted in Figure 1.

**Figure 1: Philipp explores distributive structures by interpreting rectangles as multiplications**

Philipp’s solution is stunning in some ways. The task asks him to find three further decompositions of the given product. He marks his ideas in the given three rectangle areas and writes down matching symbolic representations of the product-sums. The little dots in the first rectangle grid point at the fact that Philipp might have counted the number of squares. The other solutions do not show these presumed counting dots. Philipp apparently becomes aware of the structure and the main idea. The relation between the terms is understood individually. Philipp connects the different solution by using the verbally form of ‘oder’, which means ‘or’. This habit indicates that he is aware of the possibility of different compositions of the product but not yet sure about the equality-relation between these terms. The worksheet invites the children to find three products by giving three blank rectangles. Philipp extended the task spontaneously by drawing a fourth rectangle. This add-on again is remarkable. Philipp sketches a rectangle without drawing the grid. The countable squares obviously are no longer necessary for him. The fourth solution is the only one which decomposes the factor 5 instead of the factor 7. Philipp applies the main structure of splitting up the factor flexible for either factor now. The example of Philipp shows the multi-faceted possibilities to gain access to mathematical structures by working on challenging tasks.

As the main research question aims at evaluating effects of the implementation of the learning environments, results of a pre- and post-test are of interest. In this paper the results of the test item  $10 \cdot 5 - 4 \cdot 5 = \_\_\_ \cdot \_\_\_$  (corresponding to distributivity) are documented exemplarily (Table 2).

Category	pre-test (n = 135)	post-test (n = 133)
Algebraic	1.5 %	32 %
Procedural	32.5 %	35 %
no answer given	66 %	33 %

**Table 2: Results solving  $10 \cdot 5 - 4 \cdot 5 = \_\_\_ \cdot \_\_\_$**

The task is quite hard to handle for the participating children in the pre-test even so the curriculum expects teachers to work on derive-and-combine-strategies in multiplication. Two thirds have no idea what to fill in the blanks. Only in very few cases are children able to combine the two multiplications into  $6 \times 5$  and thereby make use of the structure (algebraic perspective). After participating in the project one third is now able to give this answer. Another third places a multiplication like  $3 \times 10$ , which is fitting because of an equivalent result (procedural, arithmetical perspective). The figures suggest a developmental step of the procedural thinkers to the algebraic thinkers apparently. This assumption actually cannot be confirmed by the data. The developments are very much individual. For instance, some children who gave no answer prior to the project are now able to see the structural relation or calculate to find matching terms and others still have no answer at all. Despite the fact that these results are still far from being satisfactory, the increase in numbers of children using an algebraic perspective is considerable.

## Discussion

The project gives an initial indication that it is possible to foster algebraic thinking by providing sound learning environments without explicit variable use in the scope of the content field of patterns and structures. The challenges offered support effects on understanding and on performance in algebraic tasks. Yet, the impact of learning environments alone is not enough to support all children. As mentioned above, the project provides no binding specifications to teachers of how, for example, to focus on distributivity, but offers different opportunities to explore this mathematical structure via the designed tasks. As a “good balance between skill and insight, between acting and thinking, is [...] crucial” (Drijvers et al., 2011, p. 22), further effort should focus on exploring the differences between procedural and structural work on tasks. Teachers’ instructions and interaction in classroom discussions as well as the specific role of representations have to be focused on in further studies.

The hope is that the developed key ideas function as bridges between arithmetical topics and algebraic ones and also as guiding principles for classroom interaction. If common arithmetical strategies –like derive-and-combine– are seen from a different angle, they actually are algebraic ones. From a meta-perspective view the procedures performed are determined by mathematical structure and the properties of operations. The shift of attention towards structures has to be made explicit to both teachers and children. Only if teachers appreciate algebraic structures can they offer effective support and take up children’s algebraic ideas. In the particular situation in Germany awareness of the multi-faceted potential of the usually underestimated core area patterns and structures is crucial. Last but not least, the sensibility implies a win-win-situation: “Awareness of structure of expressions helps students understand these better, thus leading to a better understanding of rules and procedures” (Banerjee & Subramaniam, 2012, p. 364).

*In this paper we investigate a pre-service teacher's whole-class discussion at Grade 6, where she attempts to justify the general claim that multiplication is commutative in  $\mathbb{N}$ . Our analysis points at two conditions that constrain the discussion in class: The first is that the diagram used to represent a multiplicative situation—and the way the diagram is used—is inadequate because it does not illustrate the meaning of multiplication. The second is that the diagram enables the students to respond “adequately”, even if they may not have understood why multiplication is commutative. The latter is a constraint because it deprives the pre-service teacher of the opportunity to get feedback that might have let her understand that she would need to revise her intervention.*

*Keywords: Multiplicative situation, commutativity, representation, justification, teacher education.*

## Introduction

Addition and multiplication in  $\mathbb{N}$  (or, more generally, in  $\mathbb{R}$ ) are commutative and associative. Moreover, multiplication is distributive over addition. These basic properties of addition and multiplication play a crucial role in abstract algebra, but also in arithmetic and algebra in elementary school. The work on fluency of the multiplication table gets considerably easier if the students make use of the basic properties. In fact, all arithmetic strategies can be shown to have origin in the basic properties of commutativity, associativity and distributivity. Promoting these properties in elementary school is important for integrating arithmetic and algebra (Carpenter, Franke, & Levi, 2003). Involved in this is the activity of generalising and formalising relationships and constraints, which is one of three strands of algebra identified by Kaput (2008). Furthermore, the basic properties of addition and multiplication are also important in “transformational activities” (Kieran, 2004), which involve syntactically guided manipulation of symbols (e.g., simplifying expressions, exponentiation with polynomials, and solving equations).

At the background on the above, the question raises as to how it can be discussed with students that addition and multiplication are both commutative and associative, and that multiplication is distributive over addition? If we want these properties to emerge from students' mathematical reasoning in the classroom—and not from the teacher's just presenting them as rules—how could it be done, and what challenges may arise? In this paper we discuss this question with data from teacher education, where a pre-service teacher has designed and implemented a lesson, aimed at whole-class discussion with 12 year-old students on basic properties of multiplication. The research question set out to answer is: *What conditions constrain a pre-service teacher's whole-class discussion with Grade 6 students about commutativity of multiplication in  $\mathbb{N}$ ?*

## Theoretical framework

### Multiplicative structures—modelling situations involving equal-sized groups

From a mathematical point of view, multiplication and division by natural and rational numbers may appear easy. However, from a psychological point of view, it is more complex. In a teaching situation,

these operations are dealt with not only as abstract binary operations, but also in terms of how they model different situations. Vergnaud (1988) claims that “[m]athematical concepts are rooted in situations and problems” (p. 142). Because a single concept does not refer to only one type of situation, and a single situation cannot be studied with only one concept, Vergnaud proposes that researchers study “conceptual fields”. This is defined as a set of situations, the mastery of which depends on mastery of a conceptual structure. For instance, the conceptual field of *multiplicative structures* consists of all situations that can be analysed as simple and multiple proportion problems, where the necessary operation is multiplication or division (Vergnaud, 1988).

According to Greer (1992), the most important types of situations where multiplication of integers is involved are:

- equivalent groups (e.g., 6 tables, each with 4 children)
- multiplicative comparison (e.g., 3 times as many girls as boys)
- rectangular arrays/areas (e.g., 4 rows of 7 students, or area of a rectangle)
- Cartesian product (e.g., the number of possible trousers-sweater pairs)

Fishbein, Deri, Nello and Marino (1985) investigated how 623 pupils enrolled in 13 Italian schools (Grades 5, 7 and 9) responded on 26 multiplication and division word problems. Their findings confirmed the impact of *repeated addition* as an intuitive model on multiplication, in which a number of groups of the same size are put together—that is, equivalent-groups situations.

In Norwegian schools, multiplication is usually introduced through situations with equivalent groups, where  $4 \cdot 7$  means  $7 + 7 + 7 + 7$ , while  $7 \cdot 4$  means  $4 + 4 + 4 + 4 + 4 + 4 + 4$ . Here, it is not obvious that multiplication is commutative. The first of the factors—the number of equivalent groups—is taken as the operator (termed *multiplicator*); the other factor—the size of each group—is taken as the operand (termed *multiplicand*). In this model, the multiplicand can be any positive quantity, but the multiplicator must be an integer (Fishbein et al., 1985).

### Justification in the elementary classroom

Algebraic thinking is a term used to describe particular ways of thinking applied when we are looking beyond quantities and operations on quantities. It includes analysing relationships between quantities, noticing structure, studying invariance and change, generalising, problem solving, modelling, conjecturing, justifying and proving (Cai et al., 2005). In this section we concentrate on justification. There are several ways of approaching justification and proof in school mathematics. Balacheff (1988) has identified four types of reasoning in 14-15 year-old students’ practice of proving a conjecture that applies on infinitely many examples:

- *Naïve empiricism* is where students think that some examples (even one or two) are sufficient to justify a conjecture.
- The *crucial experiment* is where students think that the validity of a conjecture is accomplished by testing it on an instance that has some complexity—the reasoning being “if it works here, it will always work”. The crucial experiment is different from naïve empiricism in that the generality at stake is explicitly articulated.
- The *generic example* involves making explicit the reasons for the truth of an assertion by means of operations on an object that is a representative of the class of elements considered. A generic example is an example of something—the validity of a hypothesis is argued for by the characteristic properties of this example.
- The *thought experiment* requires that the one who produces the proof distances him from the actions of solving the problem—he must give up the actual object for the class of objects on

which relations and operations are to be represented in formalised symbolic expressions. Proof by induction is an example of a thought experiment.

Proofs by naïve empiricism, the crucial experiment, and the generic example are based on actual actions and references to examples—these proofs are referred to as *pragmatic* proofs (Balacheff, 1988). The thought experiment is based on abstract formulations of properties and of relationships among properties—this proof is referred to as a *conceptual* proof. Balacheff emphasises that a proof by naïve empiricism or by a crucial experiment does not establish the truth of an assertion, and the reason why he refers to them as “proofs” is because they are recognised as such by the students who produce them. He asserts, further, that the generic example and the thought experiment are mathematically valid proofs. They involve a fundamental shift in the students’ reasoning because the nature of the truth of a claim is established by giving reasons. When using a visual representation to justify a claim of generality, the representation needs to have some properties. Schifter (2009) has identified three criteria for a representation in elementary grades to be adequate: (1) the meaning of the operation(s) involved is represented in diagrams, manipulatives, possibly complemented by story contexts; (2) the representation is accessible for a class of instances; and, (3) the conclusion of the claim follows from the structure of the representation (p. 76).

Justification in the elementary classroom of the commutative property of multiplication can be done through a generic example based on a rectangular-area situation. In this situation, multiplication in  $\mathbb{Q}^+$  is commutative because the area of a rectangle is the same regardless of the order in which its side lengths are multiplied. However, given the impact of the equivalent-groups situation, we consider it important also to be able to build on this intuitive interpretation in justifying that multiplication is commutative. Then of course, the asymmetry of this situation is a challenge. In the following we explain how a justification of commutativity of multiplication in  $\mathbb{N}$  can be constructed, taking the situation of equivalent groups as a starting point. We discuss a justification first by a generic example, then by a thought experiment.

Let  $4 \cdot 3$  be interpreted as the total number of discs when we have 4 equivalent groups of 3 discs, as shown in the upper row of Figure 1. The discs can be regrouped into 3 equivalent groups of 4 discs, which corresponds to  $3 \cdot 4$  (illustrated in Figure 1<sup>1</sup>).

**Figure 1. A generic example illustrating the symmetrisation of an asymmetric situation**

The total number of discs is not changed, and consequently we have that  $4 \cdot 3 = 3 \cdot 4$ . This process of regrouping can be imagined with an arbitrary number of groups  $a$ , and an arbitrary number of discs  $b$ —that is, for any  $a \cdot b$  where  $a$  and  $b$  are natural numbers. The number of discs in the equivalent groups in the original grouping transforms into the number of groups in the new grouping. The

<sup>1</sup> The discs are coloured to make the process clearer. The arrows signify the movement of the discs.

example with the transformation of  $4 \cdot 3$  into  $3 \cdot 4$  is thus used as a generic example in the justification.

Justification by a thought experiment can be rather similar to the generic example presented above, though the reasoning is done in general terms: Given natural numbers  $a$  and  $b$ , then  $a \cdot b$  can be interpreted as the total number of discs when we have  $a$  groups with  $b$  discs in each group. Regrouping of discs by taking one by one disc from each group to make a new group gives  $b$  groups with  $a$  discs in each group—that is, a situation in which the total number of discs can be represented by  $b \cdot a$ . Since the number of discs is not changed in the process of regrouping, we can conclude that  $a \cdot b = b \cdot a$  for all natural numbers  $a$  and  $b$ .

## Methodological approach

The pre-service teacher (henceforth PST) participating in the research reported here was in her first year of a 4-year undergraduate teacher education programme for Grades 1-7 in Norway. The investigation has been done within a compulsory mathematics course in the programme, which involves an integration of mathematics and didactics. The data were collected at the end of the second semester. The main content of the mathematics course previous to data collection was multiplicative thinking, and the emphasis was on different strategies for, reasoning with, and properties of, multiplication and division. The second author, together with a colleague, taught the mathematics course and carried out the data collection.

During the mathematics course, the PSTs in the class worked on several assignments that involved practice of teaching in school (Grades 4-7), all concerned with strategies for and properties of multiplication. In the fourth assignment, from which the data analysed in this paper emerged, the PSTs were asked to plan and carry out a discussion with students concerning a given strategy or property of multiplication or division. The PSTs video-recorded and transcribed their discussions with students. The transcript analysed here is from one of 25 classroom discussions that were carried out and analysed.

Our research question concerns basic properties of multiplication, and we are interested in PSTs' handling of general justifications—that is, justifications for an infinite number of cases. In most episodes where the PSTs discussed properties of multiplication with the students, there was no attempt to generalise and justify. There were discussions of particular examples, usually succeeded by a conclusion along the lines of “this will apply for all numbers”. In this paper, we present an analysis of one of the discussions, the case of Janet (a PST). This case is chosen because Janet actually tried to discuss with students *why* a property of multiplication applies in general (in  $\mathbb{N}$ ) and it demonstrates challenges thereof, which are also traced in some of the other transcripts (not analysed here). We will explain what conditions that prevent the case of Janet from being successful in the sense of including a valid argument for the claim of generality.

## Results

### Establishing a situation to interpret a multiplication problem

Janet and the students have discussed the products  $12 \cdot 10$  and  $10 \cdot 12$ , and the students have come to the recognition that the products are the same. David says it is because “the numbers have simply changed places” (turn 10). Then Janet provides another example:<sup>2</sup>

11. Janet: We will get the same answer, it's just the calculation that is reversed... If we take another arithmetic problem, will that be similar, too?  $13 \cdot 17$  and  $17 \cdot 13$  [writes on the blackboard]. [Pause 7 sec.]. Will this be the same, or are they different? [Pause 11 sec.]. What do you think? Do you think it will be the same answer, or are they different?
12. Brian: I think it will be the same, because you have just exchanged the numbers.
13. Janet: You think it will be the same? Mary, do you think it will be like Brian said?
14. Mary: Yes.
15. Janet: I don't know whether you have done this before, made a story or a drawing. Is there anyone who would try to make a story for  $13 \cdot 17$ , if we just concentrate on this [product]? Can someone make a story or drawing that might explain  $13 \cdot 17$ ? Is there anyone who dares to do that? [Pause 5 sec.].
16. Janet: What does it mean? Could it mean that we have 13 of something that we shall have 17 times? If we imagine having a baking tray with muffins for instance. If we imagine having a baking tray [draws on the blackboard]. Can someone try to figure out how the drawing will be, if we have a baking tray with  $13 \cdot 17$  muffins? [Pause 3 sec.].
17. Janet: Where should we place 13 for instance? Should we just draw them all over the place, or should we place them across or down? Anyone who dares to try? Trying is allowed. Remember, no answer is silly. [Pause 5 sec.].
18. Janet: Nobody dares to try? Well, OK. If we imagine that we have 13 muffins across here [draws on the blackboard], and we have 17 down. We fill out the whole tray, but I don't bother to draw them all. You understand that we have 13 across and 17 down. If we were to calculate this instead of counting all the muffins, how could we do that? You may want to take  $13 \cdot 17$ . Then we can think that we have 13 across and 17 down [points at the blackboard]. However, if we had  $17 \cdot 13$  [points at the blackboard], can someone figure out what the drawing would look like? Carl?
19. Carl: It will be 17 across and 13 down.
20. Janet: Uh-huh. Anne, can you repeat what Carl said?
21. Anne: It will be 17 across and 13 down.
22. Janet: Yes, we would have had 17 here and 13 down [points at the blackboard and explains]. Have we changed how many muffins we have on the tray? [Tim shakes his head].

In turn 15, Janet invites the students to give an interpretation of the product  $13 \cdot 17$ . Nobody responds, after which Janet (turn 16) introduces multiplication in terms of equivalent groups:  $13 \cdot 17$  is explained as the number of objects we will get when “we have 13 of something that we shall have 17 times”. This is a non-commutative situation, where 17 is the multiplicator and 13 is the multiplicand.

Then there is a shift to a rectangular-array situation, when Janet introduces a context of muffins on a baking tray to interpret the product  $13 \cdot 17$  (turns 16-17). In turn 18 she explains how the product can be placed on the tray: 13 muffins across and 17 down. She says that the whole tray should be filled out, but draws only the first row and first column. The resulting diagram is reproduced in Figure 2, and we will refer to it as a “degenerated” array. With a proper  $(13 \times 17)$ -array, it would have been possible to interpret the multiplication problem as an equivalent-groups situation in correspondence

---

<sup>2</sup> The transcript has been translated into English by the authors. Names are pseudonyms.

with Janet's initial explanation of multiplication: 13 muffins in a row could be interpreted as a group, and 17 rows could be interpreted as equivalent groups of 13 muffins. But the degenerated array and Janet's use of spontaneous concept ("across" and "down") instead of the scientific concepts "row" and "column", makes it unclear how the presented situation should be interpreted as the product  $13 \cdot 17$ .

**Figure 2. The diagram used by Janet to illustrate the product  $13 \cdot 17$**

The operation aimed at is just declared by Janet (turn 18): "You may want to take  $13 \cdot 17$ ". When she asks how it would be if they had  $17 \cdot 13$ , Carl gives the desired answer (turn 19, repeated by Anne in turn 21). Nevertheless, this does not imply that Carl has understood what  $17 \cdot 13$  means—it indicates only that he is able to substitute the numbers used by Janet. The diagram in Figure 2 does in fact represent two numbers (one across and another down), but the diagram does not represent the operation of *multiplying* these numbers.

### **Justifying that multiplication is commutative in $\mathbb{N}$**

After having indicated how the products  $13 \cdot 17$  and  $17 \cdot 13$  should be interpreted as (degenerated) array situations in terms of muffins on a tray (as presented above), Janet sets out to justify that multiplication is commutative for all numbers in  $\mathbb{N}$ :

23. Janet: When we have  $17 \cdot 13$ , the tray would look like this, and if we have  $13 \cdot 17$ , we can just imagine that we rotate the tray. Then the arithmetic problem will be different. We may also think that we have a sheet of paper. If we imagine having  $13 \cdot 17$  like this, and  $17 \cdot 13$  like this [demonstrates on the sheet]. Then we can see that these arithmetic problems will be the same.

Janet uses the products  $13 \cdot 17$  and  $17 \cdot 13$ —represented as drawings of muffins on a tray—to exemplify that multiplication is commutative. In turn 23, she refers to these products as being different arithmetic problems. The imagined rotation of the tray (possibly 90 degrees) is used to show that the arithmetic problems have the same result, the reasoning being that the rotation of the tray does not change the total number of muffins—hence  $13 \cdot 17 = 17 \cdot 13$ . We interpret the sheet mentioned in turn 23 as a representation enabling Janet to actually show the rotation and its effect on the arrangement of the muffins (a feature not afforded by the representation on the blackboard).

Having established that  $13 \cdot 17 = 17 \cdot 13$ , Janet then asks whether this property applies for all numbers:

29. Janet: How do you think it will be? Does it apply only for these numbers, or does it apply for all numbers? When we multiply two things... [Pause 5 sec.]. Mary?  
[Mary says that she thinks that it applies for all numbers, and exemplifies by  $1 \cdot 2$  and  $2 \cdot 1$ ]

33. Janet: Uh-huh. Do you think it applies for all numbers, all whole numbers? [Pause 4 sec.]. Or are there numbers for which it doesn't apply? [Pause 5 sec.].

Several students respond that they think it applies for all numbers, and Janet asks why they think so.

37. Mary: I think it has to apply for all numbers. Because it's about the same [pair of] numbers.  
 38. Brian: It can be a little demanding when you have very large numbers, like 1 million times 2 millions. It will be challenging to draw.  
 39. Janet: Uh-huh. Well, it will indeed be much to draw if we were to draw a million. But if we imagine that we take away all the muffins. If we imagine that we have only one sheet of paper [erases the muffins on the blackboard drawing]. We can imagine that we have 1 million times 2 millions, then we can place it like this [points at an array-model on the blackboard]. So, does anyone dare to formulate a rule for multiplying two numbers. When we use what we have just seen, which applies on those [points at the blackboard drawing]. [Pause 10 sec.]  
 40. Mary: It will be the same if we swap the numbers.  
 41. Brian: It is possible also to check out with this tray in case one is insecure.  
 42. Janet: Uh-huh. A rule can be that, when we do multiplication problems, the order does not matter. Whether we take  $13 \cdot 17$  or  $17 \cdot 13$  does not matter. We can see this [property] if we make such a drawing. If we rotate the drawing, the [total] number has not been changed, we just rotate the drawing.

The multiplication problem  $13 \cdot 17$  is used as a generic example in the dialogue to justify the commutative property of multiplication in  $\mathbb{N}$ . The property that the factors in a multiplication problem commute is based on the idea of rotating a tray (or sheet) with muffins arranged in a rectangular array—this is Janet's intention, even if the diagram used is not a proper array. The generic properties of the example are, however, vaguely expressed: Janet suggests that the total number of muffins on the tray is not changed by a rotation (turns 23 and 42), but she does not express in clear text what the commutative property means in the actual situation (i.e., exchanging row and columns). When Brian (turn 38) provides an example that involves the product 1 million times 2 millions, it can be considered a crucial experiment (supplemented by Janet in turn 39): the validity of the conjecture of commutativity is accomplished by testing it on an instance that is quite complex (and impossible to draw). In turn 42, Janet utilizes the generic example of  $13 \cdot 17$  when she articulates the conclusion of the claim—an important, last step in a justification process.

## Discussion

The decision not to draw all the muffins (possibly because it would take too long) prevents the diagram in Figure 2 from representing the *meaning of the operation* at stake (even if Janet says that the whole tray should be filled out). Hence, Schifter's (2009) first criterion for a representation to be adequate is not met. It can be noticed that the other representation used, the sheet, does neither illustrate the meaning of multiplication, but it affords the rotation to be demonstrated physically. For the meaning of multiplication to be represented in a diagram, the total number of objects—the result of the operation—needs to be displayed. This entails that the numbers involved must be of manageable size, thus enabling them to be represented in diagrams or manipulatives. That Janet failed to draw the complete array indicates that the numbers she used in the generic example (13 and 17) were too big, as she possibly conceived of it.

It is possible to represent any pair of natural numbers in the diagram used by Janet, and hence, it seems as if Schifter's (2009) second criterion is met. Yet, this is irrelevant since the meaning of the operation is not represented in the diagram. Further, since the diagram does not represent

multiplication at the outset, it is useless to check if Schifter's third criterion is met (i.e., whether the conclusion of the claim follows from the structure of the diagram).

The discussion in class (based on Figure 2) enables the students to evidence possession of some knowledge. This knowledge is, however, different from the knowledge aimed at by Janet: The students were able to say that the result—in the general case—would be the same even if the numbers in the multiplication problem were reversed. Yet, there is no indication that the result they refer to is the *product* of the two numbers. It is likely that the students imagine a diagram with objects in a formation similar to the one in Figure 2, and that they see that rotation does not change the total number of objects in the diagram. This is basically an aspect of the principle of number conservation, and it is doubtful whether the students have understood why multiplication is commutative for any pair of natural numbers, which was the aim of the lesson.

In conclusion, there are two conditions that constrain Janet's discussion with the students about commutativity of multiplication in  $\mathbb{N}$ : The first is that the diagram, as used by Janet, is inadequate because it does not illustrate the meaning of multiplication. The second is the matter of fact that the diagram (and the way it is used) enables the students to respond "adequately" (i.e., as expected by Janet), even if they may not have understood why the commutative property applies for multiplication. The latter is a constraint because it deprives Janet of the opportunity to get feedback that might have let her understand that she would need to change her approach.

The case of Janet can be used in teacher education to discuss with pre-service teachers criteria for, and impact of, generic examples (or representation-based proofs) used to justify general claims about properties of arithmetic operations. It is relevant to extend the research reported here by analysing written material from students' justification of properties of arithmetic operations.

# Shape patterning tasks: An exploration of how children build upon their observations when asked to construct general terms

Aisling Twohill

Dublin City University, Ireland; [aisling.twohill@dcu.ie](mailto:aisling.twohill@dcu.ie)

*Generalisation is a key element of algebraic thinking, and children's developing thinking is supported by engagement with algebraic activities when they attend primary school (Kaput, 2008). Shape patterns provide a context within which children may identify structure, and construct general terms. Within my research I presented children with shape patterns and observed their interactions as they discussed the structure of the patterns and sought to construct general terms. In this paper, I discuss the elements of the patterns to which they attended, and how their focus supported some children in constructing general terms, while other children experienced more challenge in their engagement with the patterns. Specifically I focus on children who observed both numerical and figural aspects, and I examine the varying levels of success they experienced.*

*Keywords: Algebraic thinking, generalisation, shape patterns, reasoning, task-based interview, group interaction.*

## Introduction

Kaput (2008) defined generalising, representing generalisations, and syntactically guided reasoning on generalisations as core aspects of algebraic thinking. Providing a context for functional thinking, shape patterning tasks may facilitate children in engaging with these core aspects. Strømskag (2015) defines a shape pattern as a sequence of terms, composed of 'constituent parts', where some or all elements of such parts may be increasing, or decreasing, in quantity in systematic ways. While a limited number of terms of a shape pattern may be presented for consideration, the pattern is perceivable as extending until infinity. In order to construct a general term for a shape pattern, children must "grasp a regularity" in the structure of the terms presented, and generalize this regularity to terms beyond their perceptual field (Radford, 2010, p. 6). In seeking to construct general terms for shape patterns, children's opportunities for success improve when they attend to both the spatial and numerical aspects of the structure of the pattern (Radford, 2014). In seeking to extend a pattern, children identify the position of pattern elements by attending to the spatial structure, and in order to quantify such elements they must attend to the relevant quantities within the pattern terms presented.

In the Irish context, the Primary School Mathematics Curriculum (hereafter PSMC) includes an 'algebra' strand, and there are content objectives prescribed for teachers to address in their teaching, from when children commence primary school at four or five years of age (Government of Ireland, 1999). The curriculum does not, however, include the construction of general terms in any context, and beyond the first two reception years the patterns prescribed are strictly numerical in nature. During task-based group interviews, I asked children to construct general terms for each of three shape patterns. In this paper I will explore the tendency of children participating in my research to attend to the spatial and numerical aspects of pattern structures, as they worked towards the construction of general terms. Of the children who attended to both numerical and spatial elements, some children experienced success in applying their observations in order to construct general

terms, whereas some children seemed to experience a challenge in translating their observations into meaningful understanding of the structure of the pattern.

## **The construction of general terms**

Building upon the core aspects of algebraic thinking outlined by Kaput (2008) and mentioned above, Blanton, Brizuela & Stephens (2016) identified four key practices of algebraic thinking as: a) generalising, b) representing, c) justifying, and d) reasoning with generalisations, emphasising that these practices must focus upon structures and relationships. Blanton et al. (2016) also presented the following three content domains within which children may apply the key practices of algebraic thinking: a) generalised arithmetic, b) equations, and c) functional thinking.

In particular, Blanton et al. (2015) highlighted the relevance of functional thinking to the algebraic thinking of young children, stressing the connection between functional thinking and the four key practices of algebraic thinking highlighted above. Blanton et al. (2015) emphasised the role of functional thinking in young children's algebraic thinking by stating that functional thinking includes generalisations of co-varying quantities and their relationship; representations of these relationships, and reasoning with the relationships in order to predict functional behaviour. As functional thinking, and specifically shape patterning, is absent from the PSMC, it is therefore highly improbable that most children attending Irish primary schools will have engaged with activities designed to develop functional thinking.

Rivera and Becker (2011) identified two approaches utilised by children in seeking to construct general terms for geometric patterns. Some children in Rivera and Becker's longitudinal study focused solely, or primarily, on numerical aspects of the terms provided, and sought to use the numerical patterns observed in order to identify a commonality, extend the pattern and construct a general term. Such children the authors described as adopting a 'numerical' mode of generalising. In comparison, Rivera and Becker considered a child to have adopted a 'figural' approach if he/she used figural aspects of the pattern such as the shape of terms, or the position of elements, both within the term and relative to each other. A figural approach may include attention to numerical elements, but not in a manner that supersedes the child's perception of the spatial aspects of the pattern structure.

Along with observations of the structure of terms, children may observe various relationships within patterns which support their understanding. A 'recursive' strategy involves an examination of the mathematical relationship between consecutive terms in a sequence, and if using an 'explicit' strategy, a child identifies a rule for the relationship between a term and its position in the pattern (Lannin, 2005). Such observations work in tandem with children's numerical or figural approaches, and in this paper I will refer to children's explicit, or recursive thinking when relevant.

Radford asserted that children's constructions of generalities may be factual, contextual or symbolic. Factual generalisations involve instantiating a general structure to specific terms, whereby children do not express a generalisation as applicable to all terms, but apply an "operational scheme" which allows them to calculate a value for particular terms (p. 82). Many of the children involved in this research project applied factual generalisations when they described the near and far terms for the patterns, as in the example of Emily for Pattern 3 when she said "You'd need a hundred and twelve horizontal and then fifty-seven vertical". Emily applied her understanding of the

$2n$  horizontal poles, and  $n$  vertical poles in order to calculate the number of poles for this far term. Equally she could apply this thinking to any term of this pattern, and could therefore be said to have factually generalised, even though there is no abstraction evident in her expression, and she is describing a specific term.

Contextual generalisations, by comparison, involved the consideration of non-specific terms (*ibid.*). While contextual generalisations are not completely abstract, or general to all terms, they indicate a distancing from the specific, whereby children may make reference to “the next term” or to a generic term. As an example, Grace could be said to have constructed a contextual generalisation for Pattern 1 when she said “whichever number it is at the top it will just be one more than it, and at the bottom”. Symbolic generalisations involve the abstract expression of disembodied mathematical objects, wherein children express the algebraic concepts with no reference to the method of their calculation, or to any specific term. Throughout this paper I make use of ‘ $n$ ’ to refer to a general term number, but all such expressions were generated by me, as representations of children’s verbal utterances, constructions and gestures. The children were not prompted to construct symbolic generalisations.

## Methodology

In seeking to explore children’s constructions, I facilitated their engagement with the patterns in groups of four in a ‘task-based interview’ setting. Goldin (2000) emphasised that task-based interviews, involving individuals or groups, have become an essential tool within mathematics education research, as the goal of mathematics education has moved from the transmission of disconnected facts, to the development of children’s rich understanding and “internal constructions of mathematical meaning” (p. 524). In order to explore children’s complex understandings, and to observe their approaches to the solution of problems, it is necessary to adopt a research approach designed specifically for this purpose. In this way, it may be possible for educators and policy makers to assess whether the application of progressive approaches within classrooms are working to develop children’s mathematical understanding and robust problem-solving skills.

Sixteen children (with a mean age of 9.6 years) participated in the task-based interviews, when they were presented with three patterns (see Figure 1). When presented with the patterns, the children were asked to describe what they observed, to extend the pattern to subsequent or previous terms, and to construct near and far terms, as factual generalisations. The children were provided with concrete materials, and asked to construct pattern terms during their discussions. Having considered far terms, I asked the children to describe “any term” in the pattern to facilitate their articulation of a contextual generalisation. At the commencement of each interview, and at regular intervals throughout, the children were encouraged to work collaboratively, by constructing terms together, by sharing their ideas, whether they agreed or disagreed, and by asking questions of each other. The children did not receive any instruction before participating in the interviews.

**Figure 1: The three patterns presented to children.**

Seeking to explore the reasons for children's strategy choice, as well as the strategy chosen, the research approach I considered most appropriate was phenomenological, as a phenomenological approach to research seeks to explore a phenomenon where it occurs, and acknowledges the many factors which influence how the phenomenon plays out within the given setting (Creswell, 2013). In exploring the children's thinking, I not only analysed the children's actions, but I also sought to analyse the contributing factors that impacted on the strategies children employed.

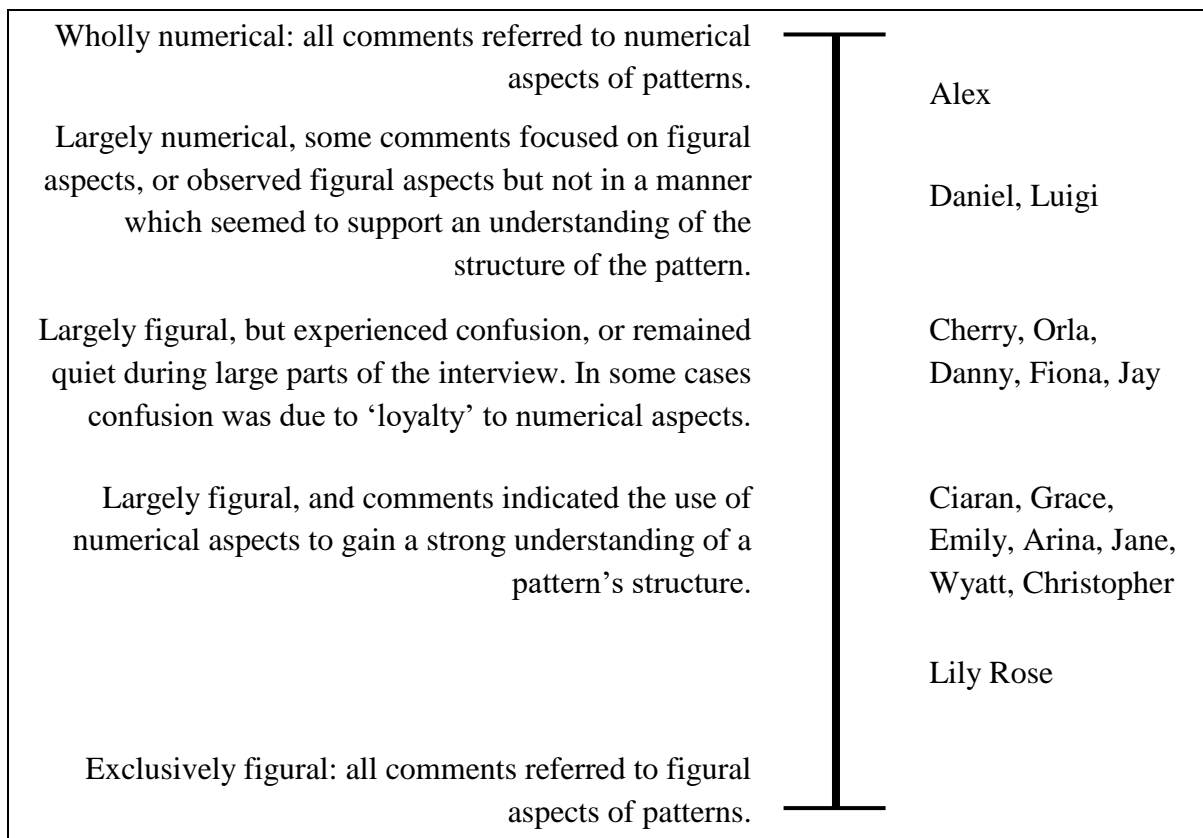

Goldin (2000) advises that "by analysing *verbal and nonverbal* behaviour or interactions, the researcher hopes to make inferences about the mathematical thinking, learning or problem-solving of the subjects" (p. 518, my emphasis). In seeking to explore children's mathematical constructions, I was conscious throughout that my inferences from children's comments were approximations of their true meaning. As Van Manen (1990) attests "a *good* phenomenological description is an *adequate* elucidation of some aspect of the lifeworld" (p. 27, my emphasis) and while I sought to unpick as best I could how and why children thought about the mathematical tasks, I posit that it is not possible to feel a sense of completion, or closure, in relation to the children's thinking, but rather that interpretation is ongoing (Postelnicu & Postelnicu, 2013).

In exploring the children's verbal utterances, I coded comments as referring to figural or strictly numerical aspects of a pattern. Rivera and Becker (2011) state that adopting a figural approach is to "figurally apprehend and capture invariance in an algebraically useful manner (p. 356). When coding children's statements, I identified a statement as indicating a figural approach if it included reference to the position of an object within a term, by using words such as 'top', 'bottom' or the deictic 'there' along with an associated gesture (Radford, 2006). An object in this context referred to a square, a diamond, a tile, a line, or any item which formed a constituent part of a term. Comments were deemed to indicate a numerical approach if no reference was made to the position of objects within a term. The term 'growing' was used regularly by children, and required some thought with regards to whether it indicated a figural approach. Typically, when mentioning growth children were referring to a sense of the terms' shape growing in size, that is "selectively attend[ing] to aspects of sameness and difference among figural stages", but I could not assume that this was always the case

(Rivera & Becker, 2011, p. 356). Rather, it was necessary to attend to some term, or deictic within a child's comment, and to seek to determine the referent, which would indicate whether the child was referring to the shape as growing, or the quantity of constituent elements.

## Findings and Discussion

In seeking to explore the strategies used by children, and the reasons underpinning their strategy choice, I firstly considered an overview of each child's approach across all three patterns. As the length of this paper does not allow for a complete explication of the approach of each child, Figure 2 presents an overview of my interpretation of the children's thinking, as it pertained to the balance between numerical and figural observations. In collating and analysing this data, I referred to the comments children made in the context of the exchanges they participated in. I also referred to field-notes made during the interviews, photographs of the children's constructions, and the children's drawings and jottings which I had retained as artefacts of their thinking during the interviews. I had video recordings for three of the four interview groups, and audio recording for the fourth, as not all participants of this group had assented to video recording.

**Figure 2: An overview of my interpretation of the children's thinking, as it pertained to their focus on numerical and figural aspects of patterns**

As can be seen from Figure 2, rather than demonstrating a dichotomy between children who approached all patterns figurally and children who approached all patterns numerically, this small group of children (n=16) span a continuum from children who made comments focusing largely on numerical aspects, through children who commented on both numerical and figural aspects in meaningful ways, to children who referred largely to figural aspects. In considering the aspects children were attending to, I sought to distinguish between children's observations which supported

their thinking, and observations which they made and didn't build upon or apply in order to construct a general term. Later in this paper I will further explore how two of the children applied their observations of figural aspects.

While attending to figural aspects may have supported some children in constructing general terms, figural observations did not lead inevitably to generalisation. In order to compare children's tendency to observe figural aspects with their success in constructing factual or contextual generalisations, I generated a scoring rubric for children's progress towards the construction of a general term. A score of 0 indicated no progress, a correct extension of the pattern scored 1, some description of general terms scored 2, factual generalisation scored 3 and a contextual generalisation scored 4. I generated a total score for each child and calculated the mean score for each cluster of children identified in Figure 2 above. I found that the cluster of children identified in Figure 2 as making "largely figural" observations while applying numerical observations succeeded well, achieving a mean score of 8.6, where a score of 9 would equate to, for example, factual generalisation of all three patterns. In contrast the group of children who also made many figural generalisations, but expressed some confusion fared considerably less well, achieving a mean score of 3.2, where a score of 3 would equate to extending each pattern correctly, but not making any progress in describing a general term.

To explore what other factors may have impacted on children's progress, I chose to contrast the thinking of two children, Cherry and Arina, who worked together, and who both articulated figural observations, but made strikingly dissimilar progress. Arina achieved a score of 9 overall, while Cherry achieved a total score of 2. In this section I will discuss the girls' observations of Pattern 3, a 'fences' pattern presented in Figure 1 above. Arina had demonstrated strong figural thinking on two previous patterns, and succeeded in describing factual generalisations for both. When the children began their deliberations about the pattern discussed here, Arina remained very quiet, making few comments, but succeeded in constructing the 56th term using an explicit approach. She didn't verbally articulate her thinking enough to confirm whether this factual generalisation was based upon a numerical or figural mode of generalising, but she could be seen on the video footage counting up in twos to quantify the horizontal posts, and adding on a number equivalent to one more than the term number. Figure 3 presents an illustration of how Arina may have been quantifying the number of posts for terms in this pattern.

5th Term in the Pattern:  $n=5$ .  $2n$  horizontal Posts and  $n+1$  Vertical Posts

$$\text{Total number of posts: } 2n + (n+1) = 3n+1$$

**Figure 3: A representation of Arina's perceived structure of the Fences pattern.**

By comparison, Cherry's verbal articulations of her thinking indicated that she observed within each fence one panel containing 4 posts, and every other panel containing three posts. When finding the number of posts needed for the nine-panel fence, she used a recursive approach, counting on six posts from the seven-panel fence she had constructed with match-sticks. I interpreted Cherry's perception of this pattern as including figural aspects, as she referred regularly to 'posts' and

grouped the posts into groups of three or four, as appropriate. However, Cherry's approach to this pattern was dominated by a counting strategy, an analysis of which is beyond the scope of this paper. This counting strategy did not support Cherry in constructing far generalisations, and in seeking to construct a far generalisation, Cherry drew 56 panels, and began to count the number of posts needed.

## Conclusion

Rivera and Becker (2011) suggest that when children only attend to numerical aspects of a pattern, they are grasping the commonality within the structure of the pattern at a superficial level. In analysing the comments made by the children in this research study, it may be seen that one cluster of children attended to figural elements but did not succeed in generalising. I would suggest therefore that some children who attend to figural aspects of the pattern, may persist with a limited and superficial understanding of the structure of the pattern, and that a figural perspective may not lead inevitably to successful construction of a general, or generic term. Other perceptions of the pattern structure seemed to be required in tandem with observations of both figural and numerical aspects. In the examples given here, Arina's explicit approach supported her thinking, and in marrying an explicit approach with observations of both numerical and figural aspects, Arina grasped the structure of the pattern and successfully constructed a factual generalisation. In contrast Cherry demonstrated a consistent tendency to use counting as a strategy in seeking to quantify the number of elements of components of far terms of this pattern. While she could describe the figural structure of the pattern, her thinking seems to have been hindered by difficulties she encountered in seeking to conceptualise an expression which would allow her to calculate the number of posts without counting them. Even though this was the third pattern, and other children in her group had described explicit approaches during the interview, Cherry might not have made sense of the explicit thinking articulated by others. Equally, limitations in her multiplicative thinking may have contributed to this, and restrained her from exploring the explicit relationship between each term and its position in the pattern. Further research is merited into the interplay between the many aspects of patterns to which children may attend in seeking to grasp the structure.

# Multiple models for teaching logarithms - with a focus on graphing functions

Christof Weber

School of Education, University of Applied Sciences Northwestern Switzerland,  
Liestal, Switzerland; [christof.weber@fhnw.ch](mailto:christof.weber@fhnw.ch)

*This argumentative paper focuses on graphing logarithmic functions and presents some mathematical knowledge for teaching, employing vom Hofe's construct of basic models (or 'Grundvorstellungen') and Sfard's distinction between operational and structural conceptions. On the assumption that difficulties students have with graphing might be a consequence of the standard interpretation of logarithms as inverse exponents, it claims that logarithmic functions should not be introduced structurally, as inverse exponential functions. Instead, several operational models of the logarithmic concept are proposed, and their explanatory power for graphing logarithmic functions is expounded. These models are intended to serve students as a meaningful basis for argumentation.*

**Keywords:** Logarithmic functions, basic models, operational—structural, knowledge for teaching.

## Introduction

Logarithms as functions differ from logarithms as numbers (e.g. determining  $\log_2 1024$ ) or operators (e.g. using logarithms to manipulate expressions and solve equations), especially when it comes to teaching and learning (Smith & Confrey, 1994). To make logarithms as numbers and operators meaningful and thus more accessible to learners, some subject matter knowledge for teaching has been developed by Weber (2016). This was achieved by combining the theoretical construct of basic models (or 'Grundvorstellungen', vom Hofe & Blum, 2016) with the construct of operability and structurality (Sfard, 1991; 2008). The present paper focuses on the functional side of logarithms and its teaching, namely on the sketching of logarithmic graphs. After recalling various conceptualisations of logarithms and analysing some students' difficulties in graphing logarithmic functions, four basic models are discussed with regard to their explanatory power for graphing logarithmic functions. Because of the mathematical analogy between logarithms and division (cf. Weber, 2016), some arguments used here are analogous to those familiar from the teaching of division (Ball, Thames, & Phelps, 2008; Greer, 1992; vom Hofe & Blum, 2016).

## Background

### Various conceptualisations of the logarithmic concept

As we are interested in different ways of viewing logarithms, it is worth taking a quick look at the history of mathematics. Several properties of logarithms have been discovered since their invention in the early 17th century (for details, see Weber, 2016):

- (P1) Napier and Bürgi conceptualised logarithms as numbers that count divisions. For example,  $\log_2 8$  equals 3 because 8 has to be divided by 2 three times (to yield 1). In analogy to the standard division algorithm, this interpretation can be extended to a *logarithm algorithm* for the manual calculation of logarithms proceeding by repeated division down to 1 instead of re-

peated subtraction down to 0: one divides instead of subtracting, exponentiates by 10 instead of dividing by 10, trying to yield 1 instead of 0 (ibid., pp. 79–80).

- (P2) The conception found in current collections of formulas only became possible after Descartes had invented the symbol for powers,  $a^n$ . This notation enabled logarithms to be seen as particular exponents, a property that Euler used in his 1765 definition  $\log_a b = x \Leftrightarrow a^x = b$ . Moreover, the left-hand equation can be read not only arithmetically (focusing on the number  $x$ ), but also functionally, taking “log” as a function of the argument  $b$ .
- (P3) Another conceptualisation was provided by Cauchy in the 19th century. He proved that logarithmic functions are, apart from a factor, the only continuous solutions  $F$  of the functional equation  $F(x \times y) = F(x) + F(y)$  ( $x > 0$ ,  $y > 0$ ). Specifying the logarithmic function in implicit form, this conceptualisation is a purely functional one.

Each of the properties (P1) to (P3) highlights a particular aspect of logarithms. Because, from a mathematical perspective, they are all equivalent, each property could serve as a definition of the concept. From an epistemological perspective, however, their qualities are distinct, as discussed below.

### **Logarithmic functions, their graphing and some of the difficulties students face**

Logarithmic functions are essential in calculus and for modelling processes, which is why they are taught at secondary level and in undergraduate courses. As with other types of functions, there are several challenges for students, such as when it comes to interpreting graphs verbally, or deciding whether or not a given graph represents a certain function (e.g. Leinhardt, Zaslavsky, & Stein, 1990; Markovits, Eylon, & Bruckheimer, 1986; 1989). For instance, one well-known student misconception says that any function should be linear (e.g. Sfard, 2008, p. 21). An issue specific to logarithmic functions is the confusion of the logarithmic graph with the “combined graph” (Kastberg, 2002, p. 129), i.e. with the exponential and the logarithmic graph merged into a single image. A similar misconception reported is students viewing the graphs of  $y = 2^x$  and  $y = \log_2 x$  as being “exactly the same” (Williams, 2011, p. 54). Misconceptions like these might be caused by the standard introduction of logarithmic functions as inverse exponential functions.

As space precludes other aspects, this paper deals with the graphing of logarithmic functions only, i.e. with manually sketching the graph of a function in a Cartesian plane, based on its logarithmic equation  $y = f(x)$ . To analyse some of the difficulties that can arise here, the following steps (S1) to (S4) involved in graphing logarithmic functions are identified:

- (S1) *Determining and calculating an appropriate number of pairs* (table of values): This step involves selecting a finite series of  $x$ -values that lie within the domain of the function, which in the case of logarithmic functions is a proper subset of the real numbers. In particular, one has to determine a first  $x$ -value, a last  $x$ -value, and the pattern the series follows (e.g., if there is a pattern, whether the difference or the ratio of two consecutive  $x$ -values is constant).
- (S2) *Drawing the axes and scales, and plotting the corresponding points* (“local construction,” Leinhardt et al., 1990, p. 13): The plotted points form the supporting points of the graph to be drawn.

- (S3) *Connecting the supporting points with a line segment* (“prediction,” *ibid.*, p. 13): This step involves making a conjecture based on the visual characteristics of the plotted points. It will therefore be referred to here as “graphical interpolation”. It includes decisions regarding the curvature and the degree of smoothness of the line (e.g. differentiable at the points).
- (S4) *Extending the graph to the right and left of the line segment*: This is a second prediction to make, based on a part of the graph, referred to here as “graphical extrapolation”: Does the graph straighten out to a straight line? If not, in what way does its curvature change? Is it bounded, does it have vertical asymptotes, intercepts with the axes, etc.?

In each of these steps, the lack of a meaningful basis for argumentation can result in difficulties: Firstly, determining the domain in (S1) is a known issue (e.g. Markovits et al., 1986, 1989). As an illustration, Figure 1 shows two students’ graphs of the function  $y = \log_2(x) - 3$ . Student A’s graph extrapolated to the left intersects the  $x$ -axis and thus exceeds the domain. Moreover, his  $x$ -values form an arithmetic progression, which is not optimal in terms of the corresponding  $y$ -values.<sup>1</sup>

**Figure 1: Students’ documents showing their tables of values for  $f(x) = 2^{x+3}$  and  $g(x) = \log_2(x) - 3$ , together with the corresponding graphs (left side: student A, male; right side: student B, female)**

Secondly, graphs are sometimes thought of as isolated points (Leinhardt et al., 1990), or the supporting points may be interpolated with a straight line (Markovits et al., 1989). Figure 1 shows that in their third step (S3), both students chose the graphical interpolations to be a more or less straight line, at least piecewise. And thirdly, in (S4), the graph is sometimes not extended beyond the range of the supporting points at all, or only by a little; or there may be an extrapolation to one side which suggests a progressive growth of the logarithmic function (cf. student B in Figure 1).

<sup>1</sup> The two first- and second-year undergraduate students (18 and 19 years old) had attended a precalculus course held at a public university on the east coast of the USA in spring 2016. Logarithmic functions had been introduced in the traditional way, i.e. as inverse exponential functions. The documents shown in Figure 1 are from their final examination. The exact wording of the task was: “Consider the two functions  $f(x) = 2^{x+3}$  and  $g(x) = \log_2(x) - 3$ : a) For each function, create a table of values, choosing your  $x$ -values carefully. b) Graph both functions on the same set of axes.”

Students' difficulties like these give rise to the following question: *What mathematical knowledge for teaching logarithmic functions could endow learners with a meaningful basis for argumentation in order to potentially reduce their difficulties?*

## Understanding functions and logarithms

There are many ways to conceptualise what it means to understand the concept of a function in general (e.g. Lauritzen, 2012; Markovits et al., 1986; Sfard, 2008), or the concept of logarithmic functions in particular (Berezovski & Zazkis, 2006; Kastberg, 2002). Interestingly enough, graphs are rarely included in conceptualisations of how functions are understood; when they are, they are used to gauge whether it is possible to derive the equation of a certain function (Markovits et al., 1986).

### Graphing as a vital aspect of understanding functions

Focusing on the opposite — graphing equations — here, Lauritzen's (2012) conceptualisation of procedural and conceptual knowledge of functions is useful, because he attaches importance to the construction of graphs. To measure the ability to perform “graphic procedures” (ibid., pp. 52–53), he asks students to sketch the graph of a function, thus subsuming graphical interpolation (S3, see above) and extrapolation (S4). On the other hand, he considers calculating values (S1) a type of “algebraic procedure” (ibid., pp. 54–55). In Lauritzen's theoretical framework, graphic and algebraic procedures together operationalise the *procedural knowledge of functions*. In other words, graphing can be seen as a vital part of understanding functions.

### Operational and structural conceptions of functions, and the discourse on functions

Sfard's analysis of how mathematical notions are formed shows that conceiving mathematical notions (1991) and talking about them (2008) can happen in two fundamentally different ways: as processes (*operationally*), or as objects (*structurally*). For instance, learners tend to read equations of functions and tables of values operationally, whether as prescriptions of how to calculate values of the function, or as a covariation between two quantities (Sfard, 1991, p. 15). By contrast, they tend to perceive graphs of functions structurally, as “[...] infinitely many components of the function [...] combined into a smooth line, [...] as an integrated whole [...]” (ibid., p. 6). According to Sfard (1991), firstly, operational approaches are more accessible to learners when forming new concepts. Secondly, concept formation, for instance of functions, means subsuming the discourses on equations and graphs in a new discourse. For example, the concept “logarithmic function” is reified as soon as the discourse on logarithms as numbers and operators is merged with the discourse on logarithmic graphs, as soon as they “become mere representations” (Sfard, 2008, p. 122).

As such, the history of the logarithmic concept reminds us of the reification of rational numbers (Sfard, 1991, 2008): On one hand, because the conceptualisation (P1) of logarithms as numbers that count divisions can be transferred to a set of computational rules that make it possible to calculate logarithmic values step by step, it expresses *an operational view* (similar to the division  $1 \div 2$ ). This is why Sfard's findings on functions could apply to logarithmic functions as well, as her analysis of understanding functions relates to polynomials only, and their operational character. On the other hand, a historically more recent conceptualisation such as inverse exponents (P2) expresses *a structural view* (similar to the fraction  $1/2$ ).

## Basic models for logarithms as numbers and operators

To help students access and understand a certain mathematical concept, it is sometimes embedded in a context that is realistic or, if this is not possible, in a context that is at least familiar to the students (cf. the Dutch “realistic mathematics education”, van den Heuvel-Panhuizen, 2003). In the German-speaking countries, *basic models* is a theoretical construct to capture what is meant by making concepts accessible, or understanding them (referred to as “Grundvorstellungen”, vom Hofe & Blum, 2016). Put simply, a basic model for a concept must have two characteristics: Firstly, it is an interpretation of that concept in a context in which students are likely to have more experience, and secondly, it has a certain explanatory power, that is, it is flexible enough to be applicable to different mathematical situations. For instance, when division is seen within the everyday context of fair-sharing, an equation such as  $30 \div 1/2 = 60$  is difficult to follow or perform. However, within the context of splitting-up or measuring, it can be explained as “ $1/2$  fits into 30 sixty times”. Both basic models of division, fair-sharing and splitting-up, are thus indispensable for understanding division (referred to as “partitive” and “quotative division”, Greer, 1992). For Ball and colleagues, they constitute the *specialized content knowledge* for teaching division (Ball et al., 2008, p. 400).

For the teaching of logarithmic functions, no basic models are known thus far. For logarithms as numbers and operators, however, I have previously identified four models (for details, see Weber, 2016):

- (BM1) *Logarithms as multiplicative measuring*: The logarithm of a number  $b$  (to base  $a$ ) indicates how often the base  $a$  fits into the number  $b$  as a factor. This interpretation derives from the algorithm mentioned above (P1), or from the relation  $b / a^{\log_a b} = 1$ . Example:  $\log_2 1024$  can be simplified to 10 because 2 as a factor fits into 1024 ten times. As it generates *result*, multiplicative measuring emphasises the *operational* side of logarithms most strongly.
- (BM2) *Logarithms as counting the number of digits*: The (common) logarithm of a number  $b$  finds the number of digits of  $b$  needed to represent  $b$  in positional notation, minus one. This interpretation derives from the fact that the number of digits of any natural number  $n$  (in decimal notation) is equal to  $\lfloor \log_{10} n \rfloor + 1$ . Example: The number  $2^{2000}$  has 603 digits when written out in decimal notation because  $\log_{10} 2^{2000} \approx 602.06$ . In describing the *effect* it has on numbers and thus dealing with a specific application, this interpretation could be used to support the *operational* explanation of logarithms in the case of numbers.
- (BM3) *Logarithms as decreasing the hierarchy level*: The logarithm of an expression reduces third-level operations (powers, roots) to second-level operations (multiplications, divisions), and it reduces second-level operations to first-level operations (additions, subtractions). This interpretation derives from property (P3). Example: The expression  $\log \sqrt{cd}$  can be expanded to  $\frac{1}{2}(\log c + \log d)$  because the taking of square roots, as a third-level operation, becomes dividing by two, and multiplication of the variables becomes addition of their logarithms. In describing the *effect* it has on expressions and thus dealing with another specific application, this interpretation could support the *operational* explanation of logarithms for expressions.
- (BM4) *Logarithms as inverse exponents*: The logarithm of a number (or expression) to base  $a$  is the exponent by which the base  $a$  must be raised to yield the number (or expression). This

derives from property (P2), and is useful for solving exponential equations. Example: 40 as a power of 2 is approximately  $2^{5.32}$  because  $\log_2 40 \approx 5.32$ . Because this interpretation *relates* logarithms to another object (exponents), it reflects the *structural* view of experts.

In the next section, this collection of operational and structural basic models will be shown to have the potential to serve as a basis for argumentation for the graphing of logarithmic functions as well.

## Basic models for logarithmic functions and their explanatory power

From a mathematical standpoint, every property of logarithmic graphs can be derived from exponential graphs, using (BM4) as a basis for argumentation. From an epistemological viewpoint, however, conceiving logarithmic functions as inverse exponential functions reflects the structural view of experts who have reified their experiences, and not the view of learners. Perhaps, as Sfard (1991) and others suggest, operational conceptions should instead *precede* structural ones as consecutive steps to be passed through when teaching a new concept such as logarithmic functions? As basic models (BM1) to (BM3) do not replace logarithmic functions with another class of functions, they could be more appropriate for learners than model (BM4). Instead, they inform students about what logarithms “do” and what logarithms “are good for”, interpreting them within contexts in which learners are likely to have some experience (counting, long division, having an effect on ..., etc.).

In what respect, then, could the three basic models described offer students a meaningful basis for argumentation when they are introduced to graphing logarithmic functions? And in what way could they potentially reduce the difficulties described above? Here are some arguments:

1. *Operational conceptualisation*: The logarithm algorithm, which stems from property (P1), “logarithms are numbers that count divisions”, and is captured by basic model (BM1), can allow students to conceive a logarithmic equation such as  $f(x) = \log_2(x) - 3$  operationally, much like a polynomial one: “First, calculate how often the base 2 fits into  $x$  by repeated division, then subtract 3.”
2. *Domain of the function*: In order to graph a logarithmic function, it is essential to determine its domain (cf. (S1) and Figure 1). With reference to the model “logarithms as multiplicative measuring” (BM1), values such as  $\log(0)$  and  $\log_2(-8)$  can be recognized as incalculable because there are no reasonable answers to the corresponding questions “How many times does 10 as a factor fit into 0?” and “How many times does 2 as a factor fit into  $-8$ ?”; neither 0 nor  $-8$  can be converted to 1 through repeated division. This is why logarithms of 0 and of negative values cannot be defined.
3. *Pattern of the finite series of  $x$ -values*: Another choice to be made for graphing a logarithmic function easily is the pattern that the series of  $x$ -values follows (S1). In view of the basic model “logarithms as decreasing the hierarchy level” (BM3), the  $x$ -values should follow a geometric series, with the ratio of two consecutive  $x$ -values equalling the base. The logarithm would then transform the geometric series into an arithmetic one, resulting in equidistant  $y$ -values.
4. *Growth of the graph*: As we have seen above, both graphical interpolation and graphical extrapolation can cause many problems (cf. (S3), (S4)). Referring to the basic model “logarithms as counting the number of digits” (BM2), the growth of logarithms can be recognized as non-proportional: In general, doubling a number does not double its number of digits. Furthermore, it

is strictly increasing and unbounded above because this is how the number of digits behaves. Thus neither the interpolated nor the extrapolated graph can be a straight line, but must increase monotonically, growing degressively.

## Discussion

This work builds on my earlier paper about the basic models for logarithms as numbers and operators (Weber, 2016). There, the supposition was discussed that the standard textbook explanation  $\log_a b = x \Leftrightarrow a^x = b$  could be too compact or “dense” for many learners to serve as a meaningful basis of argumentation, which may be why dealing with logarithms often turns into mere manipulation of formal symbols, causing students’ difficulties (ibid., pp. 85–86). If this applies to logarithmic functions as well, an alternative, broader way of introducing and teaching logarithms is required. For this reason, this paper discusses some content knowledge for the teaching of logarithmic functions. The guiding theoretical construct is that of basic models (vom Hofe & Blum, 2016), combined with the construct of operationality and structurality (Sfard, 1991, 2008). The four basic models, developed previously for logarithms as numbers and operators (Weber, 2016), are shown here to have some explanatory power for logarithmic functions and their graphing, that is, that they could potentially help to make logarithms meaningful and reduce some common difficulties that students encounter.

This paper lays some theoretical foundations for future research. To what extent an approach with multiple basic models can facilitate more meaningful teaching and understanding in the actual classroom will have to be investigated carefully. There has been a first encouraging episode from my own teaching, where a student who in general struggles with mathematics realized why logarithmic functions cannot be proportional: Making use of basic model (BM2), not the standard interpretation (BM4), she argued precisely as in point 4 in the previous section. A teaching experiment is therefore planned in the near future to study the affordances and limitations of the basic models, exploring the discourse of students who are taught not just one but four interpretations of the logarithmic concept. In analogy to the teaching and learning of division with multiple models, a crucial point will be the students’ shift from the multiple basic models proposed here to the object of logarithmic functions. Or, to cite Freudenthal (1975, as quoted in van den Heuvel-Panhuizen, 2003, p. 15, italics in original): “Models *of* something are after-images of a piece of given reality; models *for* something are pre-images for a piece of to-be-created reality”.

## Introduction

The problem of taking a data set and separating it into subgroups, where the members of each subgroup are more similar to each other than they are to members outside the subgroup, has been extensively studied in science and mathematics education research. Student responses to written questions and multiple-choice tests have been characterised and studied using several qualitative and/or quantitative analysis methods. However, there are inherent difficulties in the categorisation of student responses in the case of open-ended questionnaires. Very often, researcher bias means that the categories picked out tend to find the groups of students that the researcher is seeking out. In our contribution, we discuss an example of application of hierarchical and non-hierarchical analysis method, to interpret the answers given by 118 Tenth Grade students in Palermo (Italy), to six open-ended questions about algebraic thinking. We show that the parallel use of the two quantitative analyses allows us to interpret in deep way the reasoning of students solving different mathematical problems using Algebra. These clustering methods also allow us to highlight different students groups, that can be recognised and characterised by common traits in their answers, without any prior knowledge on the part of the researcher.

## Methodology

In recent years, some papers have tried to develop detailed models of the reasoning competences of the student populations tested, or to subdivide a sample of students into intellectually similar subgroups, by using quantitative or qualitative analysis methods. (Everitt, Landau, Leese & Stahl, 2011; Prediger, Bikner-Ahsbahr & Arzarello, 2008) It is worth noting that research papers using quantitative analysis methods to study student responses to open-ended questionnaire can be found in Science education; not many research work can be trace in Mathematics education (Di Paola, Battaglia & Fazio, 2016), especially on the application of clustering analysis. In this paper we focus on the application of hierarchical and non-hierarchical clustering methods referred to dendrograms representation and k-means algorithm (Everitt, Landau, Leese & Stahl, 2011), trying to make sense to answers given by 118 Tenth Grade Italian students to six open-ended questions on algebraic thinking. The questionnaire was administered to the students at the beginning of the school year, before any discussion about Algebra had taken place. They answered in 45 minutes.

In particular we discuss the results on the study of typical students' behaviour in tackling the algebraic resolution of word problems and, at the same time, at understanding how the student semantically and syntactically control questions containing symbolic algebraic expressions (Radford & Puig, 2007). Our decision to refer to word problems, according to the PISA test, can allow us to study student literacy in using algebra (Bohlmann, Straehler-Pohl & Gellert, 2014) and in the transition from arithmetic to the modelling of problems expressed in a not-symbolic language, called "natural language (NL)" (Prediger, Bikner-Ahsbahs & Arzarello, 2008). K-means and dendrograms approach allowed us to partition and characterize our student sample, without making any a-priori assumptions and giving interesting output about student's behaviour.

## Clustering results

The k-means method (showed in Figure 1) allowed us to simply group and characterize the common students traits related to their solution strategies of the open-ended questions about algebraic thinking (procedure choices, mistakes, failings etc.). This gives us the opportunity to safely partition students into three groups: these are characterized by centroids  $C_i$  (called *Arithmo*, *Pre Al-gabr* and *l-gabr*) that represent the answering strategies given with maximum frequency by the students who

are part of the cluster. The Hierarchical clustering method (showed in Figure 2), obtained using the Weighted Average linkage, identified five groups of students (called *Arithmo*, *Pre Al-gabr 1*, *Pre Al-gabr 2*, *Pre Al-gabr 3* and *Al-gabr*) allowing us to better highlight their difficulties in the answering strategies related to the transition between the NL (typical of word problem) and the symbolic one. The results we found

are largely coherent with the ones already reported in the literature obtained by means of qualitative methods. For this reason, we can consider the use of both hierarchical and non-hierarchical clustering a valid tool to complement the use of qualitative analysis to study a large number of students with respect to the way they give answer to the questionnaire.

# Conceptualizing the core of the function concept – A facet model

Carina Zindel

TU Dortmund University, Germany; [carina.zindel@math.tu-dortmund.de](mailto:carina.zindel@math.tu-dortmund.de)

*This paper presents a model for conceptualizing the core of the function concept, which is made up of those facets that are equally important for all types of functions and common to all representations. The so-called facet model enables the identification of potential obstacles and a detailed description of students' learning processes when connecting representations (e.g. verbal and symbolic representations when solving word problems). In total, 19 design experiments with overall 96 learners were conducted and qualitatively analyzed.*

*Keywords: Function understanding, concept formation, functions, word problems, lower secondary school.*

## Theoretical background

### Conceptualizing function understanding

Functions are regarded as an important learning content in school. Consequently, many theoretical and empirical studies have investigated the teaching and learning of functions since the beginning of the 20<sup>th</sup> century, working with very different conceptualizations of “function understanding” (Niss, 2014). For examples, cf. Oehrtman, Carlson, & Thompson (2008); Leinhardt, Zaslavsky, & Stein (1990); Vinner & Dreyfus (1989); common in German didactics is the concept of basic mental models (GVs), cf. vom Hofe (2016). Niss (2014) emphasizes the complexity of the function concept and the necessity of “intentional and focused work on designing rich and multifaceted learning environments” (Niss, 2014, p. 240). Most studies share the overarching claim that students should really *understand* functions, even if this aim is interpreted in different ways, e.g. being able to identify a function (Vinner & Dreyfus, 1989), taking a process view of functions (Oehrtman et al., 2008), and more. Thereby, some of the conceptualizations are more specific than others with regard to their incorporated aspects of single representations or types of function. One example is the role of slope, which is only important for linear functions. This paper now presents a conceptualization of the core of the function concept as a dependence relation that is independent of (1) specific aspects of representations, (2) types of functions, and (3) different perspectives which all still can and should be taken. The facets making up this core were reconstructed empirically and are summarized in Figure 1.

The different function types (linear, square, exponential ...) are introduced one after another within the German syllabus for example. Hence, when students deal with square functions it is not surprising that they tend to incongruously adopt specific attributes of linearity to square functions (e.g., Leinhardt et al., 1990). One reason might be that square functions are presented as “new” learning content without making explicit commonalities (especially the facets of the core of the function concept) and differences (e.g., the relevance and usability of constants for interpreting functional equations) to linear functions. This problem also occurs when connecting representations. The aim of this study is to develop teaching-learning material that makes these common core facets explicit.

## Connecting representations – learning medium and learning content

An important activity when dealing with a functional relationship is connecting its representations. The notion “connecting representations” resonates with the activity Duval (2006) describes as the conversion of semiotic registers. Studies consider this activity in two different roles: On the one hand, connecting representations is regarded as useful medium for concept formation processes (cf. Duval, 2006). On the other hand, studies emphasize that connecting representations proves to be demanding for learners (Niss, 2014; Leinhardt et al., 1990). Therefore, connecting representations is not necessarily a resource one can build on when designing teaching-learning material, because it already requires some kind of conceptual understanding itself. Hence, before using it as a resource for higher concept formation processes the students’ understanding of the core facets needs to be supported. Many studies focus on the symbolic, numerical and graphic representations (e.g. Moschkovich, 1998; Duval 2006). In this paper, the verbal representation will be used to explicate the common core facets. Dealing with functions means dealing with their representations (e.g. Duval, 2006; Leinhardt et al, 1990; Swan, 1985). However, the representations can be considered under different lenses or perspectives. Some perspectives are more obvious in one representation than in the other. Niss explains this fact as follows:

One important issue that arises in this context is the fact that functions can be given several different representations (...), each of which captures certain, but usually not all, aspects of the concept. This may obscure the underlying commonality – the core – of the concept across its different representations, especially as translating from one representation to another may imply loss of information. (Niss, 2014, p. 240)

Considering the activity of connecting representations as a learning content raises the question of which detailed aspects form the core of the function concept that students have to understand. The core of the function concept shall include those aspects that are common in all representations and equal for all types of functions. This requires an adequate conceptualization to describe this core explicitly and in a differentiated way.

## Facet model

### Conceptualizing the core of the function concept

This study approaches the question which facets form the core of the function concept by using the construct of „comprehension elements“ (Drollinger-Vetter, 2011), which is based on cognitive psychological theory. Comprehension elements (further called: facets, indicated by ||...|| in the text and designated in the boxes of the model) of a concept are defined as central mental schemes, which are mirrored differently in different representations. This theory draws on Aebli’s (1981) conception of understanding as a network of facets that are com-

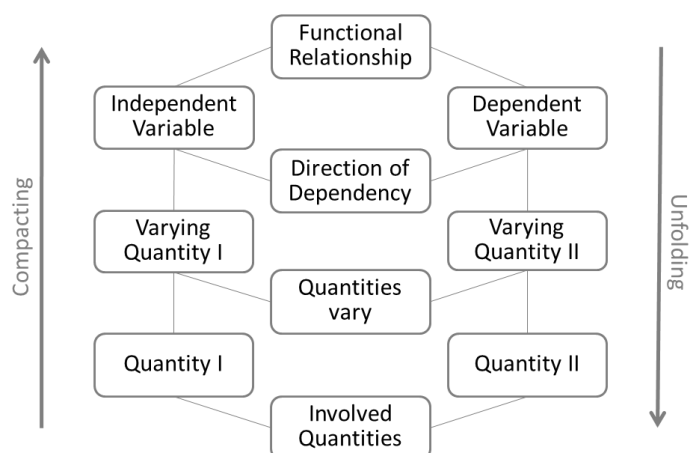

Figure 1: Facet model

pacted into denser concepts: concept formation processes require the acquisition of single facets of the concept and then the relation between the facets. The most compact facets are in the top region of the model while the more unfolded ones are located in the bottom region. Processes of understanding are initiated through processes of unfolding and compacting (Drollinger-Vetter, 2011). Depending on the situation, the edges of the model can be interpreted either as a process of compacting or as one of unfolding.

This construct is now adopted for the function concept. The facets have been reconstructed in the first design experiment cycle. When considering the facets common to linear and square functions for example, one can identify that first it is important to know that there are two ||involved quantities||. General facets like this are shown in the middle column of the model, the concrete manifestations in the situation are shown in the outer paths. Having identified the concrete ||quantity I|| and ||quantity II||, students have to realize that these ||quantities vary|| and that the ||direction of dependency|| matters. These are the facets necessary to finally identify the two quantities as ||independent variable|| and ||dependent variable|| in the concrete situation. Considering the ||independent variable|| and ||dependent variable|| by describing the whole ||functional dependency|| is the most compact way to talk about the core of the function concept. But when dealing with word problems it is equally important to be able to unfold compacted facets. Other “facets” as the ||meaning of the slope|| for example, are only helpful when dealing with linear functions. When dealing with square functions, the constants can only be interpreted in the graphic representation. Accordingly, using the facet model allows the following conceptualization of understanding the core of the function concept:

“Conceptual understanding of [the core of] functional relationships can be defined as the ability to adopt different perspectives in different [representations] and to coordinate them by flexibly and adequately addressing the facets from [here: Figure 1]. The adequate addressing comprises flexible compacting and unfolding of conceptual facets, thus moving upwards and downwards in the facet model.” (Prediger & Zindel, in press, p.9)

This model has proven successful to identify and describe potential obstacles (for examples cf. Prediger & Zindel, submitted). Of course, learners might address other additional facets than the normatively expected ones. The model is sensitive for these individual facets which can also be noticed and combined with other facets.

### Research questions

Connecting representations is not necessarily a resource that can be used to support conceptual understanding, because it already requires some kind of conceptual understanding itself, namely flexibly unfolding and compacting the associated facets (Figure 1). This is a starting point to focus on the question of how to support conceptual understanding. In the overarching study teaching-learning material has been developed and empirically tested. In this paper the focus is on the following research question:

How can the facet model be used to describe and visualize learning processes (especially processes of connecting representations)?

## Design

The methodology of this project is Topic-specific didactical Design Research (Prediger & Zwetzscher, 2013), which relies on an iterative interaction between designing teaching-learning material, conducting design experiments and analyzing the processes. In the overarching project, three design experiment cycles in laboratory setting and a fourth design experiment cycle in classroom setting were conducted. In total 39 learners participated in 16 design experiments in laboratory setting and further 57 learners participated in 3 design experiments in classroom setting (usually grade 9-10). The overall 42 sessions were videotaped (1890 minutes), partly transcribed and qualitatively analyzed.

### Facet model as methodical framework to describe learning processes

This facet model, which has just been introduced, can be used now as a starting point for supporting conceptual understanding by explicitly addressing its facets. The teaching-learning material intends to give the opportunity to get to know, address and combine facets from the facet model. The following part starts dealing with the design element of varying phrases and proceeds with a presentation of the empirical insights regarding its effects.

#### Varying phrases – a design element

Due to limitations in length of this paper Figure 2 shows only an excerpt of activities from the learning arrangement, realizing the design principle of connecting representations and including the systematic variation of phrases.

**Comparing Streaming Offers**

- (1) Compare the different offers. Which one would you choose?
- (2) Which offer is better after how many months?
- (3) What is the total price, if you use the offer for 12 months?
- (4) Find the equation which describes the general relationship.
- (5) Which description does match to which of your equations?

**DREAMSTREAM**

In our online video store you can book a film flatrate for only 19,99€ per month. For this, you can rent every month as many films as you like. Additionally you have to pay a one-time registration fee of 5€.

Number of months	Total price

$f(x) = 19,99 \cdot x + 5$

Description A: The equation indicates the total price in dependency of the number of months.

Description B: With the equation, I can - in dependency of the number of months - calculate the total price.

**STREAMOX3**

Watch our complete offer of films and series conveniently on your television with our new Streamox3-TV! For the TV box you pay 49€ once, the belonging film flatrate you already get for a price of only 9,99€ per month!

Number of months	Total price

$f(x) = 9,99 \cdot x + 49$

Description C: The equation indicates the number of months in dependency of the total price.

Description D: With the equation, I can - in dependency of the number of bought films - calculate the price in one month.

**Figure 2: Excerpt from the learning arrangement (Descriptions A-D literally translated from German)**

From a normative perspective, different facets should be addressed by dealing with varied phrases. To achieve this, all the phrases vary in at least one of the facets. No sequence of phrases to be considered is given to the students.

## Empirical insights: Describing learning processes by using the facet model

In order to connect representations it is necessary to address the same facets in both representations adequately. Both representations (each visualized by one model) refer to the same functional relationship (here: verbal representations on the left, symbolic representation of the DreamStream offer on the right). Each model visualizes the facets that are addressed in the respective representation. Adequately addressed facets or connections are framed by green lines, inadequately addressed facets or connections by red dashed lines. Depending on the situation the lines can be interpreted as process of either unfolding or compacting.

A brief insight into the case study of Tatjana (15) and Alexandra (14) illustrates how dealing with varied phrases makes students aware of the facets from the model. Tatjana starts with description D.

- 100 Tatjana [3s] Well, the first one definitely fits [points to “With the equation, I can - in dependency of the number of bought films - calculate the price in one month”].
- 101 Alexandra Yes, I think so, too. [laughs]
- 102 Tatjana [laughs] [3s] Because actually it doesn’t matter how many films one takes. One still pays the same per month anyway.

First Tatjana (Figure 3) misjudges the matching of description D and explains it in 102 with the argument that it does not matter how many films one buys. She does not consider the two quantities in the phrase as ||varying quantities|| that are connected by a dependence relation. Instead she focuses on the two ||involved quantities|| and creates a connection

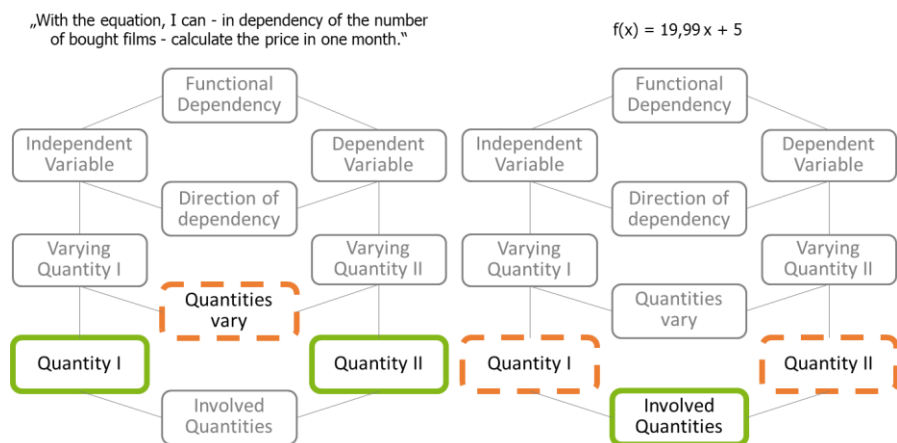

Figure 3 Tatjana (100 and 102)

between them by herself. This connection corresponds neither to the phrase nor to the functional equation. She identifies ||quantity I|| and ||quantity II|| in the equation, but she does not realize that these quantities and the ones in the phrase are not the same. Following this thought, they pay attention to the next phrase.

- 104 Alexandra [12s] I think the second one is right, too [points to “With the equation, I can - in dependency of the number of months - calculate the total price”]. Because with the number of months, this would be x indeed – hum – calculate the total price, how much (...)
- 105 Teacher Mhm.
- 106 Tatjana [11s] This is the same like this [points to “The equation indicates the total price in dependency of the number of months”], right?

107 Alexandra Yes.

Alexandra (Figure 4) correctly explains in 104 the matching of description B by identifying the same ||independent variable|| in the phrase and in the functional equation. Moreover, she addresses the ||functional dependency|| by identifying that one can calculate the total price

„With the equation, I can - in dependency of the number of months - calculate the total price.“

$$f(x) = 19,99x + 5$$

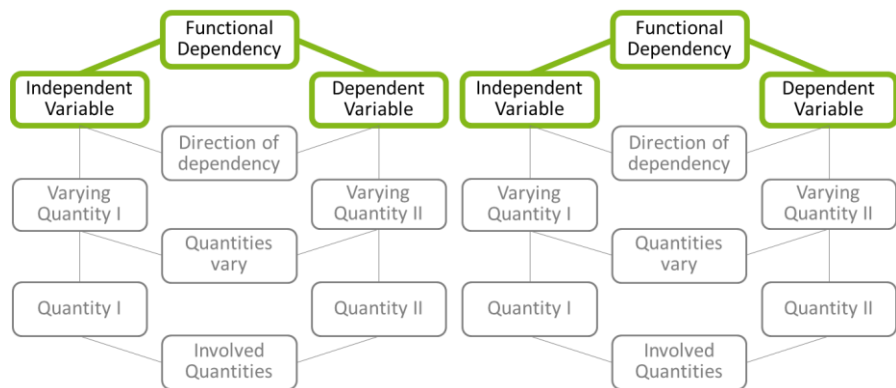

Figure 4 Alexandra (104)

(||dependent variable||) with the identified ||independent variable|| (number of months). Afterwards, Tatjana determines that the descriptions B and A mean the same and only vary linguistically (106).

Finally in this scene the tutor asks Alexandra's opinion to description D.

141 Alexandra Yes. I think so, too, that this is right, because one – x is indeed – are indeed the films and thereby one can just – no these are the months! So I don't think that this is right. I think this is wrong.

In 141 Alexandra (Figure 5) reasserts her approval to Tatjana's judgment in 100 that the phrase fits to the DreamStream offer. She starts to explain this decision by reasoning about the meaning of the ||independent variable|| in the functional equation and falters. Beginning

„With the equation, I can - in dependency of the number of bought films - calculate the price in one month.“

$$f(x) = 19,99x + 5$$

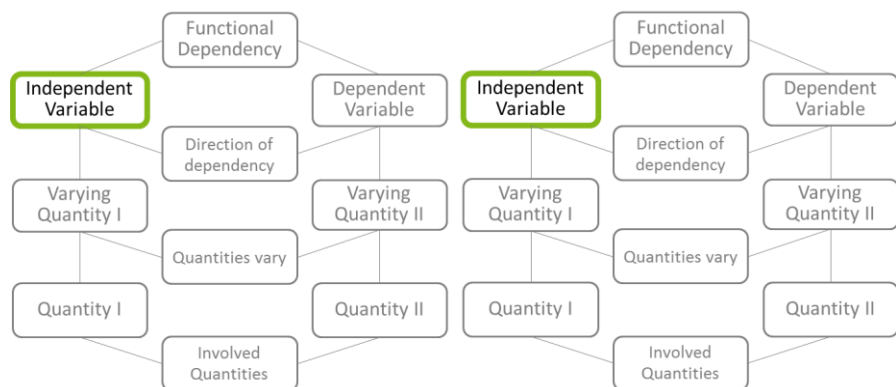

Figure 5 Alexandra (141) and Tatjana (146 and 148)

ning with interpreting the phrase she identifies that the

||independent variable|| would be the number of bought films. But then she correctly states that this fact does not apply to the functional equation because the ||independent variable|| is the number of months. She concludes that the phrase does not fit after all, which suffices for a non-match.

145 Teacher [laughing] If you like to say something about this, here you are.

146 Tatjana Yes, now I think, this is wrong.

147 Teacher Why?

148 Tatjana Well, because it is put on the number of bought films there.

Then Tatjana revises her first judgement, too. In 148 she explains this fact by referring to the different ||independent variables||.

Summing up, contrasting the varied phrases initiated the addressing of different facets. The learning process is visible in the increased precision and explicitness in students' utterances. In the begin-

ning, Tatjana's utterance was not precise enough to match the phrase to the equation adequately because she could not identify the differences in the functional relationships described. This fact becomes visible in the model through the non-adequately addressed facets (Figure 3). One reason may be that she could not interpret the verbal representation. In contrast, Alexandra is able to address the facets of the core adequately and precisely. This fact becomes visible in the model due to the same adequately addressed facets in both representations (Figure 4). When Alexandra deals with the first phrase, she first approves Tatjana's assessment. However, in her explanation she struggles and realizes that the ||involved quantities|| are not the same in the verbal and symbolic representation. She adequately concludes that these representations do not belong together. At the end of the scene, Tatjana revises her first judgement (Figure 5). Thereby, she focuses more on the meaning of the given phrase than on the situation itself.

Of course, this excerpt is only an illustrating example of such a learning process. In other cases the developments look very different. One reason for this fact is that the sequence and number of considered phrases varied due to the fact it was not preset in the material, but adopted for each process by the teacher. Overall, the empirical analysis of students' learning processes indicates the analytic power of the facet model and that dealing with varied phrases can support the process of addressing facets as well as unfolding and compacting them.

## Conclusion

This paper presented a conceptualization of function understanding focusing on the core of the function concept, which is based on cognitive psychological theories. It provides not only the identification of potential obstacles but also a normative framework for supporting function understanding. These facets of the core of the function concept are not specific to single representations or function types. Nevertheless, it is of course important to learn specific knowledge about representations and different types of functions. However, the core facets should be emphasized whenever students get to know new aspects of functions and should be addressed consistently and repeatedly in order to make students aware of the commonalities of every functional relationship.

Dealing with varied phrases stimulates addressing the core facets as well as unfolding and compacting them. This has been illustrated in the empirical insights. The facet model enables both, visualizing and describing processes of connecting representations by contrasting the facets that are addressed in each representation. An adequate connection of representations requires adequately addressing the same (core) facets in both representations. However, using the model not only enables describing these normatively prescribed core facets but it is also sensitive for individually activated facets.

Within these brief empirical insights, the model enabled the investigation of the connection of verbal and symbolic representations of functional relationships when dealing with word problems. Presumably this is compatible to other connections of representations. Furthermore, the conceptualization presented here focuses on the core facets of the function concept. To what extent this conceptualization can be combined with others in order to form a broader understanding of the function concept ought to be subject of further analysis.

# A classical dot pattern-based approach to algebraic expressions in a multicultural classroom

Marc Sauerwein<sup>1</sup> and Malte Mink<sup>2</sup>

<sup>1</sup>University of Bonn, Germany; [sauerwein@math.uni-bonn.de](mailto:sauerwein@math.uni-bonn.de)

<sup>2</sup>Otto-Kühne-Schule, Bonn, Germany; [maltemink@googlemail.com](mailto:maltemink@googlemail.com)

*Keywords: Algebraic expressions, secondary school mathematics, refugees.*

## Introduction

In February 2016, the Otto-Kühne Schule in Bonn, Germany, established an International Preparation Class (IVK, Internationale Vorbereitungsklasse) for 20 foreign pupils from different conflict and war zones all over the world. In this class, they learn the German language as foreign language adequate to their skill level (12 hours per week) and other subjects such as mathematics (5 hours per week). Their educational background is very heterogenous and therefore their mathematic class is usually split into at least three different groups covering topics from multiplication tables to quadratic functions. This project focuses on learning material developed for one group in their first lessons about algebraic expressions and their manipulation. The above-mentioned restrictions and conditions led to the necessity to develop a special approach<sup>1</sup> with few lingual prerequisites and the potential to support the development of mathematical language.

## Theoretical background

According to an analysis of German textbooks by Prediger & Krägeloh (2015, p. 91), variables are usually introduced by lingual means. In particular, for the generalising aspect (Arcavi et al., 2016), it is referred to the everyday language. Taking important literature on structure sense resp. structuring (Hoch & Dreyfus, 2004, 2006; Rüede, 2012) into account, the learning material was constructed with a twofold goal: on the one hand the material should be easy accessible (in a linguistic way) in which the students can broaden their notion of variable while on the other hand the material may foster the activity of structuring on a beginner level. For this, dot patterns (or: figurative numbers) were chosen. By a figurative number, we mean a sequence of pictures consisting of dots (Figure 1) and the related number sequence.

Figure 1: The “filling glass” with the sequence 6, 10, 14, ...

<sup>1</sup> For more details on the current status of the project, we refer to: <http://www.math.uni-bonn.de/people/sauerwei/>

## Actual setting

The class started with a discussion of the dot pattern in Figure 2. The leading questions were: How many dots are in each picture? Can you continue the pattern? How many dots are in the 4<sup>th</sup> picture? How many dots are in the 100<sup>th</sup> picture? How many dots are in arbitrary picture?

**Figure 2: Adding three dots with the sequence 3, 6, 9, ...**

This very basic introductory example could catch the attention of every pupil. Even pupils with a usually low motivation for mathematics participated actively. All the questions were answered promptly and correctly and the only reasonable formula was found ( $3x$ ). At this point, we did not introduce the formula  $(x+x+x)$  for adding the rows since we did not want to lead the pupils in any direction. From there on, the class worked individually or in smaller groups with the same leading questions on other dot patterns. It was stressed by the teacher that there can be many correct expressions for each pattern, but that each expression requires its own justification. Moreover, it was agreed on that two expressions are only equal if they yield the same result for every number plugged in. Hence, the only chance to verify equality was via the dot patterns and their structure. Thus, the dot patterns became a tool for argumentation.

This project is ongoing and more cycles of implementation in different regular and international classes are in preparation.

*Keywords: Elementary algebra, conceptual understanding, algebra concepts, tertiary education.*

Elementary algebra and other developmental courses have consistently been shown to be barriers to student degree progress and completion in the United States. Significant research has been done in the primary and secondary context, but little research has been conducted with students enrolled in elementary algebra courses in the tertiary context, despite the fact that there is significant evidence to suggest that mathematics learning is likely somewhat different in this context (Mesa, Wladis, & Watkins, 2014).

## **Teacher beliefs and expertise**

There is significant research suggesting that teacher beliefs are often strongly related to the teaching practices that teachers implement in the classroom, and therefore are also related to student beliefs and learning experiences (see e.g. Fang, 1996; Maggioni & Parkinson, 2008). In addition, teacher expertise also has the potential to benefit the research community by contributing important information about what teachers have learned while teaching.

## **Theoretical framework**

This study uses Vygotsky's (1986) theory of concept formation: learners begin to use algebraic symbols, graphs and other representations before they have "full" understanding of them, and through this experimentation and communication with "more knowledgeable" others, they internalize more formal and correct meanings for the objects that the representations symbolize.

## **Methodology and results**

Five elementary algebra instructors collaborated on this action research project, some of whom are also educational researchers. This included faculty with doctorates in both mathematics and mathematics education, with varied backgrounds and different teaching styles. This study used the *Action Research Spiral* Framework (Kemmis & Wilkinson, 1998) to guide the process of collaborative exploration into student thinking about elementary algebra concepts. This framework outlines a cyclical practice in which practitioners go through the following steps repeatedly: 1) plan; 2) act and observe; 3) reflect; 4) revised plan, etc... In a cyclical process of experimentation, instructors developed assignments and assessment questions intended to assess student

understandings on the framework (see Table 1) that they had initially developed through discussion based on prior teaching experience. An example of one type of assessment question is below:

- Assume that  $a \neq 0$ . Dale simplifies the expression  $a^3a^{-2}$  and gets the correct expression  $a$ . Which of the following must be true? There may be **more than one** correct answer—select **ALL** that are true.
- $a^3a^{-2} = a$
  - If Dale lets  $a = 10$  in both the expressions  $a^3a^{-2}$  and  $a$ , he will get two different answers.
  - Dale can substitute  $a$  for  $a^3a^{-2}$  anywhere it appears in an algebraic expression.
  - If Dale lets  $a = 20$  in both expressions, he will get the same value for each expression.
  - Dale needs to know the value of  $a$  before he can say whether  $a^3a^{-2}$  and  $a$  are equal.

This question was designed to test the extent to which students understand 4.a. in the framework. Based on student responses, instructors probed students about their understanding of specific components of item 4.a. in order to better understand what those are and how they relate to one another. Based on this process, the framework was revised: The first draft contained only item 4.a.ii.1; after repeated cycles the other items under 4.a. were added and structured hierarchically.

1. <b>Algebraic Symbolism</b>
2. <b>Algebraic Structure</b>
3. <b>Properties/Generalizing Arithmetic Operations</b>
4. <b>Equality/Equivalence:</b> Understands equality/equivalence. The student understands: <ol style="list-style-type: none"> <li>what it means for two expressions to be equal <ol style="list-style-type: none"> <li>that two expressions are equal iff they are equal for all possible variable values</li> <li>that if two expressions are equal, one may be substituted for the other in any context <ol style="list-style-type: none"> <li>that rewriting expressions is a process where an expression is replaced by an equivalent one</li> </ol> </li> </ol> </li> <li>what it means for two equations to be equivalent</li> </ol>
5. <b>Equations as Relationships between Variables</b>
6. <b>Thinking Graphically</b>
<i>Note: Because of space constraints, not all details of the framework could be reported here</i>

*Keywords: Geometry education, instruments, proof and argumentation, spatial skills, visualization.*

### Introduction

Around 25 researchers of various geographical origins (from across Europe and also from North America, the Middle East, East Asia) participated in Working Group 4 on Geometry Education. Some 20 contributions (15 papers and 5 posters) informed five discussion sessions and two further sessions dedicated to debates and the preparation of a final report that was presented at the end of the conference. Each discussion session was structured around a selection of contributions, each of which was briefly introduced and followed a reaction from a pre-arranged reactor to inform the collective discussion.

The name of this group was previously *Geometrical Thinking*, and this was modified for this CERME to emphasize the focus on the teaching and learning of geometry. During the previous CERME, four competencies were used to describe geometrical thinking: reasoning, figural, operational and figural. The group took these dimensions as a background that was very helpful to understand each other and to compare our approaches to the issue of what is at stake in the teaching and learning of geometry.

This choice was all the more crucial given that many approaches and issues were discussed during the group sessions. Three main issues were addressed during the working group:

- The role of material activity in the construction of mathematical concepts, including using instruments, manipulation, investigation, modelling...
- Visualization and spatial skills;
- Language, proof and argumentation.

In comparison to the previous CERME, this time psychological points of view, among others, were represented. This raised new questions, often with very different theoretical and methodological backgrounds. As rich as the discussions were, mutual understanding was a great issue. Consequently, we did not focus, during the discussions, especially on one single topic at a given school level. In each of the three issues aforementioned, we tried to identify the interest of various theoretical or methodological approaches, of different cultural or institutional contexts, and the ruptures or continuity during the education process.

It is important to note that almost all the papers addressed ‘classical’ issues in this WG: this means teaching geometry to young children, the impact of specific contexts, geometrical activities in pre-service teacher training, moving from practical to theoretical geometry, using Digital Geometry Environments, and so on. Nevertheless, the main part of the discussions were about confronting,

sometimes in passionate ways, the theoretical and methodological approaches (for instance, didactical engineering was a 'classical' element for this WG) of the phenomena being studied. We try here to give an overview of these debates.

## **Topics of rich debate in the group**

### **Role of manipulation and thoughtful experiment**

This very broad topic has been a great field of study and experiment during the previous CERMEs. The discussed papers concerned students at all level, from kindergarten to university and included the use of instruments for investigation, manipulation and modeling. As these subtopics were strongly linked in the papers, we decided not to split the topic.

The use of two kinds of instruments was evident. One kind of instrument was in the form of 'material manipulatives' used as ways to enhance the didactical potentialities of the manipulation by pupils: such manipulatives include the protractor, paper-pin, mathematical machine, 2D and 3D shapes, miniature, compasses, and so on. The other kind of instrument the participants studied comprised various technological tools, including DGEs, videos, IWB, tutorial system, touch-screen tablet. Some papers described the use of only one kind of instruments, while other ones proposed educational environments in which the two kinds of tools were used by students and teachers within complementary and synergistic approaches.

Those papers had different approaches and theoretical backgrounds. For instance, there was discussions about papers that aimed at fostering the use of tools to mediate mathematical meanings (e.g. geometric reflection, Pythagorean theorem), with explicit reference to the theory of semiotic mediation. In papers that used DGEs or manipulation (of shapes, 3D models, geometric miniatures) to pass from the global spatial perception (iconic visualization) to an analytic visualization and to identify proprieties (non-iconic visualization), the main references were to the instrumental approach, the works of Duval and Van Hiele's levels.

Some of the papers examined how the use of tools give opportunities for new experiments that can be useful in teaching. These tools included images used as a way to stimulate dialogic talk amongst student, or technological tools used to change the way of teaching. In this last case, the double approach (didactic and ergonomic) was used.

Two papers focused on teacher education (pre-service and in-service) and reported on the use of DGE to improve generalization and geometrical construction (with their justifications within Euclidean geometry). Here it seems that DGEs are no longer 'new' and specific in the classes but nevertheless remain somewhat complicated within teachers' education.

The group noted, as detailed later, that there is a true need for improving the 'networking' between the didactical approach and the psychological approach concerning the use of tools.

### **Visualization and spatial skills**

Some 8 contributions mentioned visualization or spatial skills as a keyword. This topic has been raised over the three previous CERMEs and continues to be an important and autonomous subject in our discussions. We chose to use the word *skills* rather than abilities, capacity or capability, as it can be that these latter terms induce pejorative interpretations, seeing it as something innate that cannot

be changed or trained. The research questions were multiple and intertwined: What are the children spatial skills? How can we evaluate or train it? What is the role of spatial skills in the teaching and learning of mathematics? Visualization: what are we talking about? How to train visualization in geometry? What for? What are the links with language issues? We first had to clarify the relations between visualization and spatial skills: are these referring to the same thing?

In terms of spatial skills, these are related to a psychological point of view. They are linked to the perception, representation, (mental) manipulation of objects, orientation (following a path...), spatial knowledge, location in space. Spatial skills have many facets, and from a psychological point of view visualization is one of these (but it is not very precisely defined in the literature). Spatial skills are very important in mathematics education and has various meanings: sometimes it is not specific to geometry (STEM education), and sometimes it is linked to spatial problems and spatial knowledge (Berthelot & Salin). We pointed some mutual understanding issues between the two fields: for instance, micro/macro space (Berthelot & Salin) are similar to small/large scale (Montello).

What we called visualization is more specific to geometry, and involves combination of perception, interpretation and reasoning. It links perception to reasoning, and helps back and forth between practical and theoretical matters in geometry, so that it depends on spatial skills, mathematical constraints and language. Then, the precise meaning of visualization depends on the topics: visualization is not the same when drawing plane projections of 3D models or when trying to prove a result. From a didactical perspective it has a double nature – psychological and mathematical – and, in this case, spatial skills are a part of visualization. We will keep this acceptance in this text.

Spatial skills are very important for early geometry, as most of the tasks are related to the perception of the space: role in the learning of geometric characteristics of the shapes (Douaire & Emprin), need for the coordination of small/large scale, micro/macro space, local/holistic perception (Vendeira, Papadaki, Klaren)... A psychological point of view is crucial to make more clear general cognitive difficulties of the tasks, and a didactical one links it to the teaching of mathematics. Visualization is more a mathematics education issue, so it is related both to spatial skills and to mathematical knowledge. In a general way, the question is “*How to get enough information using a drawing to solve a given problem?*”. It is declined, with very different aims, in every context: as an obstacle (prototypical shapes or too obvious results), using DGS, differences with Autistic Syndrome Disorder students, identification of geometrical properties or characteristics on a drawing... It is a great issue for early geometry, but it is often neglected when students get older, and we suggest this should be studied.

### **Language, proof and argumentation**

The former topics are linked to proof and argumentation by language. Argumentation and formal proof are linguistic activities about abstract objects, but they involve working on material objects (and then manipulation and visualization). Many works pointed this out. For instance Fujita’s dialogic process involves both visualization and social interaction, Klaren’s work on ASD students suggests that not seeing a square as a rectangle could be linked to the dutch word for rectangle, and we worked on Duval’s dimensional deconstruction which is a discursive process and visualization at the same time.

Some five contributions addressed proof and argumentation, not necessarily about proof itself but about ways of motivating proofs or argumentation. One topic for discussion was the influence of prototypical images on the reasoning process. Another topic was how teachers can have different concept images of a geometric figure (such as a rhombus) and different conceptions of a valid geometric construction of the shape. A third topic for discussion was the design of tasks that can provoke surprise, uncertainty or cognitive conflict, and tasks that can provoke the reconsideration of conjectures or proofs. This last consideration was strongly linked to the visualization issues, as for instance using non-euclidean geometry was seen as a way to give less visual information and to provoke the use of mathematical proof.

A particular focus for discussion was the digital environment *QED Tutrix* which is being designed to provide hints to the student user, while taking into account a judgment of the student's cognitive state based on the way they are using the system.

## Perspectives and conclusion

As might be discerned from the introduction, and as can be found in the papers that follow, there are a number of topics that continue to be of great interest to this topic working group. These include the role of instruments, manipulation, representations, proof and argumentation, and initial geometrical knowledge, in geometry education. We also note that the variety of the teaching and learning contexts increased: young children, secondary school, pre and in-service teachers training, but also university, specific education (ASD students), clinical studies... The synthesis of this numerous points of view required intense and rich debates. At this CERME, in the continuity to the former ones, a number of topics became more important. These include visualization and spatial skills which had already been discussed in the last CERMEs, and language in doing geometry, whose role has increased during this session.

In conclusion, the working group continues to feature great diversity: in cultural backgrounds (curricula, school culture, teaching culture, research culture ...), research questions, theoretical backgrounds and methodology. This continues to present some challenges in people understanding each other, sometimes linked to language and sometimes to what can be implicit meanings due to different research backgrounds.

A very visible benefit of the great diversity is that it invariably leads to very fruitful discussions and to attempts (and success) to clarify participants' points of view. In taking forward the work of the group, there is an increasingly important need for combining the frameworks, both theoretical and methodological.

# Learning to use a protractor: Touch screen tablet or not?

Cécile Allard<sup>1</sup> and Edith Petitfour<sup>2</sup>

<sup>1</sup>University Paris Est Créteil, Créteil, LDAR (EA4434) Créteil, France; [cecile.allard@u-pec.fr](mailto:cecile.allard@u-pec.fr)

<sup>2</sup>University of Rouen, Rouen, LDAR (EA4434) France; [edith.petitfour@univ-rouen.fr](mailto:edith.petitfour@univ-rouen.fr)

*In the present study, we compare the practice of one teacher in two 5<sup>th</sup>-grade classes for the same teaching concept (about angles) according to different working arrangements. In one of her classes, the teacher combines lecturing and interactive class: she talks and she exposes knowledge in front of her students. In the second class, she decides to try a new working arrangement: the flipped classroom. We compare the knowledge at stake by studying actions, gestures and language when video lectures are used on the one hand and when such devices are not used on the other hand. Thus, we compare the knowledge, which was shared and discussed in the classroom.*

*Keywords: Practice, protractor, language, angle, touch screen tablet.*

## Introduction

Our goal is to study the impact of the working arrangements' modifications (use of the touch screen tablet or not) about knowledge exposure (Allard, 2016). More specifically, we study the geometric knowledge exposure when the students learn to use an instrument (the protractor). We think that the use of artifacts have a contribution at the cognitive level (Mariotti & Bartolini Bussi, 2008). Thus learning to use a protractor contributes to the construction of the angle's concept.

This paper focuses on the teaching and learning of the angle's concept. It involves one teacher, Marie, and her grade 5 students in their use of the protractor. In France, at primary school level, students learn how to compare angles and how to reproduce a given angle using templates or tracing paper. In 5<sup>th</sup> grade they are then trained to use a protractor to measure angles and to construct an angle with a given measurement.

For several years, ministry of education recommends the use of new technologies and more recently emphasizes the need to individualize teaching: the flipped classroom may provide the means to meet these demands. This model of classroom instruction can be defined as an educational technique that consists of two parts: interactive group learning activities inside the classroom, and direct computer-based individual instruction outside the classroom (Bishop & Verleger, 2013).

## Theoretical framework

This qualitative study is built on prior work on the Double Approach by Robert & Rogalski (2005), current work on the concept of angle and on the study of actions with instruments Petitfour (2015).

## About practice

To analyse and interpret teacher's practices, we use the theory of the Double Approach defining five components: personal (teacher's choices, beliefs), social (teachers' working place, their colleagues and the social environment of their students, in both disadvantaged and advantaged areas), institutional (curriculum, relationship with supervisors), cognitive (choices about mathematical contents, tasks, organization and forecasts on how to manage the session) and mediative (improvisations, speeches, motivation of the students' participation, devolution of instruction and

knowledge exposures). The study of the students' activities allows to give information on cognitive and mediative components (what students did, what they said about their activities and what they learnt). Consequently, we have to clarify the elements of knowledge at stake, misconceptions and difficulties in the learning of the concept of angle.

### About angle

*Angle* appears to be a very complex and multifaceted concept, which can be defined in three different aspects: turn (an amount of turning between two lines meeting at a point), ray (a union of two rays with a common end point) and region (the intersection of two half-planes) (Mitchelmore & White, 1998).

Students encounter numerous difficulties in the learning of angles and misconceptions have been pointed out in several experimental studies (Berthelot & Salin, 1995; Mitchelmore & White, 1998; Devichi & Munier, 2013). Many students for instance consider that an angle's size depends on the length of its arms; or that one arm must be horizontal and the direction always counterclockwise; or that the angle is a sector in a circle (i.e. a "slice of pizza"). Tanguay and Venant (2016) hypothesize that this misconception is a possible effect of the systematic use of the protractor, when measures in degrees are at stake. Moreover, the confusion between the mathematical concept and the shape that represents it generate mistakes when students consider the spatial characteristics of the design representing the angle (Balacheff, 1988).

Students face some difficulties in using a protractor, which have been stressed in the literature. For example, Close (1982) observed mistakes due to a lack of mental representation of the protractor's angle to superimpose to the angle to be measured or due to the complexity of the dual scale. Tanguay (2012) summarizes some well-known difficulties encountered by students: they align the edge of the protractor body itself along one of the angle's arm instead of the baseline; or they don't place the protractor origin over the vertex of the angle to be measured. They can also read the measure on the wrong scale or on the right scale but in the wrong direction, for example by reading on counterclockwise graduation  $39^\circ$  left to  $40^\circ$  instead of  $41^\circ$ .

### About actions with instruments

We consider four categories of knowledge according to a theoretical framework to study actions with instruments (Petitfour, 2015)<sup>1</sup>:

- *geometric knowledge* about geometric objects, relations and properties
- *graphic knowledge* about representation of geometric objects (symbolic signs, drawings)
- *technical knowledge* about the instrument functionality, its use to obtain the graph and the theoretical relationship between the graphical trace and parts of the instrument
- *practical knowledge* about a given artifact, connected to its concrete handling and to a concrete organization of the action with it

### Methodology

We study the practice of one teacher, Marie, who wanted to experiment with a new style of instruction: the flipped classroom. Thus, her students should learn some mathematical content online,

---

<sup>1</sup> This framework is based on an instrumental approach (Rabardel, 1995).

by watching video lectures at home before the class session, whereas in the classroom, they should solve more exercises. Consequently, the teacher would be freer in the class session for discussing with the students: that should lead her to a more personalized guidance and to greater interactions with students than traditional teaching.

In our study, three components are common to the two situations that we analyze here: institutional, personal and social. Marie's components can be defined as follows: she is appreciated by her supervisors, colleagues and students. She thinks that in order to learn (and to teach) well it is necessary to handle and to solve a lot of exercises. She finds that she has never enough time. She is concerned about the learning of her students. She teaches in a rural school without social difficulties. In her two 5<sup>th</sup>-grade classes, she volunteers to include gifted students. These three components are stable and the same in the two situations. Thus, we can compare the practice of the same teacher in two 5<sup>th</sup>-grade classes in the same area. Consequently, we can focus only on the mediative and cognitive components. In order to foster the comparison, we asked Marie to teach the same content and to propose the same tasks in her two different classes, one with video lectures and the other one without.

### **Data**

In order to describe practices and inform mediative and cognitive components involved in the Double Approach, we focused on:

- one video for the 'flipped classroom' and two for the ordinary class that we have transcribed
- two short video lectures which we have transcribed
- the notebook lessons, exercises book and topics of assessment
- the teacher's interviews conducted before and after the sessions

We have split each session in episodes. We have identified different types of episodes in relation with the teacher's specific goals and exposure of knowledge (Allard, 2016). For example, in the lecturing session, the teacher remembers specific words (how to call angles according to their openings measured in degrees) at the beginning of the class session. The teacher also recalls to the students the specific symbol to note an angle ( $\widehat{ABC}$ ). These moments are reminder episodes (type 1): the teacher recalls of previous knowledge. Regulation episodes (type 4) are moments when the teacher intervenes to explain and to anticipate difficulties. The main goal of the regulation episodes is to provide students' progress. So we have identified six types of episodes.

#### *For lecturing sessions*

The two lecturing sessions last 45 minutes. The aim of the first session is to measure an angle with the protractor. The aim of the second session is to draw an angle of a given measurement. They follow the same organization in six types of episodes (table 1).

1	Reminder episodes: <ul style="list-style-type: none"> <li>- categorizing angles according to their opening measured in degrees (1<sup>st</sup> and 2<sup>nd</sup> sessions)</li> <li>- noting and naming the angles (1<sup>st</sup> and 2<sup>nd</sup> sessions)</li> <li>- defining the center of the protractor, based on a description of the artifact (1<sup>st</sup> and 2<sup>nd</sup> sessions)</li> <li>- measuring angle with a protractor (2<sup>nd</sup> session)</li> <li>- estimating and controlling the measure (2<sup>nd</sup> session)</li> </ul>
2	Methodological episode: estimating and controlling the measure
3	Presentation of the new knowledge: presenting and discussing the methodological sheet about measuring (first session) and drawing angles (second session) with a protractor.
4	Regulation episode: <ul style="list-style-type: none"> <li>- anticipating difficulties (in relation with the dual scale or extend ray)</li> <li>- reviewing any personal concerns or difficulties that are raised during the session</li> </ul>
5	Exercises episode: providing activities and handing out methodological and exercises sheets
6	The correction of the exercises: exposing knowledge and the difficulties encountered

**Table 1: the six types of episodes for ordinary session class**

The teacher talks to the entire class during certain types of episodes: 1, 2, 3, 4 and 6. Students are then facing the blackboard. It is only during the episode of type 5, that students work individually to solve exercises and the teacher interacts with them about their errors or difficulties.

#### *For the classroom with tablet*

Some students did not have access to the learning platform at home (because of one technical problem), as a result they did not watch the video session before the session in the classroom. Therefore, the teacher improvised and gave time during classroom session to watch and to listen to the video-class on the touch screen tablet. So, it's an opportunity for us to observe students discovering by themselves a mathematic lesson. This session lasts 45 minutes. We have then identified three types of episodes (table 2).

3	Presentation of the new knowledge by the video sessions about measuring and drawing angles with a protractor
4	Regulation episode: reviewing any personal concerns or difficulties that are raised during the session
5	Exercises episode: providing activities and handing out methodological and exercises sheet

**Table 2: the three types of episodes for video session**

Students worked in groups (by pairs) and watched the video lessons (episode of type 3). After that, they completed some exercises (the same ones that in the ordinary session class). The teacher walked around and talked with students to regulate their work one by one. For example, once more she explained how to handle the protractor.

## **Data analysis**

### **Comparison of the episodes**

Ordinary class requires two sessions instead of only one for the class with the touch screen tablet in order to learn the same content. For the teacher, it seems to be an efficient method. But our study shows that less knowledge is going around in the class in the case of touch screen classroom (episodes of type 1, 2, 6 are absent), there is no link between previous knowledge and the new one, no collective reminder by the teacher and a lack of formulation of the knowledge by the students.

In the ordinary classroom, students listen to each other and listen to the teacher, they raise their hand in order to come to the blackboard, they do individual exercises and sometimes ask questions or answer question the teacher's ones. They are facing the blackboard, which promotes discussions between themselves and the teacher. In the touch screen tablet session, students watch the first video session several times and they solve the exercises individually. While they work on the exercises, many students listen to the touch screen tablet: they look at the gestures in the screen and they try to do the same, they stop, observe and copy. After that, they watch the second video and do exercises. Meanwhile, the teacher walks around the pair groups, corrects mistakes, rectifies the bad handling of the protractor.

In the ordinary classroom, the teacher leads her students to use an appropriate language during the presentation of the new knowledge episode: for example, "center" for the center of the protractor instead of "hole". We can see that the students appropriated this formulation in the ordinary classroom whereas they did not in the other classroom even if they had listened to the session video several times. We can see in this comparison to what extent the working methods seems to change what is said and what is shared.

Now we compare what changes at the level of the potential learning about angle and the use of the protractor.

### **Knowledge at stake**

Actions with a protractor in order to measure an angle or to draw an angle with a given measurement involve different pieces of knowledge. We study the knowledge at stake in the types of episodes where this knowledge is exposed to all the students, that is to say where the whole class has the opportunity to hear or to see the same thing. It concerns episodes of types 1, 2, 3, 4, 6 in the sessions without a tablet and type 3 in the session with a tablet.

Some geometric knowledge appears explicitly in the session without a tablet whereas it does not in the session with a tablet. On the one hand, the classification of angles based on the degree measurement is recalled: angles are categorized according to their openings measured in degrees: an angle can be right, acute, obtuse, straight, zero or reflex. On the other hand, "angle" is defined as formed by two rays (sides) that have the same endpoint (vertex), and "ray" is defined as a line extending indefinitely in one direction from a point. In the same way, graphic knowledge appears explicitly only in the session without a tablet: first, the symbol  $\angle$  enables to distinguish an angle and a triangle; second, an angle can be named with three letters, the second letter names the vertex, the first names a point on one side and the third a point on the other side. The fact that the line representing the ray can be extended in one side is mentioned in both sessions but only explained referring to some geometric knowledge in the session without a tablet.

As far as the representations of an angle are concerned, drawings are more numerous in the session without a tablet. Indeed, in this latter session, five angles are drawn on the whiteboard, one is freehand traced and the others are traced with one of the edges of a set square. Besides, one is obtuse and four are acute with similar opening around  $45^\circ$  but which one with the vertex at right (it allows to use both protractor's scales) (Figure 1). At last, the five drawings have a horizontal side and are named with three points.

**Figure 1: Drawings of angles in the session without tablet**

The drawing of the angle  $\widehat{FOG}$ ,  $52^\circ$  had been presented by two students on the blackboard and each time, they have drawn an arc of a circle along the semi-circular edge of the protractor despite the fact that the teacher mentioned the uselessness of this curved line. This representation has led some other students to speak explicitly about “cake slice” which reveals the misconception of the angle as a sector in a circle.

Only two acute angles are drawn on a paper in the session with tablet. They are oriented in a non-prototypical way and are named with the letter of the vertex (upper case) and the letters of the direction of each ray (lower case) (Figure 2). It is not this latter notation that is used in the application exercise but the notation with three points.

**Figure 2: Drawings of angles in the session with tablet**

In both sessions, drawn angles are named both spoken and written. In the session without a tablet, the teacher sometimes used gestures too (Figure 3) expressing either the “ray” aspect or the “region” aspect of an angle.

**Figure 3: Gestures about angles (Left, “ray” aspect and middle and right, “region” aspect)**

Moreover, in the case of the obtuse angle  $\widehat{AOC}$  (Figure 1), she used a symbolic sign – a small arc of a circle – in order to indicate what angle is to be considered. In the session with a tablet, there are only deictic gestures pointing the letters “x”, “O” and “y” when they are uttered in order to name the measured angle.

Some technical knowledge is recalled only in the session without a tablet. This knowledge concerns the protractor’s functionality: a protractor is a measuring instrument, the measurement is expressed in degrees; and a description of the protractor parts to link with the graphical representation of an angle. Indeed, the localisation of the protractor’s centre is first given in a general way, by the use of

language accompanied by gestures, then the graduation  $0^\circ$  and the dual scale (inner and outer) from  $0^\circ$  to  $180^\circ$  are named and pointed on the protractor by the teacher.

The steps to measure an angle and the steps to draw an angle using a protractor are formulated in the same way in the two sessions. What is said is exactly what is written on the summary sheet given to the students. For example, here are stated the three steps to measure an angle: first, place the protractor so that the centre is over the vertex of the angle to be measured; second, place the graduation zero degree over one side of the angle; third, follow the graduations of zero degree, ten degrees, twenty degrees, ... until you reach the other side of the angle. It is also stated that perceptive evaluation of the opening of the angle – greater or smaller than the one of the right angle – enables to control possible measurement errors.

In the session with a tablet, the students can hear and see the operating filmed sequence as many times as they wish, pause and go back whereas in the session without a tablet, the operating sequence is presented several times by different students on the blackboard (for example, three times to measure an angle before doing the application exercise). The teacher helps the students to formulate the method they implemented.

Practical knowledge appears only in the session without a tablet. For example, some protractors have a hole to show the centre near the bottom of the protractor whereas the blackboard's protractor has his centre on the bottom; the semi-circular edge of the protractor can be damaged so that it is better to avoid tracing along this edge; if the protractor goes beyond the lines represented sides of an angle to be measured, then the lines must be extended. Regarding organizational aspects, the teacher gave students the advice to store the protractor in a pocket in their workbook to avoid breaking it.

## Results and conclusion

Our analysis of one teacher's practice about the use of the protractor allowed us to point out the following results. Some of the students' difficulties and mistakes are the same in both sessions, with and without tablet, when the students trace or measurement by themselves during the exercises episodes: wrong localization of the measure on the protractor, measurement without extending the line representing ray when it is necessary, clumsy handling of the protractor. Errors to note and to name points and rays appeared only in the session with tablet (students didn't manage to adapt what was presented in the video lecture). Moreover, there are inaccurate wordings that show confusion between length and angle. The correction of the arising errors is private in the both sessions but also public and shared in the session without a tablet. Finally, whatever the case, there is no difference between the assessment results of the two classes, according to the teacher and the collected data cannot inform us about the arrangement that would better foster learning.

This study confirms that the modifications tied to the mediative component, in particular in terms of working arrangements, have a very important impact on the knowledge exposure (Allard, 2015). Indeed, in the session with tablet, the only exposed knowledge is the knowledge of the tablet, without possible links with difficulties met by the students. In the lecturing session, there is more knowledge exposure thanks to the interactions between the students and their teacher.

# Constructing draggable figures using GeoGebra: The contribution of the DGE for geometric structuring

Lina Brunheira and João Pedro da Ponte

ESE - Escola Superior de Educação, Instituto Politécnico de Lisboa and UIDEF, Instituto de Educação, Universidade de Lisboa, Portugal; [lbrunheira@eselx.ipl.pt](mailto:lbrunheira@eselx.ipl.pt)

Instituto de Educação, Universidade de Lisboa, Portugal; [jpponte@ie.ulisboa.pt](mailto:jpponte@ie.ulisboa.pt)

*This study is a research on teaching practice, developed in the context of an elective course on Dynamic Geometry for prospective kindergarten and elementary school teachers taught by the first author of this paper. We aim to analyse the role of GeoGebra in the development of geometric reasoning, particularly the way individuals geometrically structure figures. The participants are a class of six future teachers. Data was gathered from the participants' portfolios and classroom observation while working on an exploratory task, which focuses on constructing draggable figures. The results show that this type of activity promotes spatial and geometric structuring, beginning with the perception of elements and relationships that enable the dynamic construction, and moving on to the description of the construction using formal concepts associated to the tools of the DGE.*

*Keywords: GeoGebra, geometry, structuring, visualization, teacher education.*

## Introduction

Research has shown the interest in engaging students of different ages in activities using dynamic geometry environments (DGE), for the improvement of concept learning and the development of reasoning (Sinclair & Yerushalmy, 2016). In particular, Hanna and Sidoli (2007) indicate that the DGE are a promising way “in enhancing the students' ability to notice details, conjecture, reflect on and interpret relationships and to offer tentative explanations and proofs” (p. 77). Also, in education programs, relevant research confirms the effectiveness of the use of technological tools, including DGE, to improve the knowledge of teachers and future teachers (Jones & Tzekaki, 2016). In this study, we aim to analyse the role of GeoGebra in the development of geometric reasoning, in a context of a geometry course for future kindergarten and elementary school teachers, based on exploratory tasks. In particular, we wish to understand how the construction of draggable figures in the DGE contributes to geometric structuring (Battista, 2008)?

## Theoretical framework

### Prospective elementary teacher education in geometry

The knowledge necessary for teaching includes mastery of mathematical reasoning, ways to solve problems and communicate mathematics effectively, understanding of concepts, procedures and the process of doing mathematics (Albuquerque et al., 2005; NCTM, 1991). Concerning geometry, kindergarten and elementary school teachers should understand how it is used to describe the world; analyse two and three dimensional figures; use synthetic geometry, coordinates and transformations; improve skills in producing arguments, justifications and in visualization.

Some researchers have claimed that there are few studies about teachers and future teachers' knowledge in geometry (Chapman, 2013; Clements & Sarama, 2011; Steele, 2013). However, the

existing literature provides reasons to believe this is a problematic area. As Clements and Sarama (2011) state, in many countries teachers from every level are not always provided with adequate preparation in geometry and lack of knowledge and confidence in this area. Concerning kindergarten and elementary prospective teachers, many only recognise and categorize shapes by their overall similarity to prototypes, instead of characterizing them by their properties (Clements & Sarama, 2011; Fujita & Jones, 2006) a problem we also identify in Portugal (Menezes, Serrazina & Fonseca, 2014). Overall, as Jones & Tzekaki (2016) recently stressed, studies on teachers' geometric knowledge and teacher education programs indicate that we still need to give attention on how prospective teachers build their understanding of geometrical objects. Also, we should take into account the effectiveness of approaches such as the use DGE.

### **Developing geometric reasoning and the use of DGE**

King e Shattschneider (2003) present eight reasons for a teacher to use a DGE: (i) to take advantage of the accuracy of geometric constructions and measurements, leading to confident results; (ii) to promote visualization; (iii) to encourage exploration, investigation and discovery leading to the formulation of questions, conjectures, and their test; (iv) to encourage demonstration because the experimental evidence offers the necessary conviction for such enterprise, and may provide clues; (v) to support the understanding of geometric transformations; (vi) to support the understanding of loci; (vii) to provide simulation opportunities for a wide variety of situations; and (viii) to allow the creation of microworlds, using new tools and allowing exploitation of non-Euclidean geometry.

A major emphasis on using DGE concerns the constructing of figures. Laborde (2001) compares this type of activity when performed using a DGE versus using paper and pencil. In her view, when we draw a figure using paper and pencil, the activity is often controlled by perception rather than being driven by the properties of the figure. Instead, in a DGE is not possible to construct a square in a similar way ("led by eye") and it requires more knowledge about the figure. But if the students are able to apply the properties correctly, we can ask ourselves, as does Battista (2007), what have they learned from the activity? For this researcher, "perhaps no *new* knowledge was acquired, but instead, the students' knowledge and reasoning were deepened and enriched . . . Or perhaps connections between properties were newly constructed or extended" (p. 878).

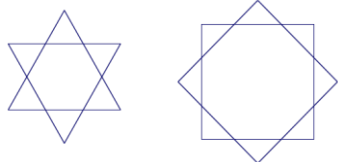

In order to analyse this reasoning we draw on the framework developed by Battista (2008). This researcher established a categorization of reasoning using three levels, corresponding to increasing degrees of sophistication: spatial structuring, geometric structuring and logical/axiomatic structuring. Spatial structuring is a special type of abstraction corresponding to the mental act of constructing an organization or form for an object or set of objects by identifying its components, combining them into spatial composites, and identifying the way they combine and relate. Spatial structuring enables a person to imagine manipulating an object, reflect, analyse and understand it. Geometric structuring describes spatial structuring using formal concepts such as congruence, parallelism, angle, transformations or coordinate systems. Geometric structuring is based on spatial structuring, that is, to be able to structure geometrically an object, it is necessary that one has interiorized the corresponding spatial structure. Logical/axiomatic structuring formally organizes geometric concepts in a system so that their relationship can be established through logical deduction. To operate at this level, it is necessary that verbal or symbolic statements can replace mental models. The research of Battista (2008) in a DGE (the *Shape Makers* microworld) with fifth

graders showed that the manipulation of shapes and the reflection on that manipulation may enable the pupils to move from thinking holistically to thinking about the geometric properties of the figure, that is, to progress from spatial structuring to geometric structuring. However, he also points that there is a need for guidance, reflection and experimentation in order to construct formal geometric conceptualizations of the DGE constraints.

## Methodology

The first author of this paper designed and taught an elective course on Dynamic Geometry in 2015/26, as a new offer in the teacher education program for prospective elementary school teachers in her institution, in Portugal. The course was divided into two phases: (i) 10 lessons dedicated to solving geometry tasks organized into four topics – problem solving, constructing, investigating and creating; and (ii) 5 lessons dedicated to didactics of geometry, projecting the work of the DGE with children from kindergarten to 6<sup>th</sup> grade. In the classroom, there was one computer for each participant, but they were encouraged to discuss with their colleagues. Regarding the assessment, each participant built a portfolio containing a task from each topic, detailed solution and a reflection on the activity, and also constructed a GeoGebraBook with the files used to solve the tasks.

This study is a research on teaching practice based on the observation of the activity of the participants and their solutions of a task and aims contributing to their professional and organizational development, “as well as to generate important knowledge about educational processes, useful for other teachers, for academic educators and the community in general” (Ponte, 2002, p. 13). Data was gathered mainly from the portfolios and GeoGebraBooks of the participants, complemented by the field notes taken by the first author, while observing the participants and supporting their work. There were only six participants: five females who were in the 2<sup>nd</sup> year of the program (also attending a compulsory course of Geometry) and a male in the 3<sup>rd</sup> year, the only one who had some experience with DGE. Since the Dynamic Geometry course is elective, the choice the participants may be considered an indicator that they like geometry and do not feel strong difficulties in this area, which was confirmed in this group. The task (Figure 1) was proposed in the 5<sup>th</sup> lesson, within the topic *Constructing*. It was intended that the participants would reproduce draggable figures, or families of figures, in GeoGebra from the properties visually identified, thus corresponding to one of the major emphases reported by Battista (2007).

<ol style="list-style-type: none"> <li>1. Construct both stars. Describe briefly the process.</li> <li>2. For each of the stars, find another building process and describe it.</li> <li>3. Construct other stars of this family with a larger number of points. Generalize one of the construction processes you used.</li> <li>4. Establish relationship between the number of star points and other elements.</li> </ol>	
---	---

**Figure 1 – Task *Constructing stars* (adapted from Johnston-Wilder and Mason, 2005)**

The data was analysed using a framework (Table 1) built by the first author of the paper (Brunheira, 2016), based on the concepts of spatial and geometric structuring (Battista, 2008). The table does not include the logical/axiomatic level, since it means that one operates at a symbolic level, which is not the purpose in this task. We use the framework to analyse the solutions, looking for the evidence

of the descriptors in order to characterize the level of structuring of the participants. However, we stress that despite the attribution of a level to a solution, this does not mean that we can characterize the level of structuring for an individual solely based on a solution of a task, so this must be seen as an indicator. Also, we cannot consider that solving a single task is enough to improve significantly, but this analysis may enable us to recognise it's potential.

Levels	Geometric structuring	
	Spatial structuring	Knowledge of concepts
N0	Does not establish geometrical relationships between figures and their elements, or does not provide most of the times.	Does not know most of the basic concepts and the language is very limited in terms of geometric vocabulary.
N1	Perceives geometric relationships involving visible elements of figures, but it may depend on the position of the figures, their elements or the context.	Knows the concepts of side and angle, congruence, perpendicularity and parallelism in the plan; in space, knows the concept vertex, edge, and face.
N2	Perceives geometric relationships involving visible elements of figures in any positions or context.  Perceives geometric relationships involving invisible elements of figures, but it may depend on the position of the figures, their elements or the context.	Knows the concepts as axe of symmetry, diagonal, bisector, midpoint and the geometric transformations in the plan; in space, knows the concept of congruence, parallelism and perpendicularity.
N3	Perceives geometric relationships involving visible or invisible elements of figures in any positions or context.  Produces generalizations of geometric relations for a family of figures.	

**Table 1 – Descriptors of the levels of spatial and geometric structuring**

## Results

Next we present an analysis of task solutions from prospective teachers Maria, Carla and Louise taken from their portfolios, which we consider to be representative of all the solutions presented.

### Maria's solution of the task

In figure 2 we present an excerpt containing two processes presented by Maria. Process A was used to build the two initial stars and process B was used for the same purpose, as well as to generalize. Both constructions begin with the image of the star as a whole figure and a regular hexagon where the star is inscribed in two different ways.

**Figure 2 – Excerpt of Maria's solution of the task**

Maria looks at the star as a whole figure inscribed in a regular hexagon in two different ways. She draws on invisible elements that were created to assist the construction. Regarding the generalization, Maria presents a process which can be applied to any star and establishes a relationship between the initial polygon and the number of points of the star. Finally, she identifies that this polygon cannot have an odd number of sides and justifies her finding. Thus, Maria's solution shows a very good geometric structuring for this family of figures, corresponding to Level 3 of the framework.

### Carla's solution of the task

Carla uses a procedure similar to Maria's process B and another process, shown in Figure 3.

**Figure 3 – Excerpt of Carla's solution of the task**

She looks at the star decomposing it into two congruent regular polygons, one of which constitutes the starting point for construction. The determination of the second polygon involves visualizing the star inscribed in a circumference, and the vertices of the second polygon on the perpendicular bisectors (a concept that she did not know). Thus, she identifies that the consecutive vertices of the

star are equidistant from each other and also equidistant from the centre of the star. Regarding the relations established, Carla identifies that the number of vertices of the initial polygon is twice the number of points of the star, but does not justify this. Therefore, Carla identifies various relationships between their elements, using visible and invisible elements and adequate concepts, such as the circle and the perpendicular bisector, thus showing a very good geometric structuring of the family of figures, which also corresponds to level 3.

### **Louise's solution of the task**

Louise builds the stars initially as Carla (draws the first polygon, traces the bisectors and finds the point of intersection). However, while Carla seems to look at the star in a static point of view, Louise visualizes the “movement” of the first polygon to obtain the second. The participant had an intuitive idea that rotating the initial triangle in a certain way, it would be possible to obtain the second triangle and form the star, although she did not know the formal concept of rotation and that we should define the rotation by a centre and an angle. She asked for help to find out if the GeoGebra could run this “movement” and the teacher explained how the “Rotation” tool worked. Next, Louise presented the following relationships: “For regular polygons with even number of sides, amplitude =  $180^\circ/(\text{number of sides})$ ; For regular polygons with odd number of sides, amplitude =  $180^\circ$ ”. Thus, we consider that her solution also reflects level 3.

### **Discussion**

All participants were successful in the task. They presented different and valid constructions mobilizing a variety of elements of the figures (visible and non-visible), relations between them, transformations and properties, some of them were unknown to them. So, the main conclusion we want to emphasize is that the construction of figures using GeoGebra significantly enhances the geometric structuring by promoting the identification of properties and relations between elements, as Battista (2008) reported in his study. This improvement stems from different features and strengths that we recognize in the DGE, some of them indicated by King e Shattschneider (2003). We start with two features – easiness of use and accuracy of the constructions – which we associate the two strengths – promoting intuition and exploration. In fact, sometimes participants started the construction from an insight of the properties and elements of the figure (or auxiliary figures) that could be useful, but they were not sure. The possibility to easily test the conjectures through a quick and accurate construction was a key aspect, as Maria explains:

With GeoGebra it was possible to explore different forms of construction of the stars using polygons, lines, midpoints, parallel lines, among others, easily, simply and accurately. If we didn't have this software this would be a long and relatively difficult process, especially the construction of regular polygons used as a basis for the construction of stars. (Portfolio)

Another potential of GeoGebra that emerged was the promotion of justification, which we did not ask for in the task. In fact, the ability to test the construction validity, as in a trial and error process, does not mean that participants do not reflect on their actions, as we note in Louise's comment:

I had to stop and think why the rotation angle depends on the number of sides, as well as to find a mathematical answer to for the correct value. (Portfolio)

In this case, we see a need to reflect on the value of the angle, which led to the justification of the chosen value and the understanding the generalization. So, although the DGE played an important role in the user's belief that a relationship is valid, did not lead to underestimate justification, instead promoted the search for it (Hanna & Sidoli, 2007).

Another feature of GeoGebra is that it leads the user to work with the formal concepts associated with its tools. In this way, we may think that we can only take advantage of the DGE when operating at the level of geometric structuring. In fact, as Battista (2007) suggests, we cannot make geometric constructions without reaching some level of “conceptual and representational explicitness”. However, this investigation shows that GeoGebra can facilitate the transition from spatial to geometric structuring. An example that supports this conclusion is the use of new concepts, like perpendicular bisector or rotation, that participants had just a vague memory from middle and high school, but were correctly applied as the DGE promoted their appropriation.

Finally, in connection to the nature of the task which favours different solutions, GeoGebra supports this diversity through a set of tools available, which also stimulates creativity. As Peter says:

The choice of this task reflects on the freedom it gives us to construct the figures using different processes . . . [which] depend on our ability to imagine overlapping figures, guidelines for the construction and other key points of the figure . . . improves the ability to find relationships between figures and their elements and encourages creativity. (Portfolio)

## Conclusion

This research was based on a construction task for which we recognize the potential mentioned by Laborde (2001). Besides, we corroborate the claims of King and Shattschneider (2003) regarding the reasons that support the use of the DGE, particularly the use of rigorous constructions and the promotion of visualization, exploration, investigation, discovery and demonstration, to which we would like to add creativity and intuition. However, the data also shows that constructing draggable figures in GeoGebra contributes to spatial and geometric structuring. The main contribution of this study concerns the importance of this work in prospective teacher education. From a mathematical point of view, the data shows the relevance of the exploratory work involving geometric constructions using a DGE, promoting the evolution in the way they structure the geometrical figures by identifying relationships and properties. Apart from this perspective, the comments of participants also show the relevance of reflecting on mathematical activity itself. This reflection – here enhanced by the portfolio – enables prospective teachers to become aware of their own learning in relation to the task, which can be an important contribution to their didactical knowledge.

*A unit on dynamic geometric construction was included in a professional development course for in-service mathematics teachers. As a final task in that unit 28 teachers were required to construct a rhombus based on their own choice of given objects and tools, using the dynamic geometry software GeoGebra. Their responses were analysed according to: the choice of given objects; the choice of tools; the explanation and validity test; and the number of different rhombuses they claimed to have obtained. The teachers were found to have different concept images of a rhombus and different conceptions of what constitutes a valid geometric construction. While many claimed to have obtained an infinite number of different rhombuses, differences were observed in the "type of infinite". Recommendations are given for improving the task design to strengthen teachers' mathematical and pedagogical knowledge.*

*Keywords: Geometric construction, dynamic geometry, GeoGebra, concept image, in-service teachers.*

## Introduction

From the use of a dynamic environment for geometric construction arise new frames of reference for the idea of construction. In this paper we present data accumulated during an in-service teachers' professional development course on dynamic geometric construction. We report on the data from two viewpoints:

1. The practical viewpoint – we will describe teachers' construction methods in the final task in which they were required to construct a rhombus in different ways (each construction according to different given objects). We will discuss issues arising from the construction, both those concerning the nature and validity of the construction and those concerning the teachers' images of a rhombus.
2. The pedagogical viewpoint – we will suggest possible ideas for improving the task design in order to hone and strengthen teachers' mathematical and pedagogical knowledge.

## Theoretical background

Construction in geometry has a specific meaning: the drawing of geometric figures using only compass and straightedge without measuring angles or lengths (Hartshorne, 2000a). Geometric constructions have been a popular part of mathematics throughout history. Euclid documented them in his book entitled "Elements", which is still regarded as the authoritative geometry reference. In that work, he uses these constructions widely and extensively, and so they have become a part of the

geometry field of study. Geometric constructions also provide insight into geometric concepts and give us tools to draw figures when direct measurement is not appropriate (Hartshorne, 2000b).

For about a decade, geometric constructions were removed from the Israeli curriculum. In 2014 geometric constructions were again included in the geometry curriculum for middle school in Israel. Curriculum decision makers claim (INMMC, 2013) that geometric construction integrates geometric content knowledge with a deductive way of thinking that is essential for geometry proofs.

The professional literature indicates that teaching mathematics using technological tools helps in the process of constructing an abstract knowledge of mathematics, and geometry in particular (Lagrange et al., 2003). GeoGebra is a powerful dynamic environment that allows testing of countless number of examples; provides effective and convenient tools for confirming or contradicting conjectures; and provides a wide selection of different tools for geometric constructions – from digital analogs of compass and straightedge, to shortcut tools, such as automatically drawing a line parallel to a given line (Fahlberg-Stojanovska & Stojanovski, 2010). GeoGebra is also a tool of assessment (Bu et al., 2012); thinking processes can be observed by examining the construction protocol which can replay step-by-step onscreen.

Vinner and Hershkowitz (1983) focused on the cognitive development of mathematical concepts, and proposed a model of two components: the *concept definition* – the verbal description of the mathematical concept, which characterizes the concept mathematically; and the *concept image* – the cognitive structure that includes all the examples and the processes related to the concept in the learner's mind. Geometric concepts have a special status: Fischbein (1993) coined the term "figural concepts" and argued (Fischbein & Nachlieli, 1998) that geometrical figures are characterized by both conceptual and sensorial properties. A geometrical figure is a mental abstract which is governed by a definition. At the same time, it is an image. In geometrical reasoning the two categories of properties should merge absolutely.

In the context of this research, geometric constructions, which are carried out in a GeoGebra dynamic environment, can be seen as figural concepts. We used our personal, not formal definition (Vinner, 1991) for geometric construction. To construct a geometric figure means to draw the figure on a computer screen using GeoGebra digital tools in such a way that essential properties of the figure remain invariant under dragging.

## **The purpose of the study**

The aim of the present study is to:

1. Characterise the in-service teachers' geometric constructions on the final task of the unit.
2. Improve the design of the construction tasks in order to increase their contribution to the development of in-service teachers' mathematical and pedagogical knowledge.

## Methodology

### The research population

This research was carried out in the framework of a 30-hour in-service professional development course whose aim was to acquaint middle-school and high-school teachers with a digital program for ninth-grade mathematics students. A part of this course was the geometric construction unit. Since our assumption (which subsequently proved unfounded) was that the teachers were already acquainted with traditional geometric constructions using straightedge and compass, the unit dealt mainly with the use of the dynamic geometry software GeoGebra. When necessary, traditional methods were referred to. The focus of the research was on the responses of 28 teachers to the final task of the unit.

### About the final task

Throughout the course the in-service teachers tried out different geometric construction activities using GeoGebra and thus learned to create a valid construction using dynamic tools. Instructions for the final task included the following reminder.

Constructing with dynamic tools is not the same as drawing on a page since the objects (points, segments, etc.) are moveable: you can drag them and observe how other objects change accordingly. Each figure must be constructed so that it retains its characteristics even after other objects are dragged. For example, on constructing a rhombus according to its diagonals, check that after changing the lengths of the diagonals the figure remains a rhombus. This type of construction is called a valid construction.

In the final task the teachers were required to:

1. Construct a rhombus by three different methods, each construction according to different given objects (according to your choice), for example, according to its diagonals.
2. Describe each construction process and prove that it results in a rhombus.
3. State and explain how many different (non-congruent) rhombuses can be obtained by each method.

Note that no instruction was given as to whether the given object is fixed or dynamic. A fixed side will yield an infinite number of rhombuses (same side length, different angles) while fixed diagonals will yield only one rhombus. Clearly if the objects are dynamic an infinite number of rhombuses are possible, but this is a feature of the software and not of the underlying mathematics.

### Data collecting and analyzing

Each teacher sent a solution which comprised a picture of the final construction of the rhombus, the GeoGebra file, and explanations and justifications for the construction process. We used interpretative methods for analyzing these data.

### Findings: Characteristics of geometric constructions

A qualitative analysis of the teachers' constructions yielded four main categories.

1. The given objects on which the construction of the rhombus was based
2. The construction process itself according to tools used

3. The teacher's explanation and validity test
4. The number of different rhombuses the teacher claimed to have obtained

We present some examples of teachers' constructions, according to the above categories. The teachers' choices of given objects on which to base their construction were varied; for example, one side, two diagonals, one diagonal, an angle, a combination of the already mentioned objects, and other objects (such as area). We will present just two of these choices: one side and two diagonals. Here are examples from three different teachers who constructed a rhombus according to its side.

### Tzila's construction

1. "The construction is according to 4 equal sides, each 5 cm long."
2. Used segments of fixed length, parallel line through a point, intersection point.
3. "I created a rhombus from two adjacent sides each 5 cm long, using parallel lines; that is a parallelogram with all 4 sides equal 5 cm."
4. Infinite number. "Using a circling movement, with point A fixed, in a sort of circling round each time getting another rhombus whose diagonals are changing."

Figure 1: Tzila's construction before and after dragging

Instead of just writing that the side of the rhombus was given, Tzila added a definition of rhombus, which, like every definition, provided a sufficient condition. Possibly she misunderstood the task, and thought that she had to state the conditions for creating a rhombus, or perhaps her concept image of rhombus is a parallelogram with four equal sides, or perhaps she misunderstood the components of deductive geometry.

### Anat's construction

1. A quadrilateral of equal sides – each side of length 2 cm.
2. Used segment of fixed length, circle with fixed radius.
3. "According to the theorem: a rhombus is a quadrilateral with all sides equal."
4. No answer.

Anat's explanation shows that she, like many of the teachers, was confused about the components of deductive geometry (stating she was using a theorem when in fact she was using a definition).

Figure 2: Anat's construction

### Yaron's first construction

1. Rhombus with side of length  $a$ .
2. Used circle with given radius, intersection point.

3. "The length of the side of the rhombus is **a** since all the sides and the radius are length **a**. The construction is valid according to the dragging test. The construction relies on the principal of the length of the radius of a circle".
4. "There can be an infinite number of rhombuses since although the sides remain equal lengths the diagonals and angles can be changed."

Figure 3: Yaron's first construction

Despite Yaron's claim that the diagonals and angles can be changed, he in fact built a rhombus in which the shorter diagonal was equal to the side and so the acute angle of the rhombus was  $60^\circ$ . He claimed that there are an infinite number of possible rhombuses given the length of a side, which is correct, but does not correspond to what he constructed. This error was repeated by many of the teachers. Interestingly, in another construction – described below – Yaron erroneously claimed an infinite number of possible rhombuses because of the dynamic nature of the given attributes.

Here are examples of two teachers who constructed a rhombus according to its diagonals.

#### Yaron's second construction

1. Rhombus according to two diagonals.
2. Used segment, perpendicular bisector, circle, intersection point.
3. "I based this on the fact that in a rhombus the diagonals are perpendicular and bisect each other, and on the principal of the length of the radius of a circle. The construction is valid according to the dragging test."
4. "There can be an infinite number of rhombuses since the lengths of the diagonals are not fixed. can lengthen or shorten them (or even only one of them). The rhombus can change – both its sides and its angles."

Figure 4: Yaron's second construction  
before and after dragging

and  
  
We  
of  
and

Yaron constructed diagonals whose length changed dynamically. He did not relate to the fact that each pair of diagonals determines only one possible rhombus.

#### Nora's construction

1. According to two diagonals.
2. Used segments of fixed length. By trial and error changing the angles between the segments.
3. Did not check validity.
4. No answer.

Figure 5: Nora's construction  
after dragging a vertex

If Nora had checked her construction she would have realised that it did not pass the validity test, as seen in figure 5.

#### Discussion and conclusion

In the discussion we will relate to the two viewpoints mentioned earlier: the practical and the pedagogical.

### **The practical viewpoint**

In the context of the practical viewpoint we will characterise the findings in each of the construction categories. The first category is: **Given objects for constructing a rhombus**. We have presented two of the teachers' choices of given objects: one side or two diagonals. All the teachers in the course chose the size of their given objects in one of two ways – either fixed size (a number) or dynamic (a parameter). This choice seems to be related to the teacher's conception of geometric construction – what is permitted in such a construction. It should be noted that these teachers had not previously learned constructions in a rigorous manner, and in particular, not dynamic constructions. Therefore we relate to their answers as based on intuitions about what is a construction and on geometric knowledge relevant to the specific topic. We suggest that teachers who chose fixed numerical givens have a concrete conception of construction that is related to particular sizes during the construction process, and did not refer to the characters of the figure which is constructed with dynamic tools. Teachers who chose dynamic givens have a broader conception of construction, not connected to size. This choice of dynamic givens corresponds more closely to the instructions – see above description of the final task. In addition, there were some teachers who were confused about defining the given objects, for example, Tzila, as described above.

The second category is: **Choice of construction tools**. We identified three types of construction process: measuring; using the extensive range of tools supplied by GeoGebra; and using a limited range of tools (cf. Fahlberg-Stojanovska & Stojanovski, 2010).

Construction by measuring involves fixing the size of the required object (side, diagonal, or angle). For example, in Nora's construction she moved two rays to form a right angle. Another teacher created four equal segments using co-ordinate axes.

An example of construction with the extensive range of tools is using the parallel line tool to ensure a parallelogram, as in Tzila's construction. Another example is using the perpendicular bisector tool, as in Yaron's construction.

Construction with a limited range of tools imitates construction with straightedge and compass. For example, Yaron built a circle of variable radius. Anat used both measurement and the limited range of tools (using a circle of radius equal to the given segment of length 2 cm).

The third category is: **Explanation and validity check**. None of the teachers gave formal proofs of their constructions. However their explanations provided us with an idea of their concept images (Vinner, 1991) of a rhombus. They explained their constructions according to their concept image and not according to the definition as given in the national school curriculum: a quadrilateral with all sides equal. A problematic concept image seems to create confusion between the different components of a deductive geometric argument, for example, between a theorem and a definition and between a theorem and a property. This confusion can be seen in the explanations of Tzila and Anat.

We discerned two problematic areas in the teachers' explanations: an incoherent concept image related to mathematical knowledge; and an intuitive conception of construction in a dynamic environment, which seem to be related to the construction process in everyday life, for example

Nora's construction which produced a rhombus. This construction did not fulfill the demand that the construction will remain a rhombus also after dragging.

This conception resulted in most of the teachers producing an invalid construction. There is not enough information in the data to pinpoint the main causes of these problems – are they connected to missing technological knowledge, or to missing mathematical knowledge, or to a faulty conception of construction, or to a combination of all three? More research is required to clarify this.

The fourth category is: **Number of solutions**. We identified three types of responses, each claiming an infinite number of solutions: relating to the dynamic nature of the given object, as seen in Yaron's second construction; relating to the mathematical properties of the given object, as seen in Tzila's construction; relating to the position of the given object in the plane. This latter type was seen in the response of a teacher who wrote: "In the plane it is possible to position the rhombus in any place you want".

### **The pedagogical viewpoint**

In the light of these research findings we recommend investigating some aspects of task design in a dynamic environment. On one hand the task design can assist teachers to execute the task, and on the other hand it can persuade them to use this task in their classroom (Bu et al., 2012). We suggest that it would be worthwhile to design the task on three levels: mathematical-pedagogical, technological-pedagogical, and reflective.

The mathematical-pedagogical level requires the teacher to define the concept and to construct the figure accordingly. In line with Fischbein (1993) we relate to a geometrical concept as a figural concept and thus its construction has practical meaning. Subsequently the teacher is required to construct the figure based on different sufficient conditions. Such a construction task would enable identification of the teacher's mathematical knowledge and her concept image, and could help to bring that concept image closer to the concept definition.

The technological-pedagogical level requires the teacher to construct the figure at first using the limited range of GeoGebra tools (imitating straightedge and compass) and subsequently using the extensive range (enabling short cuts). We would like to investigate the connection between these two types of construction and the connection between the teacher's image of the geometric concept and her conception of geometric construction.

The reflective level requires the teacher to check the validity of her construction, while considering the meaning of validity. Giving a detailed account of the results of the validity test should be an inseparable part of the task. Such an execution of the task should strengthen the connection between the mathematical and technological aspects. For example, if the construction "collapses" – after dragging the dynamic objects the properties of the required figure are not preserved – it is important to understand whether the "collapse" is due to a mathematical failure or a technological failure, or a combination of both. Such an analysis should contribute to the development of mathematical knowledge, pedagogical knowledge, and technological knowledge.

We believe that the above characterisation may provide a starting point for further research and may contribute to the technology, pedagogy, and content knowledge framework (Koehler & Mishra, 2009) – to help teachers integrate technology into their teaching.

# Transitioning from definitions to proof: Exploring non-Euclidean geometry in a college geometry course

Rebecca Dibbs and Janessa Beach

Texas A&M University-Commerce, United States

[rebecca.dibbs@tamuc.edu](mailto:rebecca.dibbs@tamuc.edu); [janessa.beach@tamuc.edu](mailto:janessa.beach@tamuc.edu)

*Geometry is the subject where U.S. students are weakest on international assessments, but college geometry is an area of proof that is understudied. Since geometry is secondary students' only exposure to proof, it is vital our secondary teachers can prove effectively in this content area. However, one obstacle to developing deeper understanding of geometric concepts in college geometry courses is that students tend to try recalling prior geometry instruction instead of engaging in any new material within a Euclidean geometric context. A document analysis of student portfolios revealed that although pre-service teachers in this document study began the semester with limited abilities to work with formal definitions, by the end of the semester all were able to propose and justify conjectures on novel surfaces.*

*Keywords: Geometry, inquiry-based learning, pre-service teachers.*

## Theoretical background

Geometry arises from a set of undefined terms and axioms through which all other theorems and definitions are constructed. Hence, a thorough understanding of geometry involves a deep understanding of proof; yet, teachers possess a narrow understanding of proof. Studies indicate that pre- and in-service teachers believe proof only helps explain ideas used in mathematical concepts, and they do not recognize the ability of proof to systemize results (Mingus and Grassl, 1999; Knuth, 2002b). Teachers lack the geometry content knowledge required for geometry proofs, and they are convinced by empirical evidence as well (Jones, 1997; Knuth 2002a). Consequently, teachers with inadequate proof and geometry understanding cannot be expected to impart adequate proof and geometry knowledge to students. Furthermore, college geometry is the only undergraduate proofs course that has not been studied in any systematic manner (Speer and Kung, 2016).

Pre-service teachers in undergraduate proof courses do not adequately understand what arguments qualify as proof (Weber, 2001). They lack comprehension of the mathematical language and concepts necessary to proof (Selden, 2012), and they possess an incomplete understanding of definitions and theorems (Weber, 2001; Selden and Selden, 2008). In typical direct-instruction, lecture proof courses, students are expected to develop proficient proof skills with little to no guidance. Without guidance, students will fail and likely cultivate ineffective strategies (Weber, 2001). These ineffective strategies are typically proof schemes dependent upon external and empirical convictions, such as the authoritarian, ritual, and perceptual proof schemes (Harel and Sowder, 2007). In order to successfully write a proof, students need to employ effective strategies or proof schemes with arguments based on axioms and logical deductions, which in turn requires understanding of definitions and the idea of conditionally true statements.

The typical instructor-centered learning environment, is the dominant paradigm, but may not induce the logic and proof techniques needed to construct a proof in all students (Fukawa-Connelly,

Johnson, & Keller, 2016). Alternatively, a proof course should consist primarily of student-student and student-teacher interactions (Selden and Selden, 2008). Given the prevalence of lecture-based proof courses in the United States (Fukawa-Connelly, Johnson, & Keller, 2016) and preservice teachers' continuing struggles with geometry, one potential approach to help improve pre-service teachers' is an inquiry-based learning pedagogy where students are active learners, and the instructor is responsible for facilitating students' exploration of the content, particularly definitions (Padraig and McLoughlin, 2009).

However, one of the additional challenges of college geometry is that the material is familiar to students. Rather than investigating the ideas presented in the current assignment, many students rely on recollections from previous geometry courses, especially if the problems seem familiar. Hence, an inquiry-based college geometry course in non-Euclidean geometry seems more likely to help pre-service teachers develop their proving skills and deepen their understanding of the geometric concepts they will eventually teach. This study was guided by the question: how, if at all, an inquiry based non-Euclidean geometry class helped deepen students' understanding of definitions and Euclid's postulates? We argue that the deep exploration of a limited number of non-Euclidean geometry problems helped students to move from primitive geometric knowledge to formalizing definitions and successfully posing and solving conjectures on novel surfaces.

## Methodology

An adaptation of Pirie and Kieren's (1994) model for student understanding was used to code students' written assignments for their understanding of definition. Although this eight-level model was originally created to model students' understanding of fractions, it adapts well to geometry, as the purpose was to describe the transition from concrete to abstract reasoning to justification to problem posting. One level, image having, was not used when coding, since students always had access to physical models of whatever non-Euclidean surface they were working with that week, so we could not determine students' facilities for understanding similar exercises without physical models. We also did not include looping back within our standards of evidence because it was not something we observed in the data.

This study took place at a midsized, rural, Hispanic-serving research university in the South, and the students who participated were those enrolled in a ten student college geometry course. The data collected was part of a larger study; this study presents a case study of five pre-service teachers Lindsey, Bradyn, Alexis, Mackenzie, and Chase. We also analyzed the work on one non-preservice teacher, Florencio, because Florencio's papers were different from the other participants. While we wanted to maintain a purposeful sampling of pre-service teachers, Florencio was enough of a disconfirming case that we felt his inclusion was necessary (Patton, 2002). Florencio was an engineering major with one prior proofs class. Lindsey has no formal proof experience, Bradyn had completed discrete mathematics in one attempt with a B, Alexis had completed discrete mathematics and abstract algebra with A's, and Chase, who has a learning disability, had completed discrete mathematics with a C after two attempts and failed another upper level proof class. Mackenzie was a non-traditional student in her final semester; she had completed all other upper level proof classes with a mixture of A, B, and C grades.

Students in the course were provided with course notes (Miller, 2010) that presented open-ended problems related to a specific learning goal. There were fifteen assignments; five of which were focused on formal axiomatic proof, eight on definitions and axioms in various non-Euclidean situations, and two assignments (the midterm and final project) which combined both strands in the same assignment. Four of the assignments were formal (one revision allowed), and the other ten were informal (unlimited revisions). On the midterm (F3), students were given new but similar problems to their assignment and asked to work through them individually, and on the final project (F4), students were asked to discover as many things as they could about the geometry of the surface a cone. For each new assignment, students were assigned a specific problem from the provided course notes and a group. If a group appeared to be making little progress or moving in an unproductive direction, the teacher would use guided questioning to redirect students' thoughts. If multiple groups stopped progressing, the teacher would initiate a whole class discussion.

To determine students' understanding of definitions and postulates, researchers examined the first submission students turned in for each assignment. Researchers also used observations to gain further understanding of students' proof comprehension. As students discussed their ideas within their group, a researcher sat behind them listening and taking notes on their interactions for about ten minutes. The submissions were analyzed by assignment and all the drafts from an individual participant were analyzed at the same time. After this initial reading of blinded assignments, researchers would journal their impressions of the coding and the overall trajectory exhibited in the multiple submissions. These journals were used to operationalize concepts in the literature review, and then they were compared to the standards of evidence table (Table 1).

<b>Level of Understanding</b>	<b>Identifiers</b>
Primitive Knowledge (1)	Students are applying prior knowledge of Euclidean geometry, stating given definitions, or providing empirical proofs
Image Making (2)	Students make distinctions and reclassify prior knowledge or use prior knowledge in a new manner
Property Noticing (3)	Students can apply a definition on a previous surface to a novel surface or situation by recognizing commonalities in the learned and novel situation
Formalizing (4)	Students can abstract a method, formula, or common property from previous property noticing
Observing (5)	Students can propose conjectures and provide justification or counterexample
Structuring (6)	The argument is logical and made up of systematic application of axioms and theorems/If any portion of the argument could be clarified, the clarification is not necessary for the argument's validity.
Inventising (7)	Students can pose new questions and solve them, creating new (to the student) knowledge

**Table 1: Standards of evidence (Modified from Pirie and Kieren, 1994)**

## Findings

With the exception of Mackenzie, all pre-service teachers struggled to complete the initial assignments with correct arguments; primitive knowledge from a previous high school geometry course was applied to the problem instead of an argued solution. However, by the fourth inquiry-based task, all participants were able to formalize definitions, and all students were at least able to successfully use definitions and postulates in novel situations to construct proofs. All students followed a similar trajectory throughout the semester and improved, on average, four levels of understanding (Figure 1).

**Figure 1: Student levels of understanding throughout the semester**

The first definition centered-assignment of the semester was an inverse categorization problem. After finding all possible symmetries on the square, students were asked to use Geogebra to start with a subset of these symmetries, construct all possible quadrilaterals with that set of symmetries, and justify why they had found all cases. Mackenzie was able to categorize on first assignment, but the other preservice teachers either listed the symmetries of each quadrilateral or could not justify if/why they had found all cases (Figure 2). Both of these difficulties indicate students making partial reclassifications of their prior knowledge.

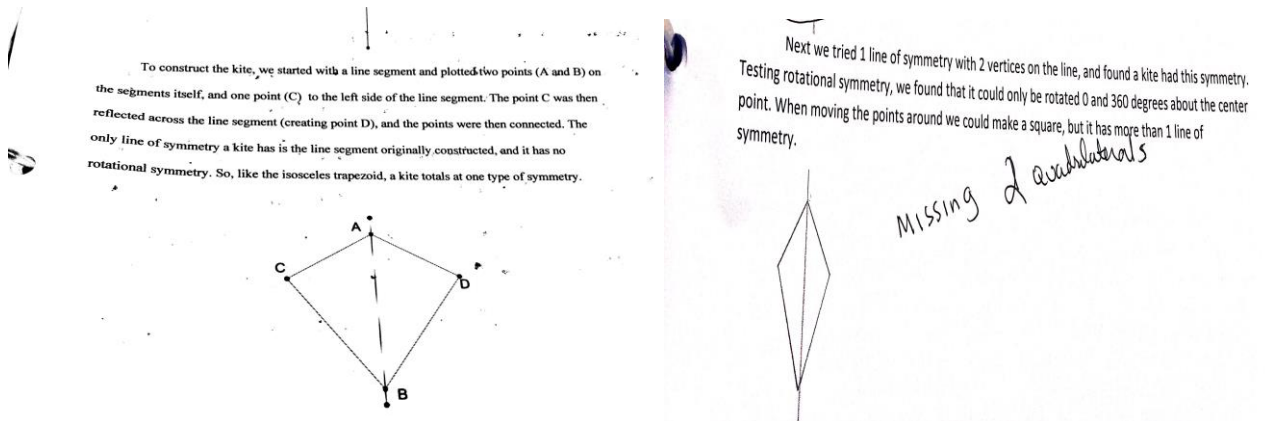

Figure 2: Typical solutions on IF2 Chase (left, primitive knowledge); Florencio (right, image making)

During the middle third of the semester, the two assignments that helped pre-service teachers move towards formalizing their understanding of definitions and counterexamples were IF3 and IF6. In both assignments, students were asked to justify which, if any of Euclid's postulates held on a sphere (IF3) and the hyperbolic plane (IF6). Students were also asked to prove the existence of asymptotic geodesics on the hyperbolic plane. On IF3, the first exposure to the postulates, Alexis was not able to work in the spherical context and reasoned through the justification of the postulate in terms of the more familiar planar geometry (Figure 3). However, by IF6 Alexis was able to provide a counterexample for false postulates (Figure 4).

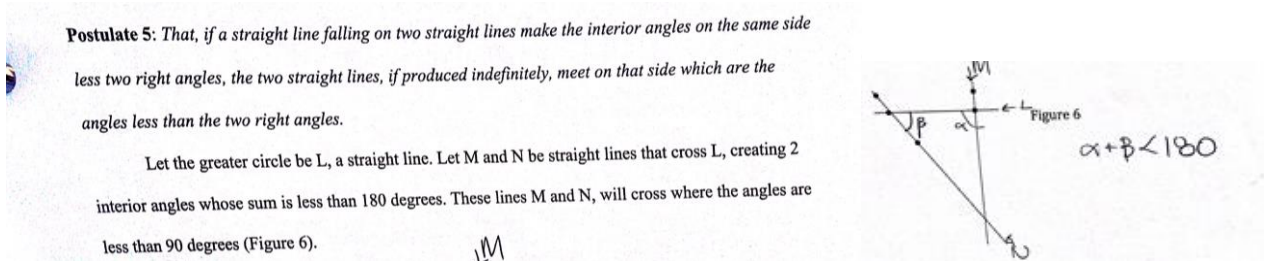

Figure 3: Alexis' IF3 (Image Making) Postulate 5 solution

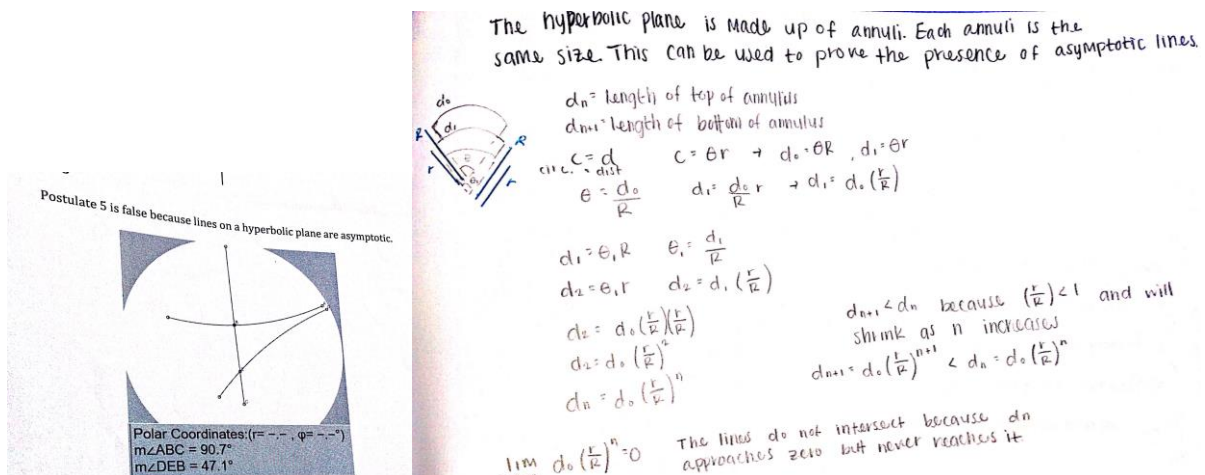

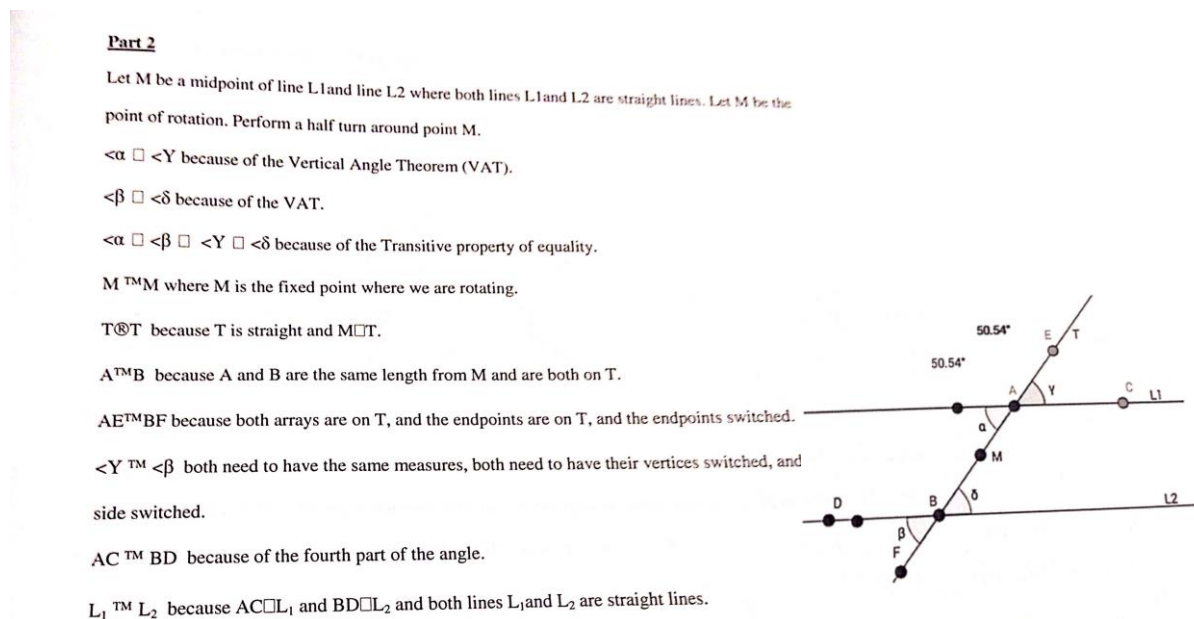

Figure 4: IF 6 (Formalizing) Postulate 5 solution

In the final third of the semester, the goal of all assignments was to integrate pre-service teachers' improved proof schemes with more formal uses of definitions. IF5 and F3 were major proofs assignments that took students most of the middle third of the semester. With their improved proof schemas, and understanding of the surfaces, were more easily able to construct proofs for parallel lines that were independent of the surface upon which the lines were drawn (IF8 and IF10). Most students were able to construct a generally correct proof, with some minor disordering of steps and missing justifications. This shows participants possessed a more structural understanding of symmetry than the understanding demonstrated in IF2. Bradyn, like Florencio, was image making on the first assignment related to symmetry, but by the time symmetry was used to construct proofs related to parallel transported lines, Bradyn was much more successful (Figure 5). Although Bradyn's language is not quite standard and he had trouble typesetting his proof, his overall structure is systematic and he has a transformational understanding of symmetry not present in his initial write-ups.

**Figure 5: Bradyn's second proof in IF8 (observing)**

The final formal assignment asked students to discover (and prove) as many things as they could about the geometry of an infinite cone. Groups were expected to prove 2-4 conjectures. Given the open nature of F4, one group chose to only investigate properties of a cone where group members had successfully revised an assignment on another surface. This limited their levels of understanding to observation. The other two groups each had at least one investigation of a conjecture about a novel concept with at least one new or newly-modified definition, which is summarized in Table 2.

Participant	Project Summary	Code
Alexis (+3 others)	Using a novel group-invented definition of straightness to investigate self-intersecting lines on cones (conjecture: no formula possible), angle sums of triangles with self-intersecting sides	Structuralizing, Inventising
Mackenzie, Lindsey (+1 other)	Holonomy, internal angle sums of a triangle with no self-intersecting sides, triangle congruence theorems, non-intersecting lines that are not parallel transports	Inventising
Brady, Chase (+1 other)	Postulates (some cone angles), collected data for self-intersecting lines	Observing

Table 2: Summary of final project

## Discussion

Regardless of prior proof course grades or experience all pre-service teachers struggled to complete the initial assignments with correct arguments; primitive knowledge from a previous high school geometry course was applied to the problem instead of an argued solution. However, by the fourth inquiry-based task, all participants except for Chase were able to formalize definitions, and all students were at least able to successfully use definitions and postulates in novel situations to construct proofs by the end of the semester.

By centering the college geometry course around understanding core geometric concepts on several different surfaces, participants were forced to engage in understanding each new situation rather than simply applying their prior Euclidean geometry knowledge to a more familiar problem. As a result, students developed more advanced understanding definitions and counterexamples. All participants got to at least formalizing definitions and seven of the ten students in the class ended the semester at either the structuring or Inventising level.

The structure of the course maximized students' opportunities to reify their understanding of definitions and postulates. The use of multiple non-Euclidean contexts was key to helping students develop better understanding of formal definitions. By switching surfaces, operationalizing definitions and determining if they were applicable stayed a problem and not an exercise. Further, the repetition of the postulates and determining geodesics in particular were important because these concepts were presented in enough slightly different concepts to allow students to develop deeper levels of understanding of the definition than a single context would allow. Students also reported that the chance to revise their written work was a valuable way to help them reflect on the current surface and how it compared to their prior work.

There are two potential limitations for this study, which could be remedied by further inquiry. First, we did not collect students' interview data; our analysis is a document study coupled with observations of students' in-class discussions. Teaching experiments or task-based interviews of students' understanding of definition in similar inquiry based classes, and comparative data to

students in axiomatic Euclidean courses would also be of use. We also had non-native English speaking students in this class, and further research on their experience with proof and geometry is still needed. Finally, although most students followed the same trajectory, Chase was about two weeks behind everyone else. However, Chase has dyslexia; and there is a dearth of literature about undergraduates with learning disabilities; more work is needed to understand how to support such students' learning.

*The ERMEL team (IFé, ENS-Lyon) in France, builds complete engineering to teach math in elementary school. For several years, we have been experimenting with teaching situations on space and geometric learning for 5-8 years old students. In this paper, we focus on the results about the relationship between actions on objects, graphs and first geometric properties about curved line. Our methodology involves an analysis of the student's way of solving problems and thus their abilities, but it also allows us to make a hypothesis on what it is that teachers need in order to carry these learning situations out.*

*Keywords: Geometry, teaching, learning, primary education, spatial ability.*

#### Issue of this paper

Our research takes place in the French context of geometry teaching in primary school. Our goal is to build a proven, complete and reliable teaching engineering and thus to improve geometry teaching.

In CERME 9, we reported our results about the knowledge of straight line for the same kind of students, not as an element of geometrical figure but as a usual or new component of the pupil's practice. Several point of view in the WG4 showed the similar approach and questions were shared:

- The relation between everyday and geometrical concept, perception, language and manipulation
- How to start with low level, and long planning time
- What kind of tools for the research and tools for teaching geometry are there? (How to help teacher to know what student are able to do)

In this paper, we aim to make our contribution to the three first topics of the WG4 group: what is doing, learning and teaching geometry at school?

#### Why working on geometry teaching?

A starting point of our research is a finding of deficiencies in the geometry teaching practices in the early grades of elementary school. A short analysis of easily available French resources for teaching geometry to young pupils shows that two mains goals are pursued: learning geometric words and drawing abilities. Spatial activities also exist but without much problem solving, and also unrelated to the pupil's initial knowledge or mathematical activity. This research is also based on the idea that students' abilities are insufficiently taken into account in geometry teaching in primary school. Thus we have to identify the knowledge at stake in this learning and take the students' already acquired knowledge into account.

## About our team

ERMEL is the research team on mathematics education in primary school (in French “Équipe de Recherche en Mathématiques à l’École Élémentaire”) belonging to the French institute of education (IFé). ERMEL team is made up of primary school teachers, teachers’ trainers and researchers working in different regions of France. Results of these researches lead to comprehensive books publications including complete teaching engineering. Studies on teaching and learning conducted since 1999 are about geometry teaching more precisely on the analysis of spatial and geometric skills that students from primary school to GS (5-6 years old) CE1 (7-8 years old) can build. Key issues of these researches are knowledge creation and resources production for teachers and teachers’ trainers as well as the study of the appropriation of these resources. In CERME 9 we have clarified our theoretical framework and the steps of our methodology: a didactic engineering, based on an experiment conducted in many classrooms for several years (Douaire & Emprin, 2015). In this paper, we try to explain the transition between space and graphic knowledge which is often underestimate.

## Purpose of the study

Our previous studies (Douaire & Emprin, 2015) showed that the knowledge developed by pupils in meso-space by solving problems does not necessarily build a geometric knowledge usable on paper. This lead us to ask many questions: in particular, what are the opportunities for pupils to understand the underlying patterns of drawings on a sheet of paper?

We have to clarify the relationship between two types of knowledge, spatial and geometric, and especially the discovery of the meanings of lines on a sheet of paper, and how these plots can provide information about objects in space. If several works address the distinction between drawing or figure at the beginning of the “college” (Parzsy, 1988) or the apprehension of the components of a figure at the end of primary school (Duval, 2005) (Perrin & al, 2013), our research concerns the emergence of graphic representations a few years earlier.

In this working group we will identify the contributions of space experiments in the construction of geometrical knowledge. Our goal is that pupils overcome the overall perception of a figure and develop the analysis of its components.

We analyze learning involved by a problem solving of closed curves figures construction, the characteristics of different implementations, as well as the needs of teachers. We present insights of learning situations for space experiments and we question the relevance of a resource based on the needs of teachers for its implementation identified in the context of ongoing Ermel research.

## Presentation of the experimentation

Experimentation concern procedures (graphics, practices, discourse ...) that can be developed by 7-year-olds pupils to distinguish circles from ellipses and other rounded shapes. We are not trying to develop early knowledge of the circle, but to promote the passage from a global perception of drawings and shapes to a geometric analysis of geometric shape underlying.

Some questions concern the comparison procedures: what are the abilities of students of CP (6 years old) or CE1 (7 years old) to distinguish a circle from another closed curve (an “almost circle”)? What use of superposability as a validation procedure for that?

We present an experiment in progress: students have to produce closed rounded shapes, and must prove if they are different from others.

### Proposed situation

The problem is to build closed shapes using four circular or elliptic arcs (quarter of a big circle, little circle or an ellipse figure 1). Identifying that shapes built are different lead students to develop and formulate analytical geometric criteria.

Two major phases of this situation are analyzed successively, the first concerns the problem solving phase to produce shapes: we briefly analyze the productions. The second concern comparison of production. We also present some exchanges during the validation of the solutions.

Finally, a brief summary will address the explicit needs of teachers.

### Presentation of the activity

Each pair of students has a deck of 16 cards: 4 quarts of a small circle, 4 quarters of a large circle and 8 quarters of an ellipse (shapes figure 1 are cut following dotted lines like in figure 2). The major axis of the ellipse is the diameter of the large circle. The minor axis of the ellipse is the diameter of the small circle. Thus, shapes can be linked.

Figure 1

Figure 2

### Several successive phases in this situation:

- 1- To ensure the pupils' appropriation of the constraints of the problems they are experimented one by one. Each pupil must first assemble pieces to form a closed shape. Then they verify that these solutions are really closed. These discussions lead to clear assembly instructions: "Are only accepted shapes that are joined edge to edge (assembly like in figure 3 are rejected)". In this first phase, the students do not need to draw, but to assemble pieces of heavy paper. Then pupils have to make closed shapes using exactly four arcs. The findings, confirmed by teachers and observers in classes are that all students are aware of the goal, namely produce closed curves ("tracks") consisting of four arcs at the end of devolution phase. Students have understood the problem's rules.

Figure 3

- 2- Then each student looks for new solutions. In order to save their shapes and be able to make new assembly pupils are asked to draw on tracing paper (or lite paper) the outline of each new shape found. When students believe they cannot find new shapes the search stops, and solutions are pooled: are they different? If a student thinks he has found another solution, it is displayed and compared with previous. Students explain why they think it is different or it's the same as another already displayed. The goals of the pooling are to identify products that meet or not the constraints and identify the identical solutions.

## Possible shapes

The solutions are:

- reconstruction of three basic shapes (large circle, small circle, ellipse) solutions 1-3
- combining two half ellipses contiguous or half a small circle (ovoid: solution 4) a large circle (such as "roly poly" or "roller" or solution ... 5). Radius or half axes being concurrent.
- combining alternative quarters of small circle and large circle (solution 6)
- combining two quarters of alternating ellipses with a quarter of a small circle and a quarter wide circle (solution 7)
- combining two quarter ellipses and a small circle (8, 9) or large circle (14,15)
- juxtaposing four quarter ellipses (10, 11)
- juxtaposing two quarters ellipse with on one side a quarter of large circle, and on the other side a quarter of small (12,13).

**Figure 4: 15 different shapes were found**

Of course, the goal of this situation is not to find all solutions but finding shapes form 1 to 5 with also one or two shapes they cannot name globally is enough for pupils to learn.

### Description of pupils' strategy to produce shapes

- choose pieces of random way;
- if unsuccessful start from scratch;
- put two pieces, then try the other two;
- replace one or two pieces in an assembly already achieved;
- place the fourth piece by estimating its size.

### Description of the comparison procedure

Solutions are shown on the blackboard (some of them may be identical but differently oriented).

We describe comparison strategy used by pupils:

1. Use of the overall look of the drawing (perceptual validation):
  - a. recognition of known shape (circle, round, egg ...);
  - b. rely on variables: overall size, width;
  - c. rely on differences of regularity in curves.
2. Identification of the elements that compose the shape (analytical aspect).
3. Recognition of identical shapes by rotation or reversal.
4. Use of construction processes, with the possibly of remaking to the class.
5. Use of symmetry properties of the shape, mention of the folding ...
6. Use of a practical validation by overlapping.

Strategies based on perception are mainly used.

Those results confirm that spatial abilities are often neglected and that it is a great challenge of our current research.

This pooling highlight some questions linked with the drawing:

- the impact of the thickness of the lines on strategy using perception,
- the acceptable tolerance to judge the compliance with constraint, for example the fact that the curve is closed.

The fact is that those questions emerge are important because it lead pupils to progressively give up perception in favor of the analysis of the shape. This dialogue during the validation of solutions illustrated this aspect.

### **Exchanges during the validation**

The solutions are exposed to the blackboard and students check if the set is suitable.

Student (S2) I believe we cannot do it ...

Teacher (T) The others, are you sure?

S2 appears to confirm

T This drawing there you think that doing it is impossible?

S2 show the drawing of the shape and try to express something.

T So, what could you do to know?

S2 Take the pieces

M So, the team who have made this track, you come back to the dashboard.

Resuming the question of drawings validity

S It looks like ...

T With four parts

S2 But then there are bumps

S ...but in all there are bumps ... because we do not succeed in drawing....

T Yes, there is the problem of drawing, we will not be going back to that. Is this circuit possible to do? ”

(Many S.) Yes

We can see in this transcript that pupils manage to move away from the drawing to analyze the shape. plutôt un”.” que “;”

After a pupil has the drawing of his shape on one hand and follows the lines of the set of pieces to check if the shapes are the same (we will show a video of this moment).

### **Analysis of learning at stake**

Firstly, the effects of the situation on pupils learning we can observe are:

- 1- A change in perception of the role of vocabulary:
  - a. The familiar vocabulary for describing the known forms, is not effective for others. Many different shapes can look like an egg ...
  - b. Since drawing on paper is not always successful students have to describe the shapes by analyzing the way they have been built: the arcs used and their sequence of use.
- 2- The progressive understanding of the role of sheet layouts to work on the lines (here curves, but straight in other situations)
- 3- A better knowledge of the circle, based on the development of procedures compared with other forms (Artigue & Robinet, 1982)
- 4- The practice of displacement to produce new solutions and to recognize identical figures arranged differently
- 5- Transition from a practical validation based on the superposition to a validation based on the analysis of the properties
- 6- The perseverance in research: the students have to rely on perseverance and go to the end of the task, and of course explain, justify, criticize, debate.

We think that, at the end of this situation, students are able to explain, with their words, several of their learnings.

Secondly, we have analyzed what are the difficulties, and what is possible to propose to pupils. We think, after several experiences, that the main obstacles are not epistemological; they do not come from the inability of students to analyze forms or working on their uncluttered representation. But it is rather didactic obstacles created by neglecting their knowledge and solving capacity. There is a necessary transition from a perceptive approach of the shapes to the analysis of their geometrical characteristics (size, composition, curvature...). In our progression of learning we also offer other situations which contribute to this passage from "global" (for instance, students perceive the regularity of form) to "analytic".

Thirdly we try to find condition of a real use in classrooms. For those of teachers who are not satisfied with their way of teaching geometry we think it is important to propose activities that are real problems (where pupils have to produce new strategies) and to clarify learnings at stake. But we think that it would be unrealistic for a teacher whose main objective would be to set a vocabulary to embrace the process. Potential learning is related to the possibility for the teacher to understand the issues: allow students to implement the different comparison procedures.

This workshop proposes to enlighten those issues.

In this presentation we have not detailed the many changes in the description of the situation, related to successive and necessary experiments for students to produce the specified procedures. On this aspect of the construction of a teaching situation, we simply discuss the question of the context: is it necessary for such young students to evoke a familiar context? The way quarter-circles or ellipses are drawn have also been chosen differently during the experiment: either simple lines (parts of the cited figures), double lines to evoke real-world objects: railway circuits. But does the latter choice provide a better understanding of the constraints (in particular the continuity of lines)? We currently believe that, on the contrary, this approach makes the problem harder to understand.

## Conclusions and prospects

Let us return briefly to the issues addressed:

On learning targeted: what learnings can be developed based on the perception (regularity of a shape) to contribute to the analysis of geometrical properties? We mentioned a shift from a parts assembly problem to a drawing problem (a graphical problem); to that extent, the sensitive space has changed. First it is the space of action on the shapes to assemble, which has been among the first personal procedures of the students in the resolution phase. During the pooling, pupils focus on curves continuity and sensitive space becomes the place where graphical plots are questioned: they are new geometrical objects.

On taking initial knowledge of students into account: how knowledge, language, gesture, participate in the apprehension of the common elements to the diverse types of spaces?

How are first procedures and knowledge of the "graphical-space" combined with previous experience on objects? In particular, this prior knowledge is not primarily "declarative" but relies on gestures (eg the difference between rotate and reverse or the use of drawing with instruments without necessarily aiming to represent a geometric object ...)

They are also expressed in the language forms, as part of a language used by the student to control his actions or to communicate about a production (formulation of a procedure, checking of constraints validation of a solution ...). The importance of this learning is often underestimated in education in favor of the use of stereotyped and offline vocabulary.

Our research aims to analyze and develop, not only in this specific example, general student abilities via experience and actions on objects with graphical plots. Thus they evolve from a spatial perception to geometric characteristics of the shapes. Our concerns are also those of Swoboda (2015) about problem solving mainly with older students: "Therefore, the problem of bringing students to the ability of making mental transformations I treat as an educational task. In the literature, there is no explicit opinion on what educational level there is possible to create such skills. »

*In this paper, we report on how a group of UK 12-13-year-old students work with hierarchical defining and classifying quadrilaterals, an area which students find very difficult to understand. We implemented a geometry test to 9 groups of students. Quantitative data suggest that the students found very difficult to undertaking hierarchical defining and classifying quadrilaterals even in collaborative learning situations. Our qualitative video-recorded data from the four groups suggest that we find that even in collaborative learning settings prototypical images of geometrical figures strongly influence students' ways of hierarchically defining and classifying quadrilaterals. In addition, groups often had opportunities to examine their ideas, but they did not explore these opportunities because each member did not see what others were saying 'as if through the eyes of another'*

*Keywords: Dialogic, collective geometric thinking, defining and classifying quadrilaterals.*

## Introduction

Geometry has been recognised as one of the most important topics in school mathematics as it provides students with learning opportunities for developing their spatial thinking, reasoning and sense making of this world. Sinclair et al (2016) reviewed over 200 research papers in geometry published since 2008, and identified six themes, including the understanding of the teaching and learning of definitions. They state that one of their research questions is about students' understanding of hierarchically defining and classifying shapes (p. 706). Our paper is concerned with this issue, in the context of hierarchically defining and classifying shapes in collaborative learning settings which can be productive ways to develop mathematical thinking and understanding (e.g. Martin and Towers, 2014). We chose this topic because the research has reported that students find the understanding of hierarchically defining and classifying shapes difficult, but how students tackle this in collaborative settings has not been sufficiently investigated.

The purpose of this paper is to examine the following research question 'What obstacles will be identified when students are working together with geometrical problems?' In order to answer this question, we first propose our theoretical framework for emergence of collective geometrical thinking in the context of hierarchical defining and classifying quadrilaterals. We then investigate students' collaborative learning process in defining and classifying quadrilaterals. In this paper, we focus on collaborative group work where teachers or instructors' interventions are minimal. Therefore, while we acknowledge that teachers' roles are highly important to support learners' mathematical thinking and understanding (e.g. Martin and Towers, 2014), we do not consider this issue in this paper.

## Theoretical framework

### Concept images and definitions and prototypical examples of geometrical figures
