narrowing the goals of the learning to obtain instructional success. Centrality of arithmetic and abandonment of formative goals are especially noticeable when teaching children with Trisomy 21<sup>2</sup>.

Our working hypothesis was that early mathematical competency, in the same way as linguistic competency, could be enhanced and analyzed in terms of naive conceptions. For this aim, we developed a list of items (including concepts and observable actions) to be used in the design of focused mathematical instructional activities, able to bring out young children's mathematical competency (avoiding initiating children in mathematics through written arithmetic), in much the same way as school activities exploit children's mother language competency (avoiding initiating children in linguistic expression through grammar). After testing the suitability of the list with a group of twelve 4 year-old children schooled in Lazio (Italy) (Colella, 2014), we faced the challenge of using it to enhance the mathematical competence of a group of children with Trisomy 21 in Spain.

### **Naive mathematical conceptions**

The fact that *there is a lot of mathematical life “before school” or “before being taught”* has been pointed out by authors such as Martin Hughes (1986), Margaret Donaldson (1978) and Liliana Tolchinsky (2003). Usage-based theory of toddlers' language acquisition (Tomasello, 2003) offers a description of the key situations leading to the first holophrases in a joint adult-child attentional frame. It helps us to understand the precocity of children and their interest and enthusiasm regarding numbers as well as geometry.

The empirical examples considered by Hughes among children in Edinburgh's Department of Psychology nursery, as well as by Karen Fuson (1988) regarding her two daughters, recorded in the mother's diary she started at 1 year and 8 months, were observations of what are considered as *naive arithmetical* conceptions, that is, conceptions that have been observed in children independently of schooling and instructional design. Fuson and Hughes go beyond Piaget and his collaborators' work on the roots of children's understanding of arithmetical ideas because they avoided concentrating solely on the search for a developmental path and on the isolation of spontaneous cognitive development. Instead, they tried to come closer to children's thoughts and feelings through close interviews, observations and task experiments, considering that elementary teaching *enters the scene* in the wider context of children's human experience and development.

We have extended this available research in arithmetic to encompass geometry, following René Thom's views (Israel, Millán Gasca, 2012; Millán Gasca 2016), as shown in later pages.

### **Insights from historical and mathematical perspectives on primitive objects and relationships**

In order to identify geometrical items we drew inspiration from Federigo Enriques (1924-27). He focused on the instructional meaning of the identification of the "primordial", primitive, undefined concepts of the modern axiomatic description of arithmetic and geometry considered in their historical context (Israel & Millán Gasca, 2012).

---

<sup>2</sup> Elisabetta Monari (2002) pointed out that the "old tree of mathematics" (the traditional view of school mathematics as introduction to written arithmetic) should be replaced by a "new tree", where different cognitive potential could appear.

It can be noted that the pivotal role of the acquisition of sequence of number-words in arithmetic is strikingly coherent with the modern Peano's (1899) axiomatic description of natural numbers. Information on undefined primitive objects (*number* and *one*) and their relationship (*successor*) is contained in axioms, such as, “*one is not the successor of any number*” or “*if two numbers have the same successor they are the same number*” that evoke counting. In addition, the first recursive definitions of addition and multiplication and the definition of “greater than” start from this information. Fuson's description of early arithmetical conceptions includes all of these mathematically critical ideas regarding an ordinal view of natural numbers defined in a child's way, together with the cardinal views and measures uses to which children are exposed nowadays (these views were also central in the ancient origins of number and of extensions of the concept of natural number). This attention to mathematically well-identified different number situations in children's experience is crucial to draw indications for instructional activities.

Following the same path, we paid special attention to the role of Hilbertian (1902) undefined concepts (point, straight line, plane), relationships (congruence, lie in, lie between) and first definitions of objects and relations (angle, segment, circle, triangle, polygon, greater than...) deduced from the axioms, in the building of naïve geometrical conceptions in young children's minds. For example, in relation to the concept of line (paradigm of the continuum) and straight line, possible naïve conceptions regard line as a path; line as a stroke on a sheet of paper with a pencil; lining up, or walking along the minimum distance between two positions. In relation with the concept of point we can observe whether they know to stand at a fixed point, or if they are able to draw them. Talking about change of direction can be a way to introduce the concept of angle.

Inspired by these primitive concepts we considered performance regarding “solving simple geometric problems”, such as drawing a circle freehand; cutting a circle; comparing circles (cutting and overlapping); drawing a straight line connecting two points; joining several numbered points freehand with a straight line; drawing a non-straight line; answering questions related to which object is longer, bigger or thicker...

### **Naïve arithmetical and geometrical conceptions list**

The list we have developed, based upon primitive arithmetical and geometrical concepts and the previous developmental insights, includes some possible naïve mathematical conceptions that children can have. Following Fuson's point of view (1988), we looked for a web of conceptions, including connections between geometry and numbers and some obvious relationships, and not for a systematic building of a theory. Naive conceptions also include the ideas on symbols belonging to the oral dimension of language (not centered at all on the decimal positional numeration system.).

As for mother language, naive mathematical conceptions include competence together with errors and misunderstanding in a dynamic setting, where exposure to new experiences or situations helps the child to correct by him/herself previous ideas or accept and include corrections from peers or adults.

From the list, we have also developed a guide for observation in action. This guide consists of several activities intended either to observe this possible mathematical competency (activities simulating a non-instructional “informal” context, such as domestic or playground experiences) or as “opportunities to learn” (becoming proper instructional, teaching activities). These activities

should be embedded in children's overall living experience and should have a human sense for them (Donaldson, 1978). Furthermore, they should at the same time, help to actually generate learning, that is, to guide first steps in mathematics. Of course the border between observation and generation of learning is not sharp. For instance, during the time expended in exploring a question, many children may learn something or reinforced their knowledge (taking into account besides that not every child has the same previous informal opportunities to build naïve conceptions).

Relating to arithmetic, activities such as *bringing enough pencils for everybody*, *telling the cook how many people to prepare lunch* may bring out naïve conceptions, skills children already possess such as *knowing some number words*, *knowing some part of the number sequence*, *counting things*. These conceptions are connected with the primitive arithmetical concepts, *idea of number one*, or *successive number*. However, children can also bring into play these conceptions to actually be able to use their knowledge to bring enough or the exact number of pencils or to try to give an answer to the cook or even to answer correctly.

In relation with geometry other activities like *walking down a road*, *holding a thread between two children*, *folding a sheet of paper neatly* are suitable for bringing to light naïve conceptions of *path* and *line*, which are closely related to the primitive concept of *straight line*. In the same way, children can use these conceptions to learn, as instance, how to distinguish a straight line from a curved one.

### **First steps in mathematics for children with Trisomy 21.**

When faced with the mathematical instruction of young children with Trisomy 21, we had to take into account the adverse general context of confusion about goals and contents mentioned at the beginning. In this context, children with Trisomy 21 appear to be in a clear disadvantage due to their well-known difficulties with arithmetic, lack of effective proposals for teaching and misunderstanding of the role of the discipline in their personal development.

There is also a problem in assessing the actual mathematical knowledge of children with Trisomy 21 (Faraguer, 2014) attributed to their scarce skills in oral and written language and their avoiding behaviour when put in stress situations (Wishart, 1993). This has lead to evaluations based upon interviews with parents or professionals (Faraguer, 2014) and consisting of solving decontextualized tasks (Zimpel, 2016). Such evaluations use to show a poor performance in mathematics by people with Trisomy 21.

From the success obtained using the list of naïve conceptions with a group of 4 year-old Italian children with no previous exposure to mathematics (Colella, 2014), this list appeared to be a suitable tool to make a proper assessment of the previous mathematical ideas of the children with Trisomy 21. We could also use this assessment as a basis for the building of an accurate teaching programme, that focus on formative values of mathematics without giving up to placing high expectations on the children.

## Methodology

The experience<sup>3</sup> consisted of a twenty-hour workshop over ten months with a group of eight children between 3 and 8 years old (three aged 3, two aged 5, two aged 6, and one aged 8) without previous selection<sup>4</sup>. The workshop was conducted by a team of four volunteer special education teachers and devoted the first three months to an exhaustive exploration of their naïve arithmetic and geometrical conceptions.

It was a *study case*<sup>5</sup> framed in what it is known as *research for practice* (Faraguer, 2014). Throughout the sessions we made an experiential observation, which allowed us to write a narration of the living experience (Van Manen, 2013) and prepare a final description of the naïve conceptions of each child in relation to the items we have observed.

## Development of the workshop

Firstly, we have to adapt the original list to make it suitable to the group of children. Table 1 shows the conceptions definitively explored.

Arithmetical conceptions	Geometrical conceptions
Numbers (any ideas)	Idea of point
Counting (transitive and intransitive)	Line and idea of continuous
Cardinality	Idea of straight and of non-straight
Subitizing	Ideas of angle
Zero	Ideas of round and circle
Spontaneous symbolic representation of quantity	Ideas of triangles and quadrilaterals
Resolution of simple arithmetical problems	Ideas of sphere and other regular solid figures
	Resolution of simple geometrical problems
Measure of time	
Distance	
Use of cardinal numbers to measure a distance (steps)	

**Table 1: Some arithmetical and geometrical naïve conceptions**

Secondly, throughout the three two-hour sessions devoted to the exploration of their naïve mathematical conceptions, we faced the challenge of designing activities also adapted to features of children with Trisomy 21 (for example most of them did not speak, so we could not use dialogue to build mathematical knowledge). We practiced oral sequence when counting balls to decorate a Christmas tree or when counting time playing hide-and-seek. We worked with the concept of

<sup>3</sup> Carried out in the context of the PhD thesis of the second writer devoted to the exploration of geometry with children with Trisomy 21, following a careful consideration of geometry in Édouard Séguin's approach. (Gil Clemente, 2016)

<sup>4</sup> Families who decided to participate in the research, were members of a local association in Zaragoza (Spain) and have more confident outlook than those of older children with a disappointing experience of primary school.

<sup>5</sup> It is a common methodology with children with Trisomy 21, because as Monari (2002) pointed out, these studies open the path to more general ones that usually confirm results obtained in singular cases.

straight line folding a letter to the Wise Men. We walked along paths to discover new worlds or join points to discover secret drawings. We also compared the length of swords before fighting as a way to compare magnitudes. We understood geometrical concepts through mimesis when training for having an adventure and we discovered surprising similarities among different familiar objects (balls, fruits, caps, towers, boxes, tins or tubes...).

We must highlight the importance of applying these activities in a happy play context in which we could witness their individual and group processes of learning without interference or pressure.

## Results

In spite of the limitations inherent with an experience carried out in a formal context and not in their real life<sup>6</sup> we obtained some useful conclusions to guide our later research.

Most of the children, especially the youngest, had very limited initial arithmetical conceptions. Only three of them were able to count to nine and the rest hardly know the numbers “one, two, three”. They could only subitize one or two objects, except the eldest child who reached six objects. They made a lot of mistakes reciting oral sequences (they counted objects more than once or forgot objects when counting) and counting objects or drawings (although they counted objects better than drawings). Only the three eldest children had well established some conception of cardinality and these children were able to solve some very simple arithmetic problems (such as “give me  $n$ ” or answering to the question “ $n$  plus  $m$ ” with low numbers and only by counting). Surprisingly, hardly any had difficulties in understanding zero in several ways, consistently with the research made by Zimpel (2016): most recognized the cipher, some knew that it was the number before one in the number sequence and some said the word “zero”.

However, their initial geometrical conceptions were much better. Through the use of their bodies, movement and mimesis they showed their understanding of point as a fixed position (standing on it without moving), of line as a path (making an effort to go along it without bending) and of straight line as the minimum distance between two points (they all walked straightly when asked to go from one teacher to another). The eldest ones were also able to distinguish none-straight lines and named them as “curves”. They all had an idea of a circle as a round (they knew how to sit in a circle or how to turn on themselves). However, they had scarce ideas of polygons (they showed more difficulties in recognizing triangles than in recognizing quadrilaterals). Surprisingly, they had a special ability to discover the similarities among every day solids. Acquisition of skills related with drawing differed substantially from one child to another due to the delay in motor development common in Trisomy 21.

Their greatest difficulties in geometrical conceptions had to do with every aspect related to measure (counting steps, for instance, was almost impossible for all of them, even for the eldest one) due to the strong relation between measure and numbers. They also showed a poor performance in understanding the relationship “to be between two objects or two persons”, basic for the acquisition of the concept of segment.

---

<sup>6</sup> We observed only one of the children, the eldest, in his everyday life. From this observation we made a diary that was very useful for extending our research (Gil Clemente, 2016).

The most remarkable conclusion was the enthusiasm and good disposition showed by all the children when facing mathematical tasks: only one child did not engage in the activities proposed; the other children enjoyed the activities and concentrated on them; many families told us their children were looking forward to coming back and doing “mathematics”. This widely confirmed our initial thesis about the natural relationship between mathematics and childhood, even for those with disabilities.

The results of our observation show a path to the possibility of seizing the power of geometry for developing some abstract thinking processes in children with Trisomy 21. This is consistent with the role attributed to geometry by Séguin (1846,1866) for awakening ideas in disabled children’s minds and with recent research regarding the strength of abstraction in Trisomy 21 (Zimpel, 2016).

## Final remarks

The experiences carried out with the two groups of children in Italy and in Spain, indicate that this approach to the encounter with mathematics actually stimulates knowledge building on a solid basis by avoiding the non-involvement of children in school mathematics and is therefore a promising path for future research. It runs in contrast with normal standardized numerical school exercises, by proposing items connected to the development of a relationship of *intimacy* with abstract mathematical objects such as points, segments or numbers (Thom, 1971) which should lay the basis for further introduction to symbolic thought.

Introducing geometry in children’s education as a result of the confidence in the relationship between mathematics and childhood<sup>7</sup> helps children to develop this abstract thinking. We have confirmed this idea with the development and application of subsequent teaching sequences based mainly on geometrical concepts after the exploration of the naïve conceptions described (Colella, 2014; Gil Clemente, 2016).

# How do preschool teachers characterize their own mathematics teaching in terms of design and content?

<sup>1</sup>Hanna Palmér and <sup>2</sup>Camilla Björklund

<sup>1</sup>Linnaeus University, Sweden; [hanna.palmer@lnu.se](mailto:hanna.palmer@lnu.se)

<sup>2</sup>University of Gothenburg, Sweden; [camilla.bjorklund@ped.gu.se](mailto:camilla.bjorklund@ped.gu.se)

*Preschool mathematics may look very different in different contexts. These differences concern both what mathematics children are offered to learn and how the learning of that mathematics is orchestrated. In this paper we present an ongoing study on how Swedish preschool teachers characterize their own mathematics teaching in terms of design and content. The target preschool teachers are those working with the youngest children aged one to three. We present two examples of how these preschool teachers describe and characterize their mathematics teaching in terms of design and content and we discuss possible contributions to research and practice.*

*Keywords: Content for learning, design for education, mathematics, preschool teachers.*

## Introduction

Preschool mathematics does not only prepare for future schooling but – and maybe even more important – provides “young children with rich and engaging intellectual stimulation” (Ginsburg, 2009, p. 405). From a time when young children were considered to be almost incapable of learning mathematics the question today is seldom whether or not mathematics belongs in preschool but rather how to organise mathematics teaching (Björklund, 2014; Cross, Woods & Schweingruber, 2009; Perry & Docket, 2008). However, the recognition of importance and the increased attention do not automatically imply consensus regarding how preschool mathematics should be designed or what constitutes an appropriate content. Cultural issues may explain some of these differences but there are also differences within countries and seemingly similar educational contexts (Palmér & Björklund, 2016).

There are several studies where researchers observe, analyze and often evaluate mathematics teaching and teachers in preschool (see Sarama, Clements, Wolfe & Spitler, 2016; Tirosh, Tsamir & Levenson, 2015). More seldom are the preschool teachers asked about how they themselves analyze and/or evaluate the observed teaching. In this paper we present an ongoing study on how Swedish preschool teachers working with the youngest preschool children, those aged one to three, characterize their own mathematics teaching in terms of design and content. To what extent do their characterization coincide with researchers and other preschool teachers? Maybe preschool teachers use different words to describe “the same kind of” mathematics teaching or reverse, maybe they use the same words to describe “different kinds” of mathematics teaching. The aim is to find out how these preschool teachers themselves conceptualize their mathematics teaching practice. In this paper we will present the frame for analysis we intend to use, to investigate one of our research questions, that is:

- How do these preschool teachers characterize their teaching in terms of design and content?

Since the study is ongoing the focus of the paper is on the rationale of the study and methodological layout with only brief discussions of two examples. First in the paper we will give some background of preschool mathematics and Swedish preschool. After this we present the study followed by two examples of the empirical material we are to work with. Finally, we discuss what we believe this study will contribute with to research and practice.

## Preschool mathematics

Preschool mathematics is an issue of current debate and may look very different in different contexts. These differences are found both in *what* mathematics children are offered to learn and *how* learning of that mathematics is orchestrated (Cross, Woods & Schweingruber, 2009; Perry & Dockett, 2008). While some emphasise basic number facts and applying computational procedures (Westwood, 2011) others emphasise advanced mathematical activities focusing on a broad spectrum of content (Claessens & Engel, 2013; Seo & Ginsburg, 2004). Regarding *what* mathematics children learn in preschool numbers and quantity are often emphasised but also concepts of space, shape, pattern, and order are central in early mathematics learning (Sarama & Clements, 2009). However, there are studies showing that the depth and quality of how the content is made an object of learning varies, where for example spatial relations, shapes and patterns are rarely problematized (Björklund & Barendregt, 2016).

One way to characterize *how* mathematics is taught is to distinguish between naturalistic, informal and adult guided learning experiences (Charlesworth & Leali, 2011). Naturalistic learning experiences are initiated and controlled by the child. A naturalistic learning experience can turn into an informal learning experience if a teacher starts to interact with the child in a way that knowledge may be reinforced, applied or expanded. Adult guided learning experiences are those being pre-planned by the teacher involving some direct instruction. Björklund's (2014) study of meaning making of mathematical concepts highlights the complexity of designing preschool mathematics education. She found three ways in which teachers planned and acted to facilitate conceptual growth among 4- and 5-year-olds. One way of approaching mathematical concepts was to give the children individual traditional tasks to solve ("I give you  $x$  number of items, can you divide them into half?"). Another way of approaching the same concept was to "hide" the mathematical content in problem solving tasks, such as games and every-day tasks. The former approach, which was clearly goal-oriented and adult guided turned into a task of "doing" where the children primarily waited for their turn but not directing attention to the mathematical content rather than the joy of being given a task to solve. The latter, which also was carefully planned by the teacher to stimulate certain concept development, failed in establishing intersubjectivity because of the children's different attention to play the game and finish the task, rather than stop and reflect on the mathematical content within the tasks. Even though the children happily engaged in the activities, the mathematics was not in focus of attention. A third way of approaching mathematical content was framing a concept in narratives where the teacher could orchestrate the direction of a story and in that manner direct the children's attention towards an intended object of learning. It turned out that this approach appealed to the children and engaged them in problem solving where concept development was made possible. This third approach was also characterized as more perceptive to the children's suggestions and creative solutions. Thus, designing teaching for preschool mathematics is a delicate work, where abstract and "invisible" mathematical principles are to be

made explicit. Preschool didactics is to make the invisible visible to the child (Pramling & Pramling Samuelsson, 2011). Björklund's (2014) study is one example of this, since the focused attention has to be made common for both teacher and child, whereas the design of the activity may constrain or enable learning.

## Swedish preschool

Swedish preschool, in which the present study is conducted, is situated within a social pedagogy tradition (Bennett & Tayler, 2006) where care, socialisation and learning constitute a coherent whole and is part of the formal education system. Preschool is offered to children between the ages of one and six, and similar to other Nordic countries (Reikerås, Løge & Knivsberg, 2012), the youngest children attending preschool are increasing in number. In Sweden, 94% of all 4–5-year-olds are enrolled in preschool or similar pedagogical practice and 88% of all 2-year-olds attend preschool or an equivalent practice (National Agency for Education, 2016).

The preschool curriculum includes several mathematics-related goals, for example that preschool should strive to ensure that each child “develop their understanding of space, shapes, location and direction, and the basic properties of sets, quantity, order and number concepts, also for measurement, time and change”. Another example is to ensure that each child “develop their ability to use mathematics to investigate, reflect over and test different solutions to problems raised by themselves and others” (National Agency for Education 2011, p. 10). These are however not goals for children to attain but instead provides direction for content and activities.

Based on the curriculum, each preschool chooses the approaches most appropriate for its own setting. Preschool teachers and child-minders are the two main types of pedagogues working in Swedish preschools. Child-minder is an upper secondary school education while to become a preschool teacher; one must complete a three and a half year university programme in preschool teacher education. Preschool teachers educated after 2001 have studied mathematics teaching in their degree, but the preschool teacher profession is mostly characterized as “educational generalists”, without specialization in any particular subject.

## Theoretical framing

Since we want to investigate how preschool teachers characterize their own teaching we needed to develop a framework that included the dimensions of *what* and *how*. To capture both these dimensions we have used Bernstein's (1999) notions *vertical and horizontal discourses* together with Claesson, Engel and Curran's notions (2014) *basic and advanced content*.

Bernstein (1999) uses the notions vertical and horizontal discourses to distinguish between different kinds of knowledge. A discourse characterized by coherence of content, hierarchically interconnected procedures, specialized language, systematically organized activities focused on general knowledge is a vertical discourse. A discourse characterized by location within communities, high relevance in the situation, every-day language, segmentally organized and maximized encounters with persons and habits is a horizontal discourse. In this study the notions of vertical and horizontal discourses is used to describe the dimension of *how*.

Claesson et al. (2014) define mathematics content as basic or advanced depending on whether the majority of children in the group focused on have mastered the content or not. Thus, basic

mathematics imply mathematics content that the majority of the children already know but that still is new for others while advanced mathematics is new content for the majority of the children. In this study the notions of basic and advanced is used to describe the dimension of *what*. However, basic or advanced will not be based on groups of children mastering some content or not, but on the preschool teachers' view of the content in each situation being characterized. Together these four notions can be used to characterize different contexts of mathematics in preschool as in Figure 1.

**Figure 1: Connecting horizontal and vertical discourse with basic and advanced mathematics.**

The two extremes basic and advanced content are to be understood as differences when it comes to which mathematics being focused on while the two extremes horizontal and vertical discourses are to be understood as differences when it comes to design. The axis basic and advanced content illustrates if the content is considered as basic or advanced, in other words if the children engaging in an activity will be familiar with and master the content or will it be a challenge. On the left side (horizontal discourse) it is sufficient that this content is part of every-day activities and routines with no need to make it explicit for the children. On the right side (vertical discourse) mathematics is the starting point with no need for applications. Thus, every-day is the starting point in the horizontal discourse and mathematics is the starting point in the vertical discourse. Along the line there is a gradual shift and somewhere in the middle there is a shift concerning everyday life or mathematics being the starting point for the design of preschool mathematics.

## The study

The authors of this paper have been part of a national network for several years that focus on toddler mathematics in preschool settings. A consortium of preschool teacher educators from different Nordic universities initiated the network with a special interest in the youngest children's mathematics learning and didactical challenges in early childhood education. There are approximately 30 active members in the network. On the network's spring-meeting 2016, the current study was presented and the members were invited to participate in generating data for analysis. Thus, the selection of participants is information-oriented and deviant (Flyvberg, 2002) which imply that we have chosen teachers that we know are interested in teaching also the youngest

children in preschool mathematics. This selection is based on the research focus not being *if* these teachers teach mathematics but instead how they characterize the mathematics they teach.

At the network meeting the study was presented verbally and afterwards the information was also e-mailed to the participants. Until the autumn-meeting 2016 the participants who wanted to (participation is of course voluntary) were supposed to document “eight situations where toddlers encounter mathematics” on a pre-prepared form. First they were asked to “describe the situation”. They got some extra help by the questions: Who was present? What mathematical content? What happened? Next they were asked to describe how the situation started. Was the situation spontaneous or planned? If the situation was planned, on what grounds? Then they were asked to describe their own as well as the children’s actions in the situation. What did they do and say? What did the child/children do and say? To find out how these preschool teachers themselves characterize the teaching situations they describe, they were asked to place the situation in a picture like Figure 1 above. If they wanted to they could motivate their placement. Having the preschool teacher to characterize the situations based on *what* and *how* makes it possible to examine what they associate with expressions as everyday mathematics, advanced content for toddlers etc which in turn may develop the professional language of preschool mathematics. Finally they were asked to estimate how common a situation like the described one, is for this/these child/ren.

## Two examples

The current study is ongoing and we have only a small sample so far and tentative results. Therefore, we will here present two examples of documentations submitted from two of the network members to illustrate the framework and how it can be used as an analytical tool.

### Example 1

The first described situation is about a child aged two years and ten months. She and one preschool teacher are sitting together. This situation was planned by the preschool teacher based on the child’s interest in sorting activities. The mathematics content is named as “sorting”.

The preschool teacher gives the girl a box with small plastic bears in different sizes and colors and asks the girl if she can sort them. The girl answers, “yes I can” and starts to pick in the box. She picks up one bear and at the same time naming its color. She says “blue, yellow, red and green. Do we have more colors? Yes we have more blue bears”.

The preschool teacher describes her own actions as “confirming what she [the girl] was saying” as well as “keeping the other children who wanted to take the bears away”. She writes that she asked the child if she could count the bears. The child then answered, “yes I can but now I don’t want to because I want to wear a dress instead”.

This situation is described as occurring two or three times a week and is by the preschool teacher categorized as in Figure 2 below.

### Example 2

The second example is a described situation with a child aged exactly two years. The mathematics content is named “training volume”. The situation arose spontaneously outdoors. The girl is standing together with three other children in a puddle. She takes 2-3 shovels with water and pours

it into a bucket. Then she pours the water out again. This procedure is repeated over and over again for about 15 minutes. After about half the time another child aged two years and ten months starts to pour water into the same bucket. The only thing the first girl says during the 15 minutes is “pour in”, this as a call to the second child. The situation is described as occurring two or three times a week and is by the preschool teacher characterized as in Figure 2 below.

**Figure 2: Example 1 and 2 as placed in the figure by the preschool teachers.**

As mentioned, our selection of participants is information-oriented and deviant (Flyvberg, 2002) why our results will not reflect toddler mathematics in all Swedish preschools. However, the empirical material will provide some insight into the context in which the youngest children in Swedish preschool meet mathematics as well as which situations these preschool teachers think of as mathematical situations. In relation to the first example in this paper one could question the preschool teacher naming the mathematical content as “sorting” instead of describing sorting as an activity with the aim to make visible mathematical concepts as shape and size. Furthermore, one could consider if the content is to be deemed as advanced in relation to the explicit child in the situation. In relation to the second example one could question what the child is engaged in. Is she exploring volume or pouring water more as a scientific activity? Other questions that can be raised are if the invisible is made visible to the children in the situations as well as if focused attention becomes common for both teacher and child? Questions like this are about the situations constraining or enabling the learning of mathematics.

### **Expected contribution to research and practice**

The preschool teachers focused on in this study are working with the youngest preschool children, those aged one to three. Based on the national network on toddler mathematics we know that these preschool teachers are interested in teaching mathematics. What we want to investigate is how they themselves characterize their mathematics teaching in terms of design and content. Since the study is ongoing we cannot present other than tentative results since only few examples of empirical material are collected so far. In this final section we will discuss what we believe this study can contribute with to research and practice.

The question of whose perspective that leads the interpretation becomes focal when starting to look into this kind of empirical data. “Volume” may be considered a quite advanced mathematical concept, since it demands attention to three dimensions and the spatial relationship between length, height and width of an object, for example. The preschool teacher may on the other hand consider the act of pouring water as a very simple exploring activity without further consideration of the complexity that the activity may entail. However, the child’s object of learning might very well be of natural scientific nature or a motor skill exploration whereas the mathematical content is left for the observer to interpret, without any conclusions of the mathematical learning value made possible.

Another reflection regards how the preschool teachers interpret vertical and horizontal discourses as well as basic and advanced mathematics for these preschool children. What similarities and differences can be found? As mentioned, one possibility is that preschool teachers use different words to describe “the same kind of” mathematics teaching or reverse, maybe they use the same words to describe “different kinds” of mathematics teaching. Making such similarities and differences visible may develop the professional language of preschool teaching in mathematics.

Since the study is conducted within the frames of a national network on toddler mathematics we believe it is important to contribute to this practice. One way of doing this is to use the empirical material to investigate to what extent the members characterize the same situation similarly. One way to do this is to ask some of the preschool teachers to present one of their situations and then let all the others do a categorization. When they place the situations into Figure 1 they define what they consider to be vertical and horizontal discourses as well as basic and advanced mathematics for these preschool children. Thus, collective but not joint categorizations can be the starting point for discussions about what we mean by spontaneous versus planned mathematics, vertical versus horizontal discourses as well as advanced versus basic mathematics.

# **“Two, three and two more equals seven” – Preschoolers’ perception and use of structures in sets**

Priska Schöner and Christiane Benz

University of Education Karlsruhe, Germany; [schoener@ph-karlsruhe.de](mailto:schoener@ph-karlsruhe.de), [benz@ph-karlsruhe.de](mailto:benz@ph-karlsruhe.de)

*There are numerous studies that confirm the importance of different skills in determining cardinality of sets for coherent mathematical learning. Some of these skills can be supported in kindergarten in a playful way. In this article we will first discuss whether it’s possible to distinguish the two processes of perceiving quantities and determining the cardinality of sets and/or when they may coincide with each other. It will also be investigated how the perception of structures in sets develop in children at preschool age and how this is used to determine cardinality in various ways.*

*Keywords: Perceiving (sub-) structures in sets, determining cardinality of sets, (structural) subitizing, preschool education, early mathematics education.*

## **Introduction**

“Two, three and two more equals seven”. This statement of a five year old girl may sound simple but profound mathematical developments underlie this statement. From the age of five to six years, the numerical knowledge increases strongly. This period seems to be a fruitful phase for the development of mathematical abilities (Weinhold Zulauf, Schweiter, & von Aster, 2003, p. 229). One of these developing abilities is the ability to perceive structures in sets and the usage of these in determining the cardinality of the set. The example above shows that the girl perceives a structure in a presentation of seven dots with the sub-structure two-three-two. This perception leads to a specific determination of the cardinality. The background knowledge about these issues is important as it enables professionals to ask adequate questions in order to support children individually or to offer suitable playing and learning areas. In particular, the different possibilities of the (individual) perceiving of structures play an important role, which will be described in detail in the following sections.

## **Perceiving (sub-) structures in sets**

Perception does not just happen incidentally but on the contrary it is a very active process. By focusing the attention and one’s own interest on the characteristics of a certain object, information from the surrounding area is actively chosen (Goldstein, 1997, p. 108). In the interviews described below, the attention is drawn to the cardinality of presented objects. Although not all ongoing cognitive processes when seeing and perceiving objects can be illustrated here, it shall be briefly referred to the gestalt psychology, in which the question is central as to why some things are perceived as a unity and others are not (Goldstein, 1997, p. 170). In order to answer the question, several gestalt principles (gestalt laws) were formulated. The six main important laws are the law of good gestalt (pithiness), the law of similarity, the law of closure, the law of proximity, the law of common fate and the law of past experience (ibid. pp. 170–176). The law of proximity indicates that things which are close together appear as belonging together (ibid. p. 173). The arrangement of objects as representations of sets may due to their distance, indicate a possible grouping of the objects. The emerging structured perception based on the grouping can then promote a determination of the set of objects in “a single glance”. In psychological and mathematical education research this “perception in a single glance” and the simultaneous determination of the set is described as subitizing. Here, it is assumed that a set

with up to four objects can be determined in a glance, without counting the objects (e.g. Mandler & Shebo, 1982). It has not been clarified whether a quick counting process lies behind subitizing (Gelman & Gallistel, 1986) or whether it's about a non-counting process (cf. Dornheim 2008). Clements and Sarama (2009) distinguish between perceptual und conceptual subitizing. Perceptual subitizing is when you just “see” how many objects there are. So it is possible to identify the cardinal number instantaneously. Conceptual subitizing is used when “seeing the parts and putting together the whole” (ibid. p. 9). With conceptual subitizing it is possible to subitize more than four objects. Clements and Sarama (2009) use the term conceptual subitizing whenever a recognized structure is used for determining the cardinality, as in the case ‘counting on’, for example (cf. Schöner & Benz, in press). For the following analyzes it is important to use a term which describes the following situation only (for a set with five elements or more): the perception of structures in a set and the immediate naming of the number. In this case, the term “structural subitizing” is used (ibid.). So the term structural subitizing means that the determination of the cardinal number of objects coincides with the process in which the set is perceived in structures. The terms “perceptual” and “conceptual” subitizing are not used in this article. Even children at preschool age “can perceive structures in representations of quantities and use this for the determination of numbers” (Benz, 2013, p. 11). The girl who is quoted at the beginning of the introduction “Two, three and two more equals seven” determines the cardinality of the set by means of structural subitizing when she recognizes the structure and immediately knows that the answer is seven. In this case, she can use the structure for determining the cardinality of the set. Söbbeke (2005) states that children use the “visual structuring ability” as a method in perceiving and using structures in arrays of objects. This also means perceiving sets not as every single item but as (different) groups of items. This ability to change from focusing every single item to perceiving and identifying structures in sets is important for the numerical development (Hunting, 2003), as well as for the part-whole understanding (Krajewski, 2008; Benz, Peter-Koop, & Grüßing, 2015). In this paper, the emphasis is on the visual level, because each time the cardinality of a presented set is considered. This is the basis for the later more abstract processes with numbers, in which composing and decomposing numbers play an important role. Additionally, to the question whether and how the structured perception of sets develop in five to six year old children, it is illustrated if and how further possibilities to determine the cardinality of sets can be observed due to the perception.

## Research questions

The following two research questions are investigated in this paper:

- (1) How does structured perceiving of sets develop in children at the age five to six?
- (2) How do children at preschool age use structures for determining the cardinality of sets?

## Design

In this paper, a case study will show how structured perceiving of sets develops in children aged five to six years. In the case study it is also examined how children of this age use structures to determine the cardinality of sets. The case study is part of a larger study. In order to understand the framework of the case study, the structure of the entire study is described first. The whole study is an efficacy study with a treatment group and a control group with more than 100 children aged between five and six years (cf. Table 1). It's a panel design so the same children were interviewed three times (t1, t2,

t3) to evaluate whether and how they perceive and use structures for determining the quantity of a collection of objects. The first interview (t1) was before the intervention. Then the intervention happened. The second interview (t2) took place shortly after the intervention. The third interview (t3) was conducted as a follow up interview.

Between t1 and t2 the treatment group got a box with different materials and games, which were suitable to discover and facilitate the structured perceiving of sets in a playful way. The kindergarten teachers were instructed and used these materials one to three times a week together with the children. At time t2, the kindergarten educators were interviewed with the help of a structured interview in which six questions were formulated. Amongst other questions, it was asked which developments were observed in the children's perception and usage of structures. In many studies concerning the determination of cardinality, a set is presented only for a short instance in order to investigate whether the children perceive the set simultaneously or not (e.g. B. Clarke, D. Clarke, Grüßing, & Peter-Koop, 2008). As it can't be eliminated that the sets may possibly be determined by a quick counting process, despite a short time of presentation, a pre-study with 27 children was conducted. Pictures with dots were presented to the children and also for only a short instance before they were asked to mention the cardinality of the dots. Statements made by the children such as for example "I have counted them again, as they could not be seen anymore" or "I have looked at the dots on a picture in my head" indicate that visual conception may play a role here. (Schönhammer, 2009, p. 178). Because a short duration of presentation does not allow a reliable conclusion whether the children use subitizing or whether they have counted the objects (quickly), the study at hand works without a time restriction. Therefore, there was no time limit for the children to look at the picture in determining the cardinality of the set of dots. To take a closer look into the processes of perceiving sets and determining cardinality, the investigation method eye-tracking was used to record the eye movement of the children. In this paper we will focus only on one part of the interview, the part with arrays of dots. Pictures with different numbers of dots were presented on a monitor. Before the interview, the children were instructed to say how many dots they can see, as soon as they know the answer. When the children said a number the interviewer asked how they came to the result. Interviews of nine children from the treatment group were previously evaluated and in the following section a thereof selected case study is presented.

## First results and interpretations

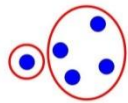

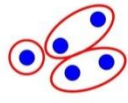

This section analyses how perceiving structures in sets develop in children in preschool age and whether and how they use these structures for determining cardinality of sets. The following results and interpretations will be illustrated by means of a single case study. Liam is a child from the sample described above which took part in the study. His age at the three investigations is illustrated in Table 1.

Time of investigation		Age of each time of investigation
t1	29th September 2015	5 years, 2 months (5;2 years)
t2	16th February 2016	5 years, 6 months (5;6 years)
t3	5th July 2016	5 years, 11 months (5;11 years)

**Table 1: Liam's age at each investigation**

The following Table shows a section of the interview. It is based on one item, which was chosen as an example for a longitudinal analysis on all three time points of investigation.

t1		Liam: One, two, three, four, five. ( <i>He counts the dots aloud.</i> )
Interpretation: Perception: Set as individual elements Determining cardinality: Counting all		
t2		Liam: Four and one are one, two, three, four, five. ( <i>When counting he points the finger at each dot.</i> ) I: Where is the one? Liam: ( <i>He points to the leftmost dot.</i> ) I: Thank you.
Interpretation: Perception: Set in structures Determining cardinality: Counting all		
t3		Liam: Five. I: How did you find out that there are five? Liam: Here are two und again two and here is one. That results in five.
Interpretation: Perception: Set in structures Determining cardinality: Structural subitizing		

**Table 2: Case study – Liam**

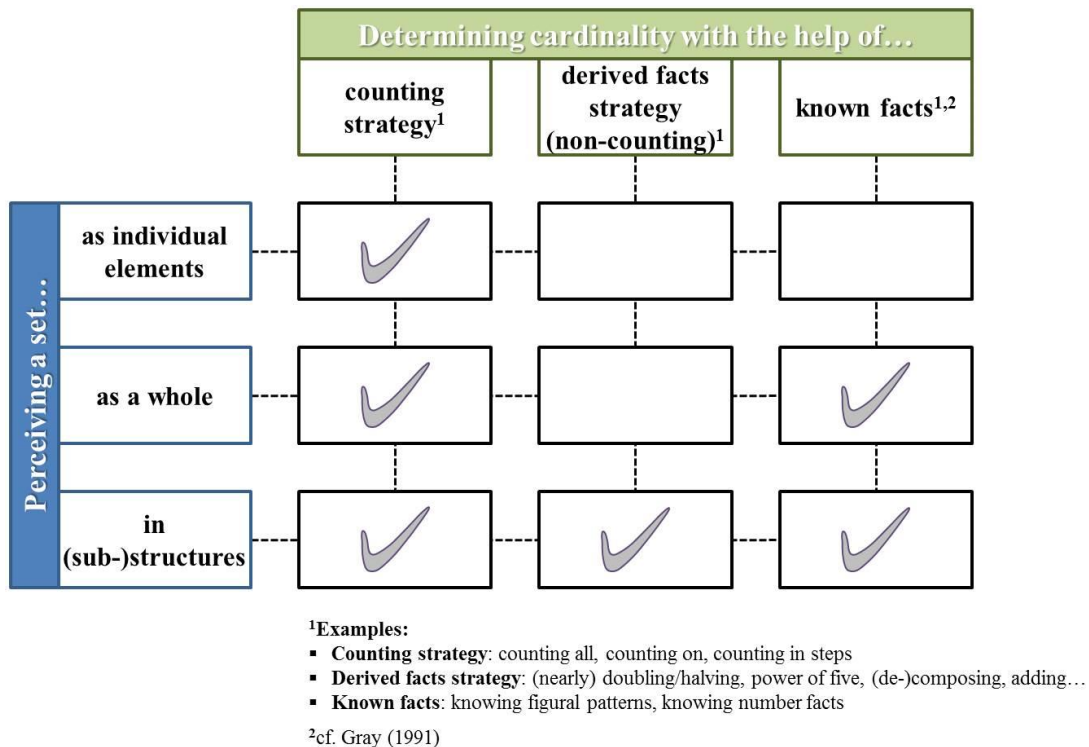

At the first interview t1 (cf. Table 2), Liam perceives the presented set of the five blue dots as single elements and uses to determine the cardinality of the set, the counting strategy of “counting all”. He uses this determination strategy for all items, independent from the kind of objects shown to him. He always counts aloud and often uses additionally, his fingers as a counting aid by pointing to each single object. Even in sets of two, three or four, he continuously uses this strategy.

At the second interview t2 (cf. Table 2), after the implementation for four months, his perception of sets changed. Liam is now capable to perceive sets in structures. In order to determine the cardinality, he still uses his familiar strategy of “counting all”. It is noticeable that he first explains the structures no matter how the objects are arranged. Then in order to determine the cardinality of the set he starts to count the objects one after another each time. By means of the eye-tracking data it can be confirmed that he really perceives structures and does not look on every single item separately. With several items he only mentions the two partial sets and only when asked again by the interviewer, how many these make up together, he answers by counting each time all the objects separately. At sets of two,

three or four, he now uses nearly every time subitizing in order to determine the cardinality. This hypothesis can be confirmed by means of the eye-tracking data and thus the possibility of an eventual quick counting process can be excluded (Schöner & Benz, in press).

At the follow-up-interview at time t3, he increasingly succeeds to use his structured perception of sets in determining the cardinality, as described in the example above (cf. Table 2). He uses structural subitizing in order to determine the cardinality of the set by perceiving the partial sets, knowing then directly how many objects there are. At some items he goes back to his familiar determination strategy of “counting all”.

In the example of Liam, a clear development especially concerning the structured perception of sets is visible. A very interesting aspect is the fact that the identification of the cardinality of a set is not *one* process, but seems to consist of *two* processes. There is on the one hand the process of perceiving a set, which in turn can be distinguished in three kinds of perceptions and the process of determining cardinality which can also be distinguished into three sub-groups. The following Figure (cf. Figure 1) illustrates these two processes and their possible relationship. The model is the result of a first evaluation and is developed by an inductive approach (cf. Benz, 2013; Benz et al., 2015, p. 134).

**Figure 1: Two processes: Perception of sets and determining cardinality (cf. Schöner & Benz, in press)**

The two processes of perceiving the structure of sets and determining the cardinality can run one after the other or coincide with each other. There are different possibilities of perceiving a set of objects (cf. Figure 1, blue boxes). Each of these three cases offers (partially different) strategies in order to determine the cardinality of the presented objects (cf. Figure 1). These processes that have been described can run successively. This is shown in Table 2 in the example of Liam at the second interview t2. He recognizes and names the structures that he perceives but he is not able to make a statement about the cardinality of the dots. This phenomenon can also be observed with many other children who were interviewed in the study at hand. In the example of Liam, the two processes

coincide at time point t3. He perceives the set in structures and then knows immediately that there are five dots altogether (structural subitizing). The perception of a set in structures offers not only the possibility of subitizing by knowing figural patterns (cf. Glasersfeld, 1982; 1987, p. 261) or by the usage of counting strategies for the determination of the cardinality of sets, but is also a necessary prerequisite in order to use non-counting derived facts strategies.

After the implementation of the tasks concerning the structured perceiving of sets at time point t2, a clear development can be observed in Liam's realization of structures. The detailed evaluations are not yet finished, but it is already conceivable that this development can also be observed in the interviews of many other children. The tendency of the follow-up study t3 is that this newly learned knowledge about the structuring of sets does increasingly stabilize itself and becomes more independent. In no case of the already evaluated interviews it is visible that the ability to perceive structures in sets is lost again. On the contrary, this newly acquired knowledge seems to be integrated as a familiar strategy in dealing with the cardinality of sets.

The kindergarten teachers from the participating kindergarten told that they could observe how children did use and explain structures in playing situations between t2 and t3, after the four months of implementation. "It [the structuring of sets] did become really independent". It was also significant that there were discussions among the children about it and arguments like: "One can put the five like this [four and one] or like that [two and three] or like that dice pattern. And it can well be seen like this [structure] and it cannot be seen very well like that, because it is mixed up." The preschoolers passed their newly discovered knowledge on to the younger children and explained to them their structured representation of a set. A mother told of a situation at home where her son arranged objects also in structures [four and five], explaining "look mum, this adds up in nine". The kindergarten teachers gave no purposeful suggestions to the materials at this time point, but still this higher attention of the teachers as well as of the children became independent and turned into an independent discovering and exploring.

## Summary and conclusion

The following section is an attempt to answer the research questions and draw conclusions. In Figure 1 on the left side it is illustrated which possibilities might occur when perceiving sets. How to perceive sets, can thus be completely different. Initially, children seem to perceive a set predominantly as an arrangement of single objects. To answer the first research question it is helpful to look again to the case study with Liam. At time t1, he perceives several sets as single elements. After four months, he perceives the set by means of its structure. This kind of perception is still present at the last investigation t3. Here, the visual structuring ability becomes visible, as Elke Söbbeke describes (Söbbeke, 2005). This could also be observed in other children, who took part in this study. To perceive a set as a whole or in structures seems to be a natural step of development. The second research question investigates how children at preschool age use structures for determining the cardinality of sets. We examine again the example of Liam. At the first interview he uses his familiar counting strategy "counting all", in order to determine the presented set. Also, at the second point of investigation, he uses this counting strategy in order to determine the cardinality although he is now able to perceive the structures. It is obvious here that the process of perceiving sets must not coincide with the process of determining the cardinality of sets, but that these two processes may happen independently of each other. Within the following months, Liam learns to use the perceived structures

in order to determine the cardinality of sets. At the third point of investigation, it is obvious that through his structured perception of sets, he is now able to use non-counting strategies to determine cardinalities. In the described item, he uses the strategy “structural subitizing.” To perceive a set in structures is therefore an important precondition for the usage of non-counting strategies and for replacing counting strategies through calculating strategies in primary school (Gaidoschik, 2010).

It is possible to support the structured perception of sets in a playful way already in kindergarten. Designing mathematical playing and learning environments which are mathematically substantial and which will enable the children to act in a discovering and exploring way through adequate games and materials, is a precondition for supporting the perception of structures in sets. In addition to providing such materials, kindergarten teachers should act inspiringly and supportively within this learning environment, in order to support this development in children. On the one hand they must be competent concerning mathematical contents but on the other hand they must be able to connect situational observations and perceptions with pedagogical-didactical activities. The knowledge about the processes of perceiving sets and determining the cardinality of sets, as it is illustrated in this paper, may serve as a basis for a differentiated, constructive and individual support in a playful learning environment.

# A framework for designing inquiry-based activities (FIBA) for early childhood mathematics

Chrysanthi Skoumpourdi

University of the Aegean, Department of Preschool Education Sciences and Educational Design,  
Rhodes, Greece, [kara@aegean.gr](mailto:kara@aegean.gr)

*Nowadays it is widely agreed that students should be involved in critical and creative thinking about mathematics concepts and ideas in order to organize and consolidate their thinking, as well as to reflect and construct their own learning. Inquiry-based mathematics education, as a teaching and learning method among many others, seems to be a fundamental way to initiate and support students' effective involvement to the teaching/learning process. In this method, in which the role of students, teachers and activities is changing, the teachers must be also able to design and implement mathematics activities that are open to an inquiry-based process. In this paper, a framework for designing inquiry-based activities (FIBA) for early childhood mathematics is proposed, accompanied with an example, aiming to assist teachers in their instructional design.*

*Keywords: Inquiry-based activities, early childhood mathematics, framework.*

## Introduction – Theoretical background

In the last decades, it is argued that instructional design should support a critical (Skovsmose, 1994) and a creative mathematics education (Leikin, 2009). The teaching that was based on the simple reproduction of given conceptual contents and the transmission of knowledge has yielded space to the teaching based on student's own activities, that contributes to a meaningful learning and stimulation of their own identity as an emerged process (Van Oers, 2010).

In this new context, in which mathematics education is based on inquiry<sup>1</sup>, teaching includes exploration, practical action, developmental thinking, connection of mathematical ideas and contents, problem solving and posing, collaborative learning, as well as autonomy to the development of ideas and methods (Artigue & Baptist, 2012; Ulm, 2012). Clarke and Clarke (2002) describing the effective mathematics teaching, set as a starting point the use of unusual problems without suggestions for their solution and the use of materials and other resources relevant to the content of the problems but also to the students' interests and needs. Moreover, they propose to address the classroom as a 'community of learning', that develops mathematical discourse and encourages the expression of students' ideas and strategies, focuses on the big ideas of mathematics, uses informal assessment methods to support instructional decisions, as well as facilitates students to act and think. In a "community of inquiry" teachers learn from students and students learn from teachers solving and posing mathematical problems to each other (Goodchild, Fuglestad & Jaworski, 2013). In this perspective, qualitative teaching, takes place by encouraging the creative and critical participation of students (Radford, Schubring & Seeger, 2011) and adoption of

---

<sup>1</sup> The IBME (Inquiry Based Mathematics Education) perspectives are based on approaches that have been developed in the field of mathematics education, such as the problem-solving tradition, among others, which tend to shape it in a particular way. But, in the problem-solving tradition the focus was on 'teaching problem solving' by developing problem solving skills and associated metacognitive competences, whereas in the IBME the focus is on 'teaching *via* problem solving'.

exploratory and expressive ways of learning. As Sierpinska argues, “it makes sense to assume that learning – mathematics or mathematics teaching – is either inquiry-based learning or it is not learning at all” (2016, p. 55).

In the inquiry-based mathematics education, the roles of students, teachers and activities, as factors that jointly shape the instructional design, are changing. Students are no longer considered as the passive recipients of knowledge but as co-constructors and co-researchers of their knowledge assuming greater responsibility for their actions (Lau, Singh & Hwa, 2009). They are at the center of the learning process; they actively participate in it and are strongly engaged with mathematics problems. They are actively involved in explorations and discussions, and they pose questions, that were usually posed by teachers, in order to express an opinion, to share and explain their ideas, to make assumptions and generalizations, to present their solutions to a problem, to justify their creations and to support or prevent the ideas of their peers. When students are forced to describe their strategies in detail and justify them, they promote their understanding. Students’ creative participation in the teaching and learning process of mathematics is related with producing new ideas, giving meaning to symbols, materials and tools, facts and procedures, understanding math problems, making plans and devising ways to solve them, as well as finding ways to assess the logic of their solution (Haylock, 1987).

The role of the teachers, since they are not the key persons of the teaching/learning process, is also changing and instead of being the sole sources of mathematical knowledge, who only focused on practicing the mathematical operations and procedures, they become supporters of children’ mathematics constructions (Lau et al., 2009). They work cooperatively with students to create the appropriate conditions and organize the process and the ongoing opportunities for them, to explore, to make connections, to build mental representations and to develop mathematics concepts based on their prior or/and informal knowledge through the interactions with others. They cultivate to students the need to communicate their actions, their creations, their solutions with the use of materials or other auxiliary means, to discuss their mathematical ideas, to share their thoughts, to cooperate (Shriki, 2010). They help students to look for multiple solution methods and multiple outcomes for a situation (Tsamir, Tirosh & Tabach, 2010), to identify relationships and common characteristics in different cases, to reflect and justify their thoughts and actions. Teachers transfer the problem-solving responsibility to students without, at least initially, intervening and suggesting ways of thinking. They encourage children to think and present their solutions to the rest of the class. The discourse, which includes the presentation of students’ results, solutions, strategies and methods, highlights students’ own considerations and encourages the exchange of their ideas (Ryan & Williams, 2007). Teachers pose questions related to students’ ideas in such a way, as to explain their thinking and imagining, as well as giving meaning to their actions and developing their own understanding. It is important that the posed questions are linked with the task and its solving. The questions are not supposed to fulfill teachers’ desire to teach mathematics, but have to encourage the emergence of multiple strategies, to make clear the relationships between these strategies, as well as to give opportunities to students to integrate the pieces of their knowledge.

Activities’ type, in the new cooperative, critical and creative classroom context, is changing. Activities arise from tasks that are problem-based with sufficient openness for inquiry-based learning (Ulm, 2012). The context of these tasks can be authentic or not, known or unknown to

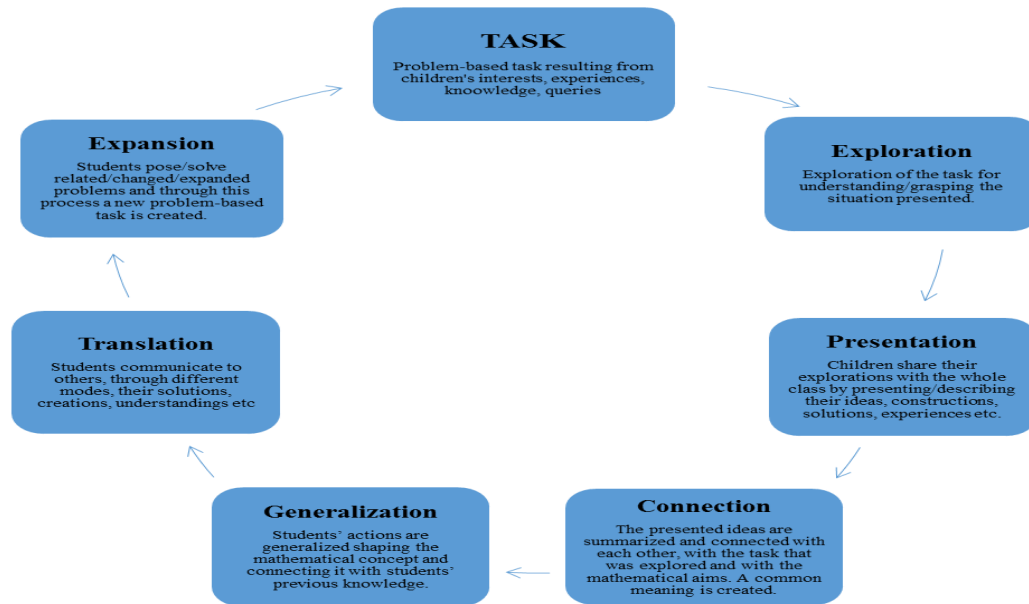

students and can be associated with everyday activities, stories, games, workshops etc. Complex and creative situations allow various solutions and reasoning. They enable the use of students' informal knowledge and empirical reality. They are 'realistic' experiences, supported by a variety of materials and other means (Varol & Farran, 2006). Materials that are related to the task are used and aim to help students to investigate the situation, to find answers to the questions posed, as well as to pose their own questions. The main aim of the activities is not just to be carried out by the students, because it is the lesson of mathematics and they should do so, but the challenge to deal with the situation presented to them. They challenge students to connect mathematics with their daily life (Van den Heuvel-Panhuizen, 2005) and encourage them to describe the different ways in which they perceive things. Activities that are realized in many ways require students to conjecture, to interpret, as well as to justify their thoughts (NCTM, 2007). They encourage reflection and communication for students, to construct mathematical meaning using skills and knowledge they already hold (Varol & Farram, 2006). Moreover, they have to be interesting, effective and developmentally appropriate inducing the active participation of students (Tzur, 2007) to mathematics discourse. The solution of the problem is not readily apparent. To solve the problem, students have to use something more than a routine solution or an algorithmic process. The solution of the problem may be proposed by a student or a group of students. It may occur during the discourse or be suggested by the teacher. The mathematical discussion is completed when the whole class agrees to a mutually acceptable solution/s for the task, which can consist of many answers. In each case, children "earn" if the discussion, that took place, has set the basis for them to understand that the proposed solution is reasonable for this reflection. Then, when possible, the solution is modified and generalized. The generalization begins when reasoning gets independent, when it does not refer to the specific context in which it was created, and continues when the common characteristics of the different ideas are combined. Tasks can be either structured or unstructured but are open to an inquiry-based implementation.

The design of creative and critical activities that can be realized within an inquiry-based process that encourages students to decide for themselves when and how to use a method, a process or a strategy, can lead to meaningful learning. Such activities allow the creation and communication of students' reasoning cultivating skills such as prediction, fast perception of information, systematic reasoning, critical and creative thinking, problem solving and posing, assessment, comparison and correlation, as well as generalization, skills that are necessary for the future citizens (Sarama & Clements, 2009). This type of activities is not usual in the mathematics classrooms because its design and implementation is difficult (Sierpinska, 2016). It is easier for teachers to teach facts, procedures and problem solving processes through structured situations even if these situations are often not understood by the students and do not influence their thinking. Children, often, because they have to deal with routine and structured mathematical tasks, that require the implementation of specific strategies, do not sense when and how to use a mathematical procedure to solve a problem. Research results pinpoint that it is essential for the mathematics education to include also inquiry-based activities (Artigue & Baptist, 2012). Thus, a framework for designing inquiry-based activities for early childhood mathematics (FIBA) is proposed, accompanied with an example, to assist teachers in their instructional design.

## Framework for designing and implementing inquiry-based activities (FIBA)

Taking into consideration the above main points of inquiry-based mathematics education, a framework for designing and implementing activities is proposed. The framework consists of seven stages (figure 1):

**Figure 1: The seven stages of the FIBA**

1. **Task** (key person: teacher): A problem-based task is invented and presented, by the teacher, through a context, resulting from children's interests, experiences, knowledge, queries (emergent from a previous free talk and sharing experiences with the students in the class which is based on the curriculum and is in accordance with a mathematical purpose). The task, which may have one or more solutions, is designed in such a way that it problematizes and incites children, in order to engage them in a problem solving and posing process. The problem to be solved could be a non-standard, unfamiliar, a bit complex and novel situation in order not to be solved just by applying existing knowledge and already-known strategies, but through exploration.
2. **Exploration** (key person: students): Children (individually or in groups) use their own (informal) problem-solving strategies to explore the problem introduced by the scenario, to choose/use materials and other auxiliary means, to make conjectures, to pose questions to each other and to the teacher for understanding/grasping the situation and to suggest solutions, in order to 'solve' the problem. In that stage, students have the opportunity to reflect and think about the problem on their own, before sharing their thoughts with their peers. They are also free to discuss their ideas about the problem with their peers before presenting them to the whole class.
3. **Presentation** (key person: students): Children share their explorations with the whole class by presenting/describing their ideas, constructions, solutions, experiences etc. Teacher, in that stage, is an observer and organizer of each team's presentation, orchestrating students' contributions, posing questions to help children describe, explain and open out their explorations. He/She also encourages students to pose questions to their peers, from other groups, in order to ensure that they understand all the presentations.

4. Connection (key person: teacher): Teacher, in cooperation with students, summarizes the results, poses questions and encourages students to ask questions that connect the presented ideas with each other, with the task that was explored and with the mathematical aims, in order to construct the common meaning that the classroom would share. Teacher's questions have to encourage mathematical thinking and reasoning and can be of several types (Carlsen, Erfjord & Hundeland, 2010). At that stage, it will become apparent if cooperative grouping strategies are effective in promoting classroom discourse.
5. Generalization (key person: teacher): Teacher is generalizing (and mathematizing when and if possible) students' actions, shaping the mathematical concept, connecting it with students' previous knowledge and giving feedback to them.
6. Translation (key person: students): At that stage, students are asked to communicate to others (students from another class, family etc.), their solutions, creations, understandings etc. through different modes—verbalizing, gesturally and schematizing (Skoumpourdi, 2016a).
7. Expansion: Students are asked to pose/solve related/changed/expanded problems.

In all the above stages, teachers are also responsible to take students' questions and comments into consideration, turn them into learning opportunities incorporating them to their instructional design, creating a new problem-based task.

### **The Pattern King: An example of an inquiry-based activity**

Given that, the importance of patterning is increasingly highlighted in recent years and that, to further improve the performance of children on patterning, teaching interventions are necessary from the early years of schooling (Skoumpourdi, 2016b), in this chapter, an example of a pattern task<sup>2</sup> is presented, through the seven stages of the FIBA, supporting an inquiry-based teaching/learning process of mathematics.

Task: "The Pattern King forgot the password of his secret room and thus he cannot enter. Fortunately, he has photographs of the passwords he used to use and he asks your help to construct them". The students, (individually or) in groups, pick a drawing with chain schematization/password<sup>3</sup>.

Exploration: Each (student or) group explores its schematization. They pose questions to the teacher to understand the situation. They observe how it is made and suggest ways for creating it. After the discussion, they choose the associated materials (connected shapes<sup>4</sup>) in order to construct the pattern/password and they create a/the chain.

Presentation: Each (student or) group presents the structure of its creation to the whole class,

---

<sup>2</sup> This is just an example of an inquiry based pattern activity. Taking into consideration the pattern's four functional characteristics (Skoumpourdi, 2016b), as well as students' pattern abilities and their type of performance (Skoumpourdi, 2013) a wide range of critical and creative pattern tasks can be designed which can engage children in challenging patterning experiences. A different combination of these characteristics leads to different pattern tasks with a varying degree of difficulty.

<sup>3</sup> Examples of chain schematizations/passwords

<sup>4</sup> Connected shapes

bringing side to side the construction with the schematic representation. The teacher is posing questions to ensure effective and understandable presentations. Also, students are encouraged to pose questions to their peers. The questions can be: “Can you describe us what did you construct? Which shapes did you use? Which shapes are similar? How many shapes did you use? Why did you put the triangle in this place? Which shapes are repeated? Do you observe any pattern?” etc.

Connection: Teacher, in cooperation with students, orchestrates a mathematical discourse trying to connect presentations/creations with each other, with the Pattern King’s problem, as well as with the pattern concept in order for a shared meaning to emerge. Questions can be: “What do you observe to this construct? In what, these constructs differ? To what are these constructs similar?” etc.

Generalization: Teacher is shaping the pattern concept, connecting it with students’ previous knowledge to generalize it. Questions are more general and are related to the pattern construct. For example: “Are these patterns the same”? “What is repeated in this pattern?” etc.

Translation: “Can you draw your creation to show it to the students of the other class?” In this stage students ‘translate’ their constructs and understandings for patterns and shapes to the paper.

Expansion: “A magician invited the King to play a game. He was sure that he would win him, to get his palace. The magician has two dice, one with numbers and one with shapes. Each of them—the king and the magician—would throw the dice and would take as many shapes as the dice indicate. The one that would create the longest chain with patterns will be the winner. Come to play the game to help the King make a very long pattern chain.” In that stage students expand their understanding by creating their own patterns.

At the end of the inquiry process, students would have used the connected shapes to copy the patterns or to construct their own ones. They would have translated their constructions to schematic representations, using paper and pencil, as well as verbalized them describing the pattern construct. They would also have discussed about the shapes’ names (circle, triangle and rectangle) and their orientations, as well as about length comparison.

## Conclusions

Teachers, in their educational practice, are asked to invent mathematical tasks for their students, to design activities relied on them and implement them, as well as to reflect on the outcomes of the implementation. Yet it is not easy for teachers to design inquiry-based activities and implement them in classroom. They prefer to stay within the comfort of the usual school tasks which are routine and structured and they design teacher-centered activities that reproduce the given conceptual contents and are solved by memorizing facts and processes.

But if we take into consideration the argumentations of the last decades for the inquiry-based mathematics education, the design and implementation of inquiry-based mathematics activities, which are beyond the usual school tasks, will help students to develop their curiosity and creativity, their ability for critical exploration, reflection and reasoning and their autonomy as learners leading them to mathematical understanding (Artigue & Baptist, 2012).

Using the proposed framework one can design and implement activities, for early childhood, supporting an inquiry-based teaching/learning process of mathematics. Through the seven stages of the framework which include: 1. the formulation of the task, 2. the exploration of the problem posed

by the task, 3. the presentation of the explorations, 4. the connection of the presentations with mathematical aims, 5. the generalization of the connections and mathematical concepts and ideas, 6. the translation of the understandings on other modes and 7. the expansion of the initial task to a modified one, students' and teachers' roles alternate. During their cooperation they are both the key persons, the co-constructors and co-researchers of the teaching/learning process.

We do not support that all of mathematics activities should be designed and implemented in an inquiry-based process but we do believe that such activities should be adopted to develop different skills in students and to actively involve them in their own learning.

# **The role of gestures in supporting mathematical communication for students with language delays**

Helen Thouless

Independent Consultant, United Kingdom; [hthouless@yahoo.com](mailto:hthouless@yahoo.com)

*Despite the fact that discourse is an important facet of mathematical learning, most research on students with language delays learning mathematics has focused on their procedural fluency, with limited focus on their communication of mathematical reasoning. This study focused on two first grade students with language delays as they engaged in choral counting, an instructional activity designed to encourage mathematical discourse. Qualitative analysis of the techniques they used to express their mathematical ideas found that the students' use of gestures in relation to an artefact supported their mathematical communication.*

*Keywords: Mathematics instruction, language impairments, nonverbal communication, discourse analysis, pattern identification.*

## **Introduction**

Discourse mediates mathematical learning (Forman, 2003) by providing a conduit for students to participate in mathematical practices, particularly when discourse is defined as comprising all forms of communication—including language, gestures, symbols, and artefacts (Lerman, 2001). The importance of discourse to mathematics education is shown by its prominence in educational policy documents (see e.g. NCTM, 2000), which state that mathematics instruction focused on discourse should enable students to express their mathematical ideas, analyse the mathematical thinking of others, and clarify and consolidate their own understanding of mathematics.

Gersten et al. (2009) found that the process of encouraging students with learning disabilities to verbalize their thoughts is effective, and yet it is uncommon to see teachers encouraging mathematical verbalizations from students with disabilities. This is because the dominant instructional paradigm for teaching students with disabilities is teacher-led algorithmic instruction (Jackson & Neel, 2006), which is characterized by the teacher demonstrating a step-by-step procedure for completing a specific type of problem, and the students then using these same procedures to solve similar types of problems. This type of instruction leaves little space for independent student verbalizations. In this paper I explore what students with language delays learn about communicating mathematical ideas by engaging in an instructional activity—choral counting—that encourages students to engage in mathematical discourse.

In this study I use the term language delays to mean that the students had persistent difficulties with expressive and/or receptive language that interfered with their academic competence and had been present since early childhood, but was unrelated to low cognitive ability, hearing loss, autism, or other known causes.

## Conceptual framework

This study is influenced by a sociocultural framework in which learning is defined as the transformation of participation in a cultural practice (Rogoff, 2003). The cultural practice examined in this study is discourse about mathematical ideas. Amongst the community of mathematicians, discourse between mathematicians about axioms and conjectures is an important cultural practice that allows them to refine and improve knowledge; this is different than the one-directional discourse that commonly occurs in school mathematics classes, with the teacher imparting knowledge to the students (Lampert, 1990). This study examines the transformation of practice as the students move from the type of discourse typical in school mathematics towards disciplinary discourse as they learn several practices that mathematicians engage in when discussing mathematics: making assertions and presenting evidence (Lampert, 1990).

Several researchers have used a sociocultural framework to understand how students with English as an Additional Language (EAL) participate in mathematical discourse (Turner, Dominguez, Maldonado, & Empson, 2013). It is often assumed that students with EAL will struggle to participate in mathematical discussions, but Turner, Dominguez, Maldonado, and Empson (2013) found that these students increased their participation when the teacher invited their participation, validated their participation by responding positively to their contributions and accepted a variety of resources as valid forms of communication including gestures, objects, artefacts, and the students' home language.

These findings about how students with EAL can be encouraged to participate more in mathematical discussions, may help us support students with language delays to participate more in mathematical discussions. At present students with language delays are assumed to fare better in environments that limit peer interactions (Griffin, League, Griffin, & Bae, 2013), however, since "content learning is inseparably bound up with language learning and vice versa" (Barwell, 2005, p. 207), students with language delays may actually need more opportunities to participate in mathematics discussions than typically developing students. They may need more practice communicating mathematically, just as they need more practice communicating in other modes. This means that mathematics lessons should be designed to support students' language goals as well as their mathematical content goals. These language goals will be more readily addressed with mathematical discussions than by direct instruction.

## Significance of research

The research question explored in this paper is: What do primary students with language delays learn about communicating mathematically as they interact during choral counting? This study contributes to the field of mathematics education by helping researchers and practitioners understand more about the intersections of language performance and mathematics learning by examining a group of students who are rarely asked to communicate their mathematical ideas as they learn mathematical content.

## Methods

### Self-study

This study is an example of self-study action research, as I was both the Special Educational Needs (SEN) teacher for the participants and the researcher in this study. I used the position of the teacher to investigate an issue, try a new method, and examine it systematically (Ball, 2000).

This type of research has several advantages and disadvantages in regards to validity. My established relationship with the students meant that I knew the history of shared understandings within the class and understood the children's use of language (Ball, 2000), and could use this knowledge to understand to what the children were referring, thus increasing the validity of the results. On the other hand, as their teacher I had a vested interest in seeing the students learn, which is a threat to the validity of the results. As an attempt to offset this threat to validity I triangulated the data with several other sources of data. The reliability of this study would have been increased if I was able to include a report of inter-rater reliability for the results.

This study was motivated by my own experiences teaching mathematics as an SEN teacher. I had tried to teach mathematics through direct instruction for several years and was dissatisfied with the limited progress that my students were making in mathematics. Therefore I decided to try a new instructional activity that emphasized mathematical discourse—choral counting—and to examine this new activity systematically to discover whether it is a fruitful way to work with young students with language delays.

### Participants

The participants in this study were two first grade (6-7-year-old) boys who received small group SEN services in the areas of mathematics, literacy, and communication in an urban area of the U.S.A.

Martin<sup>1</sup> and Ali were both members of my primary special education mathematics class (PSEM). They had both qualified for SEN services under the category of Developmental Delays. Although the category given to them by the school district was Developmental Delays, which suggests global delays, the term Language Delays more accurately reflects their difficulties. These students showed delays in their language development, but no delays in their self-help or motor skills, and only minor delays in their social skills. Therefore, I use the label Language Delays to refer to these students' disabilities.

Martin and Ali were selected because at the beginning of the study they both had Individual Education Plan (IEP) goals related to counting, were in first grade, had language delays, and remained in my mathematics class throughout the duration of the study. There were four other students in their mathematics group, but these students did not receive SEN services in my class through the entire duration of the study.

<sup>1</sup> All names are pseudonyms.

## Procedures

I chose to study the instructional activity of choral counting (Lampert, Beasley, Ghouseini, Kazemi, & Franke, 2010) because it is an activity that incorporates both appropriate mathematical content for students in first grade and an opportunity for the students to engage in mathematical discussions. There are two sections to the choral counting activity: 1) rote counting, and 2) pattern identification and expansion. It is during the second section of the activity that students engage in mathematical discourse by expressing their own mathematical ideas.

In choral counting the teacher has to first choose an appropriate counting sequence for the students. For these students the counting sequences were by ones, twos, fives, tens, or backwards by ones. When counting by ones, the count started from a number in the low double digits because the students were very familiar with counting by ones from one. These counting sequences were selected because they were identified as the essential counting sequences for first grade students in the Washington k-12 Mathematics Standards (Office of Superintendent of Public Instruction, 2008), which were the relevant state standards in the time and place where this study was situated. Once the teacher has introduced the counting sequence to the students, the class counts together while the teacher strategically records the count on the board so that certain patterns emerged.

After writing three or more rows or columns the teacher stops the count and asks the students to identify patterns in the numbers. Once a student has stated a pattern they can be asked to extend, compare, or justify their pattern, and other students can be asked to build on what the first student has said.

The students in the PSEM class engaged in choral counting approximately weekly from November until March. They then continued to participate in choral counts once or twice a month from April until June. This resulted in eleven choral counting lessons over the year, each of which took approximately 20 minutes to enact. I additionally recorded my lesson plans, my reflections of each lesson, and asked the students to complete independent counts. Although I do not report my analysis of these additional sources of data in this paper, they did triangulate the data from the videos.

## Data analysis

The data collected and analysed for this article consisted of two episodes from the videotaped choral counting lessons. The data were collected during a single school year, and were analysed systematically by drawing upon both sociocultural theory (Rogoff, 2003) and interaction analysis methodologies (Schegloff, 1997). In the initial analysis of the data, I used open coding to produce concepts, which were revised with further analysis. The resulting claims and assertions are based in the data and are therefore empirically grounded.

## Results

In this paper I show how the students incorporated gestures towards the artefact into their interactions, and why this increased their communication of mathematical ideas.

In the first couple of choral counting lessons all of the students responded to the quest for patterns purely verbally. When asked what patterns he saw, Martin responded, “A square right there...Ooh! A triangle...Circle...Rectangle.” These verbal responses did not communicate enough information

to help his classmates or teacher understand why he was responding with shape names, and the conversation about shapes petered out.

On his next turn Martin initiated a new form of communication about the numbers. Instead of remaining in his seat, he came up to the board and gestured towards the numbers he was referring to (see Figure 1):

Martin: I see zeroes

Teacher: Where. Tell me where. [Martin got up.] Tell me

Martin: Right here. [Martin went to the board and pointed to the zeroes in the final column. As he counted he pointed to each zero.] Ten. Twenty. Thirty. Forty. Fifty.

**Figure 1: Count by 2s, December**

In this interaction Martin defied the teacher's expectations that he would respond to the question purely verbally. Instead he adopted some of the teacher's communication style from the previous interaction with Ali by using the artefact to gesture towards the relevant numbers, but also innovated to convey more information. While the teacher had used a gesture that simply indicated the digits under discussion, Martin used a cohesive gesture that united two separate but related aspects of his idea (McNeill, 1992). Martin used pointing to indicate the repetition of the written zeroes in the ones place, while verbally reading the count by tens; in this episode Martin used a cohesive gesture to express his emerging understanding of the links between the symbolic and verbal representations of number. This corresponds to Garber, Alibali, and Goldin-Meadow's (1998) finding that children often use gesture to express emergent learning.

Martin's initial comment about "zeroes" was clarified and expanded by his use of gesture. This expansion allowed the teacher to respond to his statement and prompt him to further expand on his idea.

Teacher: What are they counting on by?

Martin: Tens. [Confident voice.]

Teacher: Yeah. Tens. [Writes +10 beside the zeroes with an arrow pointing down.] That's a great answer.

The positive response that Martin achieved through this interaction encouraged other students to take up his innovation and by episode 4 it had become a norm for the students to come to the board when they were trying to communicate which numbers they were discussing. For example, in episode 4 Ali communicated that he saw a similarity between the numbers in the first row (see Figure 2) by both verbalizing the numbers he was discussing and pointing to the relevant numbers. The words that he said, "Tens...got a number one zero, one one zero," could have been easily misconstrued but because he came up to the board and pointed at the relevant numbers, his listeners understood exactly which tens he was talking about.

<u>10</u>	1 <u>10</u>	2 <u>10</u>	3 <u>10</u>	<u>410</u>
20	120	220	320	
30	130	230	330	
40	140	240	340	
50	150	250		
60	160	260		
70	170	270		
80	180	280		
90	190	290		
100	200	300	<u>10</u> Ali's pattern	

**Figure 2: Count by 10s, January**

The use of gestures allowed Ali to clearly communicate his idea and the mutual understanding engendered by this exchange of ideas allowed his teacher to extend the conversation (Goldin-Meadow, 2003).

Teacher: What number will be here? [Teacher points to the right of 310.]

Ali: Four

Teacher: Four hundred [Writes 4.]

Ali: Ten. [Teacher writes 10.]

In this exchange Ali went beyond the initial statement of the pattern to extend his pattern to the next column while incorporating an unstated arithmetic sequence in the hundreds.

## Discussion

This action research project improved the participating students' educational outcomes, challenged assumptions and provides a basis for a call to social action, which are all important goals for action research (Kincheloe, 2003; Somekh & Zeichner, 2009).

The instructional activity of choral counting improved the students' educational outcomes (Kincheloe, 2003) by transforming their participation in the cultural practice of mathematics discourse by challenging the assumption that students with language-delays will not be active participants in discussions around mathematics because they find the language too difficult (Fazio, 1999). Although both boys found it difficult to express their ideas verbally, they were actively engaged in the mathematical discussions and used gestures to enhance their communication. Thal, Tobias, and Morrison (1991) found that students with specific language impairments are often worse at gesturing than their peers, but that those whose gestures develop normally will later catch up with their peers in verbal speech. Therefore it is important to encourage the use of gestures among students with language delays and this study showed that allowing students with language delays to gesture and physically interact with the numbers can support their participation in mathematical discussions. My call to action is to encourage other teachers to involve their students with language delays in mathematical discussions and to encourage them to use gestures and artefacts to express meaning.

*It is often recommended to engage young children with patterning activities. As part of a professional development program, nine preschool teachers were introduced to repeating patterns and were given the materials and instructions with which to implement an extension task with children. This study presents the various ways teachers implemented this task and investigates the impact of the various implementations on children's success in extending the repeating patterns.*

*Keywords: Repeating patterns, tasks, preschool teachers*

## Introduction and background

For several years, we have been providing professional development for preschool teachers guided by the Cognitive Affective Mathematics Teacher Education (CAMTE) framework (e.g. Tsamir, Tirosh, Levenson, Tabach, & Barkai, 2014). Our aims are to promote teachers' knowledge and self-efficacy for teaching mathematics to young children. An essential element of pedagogical-content knowledge is knowledge of tasks (Sullivan, Clarke, & Clarke, 2009). In Israel, where this study took place, there is a mandatory mathematics preschool curriculum, but few curricular materials are available. Thus, introducing preschool teachers to appropriate mathematical tasks is essential. However, studies have shown that even when providing teachers with a task, and with explicit instructions for carrying out that task, teachers may implement the task in different ways (Bieda, 2010). In turn, different implementations may affect the cognitive load of a task or a student's conceptualization of key mathematical ideas (Stein, Grover, & Henningsen, 1996). This paper investigates the various ways preschool teachers implement a given repeating pattern task.

Repeating patterns are patterns with a cyclical repetition of an identifiable 'unit of repeat'. For example, a pattern of the form ABBABBABB... has a (minimal) unit of repeat of length three. The importance of engaging young children with pattern activities is supported by mathematicians, mathematics education researchers, and curriculum developers (Sarama & Clements, 2009). Pattern exploration and recognition may support children as they learn a variety of mathematical skills developed at this age. For example, recognizing repeating patterns may help children develop skip counting, such as 5, 10, 15, 20, 25, 30 ... where the ones digit forms the pattern 5, 0, 5, 0, ... Recognition and analysis of patterns can also provide a foundation for the development of algebraic thinking and provide children with the opportunity to observe and verbalize generalizations as well as to record them symbolically (Threlfall, 1999).

Several studies have investigated ways in which young children engage with repeating patterns. For example, Seo and Ginsburg (2004) found that young children build block towers with an ABAB pattern. Fox (2005) observed young children painting stripes in ABAB patterns as well as one child who painted four sets of an ABC pattern and then said, "Look at my pattern" (p. 317). Waters (2004) observed a young girl who created a necklace out of game materials and described her necklace as "diamond, funny shape, diamond, funny shape" (p. 326). Papic, Mulligan, &

Mitchelmore (2011) found that some preschool children may be able to draw an ABABAB pattern from memory by recalling the pattern as single alternating colors of red, blue, red, blue, basically recalling that after red came blue and after blue came red. However, when shown a more complicated pattern such as ABBC, they could not replicate the pattern.

This study focuses specifically on the task of extending a repeating pattern. Pattern extension tasks mostly include showing the child a pattern and requesting the child to continue it. Papic, et al., (2011) reported that many children succeed at these tasks without necessarily recognizing the unit of repeat. Instead, they use the “matching one item at a time” strategy, also known as the “alternation strategy” which is especially successful with simple ABAB patterns. Rittle-Johnson, et al., (2013) found that some children reverted to producing an ABAB pattern while others could not produce more than one unit of repeat correctly when extending an ABB pattern. Similarly, Swoboda (2010) found that for some four-year old children, continuing a pattern means duplicating the unit of repeat once, and no more. In other words, both the complexity of the unit of repeat, as well as the number of times the unit is to be repeated, seemed to contribute to the difficulty of the task.

Another factor which may impact on the difficulty of extending repeating patterns is whether (or not) the given pattern ends with a complete unit of repeat. In one study, children were shown given repeated patterns and asked to consider extending the patterns by choosing between different possible continuations, some appropriate and some not appropriate. Children had greater success extending patterns which ended with a complete unit, than extending patterns which ended in a partial unit (Tsamir, Tirosh, Barkai, Levenson, & Tabach, 2015). Furthermore, several of the appropriate continuations would have extended the pattern in such a way as to end the pattern with an incomplete unit of repeat. Fewer children chose those possibilities as appropriate, even though they were correct extensions.

From the above studies, we see that there are several variables that may be taken into consideration when engaging with pattern extension activities: the structure of the pattern, the length of the unit of repeat, the number of times a unit appears in a pattern, and if the presented pattern ends in a complete unit of repeat or not. However, these variable all have to do with the repeating pattern. Might there be other variables that need to be considered when requesting children to extend a repeating pattern? Our first question is: Given an extension task and a set of repeating patterns, what are the various ways preschool teachers implement the task? Considering variation theory of learning and that learners may experience objects in various ways (Ling & Marton, 2012), our second question is: What can we learn about children’s patterning abilities from the different implementations?

## Methodology

This study took place within the context of a professional development course for preschool teachers, focusing on patterning for young children. Twenty-three preschool teachers participated in the program. All had a first degree in education and between 1 and 38 years of teaching experience in preschools. The entire program was planned for 21 hours. The teachers met seven times over a period of about four months in the local professional development center in their area. Approximately five of the seven sessions were devoted to repeating patterns with the other two focusing on number concepts. All lessons and tasks were planned by the four authors of this paper.

During the program, teachers were introduced to different patterning tasks as a tool for promoting their mathematical and pedagogical knowledge for teaching patterns in preschool. For the final project of the program, teachers were instructed to choose two of the tasks that were presented and analyzed during the course, and implement and video those chosen activities with one child. Those videos were then analyzed and discussed together in terms of children's solutions. In this paper we investigate teachers' implementations of one task (see Figure 1). Nine teachers (T1-T9) implemented this task, each with one child from their preschool (C1-C9). It is important to note that the task, along with the explicit instructions, was presented to the teachers by the teacher educator, who demonstrated how the task should be implemented. Furthermore, this task was not meant to be an instructive task, but instead an evaluation task in the sense that it was meant to assess children's ability to extend various repeating patterns.

Present the child with one pattern at a time. For each pattern prepare two or three separate containers, each container containing cutouts of triangles, squares, or circles. For example, when presenting the first pattern, place before the child two containers, one with blue squares and one with red triangles. For each pattern ask: What comes next? This question is repeated three times so that in the end, the child will have added three elements to the pattern.

P1      □ △ □ △ □ △

P2      △ ○ □ △ ○ □ △ ○ □

P3      □ △ △ □ △ △ □ △ △

P4      □ △ □ △ □ △ □

P5      △ ○ □ △ ○ □ △ ○ □ △

P6      □ △ △ □ △ △ □ △ △ □ △

**Figure 1: What comes next?**

Note that there are basically three different structures, from the simpler AB, to the more complex ABC, and the even more complex ABB (e.g., Rittle-Johnson, et al., 2013). In addition, the first three patterns end in a complete unit of repeat and the last three do not. In other words, the sequencing of patterns goes from the simple to the more complex.

### **Various ways of implementing the task**

We first note that none of the teachers changed the given patterns. Some variations came about from not implementing the tasks according to the instructions. For example, although teachers were told

to prepare five separate containers for each possible cutout, according to shape and color, and only present to the child those containers which contained cutouts for that pattern, only one teacher actually followed this instruction. Four teachers did separate the elements into five containers according to shape and color, but then kept all of the containers on the table, no matter which pattern was being extended. Four other teachers separated the elements into only three containers according to shape (e.g., putting blue and red squares in one container), and then placed all three containers on the table, no matter which pattern was being extended. Another explicit instruction which was not followed was the sequencing of the patterns. Two teachers did not present the patterns in the order given above. One teacher showed the patterns in the following order: P4, P6, P3, P4, P1, and P2. The second teacher used the following order: P4, P3, P2, P1, P6, and P5.

Some variations in implementation seemed to come about because no explicit instructions were given as to what to say to the child before beginning the task. That is, teachers were instructed to ask for each pattern “What comes next?”, but were not told what to say when sitting down with the child and introducing the task. Six teachers stated at the beginning of the task, as they placed the pattern down on the table, “Here is a pattern.” Five teachers asked the children to say out loud each element from the beginning of the pattern. It might be that the teachers thought that saying out loud the elements would allow children to hear the repetition of the unit of repeat and thus enable the children to pick out the correct next element. For example, at first, T5 did not ask C5 to read out loud each element of the pattern. She told her that there was a pattern and then asked her to pick out the element that should come next. After waiting a bit and seeing that the child sat still and did nothing, she then requested the child to say out loud each element of the pattern from the beginning. After that, C5 continued with the task and picked out the next element (correctly). T5 then continued with this instruction for each additional pattern (and answered each one correctly). Other teachers did not wait to see what would happen, but from the beginning requested that the child say out loud each element. T7 began her interview with C7 by saying, “Let’s read the pattern together, let’s read.” At that point, C7 did not read the pattern but stretched out her arm to take a blue square (the correct element for extending the pattern) from one of the containers and place it at the end of the given pattern. T7 stopped her, despite that C7 chose the correct way of extending the pattern, and said, “No, sweetie. Wait a minute. First, let’s read it.” Three of the five teachers who requested children to read out loud the patterns, and an additional two teachers, asked the child they interviewed to say what was in the containers.

Variations in task implementation also occurred while the child was actively engaged with the task. Some of those variations were queries into why the child chose one or another element. For example, when engaged in the second pattern (P2), one child mistakenly took a blue square, but then immediately switched it with a correct red square. The teacher then inquired, “Why didn’t you put down the blue square and why did you put down the red one?” This type of intervention did not interfere with the child’s performance, but was instead a way for the teacher to listen to the child’s way of thinking. In this case, the child answered, “because here (pointing to the pattern), the square is red.” In other instances, the teacher’s intervention came about even before the child took action. For example, when placing on the table P4 (the first pattern that did not end with a complete unit of repeat) T4 said to the child, “Now pay attention.” After placing on the table the last pattern, T4 said, “Now look closely at the pattern, and also look carefully where it ends.” This type of intervention has the potential to alternate a child’s performance. In this case, despite all these warnings, C4

incorrectly extended all of the last three patterns (those that did not end with a complete unit). Some teachers intervened when the child chose an incorrect way of extending the pattern. For example, when T6 asked C6 to extend P3 (the pattern with an ABB structure), C6 incorrectly added ABA. The teacher then pointed to each element in the unit of repeat and said, “Look closely. Square, triangle, and ...” C6 then responded correctly, “triangle.” Interestingly, C6 had previously extended P2 in an incorrect manner. Although placing the correct shapes to extend the pattern, the child chose incorrect colors. In that case, T6 did not intervene, and instead said, “Good.” Perhaps the teacher was satisfied that at least the child had chosen the correct shapes. However, when it came to placing incorrect shapes for P3, the teacher (T6) intervened.

### Children’s performances

Results of children’s performances on the task, for each pattern, are shown in Table 1 according to structure and if the pattern ended in a complete unit (Comp.) or an incomplete (Inc.) unit. An extension of the pattern was only considered correct if the child successfully extended the pattern by three elements. As can be seen, children performed better extending a pattern that ended in a complete unit of repeat than a pattern which did not end in a complete unit.

Structure	P1 (AB Comp.)	P4 (AB Inc.)	P2 (ABC Comp.)	P5 (ABC Inc.)	P3 (ABB Comp.)	P6 (ABB Inc.)
Frequency	8 (89)	6 (67)	6 (67)	6 (67)	2 (22)	4 (44)

**Table 1: Frequency (%) of successfully extending each pattern (N=9)**

We now address the question of whether different implementations affected the children’s success in extending the pattern. Comparing results of children who read out loud the elements of the pattern before extending the pattern, and those who did not, the relative frequency of success was slightly greater for those children who did not first read out loud the pattern (see Table 2).

	Reads out loud the pattern (N=5)	Does not read out loud the pattern (N=4)
P1 (AB Comp.)	4(80)	4(100)
P2 (ABC Comp.)	3(60)	3(75)
P3 (ABB Comp.)	3(60)	3(75)
P4 (AB Incomp.)	3(60)	3(75)
P5 (ABC Incomp.)	1(20)	1(25)
P6 (ABB Incomp.)	1(20)	3(75)

**Table 2: Frequency (%) of success per variations in reading out loud the pattern**

Regarding the placing of elements in containers, results (see Table 3) indicated that in general, the way the elements were presented made little difference to the children’s ability to extend the pattern. Taking a closer look, for the first three patterns that ended in a complete unit of repeat, there was a higher success rate when the elements were separated by shape and color. However, when the patterns did not end with a complete unit of repeat, there was either no difference or there was a higher success rate when the elements were separated only by shape.

	3 containers separated only by shape (N=4)	5 containers separated by color and shape (N=4)	2 or 3 containers, only necessary elements (N=1)
P1	4(100)	4(100)	-
P2	2(50)	3(75)	1(100)
P3	2(50)	3(75)	1(100)
P4	4(100)	2(50)	-
P5	2(50)	-	-
P6	2(50)	2(50)	-

**Table 3: Frequency (%) of success per variations in containers.**

Regarding other differences in implementations, few affects were noticed. For example, among the six children who were told explicitly before beginning the task that there was a pattern which needed to be extended, three children extended correctly only two of the six patterns; the other three correctly extended three, five, and six of the patterns. Among those who were not explicitly told that there was a pattern (three children), a similar variance in success rates was found. The same variance in success was noted regarding children who were requested to say which elements were in each of the containers.

When analyzing the errors made by children, we found that the most prevalent mistake when attempting to extend a pattern that did not end with a complete unit of repeat was to continue the pattern as if it had ended in a complete unit, i.e., adding the first three elements from the beginning of the pattern. For example, C2 continued P4 by adding a square, triangle, and then a square. Another type of mistake which occurred for patterns both that ended and did not end with a complete unit of repeat, was to continue the pattern with ABAB despite there being a different structure to the given pattern. This occurred for C6 who added BA to an ABC structure, and also an ABB structure. Likewise, C9 continued P6 by adding BABABABA. Another type of mistake was taking the correct shape, but with the wrong color, as was demonstrated above by C2. This last type of mistake was directly related to the way the task was implemented. Obviously, if only the correct colors of shapes would have been on the table, this type of mistake could not occur.

## Summary and discussion

As part of the professional development program, teachers were supplied with the materials for implementing the repeating pattern task. They were given laminated strips of paper with the patterns printed on them in color. They were given the matching pictures of colored squares, triangles, and circles to be cut out and placed in containers. They were even told what to ask each child. Yet, many variations occurred when implementing the task. Some of the variations occurred in the setup of the task, specifically with placing the elements in containers. Some of the variations occurred in the midst of implementing the task. When reflecting with the teachers on their implementations, it became apparent that these variations occurred spontaneously, without planning for them ahead of time. And yet, several of the teachers had the same ideas, such as having the children read out loud the pattern. Knowledge of tasks includes knowing the affordances and constraints of that task (Watson & Mason, 2006). It could be that the teachers saw this task as affording the opportunity to

review with the children names of two-dimensional figures. According to Zaslavsky (2008), teaching tools include not only materials, but other kinds of resources, such as language and time. It could be that teachers were incorporating the tool of language into this given task, having children say the names of the shapes in the pattern. It could also be, similar to other studies (Stein, Grover, & Henningsen, 1996) that teachers were attempting to lighten the cognitive load of the students by telling them that there was a pattern and having them say out loud the names of the shapes which repeated themselves. In any case, as teacher educators it is important to be aware that teachers may implement a given task in various ways. In fact, in our program, the teachers brought the videos of their implementations back to the program, and as a group, we viewed them together. This, in turn, enhanced the teachers' knowledge of tasks, including their knowledge of the way children engage with repeating patterns tasks.

Despite the variations in implementations, most of the outcomes were consistent with previous research. For example, children had greater success when extending patterns which ended in a complete unit of repeat than those which did not (Tsamir et al., 2015). Children in this study made similar errors as children in other studies, such as extending an ABB pattern with ABA (Rittle-Johnson, et al., (2013). Can we conclude then that variations seen in this study had no impact? Certainly, a study with nine children is not enough to make such a conclusion, but it does leave us with an interesting question. How come the variations seen in this study (e.g., telling the children that there was a pattern, reading out loud the elements of a pattern, placing the elements in various containers) did not seem to impact on children's performance? The answer to this question perhaps lies in acknowledging the essence of repeating patterns, which is the unit of repeat and its structure. None of the variations in implementations focused the child on the unit of repeat. What seemed to impact on results was the complexity of the structure as well as if the pattern ended in a complete unit of repeat. By reviewing these results with preschool teachers, noticing the variations as well as the little affect they had on children's performances, we strengthen teachers' appreciation for the structure of a pattern, and promote their knowledge for teaching repeating patterns in preschool.

# Teaching intervention for developing generalization in early childhood: The case of measurement

Marianna Tzekaki and Evangelia Papadopoulou

Aristotle University of Thessaloniki, Greece; [tzekaki@auth.gr](mailto:tzekaki@auth.gr) and [evanpapado@sch.gr](mailto:evanpapado@sch.gr)

*Abstraction and generalization, lying at the heart of mathematical activity, attract the interest of many researchers who mostly examine generalizing processes in patterns and algebra. Given that earlier approaches questioned the possibility of developing generalizing capabilities in early ages, in our research we attempt to examine if an appropriate teaching intervention could change this initial assumption. For the needs of this work, 23 preschoolers participated in a seven months teaching intervention with relevant tasks in various topics: figures, patterns, measures and numbers. In this paper only for length measurement is presented. The children were pre and post examined in tests designed to examine their knowledge and initial generalizing abilities in this topic. The results indicated that their long-term involvement helped these young children to improve their abilities to (a) reflect on their own activity, (b) express their ideas and (c) reach to some concluding remarks, first related to their own personal experiences and later to more general thoughts.*

*Keywords: Generalization, abstraction, measurement, early childhood, teaching intervention.*

## Introduction

A 6-year-old child saying, “When two distances begin and end together, this does not mean they are equal, we need to measure them....” shows a preschooler able to express in a more detached from his/her experience and general way a relation concerning length comparison. This reveals a generalizing ability that, lying in the heart of mathematical activity, attracts the interest of research in mathematics education.

Current studies related to generalization and generalizing processes concern mainly patterns and approaches in algebra for older students (Hitt & Gonzales-Marin 2016; Warren, Trigueros, & Ursini 2016; Zazkis, Liljedahl, & Chernoff, 2008; Lannin, 2005), while relevant investigations of younger children’s generalizing abilities also are connected to patterns and structures (Mulligan & Mitchelmore, 2013).

In our study we attempted to explore generalizing skills in early ages. More specifically, our research question focused on whether an appropriate teaching intervention could support young students’ disposition related to noticing properties, relations and structure and developing a first level of more general conclusions. Our research supports the efforts for a meaningful and effective early mathematics education, by accepting generalizing abilities as an important component of it.

## Abstraction and generalization

Humanity starts dealing with ideas related to abstraction and generalization quite early, pursuing answers related to the development of concepts in human’s mind. Similarly, psychologists systematically investigated abstraction and generalization, as integral parts of humans’ conceptual formation, supporting, thus, many explorations in mathematics education. For mathematics, *abstraction* is considered as a process during which students directly reorganize former structured

mathematics in a new mathematical structure (Hershkowitz, Schwarz, & Dreyfus, 2001). This process (as part of the generalization process) has been studied by many researchers. We could underline the advances of Dubinsky (1991) and APOS, Sfard (1992) and the theory of reification, Hershkowitz, Schwarz and Dreyfus (2001) and epistemic actions, as well as a variety of combinations of these approaches (Tzur & Simon, 2004).

*Generalization* could be identified as the level at which students, starting from specific situations, proceed to more general ideas and conclusions identifying patterns, structures, relationships, rules etc. (Kaput, 1999). Similarly the idea of generalization, as an integral part of mathematical development, holds an important place in mathematics education. Starting from Harel and Tall (1989), Tall and Vinner (1981), Fischbein (1993), Bills and Rowland (1999), Radford (2001), Becker and Rivera (2003) and Sriraman (2004), many researchers have proposed models regarding theoretical approaches for this conceptual elaboration. These models refer to concept formation (as important stage of generalization), reflection and communication (as important reason for generalization), different kinds of generalization (extension, reconstruction, disjunction/ results and process of generalization), elements of generalization (grasping and expressing) and generalization as objectification (factual, contextual, symbolic).

As mentioned earlier, most of this research is related to generalizing processes in patterns and algebraic elements, and certainly examines these processes in older students. Their findings can be organized in the following strands: generalizing abilities, generalizing procedures and strategies, teaching intervention aiming at improving generalizing skills. Related to *generalizing abilities*, Yeap and Kaur (2008) studied structure and pattern recognition with the use of heuristic tools and technology as well as the development of metacognition and critical thought. Related to *teaching intervention*, Zazkis, Liljedahl and Chernoff (2008) investigated the use of appropriate examples and tasks.

The elements or actions and elaborations that consist the integral parts of generalization cannot be defined so easily. However, elements such as reflection of action and expression of more generalized properties, rules, relationships and structures deriving from specific tasks, problems and practical experience could be identified as being essential in this conceptual elaboration and are placed in the center of students' mathematical development. Therefore, mathematical education needs to cultivate these skills from early ages and progressively improve them in the course of mathematics education.

Starting from this basic question, our research aimed at examining (a) the possibility of developing generalizing capabilities in early childhood, and (b) teaching interventions that could improve these skills in young children. Our wider research concerns teaching and findings related to four topics of mathematics curriculum: geometric figures, patterns, geometric measurement and numbers. In previous communication (Tzekaki & Papadopoulou, 2016) we presented results concerning geometric figures and numbers, while in this paper we are limited to data related to geometric length measurement. We believe that the most interesting part of this presentation is not exactly the specific topic but the development of generalization capabilities in 5 years old children.

## **Measurement and generalization**

Measurement is an important every day activity, that mathematically connects geometry and numbers, but its approach is not so evident in early years or even later (Bragg & Outhred, 2004).

Length measurement can be identified as a procedure that divides a continuous magnitude of an object to a number of specific parts (units) and connects it to the number of iteration of these parts. Thus, the conceptualization of length measurement could be analyzed in *several steps* that demand understanding and generalization (Battista, 2003):

1. Identification of length as a special (unchangeable) attribute of an object.
2. *Transfer* of this attribute to another object (intermediate).
3. *Comparison* of lengths by means of intermediate (arbitrary or conventional).
4. *Covering* with different equal units (arbitrary and conventional) and quantify this covering.
5. Connecting unit iteration (and thus measurement) to a number (Sarama & Clements, 2009).

Our research related to length measurements examines whether young children succeed to understand and express different generalized ideas for three of these steps: transfer, comparison and covering. More specifically, *generalizing levels of each of these measurement steps* was expressed and examined, both as *procedure and relation*, as following:

- *Generalization related to the transfer of a length to an intermediate* (2) means that children could identify the equality of the lengths of objects and intermediates.
- *Generalization related to the comparison of lengths (or distances) by means of intermediate* (3) means that children could identify the starting and ending points of objects and intermediates and the equality of their lengths.
- *Generalization related to covering with different units* for the needs of a measurement means that children could understand the role of equal units, the different quantification when the units are different and the role of numbers in the procedure of measurement.

Children's explanations both in tests and in classroom interchanges during the teaching intervention were classified according to this analysis.

## Methodology

For the needs of this research related to length measurement, 23 preschoolers participated in a three weeks teaching intervention with relevant measurement tasks. There were also pre- and post examined in tests specially designed to examine their knowledge about measurement and their generalization level, before and after the intervention.

### Pre and Post tests

The tests items in length measurement included four (4) items in accordance to the aforementioned analysis:

1. *For the transfer of a length*, a real object (for example a frame) hung on a specific height on the wall had to be transposed to another place.
2. For the *comparison of lengths*, cards of different width and height had to be ordered (their dimension were changing inversely, the thinner was the taller, and the thicker was the shorter).
3. *For covering with different units and comparison* there were two items: the children had to compare *unequal distances* in zigzags with common starting and ending points drawn on worksheets and

covered *with equal units*, as well as *equal distances* in zigzags with common starting and ending points, but covered *with different* (non equal) *units*.

Two of the items concerned lengths, while the other two distances. Also, two of them were real situations with material while the other two were representations of comparison situations. The children were individually interviewed on these tasks and were questioned about their reflections and conclusions. Their answers were organized in the following stages.

1<sup>st</sup> Stage: The child does not express any procedure or relation related to measurement.

2<sup>nd</sup> Stage: The child starts with a holistic measurement approach of procedure or relations that can explain his/her doing, e.g. transferring an object a child says “*I thought to put it in the same height..*” showing an imaginary line with his hand.

3<sup>rd</sup> Stage: The child starts conceptualizing length measurement and can explain the procedure presenting some relations, e.g. comparing distances in zigzags by means of batons, a child says “*for this side* (showing the starting point) *they are the same, but from the other side* (showing the end) *this one* (showing) *looks longer...*”

4<sup>th</sup> Stage: The child starts conceptualizing the measurement as iteration of units and can explain almost the whole procedure and relations, e.g. comparing distances in zigzags by means of matches, a child explains “*this one is longer because it has 1,2,3,...,6 matches and the other has 1,2,3,4 matches...*”

5<sup>th</sup> Stage: The children explain all the relations that are needed for the measurement, e.g. comparing also equal distances in zigzags by means of matches, a child explains “*they start together and end together and have the same number of matches*”.

### Teaching intervention

After the pre-test the children were involved in “generalizing experiences” concerning length measurement. They first worked with relevant measurement tasks in groups and then presented their results in the whole class. The teaching intervention consisted of five (5) lessons with eight (8) tasks. The tasks concerned all five steps of length measurement (length/distance - width – height, presented earlier) with

- Length transfer, *direct and indirect comparisons* and estimations.
- Indirect comparisons by means of *arbitrary of conventional units* (unit covering and number assignment).
- Indirect comparison by means of *conventional units with iteration* and number assignment.
- Length and height measurement by means of meter.

Tasks with *length transfer* proposed the use of batons or strings to measure, for example, the height of the position of a frame that has to be hung on a different wall. *Indirect comparisons* suggested covering with meters or other convectional units to measure and compare, for example, itineraries in stories or dimensions of furniture. Similarly, other *comparisons* presupposed the iteration of units for these measurements or comparisons.

The most important part of this intervention was the closure of activities, when children were systematically encouraged (a) to identify common characteristics, relationships and properties in the different encountered situations, (b) to express more general ideas and (c) to formulate conclusions or other overall rules about length measurement.

The discussion and the generalizing questions aimed at the understanding of measurement procedure and its principles and, more specifically, of the equal partitioning of the continuous attribute of objects, the unit iteration and the equality relations (with starting and ending points).

## Results

The results coming from the comparison of the pre and post tests indicated that, after a series of tasks and systematic discussions, young children were able to improve their abilities to reflect on their own activity, to express their ideas and reach to some kind of conclusions, initially ‘locally’ related to their own personal experiences or the specific task (e.g. way of doing it) and later to a more general level regarding mathematical ideas (e.g. whether are equal or nor) or even formulating a rule or proposition (e.g. to measure two distances we have to...).

### Findings related to measurement: Pre and post tests

The *pre-test findings* indicated that children initially didn't recognize the procedure of measurement, but approached comparisons globally and estimated lengths and distances based on their own experiences. For example, comparing distances covered with batons they didn't count the number of batons but based their responses on personal judgments of closeness. Their justifications were idiosyncratic, practical or kinesthetic, e.g. “*because I think so...*”, or “*This line is bigger because in this place there is only one animal, so the thunderbolt killed more...*”. They ordered objects based on their figure, while they covered them with units that were overlapping or had gaps. They understood that there was an equality or inequality of dimensions, but explained it based on morphological elements, e.g. “*it is more pointy...*”.

The analysis of children's responses *after the intervention* indicated a significant improvement regarding the identification of the procedure of measurement, as they did successful measurements and explained their actions based on measurement principles. They identified the iteration of units (with no overlapping and gaps) explain e.g. “*we don't put the sticks as we like, but one after the other, watching that they are not overlapping...*”. They were able to order objects based on metrical characteristics (length and height) and explained the measurement they have done. The children's improvement is illustrated in the following table (Tab. 1).

<i>Issues of Tests</i>	<i>Success pre, %</i>	<i>Success post, %</i>
Transfer of heights	0	87,5
Comparison of weights and heights	33,33	66,66
Comparison of unequal distances (in crooked lines) by means of batons	29,16	95,83
Comparison of equal distances (in straight lines) by means of matches	0	66,66

**Table 1: Results before and after the teaching intervention**

## Students' conclusions related to measurement

Examining the children's answers to the interviews and the records from their work in the classroom, we can support that the preschoolers are able to conceptualize length measurement and its principals and moreover describe it, as procedure and relations at a more general level. The following examples present the ideas developed by the young children and the level of generalization achieved after involving in generalizing exchanges. At the end, the teacher gathered the children's conclusion about measurement in drawings and utterances.

The children's utterances expressing their concluding remarks about *the transfer of heights*:

- *We must measure one distance before doing the other*
- *The two distances must start from the same point*

The children's utterances expressing their concluding remarks about *covering with units*:

- *It shouldn't be one over the other and crooked*
- *We don't leave gaps, we put start to start and back to back*
- *We put them in a line*

The children's utterances expressing their concluding remarks about the *measurement of distances*:

- *When two distances are straight and start together and end together, then they are equal*
- *When two distances are zigzag and start and end together, it doesn't mean that they are equal, we have to measure to see which one is longer and which one is shorter*
- *When two distances are zigzag and don't start and end together, it doesn't mean that they are not equal, we have to measure them.*

## Discussion

In general, this study shows that the development of generalizing capabilities in early childhood is possible on the basis of appropriate teaching approaches that encourage reflection, activity justification and concluding communication. The development of these abilities depends generally on a modification of young children's focus from personal to 'impersonal' ideas, and, thus, from 'local' to more general as a way of functioning in the mathematical class. This development was observed and recorded in all topics: figures, patterns, measurement and numbers (Tzekaki & Papadopoulou, 2016).

The development of children's ideas and generalizing remarks reaffirmed the importance of teaching approaches that orient the class to generalizing experiences (Sriraman, 2004). More specifically in the identification of the measurement procedure and relations by the children, their utterances showed that they succeeded to overcome the specific content of the tasks and proceeded to the conceptualization of measurement principles and invariants (Bills & Rowland, 1999). The children passed gradually from local generalizations related to every one of their actions and tasks to more general related to all their activity and finally to general principles of the measurement that recorded in the specific for their age way. The choice and the sequence of tasks, the group work in the classroom and the exchange between groups aiming at arriving systematically to more general remarks are the main factors that led to this result.

The findings gathered from this topic, as well as from all other topics, justify why it is possible but also of imperative to exercise children from early age, with appropriate activities and elaborations with respect to their age and their way of thinking, to generalizing skills as significant part of their mathematical development (Tzekaki, 2014).

*In this work we recognise how a group of future teacher of Early Childhood Education, analyse narratives about rich school experiences. We presented a professional task, in which we wanted to see how future teachers recognize initially the potential of the mentioned experiences to promote mathematical processes. We recognise that future teachers give a limited value to the problem-solving process and have difficulties in recognizing the processes of reasoning and proof. We found it is not because of a mathematical previous weak formation, but rather it points to the need of analysing school practices and narratives as good examples of action.*

*Keywords: Early childhood, future teachers, mathematical reasoning, problem solving.*

### Introduction

NCTM (2000, 2013), as other new national curricula, suggested that teachers could design better rich school activities, if they can identify the power to develop mathematical processes in their classrooms. In Spain, authors like Alsina (2014), pointed out that to achieve a quality of mathematics education for early years, it is important to implement curricula focusing on mathematical processes in a systematic way. It is important for the teaching and learning of mathematics to use mathematical models in relevant everyday contexts.

Preservice teacher's mathematical knowledge plays an important role when teaching mathematics. It is clear that for early years, almost no one remembers about his own experience. Therefore, their knowledge for teaching at early years is limited, and based upon personal theories and preconceptions (Jaworski & Gellert, 2003). "Little improvement is possible without direct attention to the practice of teaching ... [h]ow well teachers know mathematics is central" (Ball, Hill & Bass, 2005:14). In this paper, we assume that narratives are a wonderful way to allow students to personalize mathematics (Kurz & Bartholomew, 2013) and develop mathematical knowledge. In such a framework, the use of narratives is a powerful tool for teacher professional development and an useful research methodology for those interested in the study of teachers, teaching and teacher development (Ponte, 2001).

Llinares, Fernández, & Sánchez-Matamoros (2016) pointed out that for teacher education purposes, it is important to promote that future teachers (FT) grow on mathematical understanding by noticing mathematical aspects when future teachers analyse school experiences. It is also important for FT to know about designing rich practices. What about Early Childhood Education? In some countries as Spain, there is a global curriculum for Kindergarten, without any explicit mathematical goals for children's mathematical knowledge. Therefore, FT must have a preparation to understand the emergence of mathematical objects and processes from good early school practices. In the case of Spain, it is difficult to involve FT in implementing designed tasks, as it is for continuous training. There is a danger when considering the practice of teachers, and therefore presumably the experience of learners, of focusing exclusively on pedagogic practices, without reflective processes (Shulman, 1986). It seems to be the main reason for the need of mathematics reflective activities for prospective kindergarten teachers. In this presentation, we want to analyse the initial position of future teachers

when they analyse narratives about school experiences, in order to find how they relate the richness of school actions and the emergence of mathematical objects and processes.

## **Theoretical framework**

As Ponte (2001) wrote, we use teacher narratives as a way to represent a school experience for oneself or for others. A narrative involves three basic elements: i) a situation involving some conflict or difficulty, ii) one or more agents that act on that situation with their own intentions, and iii) a temporal sequence of related events in which the conflict is resolved in a certain way. It involves people, settings, and events that take place in a given time. The acceptance of a story is oriented by convention and by “narrative necessity” (Bruner, 1991). In pre-service teacher education, narratives such as these provide good starting points to discuss issues faced by a teacher in making curriculum decisions and conducting classroom instruction. Some authors, like Chapman (2008) and Ponte (2001), mainly use narratives to reflect on future mathematics teachers’ thinking and actions in relation to mathematics and mathematics teaching and learning, aiming to broaden their understanding of new curriculum orientations.

In this paper, we use narratives to study teacher’s knowledge when analysing innovative teaching practices (Ponte, Oliveira, Cunha, and Segurado, 1998). In the current study, we focus on identifying, planning and enriching mathematics practices, made by others. We consider such activity as a fruitful starting point for inquiring into how FT should anticipate the enactment that will occur. Some future teachers of early childhood want to know and copy nice school experiences. Instead of this, this research leads to understand that richness of a school activity relates to the possibilities for emergence of mathematics objects and processes. Our aim is to recognise the initial reflection of future teachers about the emergence of mathematical objects and processes, as a noticing professional competency (Jacobs, Lamb & Philips, 2010). In this presentation, we focus on the analysis of problem solving processes, and analysis of the reasoning and proof processes. We assume that the practices in reading, analysing, and discussing narratives generate a number of insights that provoked to modify future teachers’ planning for instruction. Many studies have reported that narrative data helps to validate the learning results as a basis for understanding of human actions (Polkinghorne, 2007), and to understand the role of intentionally drawn school practices (Font, Godino & Gallardo, 2013).

## **Methodological issues**

We use a qualitative, naturalistic research perspective (Creswell, 1998) focusing on capturing and interpreting the participants’ thinking about narratives as a case study. To achieve our aim, we designed a professional task. The professional task is structured in two parts. In the first part, FT are asked to read two articles: “The map of a treasure” (De Castro & Escorial, 2006) and “Where is Paula?” (Feixes, 2008). These articles describe two school experiences about geometrical itinerary aspects and spatial references, made with children of 5-6 years old. We select these two narratives because they describe rich (Woodham & Pennat, 2014) and high quality (NAEYC & NCTM, 2002) of school experiences for children from 3 to 6 years of age. Both school experiences use a continuous dialogue in the classroom. They also explain didactical orientations to planning and managing activities, connecting geometrical objects and processes. During the first experience, the idea is to promote a problem solving approach to “know about” the space of the school, as a provocation to find the place where a treasure is. Children spontaneously use paper and pencil itineraries, written codifications, and gestures to discuss in groups how to go from one point to another among other decisions. During the second experience, the teacher proposed to talk with Paula (a child that left the school to come back to her country, Uruguay). The five years-old children immediately ask where Paula is. A nice discussion about at what time do we call her, helps the children to discuss how the difference of time relates to the difference places in Earth, and different hemispheres. Our interest in

choosing these two narratives is to look at two sides of the problem of situating points in the real world space: the local or short distance problem (narrative 1) and global world problem (narrative 2).

In the second part of the professional task, four questions are posed to guide the analysis of the two narratives read in the first part. These questions are: 1) Talk about what raise your attention after first reading. 2) If you should recommend to your teacher friends these experiences, what do you explain for them? 3) What is the role of the teacher in both experiences? 4) Why do you think there are rich practices that develop the emergence of children's mathematical thinking?

The participants in our study are 33 FT of Early Childhood Education at the Barcelona University. To describe how they explain the emergence of mathematical objects and processes in the two narratives, we collect all the individual responses to the questions proposed in the second part of professional task. To analyse the data, we used a tool raised by Coronata & Alsina (2014). This tool includes five categories that correspond to the five mathematical processes proposed by the NCTM, (2000). For each of these categories, 6-7 indicators are provided for evaluation. In our study we only consider the indicators of problem solving and indicators of reasoning and proof processes.

The analysis takes three moments: a) The research team answer as experts giving a set of the processes observed; b) the future teachers' answers are analysed by using the methodological tool cited above; c) the research team explain some hypothesis about why the results appear. We assume that some text is related to one or more indicators, if there is a sentence evocating such principle by means of discursive argumentation (Gee, 2014). General sentences are not considered. For instance, the sentence "The teacher develop the capacity of creating arguments to explain children's curiosities in reference to mathematical concepts as distance, space and time" is assumed as relating to an indicator of reasoning and proof. But a sentence like "It is considered the interest of children" is not assigned to the indicator, because it is a fuzzy simple comment without any explanation given to what is the text or mathematical idea in the narrative.

## Results

Many mathematical objects are easily identified by almost all the FT, but it is not enough explained how these objects emerge from the examples given in the narratives. In general comments, many FT talk about the differences among space by using time, and the idea of having different periods in a year. They talk about the meridian as a reference for timing. They assume the need of codes in order to represent itineraries among other geometrical objects.

Many FT also consider that problem solving is a common framework in both school experiences, but they explained some of the mathematical processes superficially (See Table 1). We find that future teachers identify issues related to problem solving more easily than other processes, and have difficulties in explaining aspects related to the processes of "reasoning and proof".

In Table 1, we associate examples of the responses made by FT to each indicator and we include an expert comment when FT identify problem solving process in the narrative 1, as an example of the use of indicators for problem solving. Some FT tell us that children's participation in narrative 2 stimulate imagination and creativity. Nevertheless, we only observed two out of 33 FT on where is it possible to see such promotion of creativity as an inquiry problem solving process.

The main indicator found is related to the assumption that contextualisation plays a role in problem solving activity. Nevertheless almost a half of the students write sentences in which FT talk about problem solving without any explicit indicator

In some cases, as FT14 and FT 24, they do not express any sentence about contextualisation and interest. We also see that 27% of the FT talking about mediators and interest are the same as those

who talk about contextualisation. It is possible that the lack of processes recognised relate to the mathematics background of the FT.

Indicators	% FT n=33	Examples of FT's responses	Responses from experts
Questions generate inquiry and exploration	6%	<i>"Helps to develop math thinking... Formulate questions, hypothesis, to find answers, explanations..."</i> (FT 3) (FT 6)	"Where is Paula" is a challenging starting question. Teacher promotes exploration when asking for information at home about time zones
Propose open problems	--	--	The teacher use children's open (non easy) proposals to analyse cultural influences about spatial relations
Contextualise in familiar contexts	52%	<i>"learn from the surrounding environment"</i> (FT 2)	The teacher contextualise to travelling problems to see what is invariant and changing in different positions
Promote discussion and participative debate	3%	<i>"contrast and reveal with different representations as figures, pictures or the use of dialogue the different knowledge"</i> (FT25)	The teacher promotes discussion about the need of comparing points and itineraries in the space, the use of references
Maintain the interest and curiosity	13%	<i>"...From the beginning, through their (children) questions we observed that is of its interest"</i> (FT2) <i>"children achieve different learning from curiosities"</i> (FT7) similar (FT9)	The school teacher focus on a lived experience to base a set of continuous problems related to the use of images to solve the problems
Use different type of mediators when solving	30%	<i>"The maps used by children are different from those done by adults"</i> (FT 9) <i>"...It is a dream...to know about now it is early morning..."</i> (FT 24)	Children construct and read maps in big spaces with the Earth globe as a powerful semiotic mediator. It emerges the idea of meridian line as a reference. The experience itself has an emotional background.
Reinforce the process using different support	6%	<i>"...using trial and error, children structure math knowledge..."</i> (FT14)	The teacher promotes the use of the starting situation to promote the use of spatial relations and references

**Table 1: Responses associated to the indicators of problem solving process (narrative 1)**

We can see that the FT do not relate some verbal aspects as discussing as a part of the problem solving process for narrative 2 (See Table 2). They realise that contextualisation is the main aspect behind problem solving activity for having good answers. It is expected that the FT talk about the role of mediators in this initial moment of analysis, but the justification they give is very limited focusing on having a "meaningful task" without any relation to a specific mathematical knowledge. They talk about "learn from the surrounding environment" without explaining that the need of a reference line (Greenwich Meridian) appears when we have numbers to indicate points in the space (initial idea of geographical coordinates). This could indicate a rather weak mathematical background of the FT, and the need for having a professional reflection about what mathematical knowledge emerge from a mathematically interesting activity like this. Precisely, this is the role of training process and professional activity never done before. The results show that narratives help to focus the reader's attention for recognising more mathematical connections (distance/speed; codification/itineraries; real world/representation) than expected.

Indicators	% FT n=33	Examples of FT's responses	Responses from experts
Questions generate inquiry and exploration	6%	<i>"build hypothesis, elaborate representations"</i> (FT3)	The teacher promotes different strategies as situating, identifying, recognising, building hypothesis
Propose open problems	--	--	There are open strategies, but no open problems
Contextualise in familiar contexts	36%	<i>"To know what is a map, which is its use"</i> (FT4) <i>"...The problem promote meaningful knowledge"</i> (FT3)	The context of "find treasure" help to identify the role of registers when solving itinerary problems.
Promote discussion and participative debate	9%	<i>"...and the colleagues were able to decode the information"</i> (FT9)	The dialogue gives challenges for coding/decoding processes
Maintain the interest and curiosity	3%	<i>"Children take and search at home more different maps ... helping the comprehension and motivation"</i> (FT4)	The use of a school as a milieu, and the aim of arriving to a treasure, ensure interest and give opportunities for maintaining interest as a long job
Use different type of mediators when solving	15%	<i>"The maps done by children were functional, ...they served for the purpose of representing a space indicating the place of a treasure"</i> (FT9)	The maps, are used to identify itineraries, distances, directionality

**Table 2: Responses associated to the indicators of problem solving process (narrative 2)**

It is difficult to find explicit children's arguments and reasoning in the narrative of "Where is Paula?" In fact, the teachers tell us many sentences (as "we always ask why") about the use of argumentation and reasoning, without explaining all the details. Nevertheless, in the children's pictures we can observe that they talk and argue when they observe the Earth globe, or when they talk about "Uruguay is far away". We only find general statements about reasoning and proof as we can see in Table 3 and Table 4.

Indicators	% FT n=33	Examples of FT's responses	Responses from experts
Helping to develop student's thinking	12 %	<i>"Children structure their mathematical knowledge"</i> (FT 13).	The Teacher promotes reflections and arguments about the invariance of day/month/year but different time and season, by seeing to the Earth globe.
Inviting to explain conjectures	6 %	<i>"The need to have good questioning"</i> (FT4) <i>"revealing initial ideas and preconceptions"</i> (FT 16)	The practice promotes to use arguments relating conjecturing about the need for having time references
Promoting to control conjectures	3%	<i>"to establish hypothesis to understand zones having the same time...to understand why it happens in the world... and which are the lines that make the difference, when situating places in the map"</i> (FT 16)	The teacher promotes some deductive reasoning. To argue, Bernat uses if...then as a deductive reasoning. Describes the relation between numbers (+1) and going to the right. Also (-1) means going to the left.
Questioning to evaluate arguments	3%	<i>"...develops the ability to create arguments explaining the concerns of children which refer, in this case, to space and time (FT 1) "being aware of time and its difference"</i> (FT 17).	The teacher promotes adjusting variables and control validity when talking about "that fit with those from other sources as it is the case of having information about time zones"
Promote reasoning by giving feedback	--	<i>"...the children in both experiences offer the possibility to establish arguments and generating hypothesis"</i> (FT 9).	Teacher promotes inference levels of spatial reasoning: What it is possible to see; what I see without specific attention to particular students
Promoting divergent thinking when arguing	3%	<i>"Permits the children to observe, to explore, and to determine what is more important or less..."</i> (FT 16)	Promoting children arguments about why do we say "Uruguay is far away" The need of relating two points in the space. The need of having a global view to understand it, by arguing that the flight is long (according time)
Promoting discoveries, analysis and arguments	6%	<i>"About the project...it pays my attention the amount of information that children can draw (extract ideas and conclusions) from the maps....arriving to conclusions that children assume as the best and right"</i> (FT2)	The teacher promotes the need of connecting children's surprises to math or science knowledge (children see Paula as summer dressed)

**Table 3: Responses associated to the indicators of reasoning and proof process (narrative 1)**

Clements & Sarama (2009), tell us about the need for promoting reasoning since early years, however, FT in the research do not identify the amount of possible quotations in the narratives relating reasoning and proof. We observe that, in general, many of the future teachers do not offer specific mathematical examples from the narratives to illustrate the reasoning and proof processes.

It is surprising that inquiry attitude not seems to be considered as part of a problem solving process, perhaps because FT have the belief that the most important for a problem solving is to have a right solution. In fact, many of the future teachers' comments do not pay attention to the role of the teacher giving opportunities for continuous problem posing moments, promoting hypothesis and conjectures. The FT explain that the teacher in both narratives promote the use of arguments, but none of the FT mentions the importance of feedback.

Indicators	% FT n= 33	Examples of FT's responses	Responses given from experts
Helping to develop student's thinking	15 %	<i>"In this practice... the teacher ask questions to influence children's reasoning, to improve their thinking"</i> (FT 19)	The teacher tell us explicitly the use of the students' natural environment to promote spatial thinking
Inviting to explain conjectures	3 %	<i>"The teacher tries to improve autonomy to reflect, to produce hypothesis about the ways of coding"</i> (FT28)	The teacher promotes the emergence of Students' conjectures about maps and big distances o represent travelling by using descriptions.
Promoting to control conjectures	6 %	<i>"The teacher permits that children explore information given by the maps, and select which information is relevant and which one is not"</i> (FT 19)	The teacher tells about reflections and argumentation, but it is not explicit how the teacher controls the conjectures, because the focus is the codification process.
Questioning to evaluate arguments	6 %	<i>"Sharing and contrasting</i> (FT 17) <i>"Discussing about his or her discoveries"</i> (FT 23)	They discuss to have a common result, but different representations and evaluate the representation used
Promote reasoning by giving feedback	--	--	The teacher find that David, use a comparison (small globe vs big Earth) to reason that from Madrid to Lanzarote you must use a flight.
Promoting divergent thinking when arguing	--	--	The teacher promote that Children adjust their arguments about which objects must be in the map, where to place and how to represent them.
Promoting, analysis and arguments	6 %	<i>"...revealing initial ideas and preconceptions"</i> (FT 16)	The teacher promote the emergence of Students' ideas (Luke : Itinerary as a set of steps; David what we can learn from Earth globe

**Table 4: Responses associated to indicators of reasoning and proof process (narrative 2)**

After this professional task, we devote some time for collective reflection not detailed in this paper. Some new processes appear as: "The teacher drives arguments, and promotes different possible contents and meanings" (FT 19) or "by dialoguing, the teacher gives immediate answers to students, reinforcing children's knowledge about coordinates" (FT 16), or "Children almost prove their conjectures, in a way that surprises us" (FT 9).

## Conclusion

Future teachers are able to identify many mathematical objects and some processes implicit in the narratives analyzed. We see less process than it was expected. The main one is problem solving. The analysis promoted by the two professional tasks has allowed us not only to characterize some aspects of professional noticing of the future teachers, but also to establish a basis for recognizing the role of mathematical discourse (Adler & Ronda, 2015). In fact, after the implementation of the professional task, we find a more structured discourse of future teachers, more connections, didactic arguments, recognition of a greater number of processes and more justifications. With this research, we enlarge the conjecture done by Llinares et al. (2016) that noticing also promote deeper subject-matter understanding of pre-school's future teachers. Therefore, we consider that the implementation of this type of tasks is relevant in the training of future teachers of early childhood education.

Finally, it stands out that discussing and reflecting on school narratives such as those presented here has allowed future teachers to contrast school practices, different from those they have traditionally observed giving mathematics knowledge improvement.

# Early years mathematics learning – Comparing traditional and inclusive classroom settings

Andrea Peter-Koop and Miriam M. Lüken

Bielefeld University, Faculty of Mathematics, Bielefeld, Germany

[andrea.peter-koop@uni-bielefeld.de](mailto:andrea.peter-koop@uni-bielefeld.de); [miriam.lueken@uni-bielefeld.de](mailto:miriam.lueken@uni-bielefeld.de)

*Keywords: Early years mathematics, inclusive education, assessment.*

## Introduction

Following recommendations by the UNESCO, an increasing number of primary and secondary schools in Germany take on children with special needs, who were traditionally taught in special education schools, and include them in their classrooms. One organizational approach is to place the children with special needs in one class and provide a teaching team consisting of a primary teacher and a special education teacher for this class during the majority of the lessons. The study reported in this poster seeks to investigate the mathematics learning of four parallel classes during their four years of primary school in Germany. While three of these classes are taught in the traditional way with one teacher responsible for (mathematics) instruction, the fourth class is taught by a teaching team.

## Theoretical background and research interest

Studies on the learning of children with special needs in inclusive compared to exclusive settings (i.e. in homogeneous groups predominantly in special education schools) in Germany, Austria and Switzerland suggest that children with special needs with respect to their school learning frequently underachieve when taught in special education schools (Wocken, 2005). Children with special needs who attend regular schools with inclusive classrooms, in contrast, demonstrate significantly higher achievements (Dessemontet et al., 2011). Already in 1998, Feyerer, who had reviewed findings from studies on inclusive learning, concluded that children without special needs taught in inclusive classes in regular schools showed at least the same, and sometimes better achievements than their peers in traditional settings. Klemm and Preuss-Lausitz (2012) in their meta analysis of more recent studies in inclusive classroom settings found that children with special needs in inclusive classes demonstrate higher cognitive gains than their peers in special education schools, while both, children with and without special needs, who are taught in inclusive settings demonstrate substantial gains with respect to their social skills. However, none of the studies conducted in this context explicitly looked at achievement in mathematics.

## Methodology

The longitudinal study (2015–2019) reported in this poster compares the mathematics learning and achievement as well as the social and emotional school experience of four parallel mathematics classes ( $n = 100$ ) of one primary school over their four years of primary school education. Three of the classes are taught in the traditional way with one primary teacher being responsible for mathematics instruction, while one of the four classes is taught by a teaching team consisting of primary teacher and a special education teacher. Included in this class are four children with special needs. Children's mathematics learning is measured using the task-based Early Numeracy Interview (ENI) and associated Growth Point Framework (Clarke et al., 2002) that was first developed in

Australia and then translated and adapted to the German curriculum (Peter-Koop et al., 2007). Over the four years of primary school the ENI, which involves individual interviews, is conducted five times, i.e. at the beginning of school and at the end of each school year. In addition, a standardized test on primary children's social and emotional school experiences, FEES (Rauer & Schuck, 2004), is conducted at the end of each year level with the whole class. Lesson observations during the second and fourth year are also planned in order to look at the characteristics of collaboration in the inclusive classroom between the primary teacher and the special educator (in mathematics lessons) as well as at the differentiation of mathematical content.

## First results

The analysis of the ENI data shows the highest gain for the inclusive class taught by a teaching team. This class showed the weakest mathematics knowledge and understanding in terms of the Growth Points and it will be interesting to see how the students continue to develop in comparison to the other three classes in that year level. At the beginning of their second primary school year, the inclusive class also shows significantly lower values in parts of their social and emotional school experiences (measured by FEES). The significant differences relate to the sub-categories "peer acceptance", "climate in the classroom" and the "children's self-concept".

We are proposing this work to TWG13 as to date little is known about young children's early school experiences during their first year of school, that not only looks at their mathematics learning in an individualized and detailed way, but also examines the social and emotional involvement first graders experience during their first school year. Another interesting aspect will be to see how these experiences may change over the years and how they relate to their mathematics learning.

# Making maps in kindergarten

Geir Olaf Pettersen and Monica Volden

UiT The Arctic University of Norway [geir.olaf.pettersen@uit.no](mailto:geir.olaf.pettersen@uit.no), [monica.volden@uit.no](mailto:monica.volden@uit.no)

*Keywords: Kindergarten, maps, perspective.*

Maps have been used in Norwegian kindergartens in several ways, from topological to more topographical maps. The aim of this study is to develop knowledge about how exploring the terrain around their kindergarten can help children develop spatial orientation. The children in the kindergarten made different maps with pictures from a digital camera. We also used a big picture (size A1) taken with a drone from above the kindergarten. The assumption was that making the map and examining the picture would help the children translate the world around them into a scaled-down, two-dimensional representation. Clements and Sarama's (2014) framework for development of spatial orientation, navigation, and maps will be used to analyse the activity, which is based on the students' learning trajectories for spatial thinking. The children have to be familiar with the area and special landmarks, then they need to experience the one-to-one connections between the real world and objects or icons on the map. Here, it can be helpful to use drawings, such as a table with legs, so that children can recognise them from their own perspective. Clements and Sarama argue that it is important to work with mathematical questions such as 'Which way?', 'How far?', or 'What is it?' They also argue that students need experience to become competent users of maps (Clements and Sarama, 2014). Bjerva, Græsli, and Sigurdjónsson's (2011) model for map reading skill, *kartstigen*, will be used, but an aerial picture instead of a two-dimensional map will replace Level C. Young children's ability to use aerial pictures has been investigated in past literature (Plester, Richards, Blades, and Spencer, 2002).

This leads in to the following research questions: *What kind of orientation experience do children get from activities with maps in kindergarten? How do children understand the representation of the area around the kindergarten from maps they have made themselves and from aerial pictures?*

Five children, age 5, were used in the present study. The study was designed and carried out by researchers and kindergarten teachers, and consists of three separate parts. First, the kindergarten teachers took the children on a walk from the kindergarten to a small lake nearby, with which the children were familiar. During the walk, the children were invited to find special landmarks, and the teachers took pictures of them. The following week, the children, teachers, and researchers made maps from the pictures. These maps were topological and showed the path from the kindergarten to the lake, with respect to the order of the pictures. After finishing the maps, the children tried to find their way to the lake with the help of the maps. During this walk, the kindergarten teachers and researchers encouraged the children to stop at each landmark on the maps. The aim was to investigate whether the children were able to make a connection between the real world and the maps. Finally, the children were shown a big aerial picture of the same area to investigate how they managed to navigate using a picture with a bird's-eye (vertical projection) perspective.

Data were recorded with video cameras and transcribed. The study design is an explorative case study design (Cohen, Morrison, & Manion, 2007).

## Early findings

The children did not have much difficulty making a connection between the real world and the landmarks on the maps they made. However, when they were presented with an aerial photo of the same area, they were not immediately able to find the kindergarten. Monica is one of the researchers:

- Monica: What's on the picture?
- Children: Kindergarten
- Monica: Where is it? (Children pointing in opposite directions)
- Monica: Why do you think that?
- Ann: Because it is grey, and it got that kind of thing.
- Erik: Yes, it got that colour. Grey
- Ann: It is the kindergarten.
- Monica: What kind of things are outside the kindergarten? On the playground?
- Ann: The playground. What? There is no playground. Then it's not there.

The kindergarten, from the children's point of view, has the shape of a big, grey rectangle. This was the first thing they looked for. When Monica asked whether they could see the playground, they realised it could not be the kindergarten. After examining the picture for a while, they were given their self-made maps of the area. They were now able to make a connection between the landmarks on the map and the picture, even though they were taken from a different perspective.

Preliminary findings indicate that the maps were helpful for the children's experiences, in connecting landmarks on the map with the real world, but the children experienced more difficulties finding the kindergarten on an aerial picture.

# Learning of numerosity through a designed activity with dice and towers

Reinert A. Rinvold

Hedmark University of Applied Sciences, Norway; [reinert.rinvold@hihm.no](mailto:reinert.rinvold@hihm.no)

*Keywords: Numerosity, counting, continuous quantity, objectification, design.*

## Research topic and theoretical approach

The aim of this study is to develop both activities for the learning of numerosity in three year old children and theory describing the process of learning. The theoretical framework is Luis Radford's theory of knowledge objectification. His theory gives a central role to semiotic systems used within culturally and historically bound practices and social interaction in mathematical activity and learning, but also assumes an intimate and dialectical relationship between mathematical thinking and the material world (LaCroix, 2012). According to Radford (2008, p. 222), "... mathematical objects are fixed patterns of reflexive human activity incrusting in the ever-changing world of social practice mediated by artifacts.". Knowledge objectification is a matter of actively and imaginatively endowing with meaning the conceptual objects that the child finds in his or her culture (Radford, 2008, p. 223). Counting is a central mathematical activity that children normally develop. It is a procedure which children do not initially connect with properties of sets. Counting is interwoven with other quantity related cultural activities, such as for instance the How-many task, set construction and measurement. Set construction means building a set when its numerosity, for instance, is specified by a number word, as in the Give-a-Number task (Wynn, 1992). Davydov (1975) has advocated that perceptual comparison of quantity is developmentally prior to numerosity. When lengths are divided into equal units, the combination of perceptual length comparison and assignment of number words can be seen as a rudimentary example of measurement. The How-many task requires that the child assigns a number word to a presented set. The special role of the last counting word in a count is a pattern in the interface between counting and the How-many task. Children often emphasize the last counting word or insert "and" before it. Such linguistic devices are examples of semiotic means of objectification.

These objects, tools, linguistic devices, and signs that individuals intentionally use in social meaning-making processes to achieve a stable form of awareness, to make apparent their intentions, and to carry out their actions to attain the goal of their activities, I call semiotic means of objectification. (Radford, 2003, p. 41)

Typically, children for some time think that the counting procedure is the answer to the How-many question. To initiate processes of deeper objectification of numerosity, it is proposed that engagement in other uses of number words than counting is vital.

## An activity with towers and dice

In the poster presented at the congress, one designed activity with the intention of integrating counting and other quantity related cultural activities was outlined. A hypothesis behind the designed activity is that perceptual length comparison may be a semiotic means of objectification for connections between counting, the How-many task and set construction. The core of the activity

is to roll a dice and build a tower with the number of bricks the dice shows. The children sit on the floor and walk or crawl to fetch the dice when it is thrown. The plastic bricks are easy to pick up and fit exactly into the holes of the dice. An alternative way of building a tower is to put one brick into each hole in the top face of the dice and then put the bricks onto the stick. Putting the bricks into the holes can also be used to evaluate whether a tower is correctly built. A variation of the activity is that a puppet, the Easter bunny, makes a mistake when building the tower indicated by the dice. The puppet is hidden behind a screen so that the children do not see what it does. The children then are given the opportunity to respond and possibly correct the mistake.

### Background

We will present results from children aged five engaging in an activity and learning about magnets and inquiry in a kindergarten session. We want to understand how they learn and grow and in what ways the kindergarten teacher orchestrates the activities in order to engage the children in magnetism through inquiry. The study is part of a broader project in the kindergarten, aiming mainly to understand how and what skills and learnings are developed through understanding and inquiry. How do children develop inquiry skills (making observations, asking questions, making predictions, designing investigations, analyzing data, and supporting claims with evidence)? How do they conceptualize mathematics (classification, representing mathematical ideas in drawings, types of reasoning, number sense, comparison of sizes, problem posing)? The results show the importance of the questions (Carlsen et.al, 2010) and an appropriated orchestration for creating an inquiry interdisciplinary learning environment.

The Portuguese curriculum for kindergarten education (age 1-6 years old) requires an integrated and global approach to subject areas. It seems that few kindergarten teachers integrate physics into their teaching, and according to Tu (2006) only half of kindergartens are equipped with an area for experimental activities and few of those kindergarten teachers promote science and mathematics tasks. If such an approach were performed early, it would allow scientific reasoning and it would foster a better understanding of science with effect upon the children's achievement (Eshach & Fried, 2005). In this study, we adopt: an interdisciplinary approach between science and math; the perspective on early math of Clements and Sarama (2009); and a sociocultural perspective on learning and development. We view learning as a social and a situated process of appropriation where individuals make concepts, tools, and actions their own through collaboration and communication with others (Rogoff, 1998). Also, as Hedges and Cullen (2012), we consider that in the early childhood context, participation is more active than mere presence, which in itself may not engender learning without attention relationships, content, change, context and cultures. This sociocultural perspective is useful for our emphasis on the orchestration of participation in social magnet activities.

The theoretical stance of our study is in accordance with Inquiry-Based Science Education (IBSE), (Worth, Duque and Saltiel, 2009). It is an approach to teaching and learning science and math that comes from: an understanding of student learning; the nature of science inquiry which may be represented as a set of four stages (explore, investigate, draw conclusions and communicate); a focus on content and heavy dependence on the local context and the interest of students and teachers. The inquiry-based approach has important principles such as: direct experience is key to conceptual understanding; students should be taught skills (making observations, asking questions,

making predictions, designing investigations, analyzing data, and supporting claims with evidence); reasoning, talking with others and writing both for oneself and for others.

## Method and results

The study was carried out in one private kindergarten in Lisbon and adopted a qualitative research methodology under the interpretative paradigm, emphasizing meanings and processes. The researcher, first author, took the dual role teacher-researcher, conducting the study with her own 25 children (aged five years) in her own environment. In this study, we collected empirical data through the use of video camera and audio as well as field notes from one session out of seven sessions implementing the IBSE approach. Interaction and communication were captured as children engaged in magnet activities and the teacher orchestrated the group of children who were participating. Mathematical features used by children were elicited through the class interactions. We decided to analyse deeply the participation of the children in that interdisciplinary environment session above mentioned in looking for supporting the remaining research analysis.

The results imply that children's learning is influenced by their active participation and by the kinds of questions and learning opportunities that emerge, and how kindergarten teacher respond to children's ideas and orchestrates the activities. The collected data from that session indicate such an interdisciplinary environment involved playful learning and inquiry. The children developed content and competencies in science such as vocabulary (*to attract* and *magnet*) and experimentation. The children also developed: imagery, quantitative and critical reasoning; number sense (object counting, counting mental images, comparing numbers and early addition); as well as representing mathematical ideas in drawings. The children had opportunities to pose and to solve problems. Children connected ideas in play with the whole class in the game "fishing" and they learnt through collaboration and communication with one another.

*Keywords: Abstraction, combinatorics, representations, pre-school.*

### **Short description of the research topic and theoretical framework**

The focus of this poster is on the links between representations and solutions when 6-year-olds work on combinatorial tasks. The task can be explained as follows: In how many ways can three bears sit on a sofa?

Studies of young children's representations often focus on informal and formal representations. Abstraction is often perceived as a goal and teachers often value when young children use abstract representations. Heddens (1986) introduced semi-concrete and semi-abstract as connections between concrete (objects) and abstract (signs) representations. He referred to representations of real situations, for example, pictures of real items, as semi-concrete, whereas he referred to symbolic representations of concrete items, where the symbols or pictures do not look like the objects they represent, as semi-abstract. Connected to the task presented above, concrete implies real bears and a sofa, semi-concrete implies images of (resembling) bears, semi-abstract implies a symbolic, not resembling, representation of the bears and abstract implies the use of formal signs. As for the concrete level, the 'real' bears can be replaced by three play-bears, or by engaging in a role-play, enacting the situation. In both semi-concrete and semi-abstract representations, the colours of the bears and their symbols are often kept identical.

When conducting the combinatorial task in 13 pre-school classes in Sweden (125 children, age 6), children showed different levels of abstraction in their solutions of the problem. In a previous paper we problematized the apparent relation between the level of abstraction and the number of duplicate solutions. Surprisingly we found that the children who used semi-concrete representations in their documentations were more systematic in the process of finding solutions with less duplication than the children who used semi-abstract representations. We argued that a more abstract level seemed to reduce the problem from bears on a sofa to putting three coloured dots on a paper. It seemed that children moved too fast to the next level of abstraction. Internalisation of the problem had not occurred yet which led to a reduction of the problem as described above. Simultaneously, we also concluded that documentation within the semi-concrete level was very time-consuming for children, as it takes a lot of time for the children to draw bears (Palmér & van Bommel, 2017).

### **Methodology**

How could we slow down these children without slowing down the process of documentation? An application was especially designed to let children work on the semi-concrete level, and simultaneously, the time-consuming issue of drawing the bears was taken into account. The aim of the application was to provide an opportunity to develop an understanding of combinatorics and its

systematisation by letting children work within the semi-concrete level. The design-principles for the application concerned a possibility to adjust the level of the problem, resulting in a choice of the number of bears and the size of sofa. It also resulted in the possibility to save solutions as well as to offer an insight to all outcomes. By doing so, we wanted to explore the semi-concrete level more explicitly and focus on the learning opportunities this level of abstraction can offer the children.

During the autumn of 2016, 6-year-olds (about 60) from different preschool-classes have tested the application. Our reflections concern the learning opportunities created by using the digital form of documentation (in addition to the paper and pencil forms). After using the application, we let the children work on similar combinatorial tasks but only by using paper and pencil.

## **Preliminary results**

Our preliminary results show that the children who have worked with the application do not document as many duplicates when using semi-abstract representations as the children in our previous study (Palmér & van Bommel, in press). Additionally, we see an increase in the systematic way they organise and search for solutions. These first results of the study also indicate that the children indeed develop significant skills when working within the semi-concrete level, for instance they seem to have obtained a good understanding of what the concept different combinations entails. A special note has to be made towards the possibility to adjust the level of the task in the application. For example, some children explored the situations of two bears on a three-seat sofa and four-seat sofas with different number of bears. Such explorations led to discussions of similarities between two and three bears on a three-seat sofa and mathematical aspects of the tasks were discussed at another level compared to paper and pencil lessons.

### Introduction

TWG14 (*University Mathematics Education*, hereafter UME) was launched in CERME7 (Nardi, González-Martín, Gueudet, Iannone, & Winsløw, 2011) in recognition of the growing area of research in university mathematics education research. This area, although sharing in many cases approaches, methods and research topics with other areas in mathematics education research, has its own distinctiveness: the institutional characteristics at university (or postsecondary education in general) are usually quite different from those in compulsory education and do not always follow national curricular guidelines; the training of teachers (when existing) is also different from the training followed by primary and secondary teachers; there are many cases of classes with a large number of students, and teaching approaches are usually different – the amount of personal work expected from the students is also much higher; students' personal experience and aims are different than in compulsory education; very often mathematical notions and reasoning are dealt with at a higher level of complexity and abstraction; etc.. The fast growth of this research area, both outside and inside CERME, is evident in the breadth of research publications in this field and was recognized by the ERME community, in inviting the three-year leader of this TWG to present a summary of UME research as a CERME10 plenary lecture (Nardi, 2017).

Within CERME, the number of papers submitted to TWG14 has been increasing steadily since its inception. This year, we received a record number of 64 papers, with 47 getting accepted for presentation (of which, 41 are published in the proceedings, together with 17 short contributions). This indicates a substantial increase in comparison to the 31 full and 14 short contributions in TWG14 in CERME9 proceedings (Nardi, Biza, González-Martín, Gueudet, Iannone, Viirman, & Winsløw, 2015). Additionally, the substantial number of papers led to the split of TWG14 into two *isomorphic* groups (TWG14A: 23 accepted papers and TWG14B: accepted 24 papers) which ran in parallel and common sessions during the conference. This introductory paper summarises the works presented in both groups, as well as our common discussions.

Outside of CERME, the number of handbook chapters focusing on UME or dedicating some sections to it (from the pioneering Artigue, Batanero, & Kent, 2007, to the most recent Coupland, Dunn, Galligan, Oates, & Trenholm, 2016; Larsen, Marrongelle, Bressoud, & Graham, in press; Rasmussen & Wawro, in press) acknowledges the recognition of this research area for its specificities, as does the launching of the [\*International Journal of Research in Undergraduate Mathematics Education\*](#). Moreover, the activities of TWG14 have also led to two major contributions: the creation of the *International Network for Didactic Research in University Mathematics* (INDRUM) with a bi-year ERME topic conference (see [INDRUM2016](#) and [INDRUM2018](#)); and, the publication of a [\*Research in Mathematics Education special issue\*](#) summarising some of the works presented during CERME7 and CERME8, and discussing the use of *institutional, sociocultural and discursive approaches to research in university mathematics education* (Nardi, Biza, González-Martín, Gueudet, & Winsløw, 2014).

In CERME10 we intended to cement and expand further this work, as well as welcoming contributions from across the board of research approaches and topics: the teaching and learning of advanced university mathematics topics (including proof); transition issues “at the entrance” to university mathematics, or beyond; the training of university mathematics teachers; challenges for, and novel approaches to, teaching mathematics at university level (including the teaching of students in non-mathematics degrees); the role of ICT tools and other resources (e.g. textbooks, books and other materials) in the teaching and learning of university mathematics; assessing the learning and teaching of mathematics at university level; collaborative research between university mathematics teachers and researchers in mathematics education; and, theoretical and methodological approaches to research into the teaching and learning of university mathematics.

In the large number of papers received, we identified some continuities, but also some ruptures, with previous iterations of TWG14. For instance, there is still a large number of papers following sociocultural, discursive, and institutional approaches, although a considerable number of papers using cognitive approaches was also present. Moreover, among the papers focusing on a specific mathematical notion, calculus and analysis are still predominant, although we also received papers discussing other topics (such as group theory, linear algebra, or logic). There is also a small but growing number of papers addressing the teaching and learning of more advanced topics, such as algebraic topology, ring theory, and quantum mechanics. The number of papers addressing the use of mathematics as a service course (i.e., mathematical course offered to non mathematics specialists) is still growing, and papers focusing on engineering were again predominant, although we also received papers addressing the use of mathematics by biologists, economists, and physicists. The number of papers addressing teachers’ practice, training, and knowledge has also grown considerably, showing the increasing interest that this area of research is gaining. Conversely, papers proposing experimental interventions (in particular, using technology) are still rare in the group. Finally, we note that a larger number of quantitative studies were presented at CERME10 in comparison to previous CERMEs. Among the accepted papers, we could identify six main themes (although we are aware that some papers fit in more than one theme): students’ learning of specific topics; students’ experience and affective issues; interventions; didactical transposition and use of resources; mathematics for non-mathematicians; and, teachers’ practices and knowledge. In what follows, we follow the structure of these themes to summarise the main results presented during the conference. Due to the large number of papers and to space limitation, we have not included the content of the short contributions in the summary.

## Themes and paper contributions

### Students’ learning of specific topics

Nine papers can be seen as contributing to this theme. Aaten, Deprez, Roorda and Goedhart show the difficulties with applying Lithner’s framework in order to analyze ‘hybrid’ types of students’

reasoning when solving integration tasks in undergraduate calculus; the authors argue that this framework may need the addition of reasoning types that make use of some kinds of recall. Biza employs Sfard's commognitive framework to investigate first-year students' meaning-making of the tangent line, finding that they engage with analytical, geometrical and algebraic discourses in their substantiations about tangents, sometimes engaging with more than one discourse in the same response, and sometimes separating them across different responses. Chellougui uses Copi's system of natural deduction as a frame to investigate students' difficulties in producing a valid proof in mathematical contexts that involve multiply-quantified statements (e.g. the definition of an order relation in elementary set theory). Hanke and Schäfer use eight categories of mental images of continuity to show that students' mental images of real-valued continuous functions can be expressed by different forms of communication, which, in turn, depend on whether mental images are used or are explicitly verbalized. Juter investigates how students understand continuity and differentiability (and their links) during and after a calculus course, with a focus on students' choices of representations, both espoused and enacted; her study identifies that only students who preferred formal theoretical representations were able to produce formal proofs, as well as a strong coherence between students' espoused and enacted preferences of representations. Mai, Feudel and Biehler study first-year university students' personal concept definition of a vector; they identify several misconceptions and note that a vast majority of students state geometrical concept definitions that are not fully adequate and may cause conflicts in their learning of linear algebra. Ovodenko and Tsamir describe students' grasp of the notion of inflection point, and offer a detailed classification of reasons students offer to identify a point as an inflection point, and a point as a non-inflection point. In the field of abstract algebra, Ioannou studies discursive shifts in year-2 mathematics students' learning of group theory, drawing attention to some commognitive conflicts between the new discourse and other mathematical discourses, including advanced mathematics (e.g. set theory) and high school mathematics. Thoma and Nardi, also taking a commognitive approach, study first-year students' learning of the notion of variable, drawing attention to commognitive conflicts between the notion of variable, and even the notion of number, between school and university mathematics. Both these papers show that university instructors are aware of common student errors, yet they may not be aware of the conflicts that underlie these errors.

### **Students' experience and affective issues**

Eight papers can be seen as contributing to this theme. Using data from questionnaires and exploratory factor analysis (EFA), Anastasakis produces a typology of seven different types of resources that engineering undergraduates use; he refers to the role of tools within Activity Theory and uses also Wartofsky's categorization of artefacts to propose an interpretation of these resources as seven different modes of action in students when studying mathematics, concluding that the way we usually classify resources does not necessarily reflect the way these resources are used by students. In a study of first-year engineering students' note-taking, Andrà uses a narrative approach where students' notes are seen as re-tellings of a story told by the teacher; she focuses on how the students condense the mathematical content in their notes, and what conditions might prompt students to act as 'scribblers' or 'thinkers'. Bampili, Zachariades and Sakonidis conduct an in-depth analysis of one student's process of transition from secondary to tertiary mathematics studies; they consider this transition from a rite of passage perspective, finding connections between the social, academic and mathematical dimensions of the transition, for instance, an interaction between emotions and the student's reconstruction of her mathematical thinking. Griesse and Kallweit report on a quantitative analysis of the relationship between patterns of learning behaviour and examination outcome in first-year engineering courses. Kaspersen, Pepin and Sikko describe a quantitative analytical tool for evaluating students' mathematical identities and investigate the relationships between mathematical identities and grades in university mathematical courses. Kürten reports on a preliminary course for engineering students, and shows how this course can be

designed to influence students' self-efficacy. Liebendörfer, Hochmuth, Biehler, Schaper, Kuklinski, Khellaf, Colberg, Schürmann and Rothe propose a taxonomy of the goals of 44 mathematical learning support services offered by universities in Germany; the taxonomy suggests a range of educational goals (e.g. learning the language of mathematics or strategies for studying) and system related goals (e.g. reduce dropout rates or increase passing rates). Marmur and Koichu investigate the relationships between key affective events and the mathematical discourse in two university mathematics lessons where two similar problems were considered.

### **Interventions**

Five papers can be seen as contributing to this theme. Fredriksen, Hadjerrouit, Monaghan and Rensaa study the introduction of a flipped classroom approach in an engineering course at a Norwegian university, focusing on the emerging tensions when students are introduced to a novel approach with videos and quizzes; using the Cultural Historical Activity Theory (CHAT) approach, they identify some tensions attributed to the changes of rules and expectations, as well as the lack of shared understanding in the community of students about the mathematical topic, their preparation for and participation in the sessions. Hogstad and Isabwe describe the use of a digital tool that combines mathematics and kinematics aiming to help students to better grasp integrals; using the theory of instrumental genesis, they investigate the activity of two groups of students with the tool, and identify the pragmatic and epistemic values of students' techniques for solving some given tasks. Kondratieva and Winsløw develop activities dedicated to helping students relate familiar practical tasks from calculus with theoretical ideas of more advanced courses in analysis; their approach is based on a theoretical model of the calculus-analysis transition, using the notion of praxeology from the anthropological theory of the didactic (ATD), and the associated strategies from Klein, to deal with students' challenges in this transition. Lecorre uses the scientific debate methodology developed by Legrand to design and implement, at the transition between high-school and university, specific tasks on double-quantified statements (the  $Q^2$ -game) that may raise the need for conventions of interpretations before they are introduced through mathematical formalism. Schmitz and Schäfer investigate the potential of designing a course in linear algebra and in analysis using the Abstraction in Context framework to increase students' motivation and ability to engage in concept construction; their results indicate that the new courses seem to help students in the transition from school to university mathematics.

### **Didactical transposition and use of resources**

Two papers can be seen as contributing to this theme. Ghedamsi investigates the mathematical organization of complex numbers in the official textbook in Tunisia at upper secondary level; mainly building on Sfard's three stages of cognitive development and on Duval's theory of semiotic representations, she identifies three didactical variables that can be used to efficiently influence students' activities and learning process of complex numbers when they enter tertiary levels. Jovignot, Hausberger and Durand-Guerrier analyze the implicit complexity of a proof presented in a textbook, which involves the concept of ideal in ring theory; using ATD's construct of praxeology, the mathematical organization related to abstract algebra is modeled into structuralist praxeologies, highlighting the intertwined relationships between algebraic, set-theoretic and logical praxeologies and, as a consequence, the inadequacy of such proof for students' self-learning.

### **Mathematics for non-mathematicians**

Seven papers can be seen as contributing to this theme. Feudel analyses the use of derivatives in economics to introduce cost functions and marginal cost; his data indicate that many of the students participating in his study, after their calculus course, just identified the derivative as an amount of change, without showing a clear understanding of the differences and connections between the derivative in mathematics and in economics contexts. González-Martín and Hernandes Gomes analyse the use of integrals in the Strength of Materials for Civil Engineering course to introduce

the notion of bending moment in the study of beams; using tools from ATD, their analyses show that, even if bending moments are introduced as an integral, the proposed tasks do not mobilise elements related to integrals from a calculus course. Kortemeyer and Biehler investigate the mathematical skills and knowledge required in undergraduate engineering using quantitative and qualitative analytical tools developed particularly for this study. Quéré uses tools from ATD to study French engineers' mathematical needs in the workplace; using data from 237 French engineers, he identifies mathematical notions they use, but also the need of 'mathematical abilities' that allow them to use mathematics not only as a tool. Rensaa uses grounded theory techniques to investigate engineering students' own descriptions of what they mean by 'learning linear algebra'; she identifies an apparent contradiction: to describe what they have learned, students emphasize conceptual more than procedural approaches, but in order to know that they have learned something they refer to solving specific tasks in the discipline. Viirman and Nardi describe a series of activities designed for Norwegian students of biology on biology-related mathematical modeling, and follow the learners' path from ritualized participation in mathematical routines towards more explorative participation; they suggest that highly scaffolded tasks, that explicitly state which routines students should invoke, may inadvertently contribute to students' ritualized participation in mathematical discourse. Wawro, Watson and Christensen analyze one student's meta-representational competence as he engages in solving a quantum mechanics problem involving concepts from linear algebra; they correlate this type of competence with abilities to solve tasks that require thinking in, using, and relating different notation systems from physics to mathematics.

### **Teachers' practices and knowledge**

Ten papers can be seen as contributing to this theme. Branchetti analyses the resources, orientation and goals in the intended practices of a high school mathematics teacher with a PhD in mathematics, in relation to the topic of real numbers; the analysis indicates that orientations concerning the epistemology of real numbers, the goals of mathematics education in the high school and students' conceptions and difficulties lead the teacher to choose a very intuitive approach, missing the opportunity to benefit from his knowledge and expertise as a research mathematician. Cooper and Zaslavsky analyse a case of a mathematician/mathematics educator co-teaching partnership in an undergraduate course on Mathematical Proof and Proving; they find that the mathematician's main concern was with the written proof and its "correctness", whereas the mathematics educator showed a sensitivity to the person behind the proof, and to pedagogical aspects of proof and proving, suggesting that this type of co-teaching might be a way of achieving relevance for teaching in mathematics courses. Farah combines an ATD perspective with a sociocultural approach to identify institutional features that influence and transform the working habits of students in the context of French preparatory classes for business schools; she finds a great stability among the teachers' practices she investigates, these practices being strongly linked to the specific institution in which they occur. Fernández-León, Toscano-Barragán and Gavilán-Izquierdo use the horizontal and vertical mathematisation to study the conjecturing and proving approaches of a research mathematician working in a Spanish university; the analysis suggests that these practices (both in a horizontal and a vertical way) interact with each other when mathematicians create new knowledge. Florensa, Bosch, Gascón and Ruiz-Munzon report on a professional development course for mathematics lecturers in engineering; using tools from ATD and the construct of study and research path, they carried out modelling activities with a group of lecturers, allowing the introduction of some ATD notions to empower lecturers to question and put under vigilance the dominant epistemology at university. Jaworski, Potari and Petropoulou draw on their previous research to theorise and characterise university mathematics teaching within an Activity Theory perspective, developing an example concerning a lecture course in calculus with first year undergraduates; the Teaching Triad at the micro level of goals and actions, together with Activity Theory at the macro level, are used together to capture the complexity of the teaching situation,

addressing for instance the ways the lecturer engages his students and provides for their needs. Meehan, O'Shea and Breen examine 'brief but vivid' accounts of their lectures they wrote during a first-year undergraduate calculus course, and investigate the kinds of decision points they faced and how these decisions were triggered. Pinto observes and analyses the decision making and the shift of choices of an experienced mathematics teacher (Alan Schoenfeld) while he teaches a mathematical problem solving course; the Teaching for Robust Understanding of Mathematics framework (TRUmath) is used to unpack the conflicts that may underlie teachers' dilemmas and to explain their decisions. Püschl investigates the discussion patterns of teaching assistants in Germany with specific focus on how they work on tasks in small group tutorials, suggesting a typology of five discussion patterns of tasks: heuristic, pragmatic, student-oriented, problem-oriented, and minimalistic. Stewart, Thompson and Brady examine one mathematician's thought processes as he taught a course on algebraic topology; adopting the perspective of Tall's three worlds, they investigate how the teacher moves between the formal, symbolic and embodied worlds, and how he uses written handouts to ease students' movement between the worlds, particularly from the embodied to the formal, which he sees as the most challenging for students.

## **Current developments in TWG14**

As we mentioned earlier, one of the themes that has grown considerably in this CERME10 concerns teachers' practices and knowledge. The presented papers offer a variety of theoretical and methodological approaches to study teachers' practices and decision making in the preparation of their teaching as well as during their actual teaching. As evident in the papers discussed in the conference, the investigation of teaching in its complexity seems to demand the use of more than one theoretical perspective. Moreover, some of the papers have proposed ways of collaboration between researchers and teachers towards better research insight as well as further development of teaching through a research-based reflection of teachers on their practice. These works have facilitated the discussion on teacher education and professional development at university level; an area of significant teaching interest that seeks further research.

Regarding students' learning of specific topics, CERME10 contributions continue to deepen our understanding of aspects of students' learning. This year there was more interest in how learning of specific topics can be seen also in relation to students' studying practices that go beyond these topics and specific courses. For example, students' learning can be seen in relation to how they use resources, take notes or experience transition issues.

Furthermore, this year we discussed five papers proposing interventions and reporting on the evaluation of the implementation of these interventions. Also, there were studies of tensions between innovative approaches and students' experiences, especially when these approaches contradict students' expectations. As in previous CERMEs, the number of papers proposing interventions is not high (Winsløw, Gueudet, Hochmuth, & Nardi, in press), and the account of experimental uses of digital technologies is still low. Although a range of studies proposes innovative approaches, more research is needed in this area, particularly studies that go beyond specific contexts and groups of students.

Finally, another growing area in TWG14 concerns mathematics for non-mathematicians. The papers presented this year show different degrees of collaboration with experts from other disciplines, as well as the importance of understanding the needs of these disciplines and their use of mathematical notions. From research about the learning of specific topics that happens to be conducted, for instance, with engineering students, the field has moved to study specific uses of mathematics by professionals (this year from biology, economics, engineering, and physics). We believe that this is an important shift of focus, and we expect to see in the future more papers studying the use of mathematics (and the professional needs) of several categories of professionals, as well as how mathematics can be taught by targeting these professional needs.

## Reflection and ways forward

In this concluding section we reflect on the research in UME so far and suggest ways forward in terms of two directions: general questions about teaching and learning at university level; and, the role of mathematics as a service subject.

Regarding the first direction, general questions about teaching and learning at university level, we have noticed that research in UME usually reports on studies conducted in a specific educational context. As a research community, we would like to see more research conducted in joint efforts by colleagues from different countries. Strengthening communication between mathematics educators and mathematicians is also necessary towards collaborative research projects that engage mathematicians and suggest innovative approaches for future practice. There are more occasions recently where researchers in mathematics education are invited by mathematics teachers to share experiences and views and to contribute to curricular development decisions; collaborations of this type are very welcomed by our community,

Furthermore, although there is a considerable number of studies connecting students with mathematics, as well as teachers with mathematics, we would like to see more studies connecting teachers and students (teaching with learning). Aiming towards this connection may lead to new theoretical and methodological developments. Finally, we also discussed that there is a growing body of research about mathematicians teaching non-mathematics students, but there is still little research on how non-mathematicians teach mathematics as a service subject.

Regarding the second direction, the role of mathematics as a service subject, we would like to see more research on the different challenges and priorities that may occur in service courses. To name some examples, in service courses teachers may encounter large and heterogeneous groups; the content is not necessarily in the teacher's research area; there can be consequences for teachers' promotions (between giving a course of his/her specialty or a general course), which may have an impact on their motivation and practices; etc.. There is also little research on the epistemological analyses of what it means to teach mathematics to other disciplines; what makes the use of mathematics necessary in other disciplines; and, why mathematics is used as it is used in other fields. These investigations may lead to the identification of possible ruptures – and conflicts for the students – with how the content is presented in the mathematics courses. Another way forward can come from the use of discursive approaches, which would allow studying the discursive difference between communities. In most of these cases, we see the value of the collaboration of UME researchers with experts of other disciplines towards a research agenda that can address these questions.

Finally, in a general way, we would like to see more research that goes beyond single case studies, as well as research projects that expand small-scale studies to a bigger scale. We also notice that most of the papers in our group address mainly one of the themes we listed earlier, but we see the benefit of research that connects these themes by addressing the complexity of the teaching and learning of mathematics at university level. In all these scenarios, it is possible that mixed-methods studies will become more necessary. Regarding contributions to practice, the accumulated body of research results in UME should contribute to the development of research-based teacher training programmes for university teachers. Furthermore, there is a growth in the amount of mathematics learning support, and institutions are developing mechanisms to better guide and support students' learning of mathematics; we need to develop research about these new mechanisms offered to students, as well as about their impact and connections to what students learn in lectures.

This brief account of the presentations and discussions held in TWG14 during CERME10 aims to summarise our activities during the conference, as well as to invite the reader to explore the papers (long and short contributions) included in these proceedings. Our exchanges will continue in

different fora and we hope to meet again the participants to pursue our discussions and reflections, and to foster collaboration. Until we meet again in CERME11, the next meeting will take place in April 2018; we invite all participants (as well as newcomers) to join us in [INDRUM2018](#).

# Undergraduates' reasoning while solving integration tasks:

## Discussion of a research framework

Aaltje Berendina Aaten<sup>1,2</sup>, Johan Deprez<sup>2</sup>, Gerrit Roorda<sup>1</sup> and Martin Goedhart<sup>1</sup>

<sup>1</sup> University of Groningen, the Netherlands; [a.b.aaten@rug.nl](mailto:a.b.aaten@rug.nl); [g.roorda@rug.nl](mailto:g.roorda@rug.nl); [m.j.goedhart@rug.nl](mailto:m.j.goedhart@rug.nl); <sup>2</sup> KU Leuven, Belgium; [johan.deprez@kuleuven.be](mailto:johan.deprez@kuleuven.be)

*In this paper we investigate the extent to which the research framework on reasoning developed by Lithner (2008) is adequate for characterizing undergraduate students' mathematical reasoning. We conducted a small number of individual task-based think-aloud interviews in which students solved integration tasks. Several examples illustrate how we characterized reasoning types by using the framework. However, we found that some reasoning types were not covered by the framework. We propose to extend the framework by introducing a reasoning type that is mathematically founded but not creative, and as a consequence, may be intertwined with imitative reasoning.*

*Keywords: Mathematical reasoning, undergraduate students, calculus.*

## Introduction

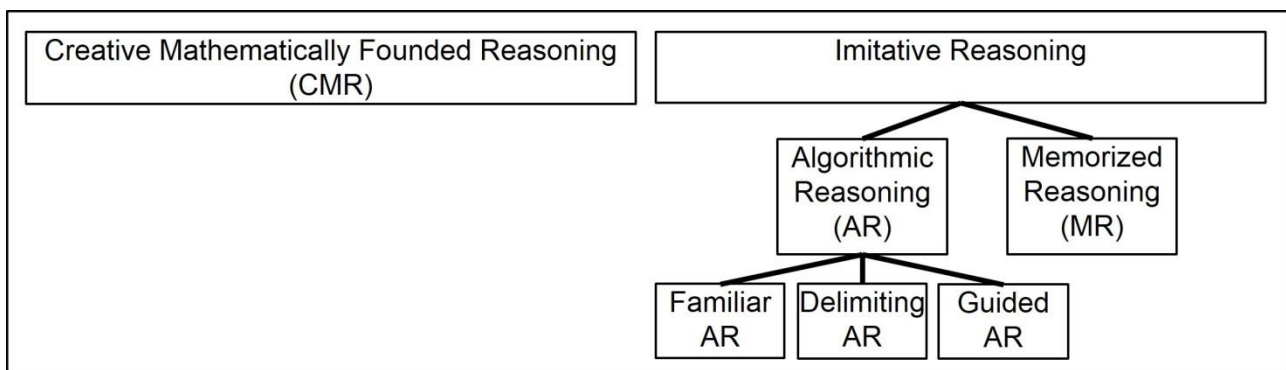

Students' mathematical reasoning while solving mathematical tasks is not always as well-founded as it appears, as has already been highlighted by Vinner (1997) in his article on pseudo-conceptual and pseudo-analytical thought processes in mathematics learning. Moreover, undergraduates' reasoning in the domain of calculus is found to be susceptible to ill-founded reasoning (Lithner, 2003). Because of its relevance for mathematics teaching, students' mathematical reasoning demands further investigation. Different frameworks on mathematical reasoning have been reported in literature. Some frameworks focus on argumentation used while solving proving problems (e.g., Blanton & Stylianou, 2014; Stylianides, 2008). Zandieh and Rasmussen (2010) constructed a framework on mathematical reasoning that distinguishes informal and formal reasoning, which seems most suited for investigating students' understanding of abstract concepts. Carlson and Bloom (2005) combined the problem solving phases Orienting, Planning, Executing, and Checking with the use of problem solving attributes Resources, Heuristics, Affect, and Monitoring. Their framework appears capable of identifying students' problem solving activities and the influence of cognitive, affective and/or metacognitive factors. However, this framework does not incorporate the foundation of mathematical reasoning. Lithner (2008) constructed a framework which does incorporate foundations of students' strategic decisions in solving mathematical tasks. This framework is often referred to when characterizing reasoning as either imitative or creative, which are the two main categories in the framework (e.g., Jäder, Sidenvall, & Sumpter, 2016; Jonsson, Norqvist, Liljekvist, & Lithner, 2014). However, the framework offers greater detail, by also defining Memorized Reasoning, and Familiar, Delimiting, and several types of Guided Algorithmic Reasoning (Lithner, 2008). Since this detailed characterization of mathematical reasoning based upon its foundation appears useful for identifying students' reasoning, we selected this framework for our research. Based upon our experiences in applying this research framework, we discuss the framework's possibilities and limitations.

## Theoretical framework

Lithner (2008) defines reasoning as:

The line of thought adopted to produce assertions and reach conclusions in task solving. It is not necessarily based on formal logic, thus not restricted to proof, and may even be incorrect as long as there are some kinds of sensible (to the reasoner) reasons backing it (Lithner, 2008, p. 257).

Based on observations of students who solve mathematical tasks, Lithner describes various ways in which students choose a mathematical strategy to solve a task, pointing out students' 'predictive argumentation' (reasoning for choosing a strategy) and 'verificative argumentation' (reflection upon implementation of strategy), where strategy "ranges from local procedures to general approaches" and choice "is seen in a wide sense (choose, recall, construct, discover, guess, etc.)" (Lithner, 2008, p. 257). The resulting framework is visualized in figure 1.

**Figure 1: Visualization of reasoning framework as described by Lithner (2008)**

The framework distinguishes two main categories, Creative Mathematically founded Reasoning (CMR) and Imitative Reasoning. CMR<sup>1</sup> refers to reasoning that is based on intrinsic mathematical properties, that is novel to the student (the reasoner) and for which the student has arguments (Lithner, 2008). Imitative reasoning is described as reasoning in which an algorithm or answer is recalled in some way. Imitative reasoning is divided into Memorized Reasoning and Algorithmic Reasoning. Memorized Reasoning implies that the student recalls a complete answer, for example a definition or a proof that is learnt by heart. Algorithmic Reasoning occurs when a student recalls an algorithm. Lithner's framework altered over time (see Lithner, 2003, 2004, 2008); in this study we applied the framework as described in Lithner (2008).

The definitions by Lithner (2008) for each of the reasoning types are listed in Table 1. In the definition of Delimiting Algorithmic Reasoning (see Table 1), the term 'set' of algorithms requires some explanation. Lithner (2008) clarifies that if no guidance is available and if the task is unfamiliar to the student, then the student must choose an algorithm from the 'set' of algorithms the student knows, based upon some kind of connection to the task.

<sup>1</sup> In earlier versions of the framework (e.g., Lithner, 2004), creative mathematically founded reasoning (which was then named Plausible Reasoning) was subdivided in a global and a local subtype, but this distinction has not remained.

Reasoning type	Criteria
Creative Mathematically founded Reasoning	Three criteria: “Novelty. A new (to the reasoner) reasoning sequence is created, or a forgotten one is re-created.” “Plausibility. There are arguments supporting the strategy choice and/or strategy implementation motivating why the conclusions are true or plausible.” “Mathematical foundation. The arguments are anchored in intrinsic mathematical properties of the components involved in the reasoning” (Lithner, 2008, p. 266)
Imitative Reasoning	No definition is given. Imitative Reasoning is subdivided into Memorized Reasoning and Algorithmic Reasoning.
Memorized Reasoning	“The strategy choice is founded on recalling a complete answer. The strategy implementation consists only of writing it down.” (Lithner, 2008, p. 258)
Algorithmic Reasoning	“The strategy choice is to recall a solution algorithm. The predictive argumentation may be of different kinds (see below for examples), but there is no need to create a new solution.” “The remaining reasoning parts of the strategy implementation are trivial for the reasoner, only a careless mistake can prevent an answer from being reached.” (Lithner, 2008, p. 259)
Familiar Algorithmic Reasoning	“The reason for the strategy choice is that the task is seen as being of a familiar type that can be solved by a corresponding known algorithm.” “The algorithm is implemented.” (Lithner, 2008, p. 262)
Delimiting Algorithmic Reasoning	“An algorithm is chosen from a set that is delimited by the reasoner through the algorithms’ surface relations to the task. The outcome is not predicted.” “The verificative argumentation is based on surface considerations that are related only to the reasoner’s expectations of the requested answer or solution. If the implementation does not lead to a (to the reasoner) reasonable conclusion it is simply terminated without evaluation and another algorithm may be chosen from the delimited set.” (Lithner, 2008, p. 263)
Guided Algorithmic Reasoning	Text-guided Algorithmic Reasoning: “The strategy choice concerns identifying surface similarities between the task and an example, definition, theorem, rule, or some other situation in a text source.” “The algorithm is implemented without verificative argumentation.” (Lithner, 2008, p. 263)  Person-guided Algorithmic Reasoning: “All strategy choices that are problematic for the reasoner are made by a guide, who provides no predictive argumentation.” “The strategy implementation follows the guidance and executes the remaining routine transformations without verificative argumentation.” (Lithner, 2008, p. 264)

**Table 1: Definitions of reasoning types, derived from Lithner (2008)**

It is important to note that the foundation of Creative Mathematically founded Reasoning is explicitly stated, while this is not the case for Imitative Reasoning: CMR is by definition founded in intrinsic mathematical properties, while the foundation of Imitative Reasoning is not clearly stated. The definitions of various sub-categories of Imitative Reasoning contain criteria like ‘surface relations’, ‘surface considerations’, ‘surface similarities’, ‘no predictive argumentation’, and ‘without verificative argumentation’. This terminology appears to stem from earlier work: Lithner (2004) distinguished mathematically founded reasoning and superficial reasoning, where the latter was based upon surface properties and not upon mathematically relevant properties. Although in Lithner (2008), ‘imitative reasoning’ is not defined as founded in superficial or surface properties, many of the subtypes are (see Table 1). Moreover, all examples and explanations given by Lithner (2008) do refer to situations in which the reasoning is founded in so-called superficial properties and not in intrinsic mathematical properties, which is a criterion for CMR.

Certain studies have already used the framework to characterize students’ reasoning. Boesen, Lithner, and Palm (2010) employed the categories of Memorized Reasoning, Algorithmic Reasoning (without subcategories) and extended the category of Creative Mathematically founded Reasoning by defining the two subtypes Local CMR and Global CMR (in accordance with Lithner (2004)). Sumpter (2013) applied the framework to label episodes of students’ reasoning in a study on the role of beliefs in mathematical reasoning, and showed three examples which were all labeled as Familiar Algorithmic Reasoning. Jäder et al. (2016) used the framework to discern whether students’ reasoning was imitative or creative. We remark that these studies have not used all sub-categories of the framework as described by Lithner (2008). In the case of Sumpter (2013), only one type of reasoning was discussed. Although these studies did make use of the framework, none of them did explicitly reflect upon its applicability. Since we consider the framework a worthwhile addition to literature on mathematical reasoning, we investigate its applicability for characterizing students’ reasoning. The research question we thus aim to answer is: to what extent is the framework by Lithner (2008) adequate to characterize undergraduate students’ mathematical reasoning?

## Methodology

The data in this study originates from interviews with three first year mathematics bachelor students, one male and two female, of varying mathematics proficiency levels, determined by previous exam scores. These students are a sub-sample of a group of 12 students participating in a longitudinal study that investigates the development of mathematical reasoning. The students are majors in mathematics at the University of Groningen (the Netherlands) or the KU Leuven (Belgium); universities which offer courses in a wide range of domains at undergraduate and graduate level. The individual task-based think-aloud interviews lasted for approximately 1.5 hours each and are administered by the first author at the end of the students’ first undergraduate year. Students were permitted to use a list with basic calculus formulas, which did not include elaborate integration formulas. The students were asked to explicate their thinking while solving tasks and, after each task, to answer the questions: “How did you come to think of using this strategy?”, “How certain were you that this strategy would help you solve the problem, and why?”, and “Have you seen this type of task before?”. The interviews are video and audio recorded.

We used tasks to create a situation in which the students must choose a suitable strategy from a wide range of possible strategies. We considered integration tasks suitable for this purpose since the

students had learnt various mathematical strategies for solving integrals, such as partial integration, substitution, partial fractions, or Euclidean division, in the courses they had taken so far. These considerations led to selection of various tasks, amongst which  $\int \sqrt{9-x^2} dx$  and  $\int \sqrt{x^2-9} dx$ . Both integrals can be simplified through inverse trigonometric substitution, e.g.  $x = 3\sin(t)$  or  $x = 3\cos(t)$  to solve the first integral, and  $x = 3/\sin(t)$  or  $x = 3\cosh(t)$  to solve the second integral. The students had taken courses in integral calculus in which they solved similar tasks, amongst many other types of tasks. The explicit discussion of these types of integrals had already taken place earlier in the academic year. Based upon teaching experience we expected that these tasks at the time of the interviews would be non-trivial to many students.

While integration tasks may be regarded as tasks that solely require application of procedures, these tasks can arouse various types of mathematical reasoning in students. Considering and selecting suitable procedures is a process in which Creative Mathematically founded Reasoning as well as Imitative Reasoning can become visible. Familiar Algorithmic Reasoning can be used if the student recognizes the problem type and recalls the corresponding algorithm; Delimiting Algorithmic Reasoning if the student does not recognize the task but recalls various algorithms such as partial integration or substitution of some kind; Creative Mathematically founded Reasoning can be employed if the student is not able to recall a solution strategy but instead constructs a solution or reconstructs a forgotten reasoning sequence, such as drawing a rectangular triangle and deducing a suitable substitution. We did not expect Memorized Reasoning, since the solutions to the tasks are extensive. Guided Algorithmic Reasoning also appeared improbable, since example solutions were unavailable and the interviewer would not offer any hints. The available list with formulas however could serve as inspiration.

Transcripts of the task solutions are split into episodes. An episode begins at the first consideration of a strategy (or a set of strategies) and ends when the strategy is abandoned and a new strategy is about to be considered. Using the framework to characterize parts of a solution is similar to the method of Lithner (2008) and Sumpter (2013). The first author tried to characterize each of the episodes through the definitions given by Lithner (2008). If this was unsuccessful, the difficulties were described. The findings from this analysis were discussed with the other authors until agreement was obtained.

## Results

Below we describe several reasoning episodes from our data, which illustrate how we characterized reasoning using the framework and which problems we encountered.

### Familiar Algorithmic Reasoning?

Example 1:  $\int \sqrt{x^2-9} dx$ ; student A chose to rewrite the integrand by splitting it into two terms and next integrating them separately:  $\sqrt{x^2-9} = \frac{x^2-9}{\sqrt{x^2-9}} = \frac{x^2}{\sqrt{x^2-9}} + 9 \frac{-1}{\sqrt{x^2-9}}$ . The student had applied this strategy earlier in the interview, when (unsuccessfully) solving  $\int \sqrt{9-x^2} dx$ . The student explained: “The task was similar to the former task, so I figured I could try using the same approach.” We observe that the task is recognized as a familiar type, which made the student decide to apply the same strategy as before. We characterize this reasoning as Familiar Algorithmic Reasoning.

Example 2:  $\int \frac{x}{\sqrt{x^2 - 9}} dx$ ; this sub-task arose while student A worked on  $\int \sqrt{x^2 - 9} dx$ . This sub-task

is of a standard form because the derivative of  $x^2 - 9$  is in the numerator, making  $t = x^2 - 9$  an appropriate substitution. Student A effectively chose this strategy and explained afterwards: “Because I knew that the derivative of this (points at  $x^2 - 9$  in the denominator), was something like this (points at the numerator) [...] So I applied substitution to this (points at  $x^2 - 9$ ), because this (points at the numerator) would then be eliminated.”. We observe that the student noticed the relevant mathematical characteristics of this task and knew what algorithm would solve tasks of this type. Either the task type was familiar or the student constructed the approach. The ease with which the student came to this conclusion and the fact that this type of task has been practiced extensively make us expect the student to be familiar with the task type: we characterize the reasoning as Familiar Algorithmic Reasoning. However, the student clearly founds the reasoning in intrinsic mathematical properties, which is very different from the reasoning that occurred during Example 1, where the student appears to base the strategy choice solely on familiarity with the task type.

We conclude that Examples 1 and 2 provide two rather distinct reasoning types while both satisfying the criteria for Familiar Algorithmic Reasoning.

### Memorized Reasoning or Creative Mathematically founded Reasoning?

Example 3:  $\int \frac{1}{\cos \theta} d\theta$ ; this sub-task arose while student C worked on  $\int \sqrt{x^2 - 9} dx$ . The student searched the primitive of  $\frac{1}{\cos \theta}$  with respect to  $\theta$ , which is  $\ln |\sec \theta + \tan \theta|$ . “It was something like

$\ln$  to the power...,  $\ln$  of, wait.  $\int \frac{1}{\cos \theta} d\theta$ . it does not have to be so complicated. There must be something that I overlook. [...] eh. Ah, no, wait wait, hey.  $\sec \theta$  times ... Secant tangent? There was something about that.  $\frac{\sec \theta}{\ln |\sec \theta \tan \theta|}$ . I rely on my memory now, because I have solved those integrals. I know it's an integral with secant, with  $\ln$ . (student calculates the derivative of  $\ln |\sec \theta \tan \theta|$ , infers it is not correct) What was it like? [...] wait, I think I know.  $\ln |\sec \theta + \tan \theta|$  is (student calculates derivative)  $\frac{\sec \theta \tan \theta + \sec^2 \theta}{\sec \theta + \tan \theta}$ . Then you can cancel this ( $\sec \theta + \tan \theta$  in numerator and denominator) and then you obtain indeed... I knew it was something with  $\ln$ .”

We observe that the student solves the task by making use of answer recall, but also reasons on the intrinsic mathematical properties of the task to be successful. In the framework, the only reasoning type that makes use of recall of an answer is Memorized Reasoning. However, the second criterion of Memorized Reasoning is not fulfilled. The strategy implementation was not just writing down the answer, since the answer was constructed and verified building upon the intrinsic mathematical properties of the components involved in the reasoning. On the other hand, the category of Creative Mathematically founded Reasoning does not reflect the important role of memory in this solution. This example shows hybrid reasoning with elements from Creative Mathematically founded Reasoning and from Memorized Reasoning.

### **Intrinsic mathematical properties or surface properties?**

Example 4:  $\int \sqrt{9-x^2} dx$ ; student B rewrote  $y = \sqrt{9-x^2}$  to  $x^2 + y^2 = 9$  and remarked it is a circle: “That gives a nice circle. Then you have got the radius, a circle with radius 9, radius 3, I mean. It’s not transformed, so you get this. Circular coordinates. Let’s take a look at circular coordinates [...] Then you get  $x = r \cos \theta$  and  $y = r \sin \theta$ . So  $r^2 \cos^2 \theta + r^2 \sin^2 \theta = r^2$ . [...] This is of course... This is just  $r^2 = r^2$  because  $\cos^2 \theta + \sin^2 \theta = \dots r^2$ .” The student stops using this strategy.

We observe that the student considered the circular coordinates (polar coordinates) since the integrand made the student think of a circle. The strategy appears to be selected based upon intrinsic mathematical properties of the task. However, the student employed the circle coordinates in an ineffective way, which shows that the student did not know why the property of the task, that it concerns a circle, implies the use of circle coordinates. The strategy of using circle coordinates are selected only because the task concerned a circle, therefore the foundation for strategy selection should be regarded as based on the task’s surface properties. This example raises doubts concerning whether it is always possible to distinguish a surface property from an intrinsic mathematical property.

### **Conclusions and discussion**

The framework by Lithner (2008) provides means to highlight foundations that underlie students’ reasoning when solving a mathematical task. However, we faced several difficulties when employing the framework as an analysis instrument. Examples 1 and 2 concern rather distinct reasoning episodes, while both satisfy the definition of Familiar Algorithmic Reasoning. Whether or not the student provides mathematically founded reasons is a relevant characteristic but not included in the definitions. In Examples 2 and 3, the predictive argumentation of a strategy was imitative (based on recall of any kind), but verificative reasoning was founded in intrinsic mathematical properties of the task. These examples reveal that the framework does not cover such ‘hybrid’ types of reasoning. Example 4 confronted us with the more fundamental issue how to decide whether reasoning is based on ‘surface properties’ or on ‘intrinsic mathematical properties’.

A way to improve the applicability of the framework is to include reasoning types that are mathematically founded as well as make use of some kind of imitative reasoning. This is not the same as local CMR (Lithner, 2004), which is reasoning that is partly Creative Mathematically founded Reasoning while the remainder is Imitative Reasoning. We propose that reasoning can be mathematically founded without being creative, and in addition, that mathematically founded reasoning can be intertwined with imitative reasoning. Whether a property is an intrinsic mathematical property or a surface property appears to depend on the student’s understanding, e.g. of why a certain task property leads to a certain strategy selection. Distinguishing between the use of surface properties and intrinsic mathematical properties therefore requires a more complete picture of the students’ reasoning as a whole. These suggestions are based upon difficulties faced when applying the framework on a small number of reasoning episodes within the domain of integration. To obtain a framework adequate to characterize any type of mathematical reasoning not only requires thorough investigation of specific examples, but also requires investigation of the structure of the framework such that the framework will be decisive for each reasoning episode to be characterized.

# A categorisation of the resources used by undergraduates when studying mathematics

Marinos Anastasakis, Carol Robinson and Stephen Lerman

Loughborough University, Mathematics Education Centre, Loughborough, United Kingdom;

[M.Anastasakis@lboro.ac.uk](mailto:M.Anastasakis@lboro.ac.uk), [C.L.Robinson@lboro.ac.uk](mailto:C.L.Robinson@lboro.ac.uk), [S.Lerman@lboro.ac.uk](mailto:S.Lerman@lboro.ac.uk)

*This paper presents results from a survey exploring the kind of resources that engineering undergraduates (N=201) use when studying for their mathematics modules. By using Factor analysis, we were able to produce a typology of these resources. The resulted typology was further analysed by combining Leontiev's version of Activity Theory and Wartofsky's hierarchy of artefacts. This helped us to draw links between the tools that students use and infer about their learning actions.*

*Keywords: Blended learning, educational resources, student centered learning, activity theory, Wartofsky.*

## Introduction

Historical records suggest that using tools has always been inseparable from expressing and doing mathematics (Roberts, Leung, & Lins, 2012) with numerous examples demonstrating the capacity of tools to influence the development of mathematics itself as a scientific discipline (Laborde & Sträßer, 2009)<sup>1</sup>. Since the end of the nineteenth century many different types of tools have been used for the teaching and learning of mathematics (Kidwell, Ackerberg-Hastings, & Roberts, 2008) however for many the term “technology” corresponds to electronic or digital in nature tools (e.g. calculators) something that manifests a kind of historical amnesia (Roberts et al., 2012). Students nowadays have access to a plethora of digital/online resources that they could use alongside more “traditional” ones (e.g. textbooks, lectures or their own notes) and thus blend their learning. As a matter of fact, Masie (2006) asserts that this has been always the case as students were always combining resources in order to support their learning. The notion of blended learning (BL) has been introduced almost 30 years ago however, the term has not been clearly defined yet (Bos & Brand-Gruwel, 2016; Graham, 2013; Torrisi-Steele & Drew, 2013). The three main definitions of BL used in education are (Sharma, 2010): BL as a *combination of face-to-face and on-line teaching*; BL as a *combination of technologies* and; BL as a *combination of pedagogical methodologies*. In this paper, we are mainly referring to BL as a combination of technologies or better as a combination of tools since each era has its own technologies not only digital ones. Despite what its name implies, BL has received criticisms and some authors argue that it should be rather called *blended teaching* because current views adopt a teacher-centred and not a student oriented perspective by focusing on the resources that instructors choose for their students (De George Walker & Keeffe, 2010; Oliver & Trigwell, 2005). If students indeed blend their learning by mixing different resources not just digital or the ones provided to them by their institution, *what kind of resources do they blend and how can these resources be classified?* In terms of the resources that students use, we have found a lack of empirical studies exploring the kind of resources that undergraduates *themselves choose and use*, with previous studies focusing

---

<sup>1</sup> Although many authors consider the terms “tools”, “artefacts”, “instruments” or “resources” to be different, for the purposes of this paper we treat them as having the same meaning.

mostly on digital/online or institutionally-led resources and thus neglecting the “blended” nature of their learning (for a short review see Anastasakis, Robinson, & Lerman, 2016). In effect, our sense of the field aligns with comments from authors suggesting that the student perspective has not been taken into account in the BL literature (e.g. Ituma, 2011; López-Pérez, Pérez-López, & Rodríguez-Ariza, 2011). Having previously identified the kind of resources that a sample of engineering undergraduates uses when studying mathematics (Anastasakis et al. 2016), our aim in this paper was to propose an empirically based typology of these tools.

## Theoretical framework

Long before the dominance of the world wide web and computers, many researchers had emphasised the significance of tools in our everyday activities; a well-developed theoretical account of human praxis which emphasises the role of physical tools is second generation Activity Theory (AT) (Leontiev, 1981). From an AT perspective, our relationship with the “objective” world is mediated by tools: the central role of tool mediation within this framework is due to the fact that tools shape the ways we interact with reality and they reflect past people’s experiences and practices (Kaptelinin & Nardi, 2006). In AT, activities have a hierarchical structure and they consist of three layers (*Ibid.*): at the top is the activity itself directed towards the object of the activity (our overarching goal); in the middle lie actions (what we do) directed at goals (what we want to achieve) and; finally, at the lower layer we find operations (non-conscious, routine processes) which are directed to conditions (non-subjective factors that affect our actions). In sum, AT asserts that tools are the means by which subjects are trying to achieve their goals and in this sense tools are bounded with a subject’s practice. Despite the central position that tools hold in AT, little is written from this perspective in regards to how they can be categorised; among the little accounts found in the literature, is Wartofsky’s typology of artefacts. Wartofsky (1973) considered tools as the genes of our cultural evolution and proposed that they can be classified into *primary*, *secondary* and *tertiary* artefacts. As primary are considered the tools themselves (Engeström, 1990); secondary artefacts represent “modes of action using primary artefacts” (Cole, 1996, p. 121) and they “synthesise the ways and procedures of using instruments and materials” (Miettinen, 1999, p. 189). Finally, tertiary artefacts are those which emphasise creativity (Kaptelinin & Nardi, 2006) and “transcend[s] the more immediate necessities of productive praxis” (Wartofsky, 1973). As an example of what constitutes a primary and a secondary artefact, Bussi and Mariotti (2008) refer to the abacus: the abacus itself is a primary artefact and the ways of using abaci for counting, keeping records or making computations represents a secondary artefact. Engeström notes that Wartofsky’s typology is closely related to Leontiev’s levels of activity (Petersen, Madsen, & Kjær, 2002): primary artefacts correspond to the level of operations/conditions, secondary to the level of actions/goals while tertiary to the level of the activity (Engeström, 1990; 2015). Our focus in this paper are primary and secondary artefacts.

## Method

This study is part of a doctoral project that aims to identify the kind of tools that undergraduates use when studying mathematics, how these tools are used and the reasons for using them. During the autumn term, a paper-based questionnaire was administered to four different groups of second year engineering students in Loughborough university and in total 201 completed it. Loughborough has one of the largest cohorts of engineering students (over 3000 undergraduates) in the UK and a well established provision of Mathematics Support (<http://www.lboro.ac.uk/departments/mlsc>). It has also

led on significant projects producing high quality printed material (e.g. the HELM project: <http://helm.lboro.ac.uk>). The questionnaire consists of three main parts and its design was guided by Activity Theory (AT) (Leontiev, 1981). Here we report only on the part related to the resources (tools) that undergraduates use. In this, students were explicitly asked to identify how often they use a list of 14 resources on a 6-point semantic scale (1/Never, 2, 3, 4, 5, 6/Always) with two additional open ended items for other resources not listed in the questionnaire. The list was based on our literature review, five in depth interviews with undergraduates conducted in 2015 and the resources that Loughborough University offers to students e.g. the Learn website (university's VLE). The list of resources was carefully generated and encompasses a great variety of tools available to students; in this way it reflects -to a certain degree- students' reality as learners when it comes to the resources they use. Students were also asked to identify which five of these 14 resources they use the most (top-5) and rank them in a descending order (not reported here).

## Analysis and results

### Summary statistics

Results for the tools that students use are presented in Figure 1. These results have been already presented elsewhere (Anastasakis et al., 2016) but we include them here for clarity. By using each tool's mean, we categorised them into three main groups: tools with a mean greater than or equal to 4.5 were characterised as *high-use*, those with a mean between 3 and 4.5 were assigned into the *mid-use* group while resources with a mean between 1.5 and 3 were put into the *low-use* group.

### Factor Analysis

Exploratory Factor Analysis (EFA) is a statistical method aiming at grouping variables which have something in common (i.e. they correlate with each other). This enables researchers to identify latent constructs in the data that cannot be measured otherwise directly. Each group (or cluster) of variables is then called a factor and the variables consisting each factor are thought to be measuring the same underlying/latent construct i.e. each factor represents one underlying construct. An initial EFA was performed on all the 14 variables for tools. We used an oblique rotation because the underlying constructs sought in our data were expected to be related (all variables are related to tool-use after all). Our sample's adequacy was measured by the Kaiser-Meyer-Olkin measure of sampling adequacy and found to be above the minimum value of .5 ( $KMO=.711$ ). Bartlett's test of Sphericity also showed that the correlations between variables are not 0 i.e. the correlation matrix is not an identity matrix: this is true when the significance value for this test ( $p$ ) is less than .05 and in our case, it was  $p<.001$ .

**Table 1: Pattern matrix of the final EFA (please note that values below .3 are omitted)**

**Table 2: Structure matrix of the final EFA (please note that values below .3 are omitted)**

The scree plot was used as a criterion for determining how many factors should be kept. Two lines that best summarise the scree plot were drawn with the intersection of these lines (called point of inflection) indicating how many factors are present in our data, excluding the factor on the point of inflection (in our case 3 factors). We additionally examined both the pattern and structure matrices and decided to exclude the variables “own written lecture notes”, “HELM workbooks”, “Learn website” and “Wolfram Alpha” from our subsequent analysis. This was done because these variables were either having factor loadings below the cut-off value of .364 that we used based on our sample’s size (see Stevens, 2002, p. 374) or because only one variable was present on a single factor (the goal of EFA is to group similar to something variables). Based on this analysis, we run a second EFA on the 10 remaining items with an oblique rotation ( $KMO = .711$ ,  $p < .001$ ) by requesting a 3 factor solution. Both the pattern and structure matrices were interpreted (Tables 1 and 2). Factor loadings (numbers at structure and pattern matrices) can be thought as the correlations between each variable

and the factors and they represent how well a variable “fits” into a factor. The final obtained factors included the following variables:

- **Factor 1** (5 variables): “Mathematics Learning Support Centre”, “other textbooks”, “lecturers”, “pre-university notes” and “staff at tutorials”
- **Factor 2** (3 variables): “other students”, “instant messaging” and “social media”
- **Factor 3** (2 variables): “online videos” and “online encyclopaedias”.

At this point, we decided to treat the 4 variables not loading on any Factor (“HELM workbooks”, “own written lecture notes”, “Learn website”, “Wolfram Alpha”) as latent constructs too. This decision was made for two reasons: first, these variables did not load on any Factor (i.e. not relating with other variables); and second, the nature of each resource is different and unique when compared with the other resources, thus they can be thought “measuring” something on their own. By adopting a descriptive approach (Rummel, 1970) we named the 7 identified types of resources as follows:

1. **The “official” mathematical textbook:** “HELM workbooks”
2. **Students’ lecture notes:** “own written lecture notes”
3. **University’s VLE:** “Learn website”
4. **The calculator:** “Wolfram Alpha”
5. **Teaching staff:** Factor 1
6. **Peers and communication tools:** Factor 2
7. **External online tools:** Factor 3

From the above types of resources, “teaching staff” (Factor 1) contains 5 variables which they seem not fitting together; is it reasonable to interpret together different in nature variables such as “pre-university notes”, “other textbooks” and “lecturers” for example? In our opinion, it makes good sense since they correspond to students’ direct interactions with university’s teaching staff (“Mathematics Learning Support Centre”, “lecturers”, “staff at tutorials”) and ways that students interact indirectly with teaching staff; this includes the use of resources probably suggested by teaching staff (“other textbooks”) or resources which are the product of prior interactions with a person holding a teaching position e.g. A-levels tutor (“pre-university notes”).

## Discussion

Our aim for this paper was to produce a typology of the resources that engineering students in our sample reported using. By performing an Exploratory Factor Analysis on our data, we were able to identify 7 different types of resources that undergraduates in our sample reported using (Table 3, left column). From a Wartofskian point of view, all the tools used by undergraduates when examined separately are primary. On the other hand, secondary artefacts represent “*modes of action* using primary artefacts” (Cole, 1996) and they “synthesise the ways and *procedures of using instruments* and materials” (Miettinen, 1999, p.189, our emphasis); this means that our proposed typology corresponds to the different *secondary artefacts* that undergraduates use. When examined from an AT perspective, the typology of tools corresponds to *thematically related actions* that students undertake when studying mathematics. This is because actions in AT are the “...specific interactions that people have with artefacts and other people...” (González, Nardi, & Mark, 2009) i.e. as actions we account the processes of *using* a tool (types 1, 2, 3, 4 and 7) and/or *interacting* with other subjects (types 5 and 6). Our Wartofskian and AT-based interpretations are also consistent from a statistical

point of view: students were asked how frequently they use a resource thus, the nature of each variable is related to using a tool or interacting with a person i.e. an action from an AT perspective (*Ibid.*) or the ways of using primary artefacts. Thus, from both a Wartofskian and AT perspective, the 7 different types of resources that undergraduates use, correspond to the following secondary artefacts/actions (Table 3, right column):

1. Studying the mathematical textbook
2. Taking notes during a lecture
3. Accessing institutionally provided material (online)
4. Performing (complex) calculations
5. Interacting with teaching staff
6. Interacting with peers (in-person or virtually)
7. Searching for external/alternative material online

Typology of Tools	Secondary Tools (Wartofsky) - Actions (AT)
(1) The “official” mathematical textbook	Studying the mathematical textbook
(2) Students’ lecture notes	Taking notes during a lecture
(3) University’s VLE	Accessing institutionally provided material (online)
(4) The calculator	Performing (complex) calculations
(5) Teaching staff	Interacting with teaching staff
(6) Peers and communication tools	Interacting with peers
(7) External online tools	Searching for additional/alternative resources of information

**Table 3: Proposed typology of tools (left) and their representations as secondary artefacts and actions**

## Conclusion

In this paper, we analysed survey data from a cohort of second year engineering students (N=201) about the kind of tools they use when studying for their mathematics modules. In contrast with common approaches found in the literature, we did not focus only on digital/online or institutionally provided resources but rather we incorporated a variety of resources that students have at their disposal. An Exploratory Factor Analysis of our data allowed us to identify 7 different types of tools that students in our sample reported using: the “official” mathematical textbook (“HELM workbooks”); their own written notes; university’s VLE (“Learn website”); a sophisticated calculator (“Wolfram Alpha”); university staff (Factor 1); peers and social apps (Factor 2); and non-institutional online tools (Factor 3). By adopting Wartofsky’s hierarchy of tools these dimensions represent secondary artefacts i.e. 7 different ways that students use primary artefacts or students’ modes of action when studying mathematics: studying the mathematical textbook, taking notes during a lecture, accessing institutionally provided material, performing calculations, interacting with teaching staff, interacting with peers and searching online for additional/alternative sources of information. This interpretation is consistent with AT because these dimensions represent students’ actions when studying mathematics. One important implication of our analysis is that although some resources are

different (e.g. people, digital) they may be used by students in a *similar* way: this was the case of Factor 1 which contained different in nature resources. This result contradicts our common assumptions when categorising resources (e.g. people, digital, online etc.) and adds an empirical basis for the argument that the way we usually classify resources does not necessarily reflect the ways these resources are used. Because of the nature of our data, we could only infer about the nature of the 7 types of tools that undergraduates use by only examining the resources included in each type. However, our preliminary analysis of 14 interviews suggests that our interpretation aligns with these resources' actual use: for example, students who interviewed reported using Facebook for communicating with peers when having an issue with mathematics (either by using Messenger or by posting a question on Facebook groups created by undergraduates). Our intention for the future is to complement the survey data with data gathered with other methods (interviews and diaries). Finally, we are of the opinion that the results of our analysis (students' learning actions), highlight the temporal nature of all primary tools used in learning and suggest that our future research foci in mathematics education should be on the ways that these tools are used rather than the tools themselves.

# An analysis of freshmen engineering students' notes during a preparatory mathematics course

Chiara Andrà

Politecnico di Milano, Italy; [chiara.andra@gmail.com](mailto:chiara.andra@gmail.com)

*I analyse the notes of a group of first year engineering students who attended a course in pre-calculus mathematics. Being interested in verbalisation skills at the beginning of university, I adopt a narrative lens to analyse the notes: I see a lecture as a story being told by the teacher and the students' notes as re-tellings of the teacher's story. I focus on the way the students condense the mathematical content in their written notes in two distinct teaching formats: a traditional frontal lesson and the concluding phase of a classroom discussion after a small group activity.*

*Keywords: Secondary-to-tertiary education transition, students' notes, narrative approach.*

## Introduction

This paper is part of a wider research project on freshmen engineering students at the Polytechnic of Milan, aimed at understanding their difficulties during the first year of their studies. Recent research has found that mathematics at tertiary level is difficult for engineering students (see e.g. Gomez-Chacon, Griese, Rosken-Winter & Gonzales-Guillen, 2015). Gueudet (2008) provides a detailed overview of mathematics education studies concerning the transition from school to university and she identifies the theme that is the core of my research, namely: the students' organisation of knowledge that is new to them at the beginning of university.

Boesen, Lithner & Palm (2010) argue that the kind of task assigned to the students affects their learning: tasks with low levels of cognitive demand lead to rote-learning by students and, consequently, their inability to solve problems that are unfamiliar to them (for instance, the ones that require conceptual understanding). Breen, O'Shea and Pfeiffer (2013) define an 'unfamiliar task' as a task "for which students have no algorithm, well-rehearsed procedure or previously demonstrated process to follow" (p. 2318), and provide evidence that this kind of tasks raises an awareness about the need for more than procedural understanding of mathematics, thus easing the students' transitions to university math practices. Also, the teaching strategies employed in the class can influence the development of one type of knowledge more than another: teacher-centred methods would favour the development of procedural knowledge and student-centred methods would favour conceptual knowledge (see e.g. Garner & Garner, 2001; Allen, Kwon & Rasmussen, 2005). Inspired by these studies, I investigate how the students organise the knowledge in their notes during a preparatory math course.

To take notes does not involve only mathematical ability. It involves also verbalisation skills. O'Neill, Pearce and Pick (2004) found that there is a correlation between performance in generating narratives and mathematical ability as early as in primary school years. With Nardi (2011), I recognise the centrality of the students' ability to use ordinary language to construct and convey mathematical meaning and I investigate undergraduate engineering students' notes in a preliminary math course at their first year at university. With Nardi (2011), I value the students' attempts to mediate the mathematical meanings through words, symbols and diagrams and I maintain that at the basis of the students' difficulties in dealing with a discursive shift from secondary to university mathematics there are: (a) undervalued verbalization and (b) premature compression. According to the former, "the

students undervalue, and often avoid entirely, expressing their mathematical thoughts verbally” (Nardi, 2011, p.2056); according to the latter, “students’ mathematical writing is typically prematurely compressed, namely ridden with gaps, leaps and omissions” (ibid.).

## Theoretical framework

Andrà (2013) examines the relationships between a teacher’s lecture and the students’ notes by viewing the lecture as a kind of story that the teacher tells and the students’ notes as retellings of the teacher’s story. A mathematical lesson seen as a story can be analysed in terms of its components: its characters, setting, action, plot, and moral (see also Bal, 2009). Mathematical objects, in fact, can be considered the mathematical characters of a story (Dietiker, 2012). They can play a central or a peripheral role, have multiple names, and have properties that can be introduced and developed gradually. The setting is the space where characters are placed. Sometimes the setting is not obvious, as it refers to underlying assumptions and/or axioms. The setting may also involve different registers, such as algebra or the Cartesian coordinate system. The action is that which the actor performs. In mathematical stories, the result of an action can be a change in an object or in a setting, or both. According to Dietiker (2012), we see that, unlike in literary stories, mathematical ones can change actions into objects (through reification). Andrà (2013) observes that the students miss important (teacher’s) mathematical actions in their notes and more in general Morgan (1998) notices a relative absence of active verbs in mathematical writing. The moral can be seen as the intended message of the lesson. The plot is the sequence of actions and it involves the shaping of the story, which is linked to its aesthetic effects: for instance, the rhythm and the frequency of the story (Bal, 2009) may affect the students’ focusing on the areas of emphasis of the story and foster his anticipative acts. Some moves might displace attention away from what the teacher wants to communicate: for example, repeating the name of a character often may lead the students to think that the actual name is important, or more important than its properties. Other moves may induce the students to believe that the setting is unimportant. These moves can be interpreted in terms of Rotman’s (1988) schema, which distinguishes between invitations for the reader to be a “thinker” and ones that prompt the reader to be a mere “scribbler”. This distinction provokes a further distinction, namely: to think about note-taking as mere consumption of mathematical meaning or to think about it as active production of meaning. It is possible to interpret Rotman’s schema with respect to the students’ notes in this way: a scribbler is a student who reports mainly the mathematical characters of the story and misses the actions, so that the notes result to be compressed and ridden with gaps, leaps and omissions (see also Nardi, 2011). A scribbler is also a student who avoids putting her thoughts in her notes, and limits herself to copying and/or reporting what the lecturer is saying/writing. The plot is the same plot as that of the story told by the lecturer. A thinker, instead, re-organises the content of the lesson, she (re)structures the plot so that it becomes accessible to herself even after the lesson ends. A thinker pays attention to the details and also records the mathematical actions so that her notes are not overly compressed and under-verbalised. In Andrà’s (2013) understanding of Rotman’s schema, furthermore, some moves invite the students to be thinkers while others invite them to be scribblers. In view of the findings of Boesen, Lithner & Palm (2010) we consider two scenarios: in the first one, the lecturer proposes a group activity on a conceptual and unfamiliar task and the students’ notes are taken during the classroom discussion that follow the group activity; in the second scenario, the lecturer assigns a procedural task and corrects it on the blackboard. The interest is to see how the students’ notes change (if so) in the two different scenarios.

## Methodology

The Polytechnic of Milan, like many universities all around the world, organizes some courses before the beginning of the first semester, which have the purpose to recapitulate the basic knowledge that is necessary for the students to successfully attend the courses at the first academic year. One of these preparatory courses is on pre-calculus mathematics. Since three years, the course is organised according to a flipped classroom pedagogy: the students (are supposed to) watch a series of videos in a MOOC and at university the lecturers of the preparatory course involve them in groupwork activities aimed at deepening their understanding of the basic math concepts and expose the students to frontal lessons with routine exercises. The mixed method of teaching serves the purpose of both exposing the students to a new, “conceptual” teaching and to make them feel comfortable with teaching practices that are more typical of secondary school. During the first lesson of the preparatory course, among the exercises given about polynomials, one had a conceptual nature, since it said “The polynomial  $p(x)$  is divisible by the polynomial  $q(x)$  if...”. This is a kind of task that is unfamiliar for Italian students, since it asks for reflection about the definitions and the students do not have a well-established procedure to resort to. It was first dealt with in small groups, then discussed at classroom level. During this last phase, the teacher wrote the steps of the solution at the blackboard and the students took notes. Another task had a procedural nature and was not unfamiliar for the students: two polynomials were given,  $p(x)$  and  $q(x)$ , and the students were asked to divide  $p(x)$  by  $q(x)$ . It was solved at the blackboard by the teacher. I compare and contrast the students’ notes in these two different situations: one familiar and procedural (i.e., linked to actions), one unfamiliar and conceptual (i.e., linked to characters). In this study, the lecturer under consideration is also the researcher and the author of this paper. At the end of the lesson, the students were informed about the study and invited to provide their notes for research purposes. I am aware of the potential issues concerning this method of data collection, and I followed ethical guidelines in order not to expose the students to risk. Ten students offered their notes; of those I selected four to be analysed in this paper since they are contrasting. The students are identified with four fictitious names: Angela, Filippo, Roberto and Vincenzo. Their notes are analysed through a narrative lens, identifying: the mathematical characters; their setting; the mathematical actions, understood in terms of operations made on/by the mathematical characters; the plot, or the organisation of the content on the sheet of paper; the moral. The four students are inferred to be scribblers or thinkers by looking at these elements. The research questions read as follows: (a) how do students organise their notes? (b) which elements of the teacher’s “story” are recorded, and which ones are discarded? (c) in which cases do the students act as scribblers and in which ones as thinkers?

## Data analysis

Figures 1-8 report the four students' notes regarding the two tasks. Since they are in Italian, a translation is provided in the caption of each figure.

Handwritten notes by Vincenzo on a grid background. The first row says "q(x) divisibile per p(x)". The second row shows the formula  $\frac{q(x)}{p(x)} = a(x)$ . The third row says "POLINOMIO a(x) t.c. q(x) = a(x)p(x)".

**Figure 1:** Vincenzo's notes about the "conceptual task". On the first row, he writes "q(x) divisible by p(x)". On the second row, he writes a formula and in the last row: "polynomial a(x) s.t.  $q(x) = a(x)p(x)$ ".

Handwritten notes by Angela on a grid background. The first row says "q(x) divisibile per p(x)". The second row shows  $\frac{q(x)}{p(x)} = a(x) \rightarrow$  followed by "risultato" and "polinomio". The third row says "quindi esiste un polinomio a(x) tale che". The fourth row shows the formula  $q(x) = a(x) \cdot p(x)$ .

**Figure 2:** Angela's notes about the "conceptual task". On the first row, she writes "q(x) divisible by p(x)". On the second row she writes the ratio, then she adds an arrow and writes "result", then another arrow and "polynomial". On the third row, she writes "hence there exists a polynomial a(x) such that  $q(x) = a(x)p(x)$ ".

Handwritten notes by Filippo on a grid background. The first row says "q(x) divisibile per p(x)" followed by an arrow pointing to  $\frac{q(x)}{p(x)} = g(x)$  and then "polinomio". The second row says "ESEMPIO" followed by the formula  $\frac{x^3-1}{x-1} = x^2+x+1$ . The third row says "quindi vuol dire che esiste un polinomio g(x) tale per cui per ogni polinomio q(x) = a(x)p(x)".

**Figure 3:** Filippo's notes about the "conceptual task". On the first row, he writes "q(x) divisible by p(x)", then he draws an arrow and writes a ratio, from which he draws another arrow and writes "polynomial". On the second row, he writes "example" and in the third row he writes a formula. In the last row: "hence it means that there exist a polynomial g(x) such that I can write  $q(x) = a(x)p(x)$ ".

Handwritten notes by Roberto on a grid background. The first row says "q(x) divisibile per p(x)  $\Rightarrow$   $\exists$  un polinomio a(x) /  $q(x) = a(x) \cdot p(x)$ ". The second row shows three parts:  $\frac{q(x)}{p(x)} = a(x)$ ,  $q(x) = x^3 - 1$  and  $p(x) = x - 1$ , and  $\frac{q(x)}{p(x)} = x^2 + x + 1$ .

**Figure 4:** Roberto's notes about the "conceptual task". On the first row, he writes "q(x) divisible by p(x)", then he draws an arrow and writes "a polynomial a(x) |  $q(x) = a(x)p(x)$ ".

Vincenzo's notes (Figure 1) report exactly what the lecturer wrote on the blackboard. From these notes, we can see that the story has: (A) two mathematical characters, p(x) and q(x) and there's a relationship between them, being the latter divisible by the former; (B) the mathematical action is a division; (C) the moral is that there exists a polynomial a(x) such that  $q(x) = a(x)p(x)$ . Vincenzo's plot is linear: each row is put below the other one, with no connections. The plot of Angela's story (Figure 2) is also linear: (A) is followed by (B) that is followed by (C). But she also adds an arrow on the right side of (B) and she writes "result", then another arrow and then "polynomial". These

details have been told by the lecturer orally. For Angela, it is worth noticing that the result of the mathematical action is a polynomial (which is  $a(x)$ , a new character), namely a character that still has the same properties of the other two. While the setting was implicit in Vincenzo's notes, it emerges in Angela's ones: the setting is the set of polynomials. Instead of the mathematical symbol for "there exists", she writes in words and she also adds "hence" at the beginning of (C): the moral is made more explicit and the verbalisation is less condensed compared to Vincenzo. Filippo (Figure 3) organises the plot in a non-linear way: he writes (A) and on the same row he writes (B), to which he draws an arrow and writes "polynomial". Like Angela, Filippo also remarks about this detail. Vincenzo and Angela do not write down the example, while Filippo does. Hence, a story in the story is told: it's the story of the two characters that become two particular polynomials. At the end of the story, Filippo writes (C) in a fashion that is similar to Angela's.

Filippo's story is slightly less linear than the stories re-told by Angela and Vincenzo, but the student that writes a different plot is Roberto (Figure 4): he writes (A), an arrow, then (C) on the first row, namely he puts at the first line the characters and the moral, then on the second row he writes the action, which is (B), and the story in the story, namely the example. We can infer that Roberto is a thinker, since he re-organizes the knowledge, while Vincenzo is a scribbler, since he reports the story in a linear way. Angela and Filippo also act as scribblers: in a sense, we can say that they are more accurate than Vincenzo, since they report more details, but do not re-organise the content of the lesson as Roberto does. Roberto, in fact, does not only remark what is worth noticing, he establishes a hierarchy in the mathematical content: characters and moral on the same, first row, and the action plus the example on the same, second row.

ESERCIZI SU DIVISIONE EUCLIDEA E RUFFINI

1.  $P(x) = (x^3 - 4x^2 - 17x + 60)$   
 $Q(x) = (x - 5)$  → SE USO RUFFINI PERCHÉ È PRONTO UN POLINOMIO DI PRIMO GRADO

	1	-4	-17	60
+5		5	5	-60
	1	1	-12	0

$A(x) = x^2 + x - 12$

2.  $P(x) = x^3 - 6x^2 + 2x - 1$  QUESTA DIVISIONE È UNA FATTORIZZAZIONE PERCHÉ NON C'È RESTO

**Figure 5:** Filippo's notes about the "procedural task". On the first row, he writes "Exercises on euclidean division and Ruffini's division". To the right of the first arrow he writes "Ruffini is used because a first order polynomial is present". To the right of the arrow pointing to -60, he writes "this division is a factorisation, because there's no reminder".

If we look at the "procedural task" in Filippo's notes (Figure 5), we notice that he employs a more linear structure compared to the "conceptual" task. He writes: (0) the title of the story ("Exercises on the Euclidean division and Ruffini"), then (1) he presents the characters  $P(x)$  and  $Q(x)$ , then (2) the series of actions in the Ruffini's grid. The new character, (3)  $A(x)$ , the result of the actions, is present to the right of the grid. At the right side of the paper he adds comments that are connected to the "story" by means of arrows: such comments better characterise, and justify, the actions that are made. Like in the conceptual case, we see them as details that are worth to be noticed by Filippo. Like in the conceptual case, we can say that Filippo is an accurate scribbler. Vincenzo's notes (Figure 6) also have a linear structure with no connections between (1) and (2), or between (2) and (3). Vincenzo also adds the comment "we use Ruffini when we divide by an order-1 polynomial", but this comment about the actions is put below the characters with no arrow.

$P(x) = x^3 - 4x^2 - 17x + 60$   
 $Q(x) = x - 5$   
 Usiamo Ruffini: quello che si fa in linea di pancia!  

1	-4	-17	60
+5	5	5	-60
1	1	-12	0

 $A(x) = x^2 + x - 12$

**Figure 6:** Vincenzo's notes about the "procedural task". The first sentence reads "We use Ruffini when we divide by an order-1 polynomial".

$P(x) = x^3 - 4x^2 - 17x + 60$   
 $Q(x) = (x - 5)$   

1	-4	-17	60
-5	1	1	-12
1	1	-12	0

 $A(x) = x^2 + x - 12$      $R(x) = 0$

**Figure 7:** Angela's notes about the "procedural task".

$P(x) = x^3 - 4x^2 - 17x + 60 \Rightarrow$  RUFFINI PERCHÉ  $x=5$  è tale che  $P(5)=0$   
 $Q(x) = x - 5$   

1	-4	-17	60
5	5	5	-60
1	1	-12	0

 $A(x) = (x-5)(x^2 + x - 12)$      $A(x) = x^2 + x - 12$      $R(x) = 0$   
 $P(x) = (x-5)(x-4)(x+3)$

**Figure 8:** Roberto's notes about the "procedural task".

Angela's notes (Figure 7) reflect exactly what the lecturer wrote on the blackboard. The notes have no words, just symbols: we can say that there's only one register present, the symbolic one. She records the characters, i.e. (1), the actions, i.e. (2), and the new character that results from the action, i.e. (3). Differently from Filippo, whose notes have a rather linear structure, Angela's ones are even more linear and essential, as if she wants to record just the essential facts. Like Vincenzo, Angela is an (inaccurate) scribbler.

Roberto (Figure 8) records (1), then (2), then (5)-(3)-(4) on the same line. To the right of (1) he remarks "Ruffini, because  $x=5$  is such that  $P(5)=0$ ", hence noticing a detail that is different from the ones recorded by Filippo and Vincenzo and also less general than those: Ruffini's algorithm can be used for any value of  $x$  when  $q(x)$  is an order-1 polynomial, not only for those polynomials where the value of  $x$  is a zero. Since the lecturer has said something different (see Filippo's or Vincenzo's notes), we can infer that Roberto added a detail that generated from his own knowledge about polynomials. As for the conceptual task, Roberto reorganises the space of the sheet and we can infer that he acted as a thinker.

## Discussion

I discuss the data analysis in terms of what the distinction between scribblers and thinkers can add to: (1) our knowledge of the students' verbalisation skills (responding to the question which elements of the teacher's "story" are recorded, and which ones are discarded?); (2) our understanding of how the students organise their knowledge (how do students organise their notes?); (3) whether the teaching

strategies have an influence on conceptual and procedural understanding of mathematics (when do the students act as scribblers and when as thinkers?). I would like to underline that I am not valuing “thinker” over “scribbler”, on the contrary I am interested in seeing which elements of the lesson provoke either modality in students. Comparing Angela’s and Vincenzo’s notes, I tend to say that both them act as scribblers in both tasks. I can further infer that Angela is a scribbler because the course is recapitulating mathematical concepts that are familiar for her: she probably does not need to put so many details in her notes. Angela’s notes of the procedural task report only what has been written on the blackboard. Looking at her notes for the conceptual task, furthermore, I commented that she had time to record details that are worth to be noticed and she didn’t give us the impression that she was rushing to keep the pace of the lecturer. For Vincenzo, it is a completely different story: he records only what has been written on the blackboard during the conceptual task and during the procedural one he added “We use Ruffini when we divide by an order-1 polynomial” to his notes with respect to what has been written on the blackboard. I can see that Vincenzo is struggling to remark all that is relevant, since the lesson is difficult for him. A conclusion that can be drawn from these observations is that a student acts as a scribbler in two cases: either if the mathematical content is too easy for her, or if it is too hard.

Nardi (2011) pointed out that the students under-verbalise and hyper-condense the mathematical discourses. As regards the conceptual task, I can see that Vincenzo and Roberto condense the mathematical content more than Filippo and Angela, but Roberto does it in a completely different way compared to Vincenzo: Roberto compresses and organises the content, to have the character and the moral on the same row, and the actions plus the example on the second row, while Vincenzo linearly puts the elements of the story one after the other. Andrà (2010) analysed the teaching styles of university lecturers and concluded that in a blackboard modality (namely, when the lecturer is mostly writing on the blackboard) the students have to adjust the pace of their note-taking to the pace of the lecturer’s writing. By comparing Vincenzo’s and Roberto’s notes, indeed, I can imagine the former making an effort in dealing with a pace that is too fast for him, to the point that he does not have time to record the details that Angela and Filippo remarked, while Roberto seems to stop and think (fast) where he wants to put what is told by the teacher. Angela and Filippo can be seen as accurate scribblers, and it seems that they tend not to hyper-condense the math content. As well, Angela and Filippo tend not to under-verbalise when they take notes on the conceptual task. Why are some students more accurate scribblers than others? Andrà (2010) interpreted this difference in terms of each student’s ability to keep the pace of the lesson at the blackboard, but I would also add that it depends on the student’s views: for some students, it seems necessary to record all the possible details, while for others it seems a question of being brief. Looking closely at Angela’s notes, and comparing her notes on the conceptual task and on the procedural one, I can see a difference: in the first case, she adds details and comments that she discards in the second case. Vincenzo does not add comments in neither case, and Filippo accurately adds details in both cases, hence Angela seems to be the student on which the procedural vs conceptual nature of the task provokes different modalities of taking notes, and actually the conceptual nature of the task invites her to remark more details. This seems to have an impact on her verbalisation skills and on conceptual reflection.

# The transition from high school to university mathematics: A multidimensional process

Amalia-Christina Bampili<sup>1</sup>, Theodossios Zachariades<sup>1</sup> and Charalampos Sakonidis<sup>2</sup>

<sup>1</sup> National and Kapodistrian University of Athens, Greece; [amabab@gmail.com](mailto:amabab@gmail.com), [tzaharia@math.uoa.gr](mailto:tzaharia@math.uoa.gr) <sup>2</sup> Democritus University of Thrace, Greece; [xsakonid@eled.duth.gr](mailto:xsakonid@eled.duth.gr)

*The transition from secondary to tertiary mathematics encompasses a complex interaction of social, academic and mathematical context changes, including a vast array of emotions, beliefs and issues. The present paper reports a study of the difficulties faced by a first year undergraduate student in a Mathematics Department during her transition from secondary to tertiary education through the lenses offered by a rite of passage framework. Data were gathered over the student's first two semesters of attendance predominately through interviews. The results indicate difficulties she faced regarding the mathematical content and a powerful interaction between emotions and the reconstruction of her mathematical thinking.*

**Keywords:** Transition, university mathematics, rite of passage, reconstruction.

## Introduction

The secondary-tertiary transition is itself an exciting and often confusing experience for students. After tough examinations, the successful students have yet to adjust to new learning environments, new modes of study, and above all, higher expectations.

The problems encountered in the transition from high school to university mathematics are common in every educational system worldwide. Several researchers identify a “gap” between school and university mathematics content (Luk, 2005; Kajander & Lovric, 2005; Winsløw, 2013), while others identify important changes that affect students during the secondary-tertiary transition. These include the new academic and social environment as well as the shift required to a different mathematical way of thinking and studying (Cherif & Wideen, 1992; Tall, 1992).

The aim of this paper is to study the ways in which a first-year student in the Department of Mathematics at the University of Athens dealt with transition issues through the lens offered by a rite of passage framework, focusing on the ways that changes in the student's social life and the academic environment shaped the reconstruction of the mathematical thinking required.

## Literature review

The transition from high school to university mathematics could be seen as an interaction of many transitions: social, academic, mathematical content transitions as well as others (Alcock & Simpson, 2002). University as an institution and university mathematics are encountered as a new world, with a new language and new rules that make the novice student feel like a foreigner (Gueudet, 2008).

With respect to the social dimension, Hernandez-Martinez et al. (2011) considered the social aspects of transition as the most important when entering university. Students argue that the beginning of university life can be a quite scary and nerve-racking phase for many but also an “exciting” personal opportunity to develop in a “better environment”. Some recall being quite shy in the beginning but becoming more confident over the first year. Going to college is about “working harder” but also about expanding social life. The change from a structured, parent-disciplined life to a self-disciplined

university life is difficult. First-semester students claim that the change of the education environment, new expectations and unlimited freedom are the biggest problems (Cherif & Wideen, 1992; Clark & Lovric, 2008).

Concerning the academic dimension, students in transition undergo changes requiring an adjustment of learning strategies, time management skills and a shift to more independent studying. They experience changes in teaching and learning styles. They often encounter a higher level of competitiveness among their unknown colleagues (Clark & Lovric, 2008). The new environment demands a different type of critical thinking, something for which students are not necessarily prepared (Cherif & Wideen, 1992).

As far as the mathematical content is concerned, first-year university students often face

the move to more advanced mathematical thinking [which] involves a difficult transition, from a position where concepts have an intuitive basis founded on experience, to one where they are specified by formal definitions and their properties reconstructed through logical deductions (Tall, 1992, p. 1)

Furthermore they are confronted with a significant change from a computational to a proof-based learning and teaching approach. Some concepts learned at high school need to be reconstructed at the tertiary level thus increasing the transition's difficulties. In tertiary mathematics courses students are exposed to the introduction of abstract concepts and formal reasoning; they witness an increased emphasis on the precision and rigor of the mathematical language, and this is very new for them (shock of the new) (Clark & Lovric, 2009). The relevant literature seems to agree that more relational and conceptual understanding as well as more flexibility in solving mathematical problems compared to high school mathematics is expected (Breen, O'Shea, & Pfeiffer, 2013). In other words, a shift from "instrumental understanding" to more "relational understanding" is required.

## **Theoretical considerations**

We employed the rite of passage approach (Clark & Lovric, 2008) to explore the ways in which the subject of the study dealt with transition issues. We considered the transition from high school to university mathematics as a rite of passage, a concept explored in anthropology and in other disciplines (e.g. in cultural studies). French anthropologist Arnold van Gennep (1960) (in Clark & Lovric, 2008) described and analyzed certain events that, in one way or another, create a "crisis" in an individual's life. He observed that these "life crises" (e.g., birth, betrothal, marriage, or death) possess a similar general structure, and based on this, developed a three-stage theory of what he called rites of passage. In the *separation* stage, the person experiencing a crisis gets "removed" from the rest of the community (family, social group, etc.). The process of achieving necessary changes constitutes the *liminal* stage. In the *incorporation* stage, the person learns about the community that she/he will belong to at the end of the rite. With the support of members belonging to the communities involved, she/he is supposed to find her/his place in the new community. Applied to mathematics, the model suggests that one could analyze problems and issues in transition by studying their dynamics within three stages: (a) separation (from high school) which takes place while students are still in high school, and includes anticipation of forthcoming university life; (b) liminal (from high school to university) that includes the end of high school, the time between high school and university, and the start of first year at a university; (c) incorporation (into university) concerning roughly the first year

at a university (Clark & Lovric, 2008). Although Clark & Lovric (2008) suggest applying the rite of passage model with regard to the mathematical content only, we utilize a methodology for revealing the dynamics and the connections within all three dimensions (social, academic and mathematical content).

## The study

Situated within the literature reviewed above, the study reported here is part of an ongoing research project aimed to examine the interface between social, academic and mathematical content aspects of the transition from high school to university mathematics. In particular, the research questions pursued in the study were as follows:

1. What was the dynamics exposed in each of the three stages of the rite of passage along the three dimensions (social, academic and mathematical content)?
2. How do academic and social dimensions interact to shape the passage from the liminal to the incorporation phase regarding mathematical content?

Greek students who want to enter University go through hard preparation to pass the exams in their last high school year. During their final high school year, most of the students undergo a strictly structured life program, including many hours of daily study almost always under the guidance of school teachers and private teachers in paid courses after school. They are introduced to Calculus, coming across proofs, the emphasis of teaching being, however, more on computational than conceptual learning/understanding. As first-semester university mathematics students, they are introduced again to Calculus but this time in formal terms, more as Mathematical Analysis. This constitutes a qualitatively big jump for their thinking. Furthermore, there is hardly any support around provided either by the academic staff, in the form of learning advisors, or by higher-years students and/or the Students' Association.

In October 2015 we started surveying incoming first-year students (October 2015-June 2016), collecting information. Twelve students volunteered to be interviewed individually to help us look thoroughly at the issues described above. Four semi-structured interviews (in the beginning of the first semester, before the semester exams, in the middle of the second semester and before the second semester exams) were carried out, each lasting between 25 and 45 minutes; these were audio-recorded and fully transcribed. Students were asked about their conceptions of university mathematics, how their experience of mathematics at school differed from that at the university, how their study habits or ways of working had changed, how they felt being a member of a new academic environment and how they dealt with the changes in their social-personal life.

One of these students, Nefeli (a pseudonym), is the focus of this work. We chose Nefeli because her responses during data collection strongly indicated that she was undergoing a rite of passage regarding mathematics: although she was doing well in mathematics (her grades were good at school and also in the university entry exams, 16/20 on average), in the beginning of her first university year she felt that perhaps it had not been a good decision to study mathematics. She was negatively affected because of the overwhelming changes imposed in her lifestyle and the new academic environment that strongly influenced her studies. She even considered quitting. Only after the first semester exams did she started adapting to the new environment, and at the end of the first year she almost felt well adjusted.

## Results

Nefeli's representative comments and thoughts related to transition and expressed in the contexts of the four interviews were organized along three dimensions, social, academic and mathematical content, within each of the three phases of a rite of passage, as presented in Tables 1, 2 and 3. In the following, some central issues emerging along each of these dimensions and across the three phases are discussed.

The social aspects of the transition were seen by Nefeli as among the most important (but also worrying) issues. She highlighted mainly two of them: (a) the home-university distance and (b) her relationships with classmates and friends (Table 1).

Social dimension	Separation phase	Liminal phase	Incorporation phase
(a) the home-university distance	S <sub>1</sub> : "School was near my home". (1 <sup>st</sup> interview)	S <sub>2</sub> : "I am negatively affected because of the long home-university distance". (1 <sup>st</sup> interview) S <sub>3</sub> : "I manage time better, but I'm still undergoing a total change in my former well organized life". (2 <sup>nd</sup> interview)	S <sub>4</sub> : "I have the opportunity to manage my time as I want, although not so effectively all the time". (3 <sup>rd</sup> interview)
(b) her relationships with classmates and friends.	S <sub>5</sub> : "I try also to spend some time with my friends from school and neighborhood which is not easy...they hardly understand that I have to study hard". (2 <sup>nd</sup> interview)	S <sub>6</sub> : "Some interesting people I have met here helped me to adjust myself to the new environment". (1 <sup>st</sup> interview) S <sub>7</sub> : "With my classmates I have the feeling that we discuss mostly issues about our studies but in a competitive way". (2 <sup>nd</sup> interview)	S <sub>8</sub> : "I met some higher-year students who helped me a lot to adjust to the new environment". (3 <sup>rd</sup> interview)

**Table 1: Social aspects through the three transition phases**

Nefeli experienced big changes in the new academic environment (academic dimension). A vast array of answers is identified in her interview responses: from great expectations for a creative teacher-

student relationship and academic staff support to her statement that some professors do not care at all if students understand their lectures. Two critical features are (a) teacher-student relation and (b) lack of support (Table 2).

Academic dimension	Separation phase	Liminal phase	Incorporation phase
(a) teacher-student relationships	A <sub>1</sub> : “I had great expectations for a creative teacher-student relationship”. (1 <sup>st</sup> interview)	A <sub>2</sub> : “I couldn’t understand what was written on the blackboard”. (1 <sup>st</sup> interview)  A <sub>3</sub> : “I believe that professors and students are not close enough.... Professors take it for granted that students understand mathematics. They have many academic expectations from them. I am afraid to ask the professor, if I don’t understand something, because he may think that I am stupid”. (2 <sup>nd</sup> interview)	A <sub>4</sub> : “I have to say that some professors guided us well enough...I felt better asking questions and the truth is that I did not receive a negative treatment from the professors”. (3 <sup>rd</sup> interview)  A <sub>5</sub> : “I was positively influenced by the guidance of some teachers who inspired me to listen to them”. (4 <sup>th</sup> interview)
(b) lack of support	A <sub>6</sub> : “I have expectations for academic staff support, like in high school”. (1 <sup>st</sup> interview)	A <sub>7</sub> : “I am negatively influenced by the absence of help from the Student Association and the absence of a Student Learning Advisor”. (4 <sup>th</sup> interview)	A <sub>8</sub> : “...my adjustment was getting better after a long time with great mental and spiritual effort...”. (4 <sup>th</sup> interview)

**Table 2: Academic aspects through the three transition phases**

Regarding studying mathematics (mathematical content dimension), Nefeli lost her self-confidence at the beginning. As time went by, she confronted studying mathematics as a challenge: to turn her

disappointment and stress to something powerful and effective. She highlighted two main issues (a) the psychological impact of the “unknown subject” and (b) the new way of studying (Table 3).

<b>Mathematical content dimension</b>	<b>Separation phase</b>	<b>Liminal phase</b>	<b>Incorporation phase</b>
(a) the psychological impact of the “unknown subject”	M <sub>1</sub> : “I thought that I was good in mathematics because of my good school grades and because I passed the university entrance exams also achieving good grades”. (1 <sup>st</sup> interview)	M <sub>2</sub> : “When I started studying university mathematics, I was desperate. I was wondering if I had taken the right decision”. (1 <sup>st</sup> interview)  M <sub>3</sub> : “I am still thinking that maybe it wasn’t a good decision to study mathematics. If I could say only one thing that I still struggle with, this is the difficulty of the subject. ... I felt I turned my love to mathematics to something sick....”. (2 <sup>nd</sup> interview)	M <sub>4</sub> : “I am in a position now to say that the more I study mathematics the more I love mathematics and I am happy with my choice”. (3 <sup>rd</sup> interview)  M <sub>5</sub> : “I feel more confident. The exams were less demanding than I expected. I passed the exams with good grades”. (4 <sup>rd</sup> interview)
(b) the new way of studying	M <sub>6</sub> : “I experienced a big change. In high school, we did not pay much attention to the conceptual understanding. Teachers told us what to study and how”. (1 <sup>st</sup> interview)	M <sub>7</sub> : “I try to change the way of studying. I try very hard on my own to understand. I try to deepen more in definitions and theorems”. (1 <sup>st</sup> interview)	M <sub>8</sub> : “...I realized that to do well on the first semester exams, I had to use my “simple” knowledge inductively to solve a problem, rather than knowing many things”. (3 <sup>rd</sup> interview)

**Table 3: Mathematical content aspects through the three transition phases**

The results show the dynamics and the connections identified within all dimensions through the three transition phases. As we follow Nefeli’s steps, we can see that in the separation phase she had to deal with her expectations concerning her social and academic life (S<sub>1</sub>, S<sub>5</sub>, A<sub>1</sub>, A<sub>6</sub>) and “move away” from her former way of living and studying (M<sub>1</sub>, M<sub>6</sub>), which is characteristic of this phase. Some of these

changes affected her almost until the end of the first year (for example the lack of studying support). She struggled a lot to achieve necessary changes (a process assigned to the liminal phase), something that also affected her self-confidence as a math student ( $A_2$ ,  $A_3$ ,  $M_2$ ,  $M_3$ ,  $M_7$ ). Her great mental and emotional effort as well as the support of some higher year students and the influence of some inspiring professors ( $S_8$ ,  $A_8$ ,  $A_4$ ,  $A_5$ ) helped her to take the next step. After the first semester exams and more clearly near the end of the first year, it looks like she had also managed to find the necessary way of studying ( $M_8$ ). Overall it seems that she was close to finding her place within her new community, which is a feature of the incorporation phase ( $S_4$ ,  $M_4$ ,  $M_5$ ). Her success in Calculus I and II exams (8/10 and 10/10) can be seen as a positive outcome of her efforts.

## Discussion and conclusions

Regarding our first research question, we found that the rite of passage framework brings out the dynamics of all dimensions. We followed Nefeli passing from one well-defined, established and accepted position in life to another, which is equally well-defined, established and accepted (Clark & Lovric, 2008). Nefeli saw university as an institution and university mathematics as a new world, with a new language and new laws that made her feel like a foreigner (Gueudet, 2008). She experienced a big change in her social and academic life which affected her studies as noted by Hernandez-Martinez et al. (2011). She struggled with the shift from “instrumental understanding” to more rational and conceptual understanding (Breen et al, 2013). As Tall (1992) suggested, in order to achieve the transition, students should adopt a new way of thinking, a prerequisite also acknowledged by Nefeli. Organizing her thoughts and comments within the phases of a rite of passage, we could identify some initial steps of the necessary shift to a new “mathematical self-identity” needed.

Regarding our second research question, the results of our analysis reveals dynamics and connections between all three dimensions (social, academic and mathematical content). To pass from the liminal to the incorporation phase concerning the mathematical content, Nefeli had to feel better in the new academic environment and also try to deal effectively with her social life. For example, she appears to shift from the position that she felt undergoing a total change (in her former well organized -by others- life) during the liminal phase, to finding some positive aspects in her new self-disciplined university life (“I have the opportunity to manage my time as I want” and “I realized I had to use my “simple” knowledge inductively to solve a problem). This is in accordance with Tall’s (1991) position that:

Advanced mathematics, by its very nature, includes concepts which are subtly at variance with naïve experience. Such ideas require an immense personal reconstruction to build the cognitive apparatus to handle them effectively. It involves a struggle...and a direct confrontation with inevitable conflicts, which require resolution and reconstruction (p. 252)

We consider that our study constitutes a good starting point for exploring specific transition issues more extensively. A deeper investigation of the interaction between different aspects of transition from high school to university mathematics is needed. The analysis of other students’ interviews indicates that the rite of passage lens allows for critical social and academic aspects shaping the passage to the new ‘mathematical world’ to be identified. Overall we view studying university mathematics as a multidimensional process requiring the reconstruction of mathematical thinking.

Fulfilling this reconstruction demands a repositioning of the student considering the new social and academic community. To this end, the institution should systematically offer students' support, and in a well-organized manner, since the lack of which, as the results indicated, might affect students' self-confidence and successful adjustment to the new environment.

# **“Points”, “slopes” and “derivatives”: Substantiations of narratives about tangent line in university mathematics students’ discourses**

Irene Biza

University of East Anglia, Norwich, UK; [i.biza@uea.ac.uk](mailto:i.biza@uea.ac.uk)

*This paper reports from a study on first year university mathematics students’ meaning making of tangent line, especially in their transition between mathematical contexts: algebraic, geometrical and analytical. The analysis draws on the commognitive approach (Sfard, 2008) in order to identify characteristics of responses to a questionnaire in which 182 students were asked to explain in simple words the tangent line, describe its properties, provide its definition and identify if a drawn line is a tangent of a given curve. Findings suggest that students engage with analytical, geometrical and algebraic discourses in their substantiations about tangents, sometimes by engaging with more than one discourse in the same response or/and across different responses in the same script.*

**Keywords:** *Tangent line, mathematical discourse, derivative, narratives, routines.*

## **Introduction**

Research reports students’ difficulties with their meaning making of the tangent line to a function graph. These difficulties have been attributed to students’ encounter with the tangent line in different mathematical contexts (e.g. Euclidean geometry, analytic geometry or analysis), disconnection between algebraic or analytical approaches (e.g. rate of change, slope, derivative or tangent line formula) and graphical approaches (e.g. limiting position of secants, visualisation of tangents) and differences between a global perspective (relation of the line and curve as a whole) and the local perspective (relation of the line to the curve at a specific point). Most challenging cases are: when the tangent has more than one common point with the graph (e.g.  $f(x)=\sin x$  at  $\pi/4$ ) or coincides with the graph or a part of it (e.g. when the curve is a straight line); tangency at inflection points (e.g.  $f(x)=x^3$  at 0); and, points in which the limit of the difference quotient from the left and the right are different real numbers (e.g.  $f(x)=|x|$  at 0) or infinity (e.g.  $f(x)=\sqrt{|x|}$  at 0) (Biza, Christou & Zachariades, 2008; Castela, 1995; Park, 2015; Vinner, 1991).

In this paper, I draw on my previous research on students’ perspectives about tangent line (Biza et al., 2008; Biza & Zachariades, 2010) by analysing not only what lines students recognise as tangent or not, but also by considering how they justify their choices. The conjecture I examine here is that students use a range of arguments from geometry, algebra and analysis to justify their choices that go beyond the correctness or not of these choices. With this analysis, my objective is to gain insight into how students make meaning of mathematical objects – in the case of this paper tangents – through their communication about them. To this aim, I analyse first year university mathematics students’ responses to a questionnaire about tangent line by drawing on the commognitive approach (Sfard, 2008). In what follows, I introduce the main tenets of the commognitive approach that I employed in the analysis, and the methodology of the study. Then, I present preliminary findings from the analysis and I discuss them also in relation to potential implications for teaching.

## Theoretical underpinnings of the study

According to the commognitive approach (Sfard, 2008) communication about mathematics in written or verbal responses is not a *window* to thinking but an inseparable part of this thinking that makes sense only in the context in which this communication takes place. A mathematical discourse is defined by four characteristics: *word use*, *visual mediators*, *narratives* and *routines*. *Word use* includes the use of mathematical terms (e.g., in the context of this study, ‘tangent’, ‘derivative’ or ‘direction coefficient’) as well as everyday words with a specific meaning within mathematics (such as ‘touch’, ‘region’ or ‘point’). *Visual mediators* include mediators of mathematical meaning (e.g., function graphs, diagrams, geometrical figures or symbols) as well as physical objects. *Narratives* include texts, written or spoken, which describe objects and processes as well as relationships among those (e.g., definitions, theorems or proofs), and are subject to endorsement, modification or rejection according to rules defined by the community (e.g., ‘a tangent line is a line that has one common point with a curve’ is an endorsed narrative for tangents in Euclidean geometry but not in analysis). *Routines* include regularly employed and well-defined practices that are used in distinct, characteristic ways by the community (such as defining, conjecturing, proving, estimating, generalising and abstracting). Sfard elaborates three kinds of routines: *deeds*, *explorations* and *rituals* where explorations are categorised into *substantiations*, *recall* or *constructions* (ibid, pp. 223–245). Recently, there has been increasing interest in discursive approaches and, especially, in university mathematics teaching and learning research, discursive approaches are gaining more momentum (Nardi, Ryve, Stadler, & Viirman, 2014) in the investigation of university teachers’ discursive practices (e.g. Park 2015; Viirman, 2015) and student learning (e.g. Güçler, 2016).

In this study, students’ responses to a questionnaire are seen as acts of communication and thus part of their meaning making about tangent lines. Mathematical routines such as investigating if a line is a tangent (see question Q3 in Figure 1) can be explorations that include recall of previously endorsed narratives, substantiations of narratives about *why* a line is (or is not) tangent or constructions of new objects such as formulae and graphs. However, there are differences in the mathematical discourses about tangency in analysis, geometry and algebra. For example, in Euclidean geometry, whether a line is tangent or not depends on the number of common points and the relative position between the line and the curve (geometrical routines) because a tangent line to a circle has one common point and keeps the circle to one side (geometrical narratives). In analysis, tangency is checked locally (analytical routine) and is defined by the derivative at a point (analytical endorsed narratives) which is the slope of the line (algebraic narrative). In algebra, the tangent line will be justified through calculations (algebraic routine) of the slope and defined through its equation or the vector that gives its direction (algebraic narratives). Identifying how students’ responses to a questionnaire engage with these discourses is the focus of this paper.

## Methodology

Data reported in this paper were collected from a questionnaire administered to 182 first year university students (97 female) from mathematics departments in Greek universities. All participants had been taught about the tangent line in Euclidean and analytic geometry, and in elementary analysis courses in Years 10, 11 and 12, but not yet at university as the questionnaire was administered at the beginning of their first year. The questionnaire included tasks (see a sample of questions from the questionnaire in Figure 1) in which the students were asked to explain in their

own words the tangent line (Q1); to describe properties of it (Q2); to identify if a drawn line is a tangent line of a given curve (Q3); to construct the tangent line, if it exists, of a given curve through a specific point on the curve or outside the graph (Q4 and Q5); to provide definitions (Q6), to write the formula, and to apply the formula in specific cases (Q7 and Q8). In questions Q3, Q4 and Q5 only the graph was provided and no formula of the corresponding curve was given; students were asked to identify or construct the tangents based on the graphs and justify their choices. The proposed curves were chosen to reflect students' common difficulties with tangent lines identified by previous research (Biza et al., 2008; Castela, 1995; Vinner, 1991). For example, the corresponding line: had more than one common point with the curve (e.g., in Figure 1, Q3.b and Q3.c in comparison to Q3.a challenge the geometrical routine of checking the number of common points and the relative position between the line and the curve) or passed through an inflection point (e.g., in Figure 1, Q3.d and Q3.e challenge the geometrical routine of the relative position between the line and the curve) – for more about the questionnaire design see Biza et al. (2008).

- Q1: Explain, in simple words, what you are thinking when you hear the term “tangent line”.  
 Q2: Write as many properties as you can think of about the relationship between a curve and its tangent line at a point  $A$ .  
 Q3: Which of the lines that are drawn in the following figures are tangent lines of the corresponding graph at point  $A$ ? Justify your answers.

- Q6: What is the definition of the tangent line of a function graph at its point  $A$ ?

**Figure 1: Questionnaire sample**

In earlier analysis (Biza & Zachariades, 2010), student choices in questions Q3, Q4, Q5, Q7 and Q8 were characterised according to their correctness and analysed quantitatively. This analysis suggested a classification of students regarding their perspectives on tangent line and its relation with the corresponding curve into three groups with *analytical local* perspectives (closer to the tangent line in the context of analysis – 25.8%); *geometrical global* perspectives (more relevant to the tangent line in the context of geometry – 17.6%); *intermediate* perspectives between the analytical local and the geometrical global perspectives (56.6%). Although this classification indicated a spectrum of students' perspectives about tangency, it does not grasp the subtlety of these perspectives as they were evident in students' choices and justifications of these choices. To this aim, student responses to questions Q1, Q2 and Q6 and their justifications in questions Q3, Q4 and Q5 were analysed qualitatively. Part of this analysis focuses on the mathematical discourses students engaged in in their responses (analytical, geometrical and algebraic) with specific emphasis on the words used, routines and narratives, substantiation of these narratives, how this discourse is related to their choices (correct or not) in the questionnaire and the consistency of student responses across the questionnaire. This paper discusses preliminary findings from the 182 student responses to the items: Q1, Q2, Q3a-e and Q6 presented in Figure 1.

## Student justifications on why the sketched line is a tangent or not

Justifications students offered in order to accept or reject a tangent line when it does not have any other common point and keeps the graph at the same semi-plane (Q3.a) or when it has other common points sketched (Q3.c) or not (Q3.b) are summarised in Table 1.

Justification	Script Example
<b>Rejection of the line as a tangent</b>	
Common points between line and curve, global view	“No [it is not a tangent], the line has 2 points in common with the function graph”
Relation of the line and the curve, global view	“No it is not a tangent, although it touches <sup>1</sup> the function graph at the point A, it cuts [the graph] at another point”
Relative position of the line and the curve, global view	“[The line] splits the curve in two semi-planes”
Only local acceptance of the tangency	“Not [a tangent] in general [...] in a small interval ( $\delta > 0$ ( $x - \delta$ , $x + \delta$ )) it is [tangent]”
Derivative / differentiability	“Although the function is differentiable at A and thus it has a tangent, the extension of the [line] $\varepsilon$ that goes through A has another common point with the function and as a result it is not a tangent”
<b>Acceptance of the line as a tangent</b>	
Common points between line and curve, local view	“[It is a tangent, b]ecause if we consider a small region ( $\kappa$ , $\gamma$ ) around the point A where [the line] $\varepsilon$ is tangent we can see that [the line] $\varepsilon$ does not touch any other point”
Relation of the line and the curve, local view	“Yes [it is tangent] because it touches exactly at [the point] A and it does not cut it [the graph]”
Relative position of the line and the curve, local view	“The part of the function graph which is close to the point A is located at the same side of the line $\varepsilon$ ”
Common points between line and curve, global view	“It [the line] has one common point with the curve”
Relative position of the line and the curve, global view	“ $f(x) > (\varepsilon)$ ”
Slope of the line	“Yes, the line $\varepsilon$ is tangent at A, the slope equals to the direction coefficient of the line” <sup>2</sup>
Derivative / differentiability	“It is [tangent] because it has slope [equals to] the derivative of the function at this point”
Opposite rays	“The rays $\varepsilon_1$ , $\varepsilon_2$ which are tangents at A are opposite”
Other	“There is only one tangent at the point A” or “There is a limit which is the same from the left and the right side or “ $\varepsilon$ : it is tangent, the point A is defined and belongs to the domain of the graph”

**Table 1: Student choice justifications to questions Q3.a, Q3.b and Q3.c**

<sup>1</sup> Data have been translated from Greek to English. In Greek, the noun *tangent* [line] (*εφαπτομένη* [*ευθεία*]) and verbs such as *being tangent*, *abut*, *touch* (*εφάπτεται*) have the same origin. In Greek, the excerpt: “No, it is not a tangent because although it touches the graph ...” sounds contradictory (“Όχι, δεν είναι εφαπτομένη γιατί αν και εφάπτεται στη γρ. παράσταση ...”), one explanation is that the noun “tangent” draws on the mathematical discourse, whereas the verb “touches” draws on the everyday discourse.

<sup>2</sup> In the Greek curriculum, the “direction coefficient” is the coefficient  $m$  in  $y = mx + b$ , that indicates the slope of a line.

Justifications students offered in order to accept or reject a tangent line when the tangency point is an inflection point (Q3.d and Q3.e) are summarised in Table 2.

Justification	Script Example
<b>Rejection of the line as a tangent</b>	
Common points between line and curve, global view	“No [it is not a tangent], because the curve and the line cut each other in several points”
Relation of the line and the curve, global view	“It is not [a tangent] because [the line] penetrates the curve”
Relative position of the line and the curve, global or local view	“It [the line] intersects the function graph by going to its both sides”
Inflection point / concavity change	“It [the line] is not tangent because A is inflection point”
Change of function formula	“Because the formula of the graph changes”
Derivative / differentiability	“The graph does not have tangent at [the point] A because the graph is an image of a function $f$ and $A(x_0, f(x_0))$ , $f'(x)=\kappa$ for $x < x_0$ and $f'(x)=\lambda$ for $x > x_0$ $\kappa \neq \lambda$ close to $x_0$ ”
Solution of the corresponding system of simultaneous equations (line and curve)	“[The line] $\varepsilon$ is not tangent because the system line – curve has one solution and not a double solution”
Other	“more than 1 lines can be sketched through point A with at least one common point with the graph” or “if we consider the figure as two figures with A as the unique common point the line $\varepsilon$ is a tangent of the two figures. If we consider the figure as a whole the [line] is not a tangent of this figure»
<b>Acceptance of the line as a tangent</b>	
Common points between line and curve, local view	“The $\varepsilon$ has only point in common with $C_f$ in the region $(x_A - \kappa, x_A + \kappa)$ , $\kappa > 0$ and very small”
Common points between line and curve, global view	“The line $\varepsilon$ is tangent because it has one common point with the curve and the concavity of the graph changes at this point” (these participants rejected the line when it had more than one points in common)
Opposite rays	“It is [tangent] but for the right part of the function after A, tangent is the right part of the tangent and respectively for the left [part]”
Slope of the line	“Yes, the line $\varepsilon$ is tangent at A, the slope equals to the direction coefficient of the line”
Derivative / differentiability	“derivative equals to the slope of the tangent”
Inflection point / concavity change	“It is [tangent] and the [point] A is inflection point”
Other	“The $\varepsilon$ is tangent at the point A especially internal”

**Table 2: Student choice justifications to questions Q3.d and Q3.e**

In both set of questions students engage with analytical, geometrical or algebraic discourses. They use narratives such as derivative, differentiability, intervals, regions close to the tangency point, inflection point or concavity (analytical discourse); common points, relative position of curves, same-plane or ray (geometrical discourse); and, slope or system of simultaneous equations (algebraic discourse). Routines include checking for common points or for the relative position between line and curve (geometrical discourse) or for derivatives (analytical discourse) or slopes (algebraic discourse). Routines are applied locally around the point A (analytical discourse) or globally for the whole figure (geometrical discourse). Indicatively, of the justifications offered in Q3.c, 83.3% were geometrical (either global or local); 12.1% analytical; and, 4.6% a mixture of analytical and geometrical/algebraic. Whereas, in Q3.d, 70% were geometrical (either global or local); 2% algebraic; 22% analytical; and, 6% a mixture of geometrical and analytic/algebraic.

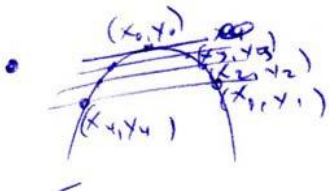

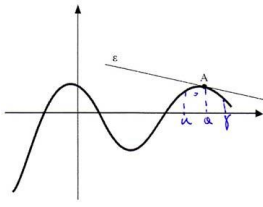

Similarly, the word use includes verbal descriptions as well as terms and symbols from geometry, analysis and algebra. The relation of the line and the curve especially at the point  $A$  are described in a range of ways, not necessarily with consistent (in terms of the different discourses) meaning. For example, in questions Q3.d and Q3.e where point  $A$  is an inflection point the line *intersects* (τέμνει); *pierces* (τρυνάει); *cuts* (κόβει); *crosses* (διαπερνά) or *bisects* (διχοτομεί). The same word can be used with a range of meanings in different scripts or across the same script. For example, “intersection” may mean the common point regardless of the position of the curve in relation to the line, whereas in other cases (in the same or different scripts) it means the split of the curve into parts. The analysis aimed to identify evidence not only regarding the common points but also regarding the overall relation of the line and the curve and their relative position. These subtle differences are not always evident in student responses.

Furthermore, the analysis indicated the use of endorsed narratives from more than one discourse in the same response or/and across responses within the same script. For example, student S[149] who performed well in all questionnaire items, writes in Q2:

$f'(x_A)=\lambda$  the direction coefficient.  $f'(x_A)=\lim_{x \rightarrow x_A} \frac{f(x)-f(x_A)}{x-x_A}$  [analytical narrative]. At this point

it [the line] has one “double” [his emphasis] common point with  $C_f$  [algebraic narrative]. It can have other common points with  $C_f$ ,  $x \neq x_A$  [geometrical narrative]

and he sketches the graph in Figure 2a. In Q3.b and Q3.c he accepts the line because “it satisfies all the conditions” and in Q3.d he writes: “The [line]  $\varepsilon$  is [tangent] because  $f$  is differentiable at  $x_A$  and  $\varepsilon$  has one (double) common point with  $C_f$  in the region  $(x_A-\kappa, x_A+\kappa)$ ,  $\kappa>0$  and very small” [a mixture of analytical and algebraic endorsed narratives applied locally].

	 <p>Απάντηση: <math>\varepsilon</math> – είναι Γιατί αν θεωρήσουμε μια μικρή περιοχή <math>(\kappa, \gamma)</math> γύρω από το σημείο Α στο οποίο εφάπτεται η <math>\varepsilon</math> βλέπουμε ότι η <math>\varepsilon</math> δεν έρχεται σε επαφή π.ε. κανένα άλλο σημείο.</p>
2a: S[149]’s response to Q2	2b: S[123]’s response to Q3.a

**Figure 2: Student responses**

Student S[123], on the other hand, who had difficulties with accepting tangency at an inflection point writes in question Q1: “The tangent line is a line that touches a graph at a point  $A$  and in a small area around it [the point] it does not intersect the graph” [geometrical narratives applied locally]. Then, in question Q2 he writes: “The slope of the tangent at the point  $A=(x_0, f(x_0))$  is equal to  $f'(x_0)$ ” [analytical narrative]. In Q3.a and Q3.b he accepts the line and justifies the choice: “Because if we consider a small interval  $(\kappa, \gamma)$  around the point  $A$  where [the line]  $\varepsilon$  is tangent we can see that [the line]  $\varepsilon$  does not touch any other point” (Figure 2b) [geometrical narratives applied locally]. In Q3.d he responds “ $\varepsilon$  – it is not [tangent] because it bisects  $f$ ” [geometrical narrative].

Another student (S[261]), who also had problems with tangency at inflection points, writes in Q1: “Gradient ( $\lambda$ ), the tangency point, the formula of the line,  $f(x)=\lambda=(y_2-y_1)/(x_2-x_1)$ ,  $M(x,y)$ ,  $y_2-y_1=f(x)(x_2-x_1)$ ” [algebraic narratives]. Then in Q2 she responds: “The [point]  $A$  is a tangency point

and belongs to the figure. It satisfies the equation of the tangent as well as of the figure. It is  $\lambda = \tan \omega$  (the angle between the figure and  $x'x$ )” [algebraic narratives]. In Q3.a and Q3.b she accepts the line and justifies the choice: “ $(\varepsilon)$  is tangent at A [the line is] at the same side of the graph” [geometrical narratives applied globally]. In Q3.c she writes “ $(\varepsilon)$  is tangent at A only. There [the line is] at the same side of the graph” [geometrical narratives applied locally]. I have highlighted “there” in her response as an indication of the focus at the area around point A. In question Q3.d she responds: “ $(\varepsilon)$  not tangent. It intersects with the graph going through both its sides” [geometrical narratives applied locally]. Finally, in Q6 she responds by using mainly geometrical narratives with symbolisation from analysis:

The tangent line of a function graph at a tangency point  $A=(x_0, f(x_0))$ , that belongs to the function and the tangent, is a line that intersects the function without going from its one side to the other but remains at the same side of the function with only one common point the [point] A. [her emphasis]

## Discussion

This paper reports on my first attempt to draw on the commognitive approach to analyse 182 first year university mathematics students’ justifications about tangent line. My initial conjecture was that students engage with different discourses (geometrical, algebraic or analytical) even for the substantiation of similar choices regarding the tangent line. Although the findings presented in this paper cover only a small slice of the data, in terms of questionnaire items, I would say that there is evidence supporting my conjecture. Students engage with analytical, geometrical or algebraic discourses in terms of the endorsed narratives and routines I identified in their responses. Also, the word use includes verbal descriptions as well as terms and symbols from geometry, analysis and algebra. Additionally, the same justification may engage with more than one discourse or/and different discourses across the script. Also, it seems that in several responses there are arguments that use analytical endorsed narratives (derivative etc.) applied through geometrical routines (check the tangency globally). I note here that my analysis considers students’ responses in relation to the discourses of the mathematical community in different mathematical areas and not in relation to their correctness. Use of analytical narratives, for example, do not necessarily ‘secure’ the correctness of the response and, the other way around, a correct choice does not necessarily draw on a coherent and consistent justification. Furthermore, the type of the task may also affect the type of discourse students engage in. For example, a graphical question (e.g. sketch the tangent line) may trigger geometrical discourses whereas an algebraic question (e.g. calculate the formula) may trigger analytical or algebraic ones. The reported findings are indicative and further investigation is in process also in relation to inconsistencies within a response with potential commognitive conflicts between geometric, algebraic and analytical discourses of tangent lines as well as to the extent student responses are mediated by the task formation.

This work contributes to our insight into what students bring with them when they join post-secondary mathematics courses and I credit to the commognitive approach the deepening of this insight in the case of students’ meaning making of tangency. I envisage teaching implications of the outcomes of this analysis in calculus or analysis introductory courses. For example, the observed mismatch between lecturers’ and students’ discourses (Park, 2015) would be dealt by explicitly addressing commognitive conflicts with the use of appropriately selected examples – see (Biza,

2011) about the role of examples in student meaning making of tangency.

## Acknowledgements

I would like to thank Elena Nardi and Athina Thoma for the inspiring conversation about the analysis of these data from a commognitive perspective.

*Lecturers' professional activity is, at least, twofold: research and teaching. However, their professional development is generally mostly based on research achievements and little effort is made to empower lecturers overcome the difficulties experienced during their teaching activities. We postulate that didactics of mathematics can be a powerful tool to help lecturers question and reorganize the knowledge to be taught, and to make them aware of the conditions enabling and the constraints hindering new modalities of teaching mathematics, more based on its use as a modelling tool to approach open questions. We present in this paper a first edition of a professional development course for lecturers designed for and experienced in an Engineering School in Barcelona. The results obtained are then used for a subsequent course redesign to be conducted with lecturers of a similar university school.*

*Keywords: Lecturer education, mathematical modelling, Anthropological Theory of the Didactic*

### Introduction

Traditionally, lecturers' development courses have not been considered relevant by research in teacher education. This is a normal phenomenon considering universities' criteria when hiring lecturers and evaluating those already lecturing: mainly research activities and merits are considered. In contrast, lecturers' didactic or pedagogical education is usually ignored or, at most, considered as a positive complement. The absence of regular lecturers' teaching training is a worldwide phenomenon with few – and not always successful – exceptions. In the United Kingdom, the Higher Education Academy (HEA), the UK Professional Standards Framework (UKPSF) and its accreditation process made a first attempt to incorporate lecturer training as a requirement to teach in UK universities (Department for Education and Skills, 2003). Nevertheless, this program that was thought to be central in lecturers' professional development has finished as a volunteer training and accreditation scheme for both individuals and institutions involved in teaching at higher education (The Higher Education Academy, 2011).

We consider that, as long as their activity has a clear twofold character based on research and teaching, in addition to the traditional training in research (Master's Degree and PhD program), lecturers also need an explicit pedagogical and didactic education. In fact, universities are among the sole existing teaching institutions where teachers are not required an explicit training course on teaching and learning processes. We consider that this crucial difference should not be accepted as a given: the conditions of existence of a university teacher education course have to be studied, especially with the possibility to base it on contents emerging from research in didactics.

In order to have a first set of empirical data to evaluate the conditions of existence of such a course for lecturers at university level we designed a course for 14 lecturers of an Engineering School in

Barcelona ([www.euss.es](http://www.euss.es)). Lecturers participating in the course teach Analysis (3), Strength of Materials (4), Physics (2), Electronical Technology (2) and Informatics (2). We took as starting point the frame of “study and research paths for teacher education” (SRP-TE) based on recent investigations in the Anthropological Theory of the Didactic (ATD) for pre-service and in-service secondary teachers. The lecturers’ course was experienced in February 2016. We present the design principles and results of this first edition, as well as the subsequent re-design for new editions, to overcome the experienced difficulties and take advantage of its potential strengths.

## University teacher education: A field to be explored in ATD

Courses for pre- and in-service lecturer professional development are an unexplored field in research. There exists very little literature regarding this subject and the few experiences reported involve only general pedagogical contents not taking into account the very nature of the knowledge involved in the teaching and learning processes. It is important to highlight that no paper on this field was presented at the last CERME9 (neither at TWG 14, *University Mathematics Education*; or at TWGs 18, 19 and 20, *Teachers’ Knowledge, Practices and Education*), or at groups regarding teacher training or university teaching at the last ICME 13, except for a preliminary version of this paper (Florensa, Bosch, & Gascón, 2016b). The structure of ICME13 Topic Study Groups about teacher education is especially revealing at this respect: there were four groups on teacher education, two (in and pre-service) centered on the elementary level and two on the secondary level, but none on the tertiary level. At the recent conferences on Mathematics Education in North America, only Ellis presented research on teacher assistants training (Ellis, 2014a, 2014b).

Regarding the presence of papers in journals about lecturers’ education we have found very little production: only two papers (Guasch, Alvarez, & Espasa, 2010; Postareff, Lindblom-Ylänne, & Nevgi, 2008) and the *Handbook on Teaching and Learning in Higher Education* (Fry, Ketteridge & Marshall, 1999). We have developed a research from the initial year of publication to the end of 2015 in these journals: *Educational Studies in Mathematics*, *Higher Education*, *Journal of Mathematics Teacher Education*, *Mathematical Thinking and Learning*, *Journal of Teacher Education*, *Recherches en Didactique des Mathématiques*, *REDIMAT*, *RELIME*.

As said before, we consider that research in didactics can be used as the basis for courses on lecturer education regarding teaching and learning processes. Our starting hypothesis is that results emerging from secondary teacher education can be used at this level. Our results will be used to partially confirm this assumption. The *Solid Findings in Mathematics Education on Teacher Knowledge* (Education Committee of the EMS, 2012) state explicitly that “content knowledge” (CK) is necessary but not sufficient for teaching. The report of the Education Committee highlights as crucial notions to be developed in teacher education the “pedagogical content knowledge” (PCK) (Shulman, 1987) and the different dimensions of the “mathematical knowledge for teaching” (MKT) (Ball, Thames, & Phelps, 2008). Both approaches clearly go further than the traditional conception of teaching as transmission of knowledge and consequently ask for changes in teacher education concerning the way mathematical knowledge should be approached.

We use the Anthropological Theory of the Didactic (ATD) as a main framework for the design, experience and analysis of the course. The last investigations on teacher education in ATD show that the use of notions such as PCK and MKT do not ensure researchers/educators to include a

questioning of the nature, selection and organization of the contents to be taught (Ruiz-Olarría, 2015). Under the ATD approach, the role of teacher education is not limited to enrich teachers' pedagogical performance, but also to provide them with tools to contest the so-called *dominant epistemology* and emancipate from it when designing study processes (Gascón, 2014).

This questioning and reorganization of the knowledge to be taught is not spontaneous for teachers (nor for lecturers) because they tend to assume the institutional dominant epistemology as their own. The way proposed by ATD research to locate it at the core of teacher educational processes has very much evolved in this last decade. It started with a first experience in secondary teacher education based on the “questions of the week” (Cirade, 2006) and nowadays takes the form of an inquiry-based device called “study and research path for teacher education” (SRP-TE), which starts from a problematic question appearing in the field of the teacher profession and leads to the search, development and analysis of alternative teaching proposals (Barquero, Bosch, & Romo, 2015, 2016). The main idea of the SRP-TE is to generate a practical and theoretical questioning of the school activities linked to the teacher professional initial question. It is structured in five modules:

- M0: Formulation and first exploration of the generating question  $Q_0$  of the SRP-TE, for instance one of the kind: “How to teach (a specific content)?” which is to be partially answered at the end of the process.
- M1: Living a “study and research path” (SRP) as a student. The main goal is to make teachers encounter an unfamiliar inquiry-based activity related to  $Q_0$  that could exist in a normal classroom of the considered educational level.
- M2: Adaptation of the lived SRP to be experienced in a real school situation. During this adaptation, many of the institutional restrictions teachers should face are expected to show up. They can thus be afterwards analyzed from an epistemological, didactic and *ecological* perspective (what can “live” and under what conditions in a given educational setting).
- M3: Experimentation, management and carrying out of in vivo and a posteriori analyses of the adapted teaching proposal.
- M4: Joint elaboration of a critical analysis of traditional teaching practices and the possibilities (and limitations) of introducing new proposals, as well as generation of a partial answer to  $Q_0$ .

During the development of SRPs-TE for secondary school teachers, an epistemological tool has been adapted and developed to facilitate the analysis of the SRP and the questioning of school contents: what we call “question-answer maps”. Following other authors, we consider these maps, which are used as a key tool in ATD research, as a powerful instrument for teacher education:

We hypothesize that such a representation is sufficiently close to teachers' concerns, and also captures such essential parts of a didactic design, that one could use it as a tool for collaboration and communication with and among teachers, regarding concrete teaching designs (Winsløw, Matheron, & Mercier, 2013, p. 281)

Some preliminary and promising experiences exist in using these maps in teacher training courses to describe the dynamic and collective aspects of mathematical activity (Barquero, Bosch, & Romo, 2016; Florensa, Bosch, & Gascón, 2016a; Jessen, 2014). The work with the maps seem to be useful for teachers in order to describe knowledge in inquiry activities and to act as a counterpoint of the official curricular organization of contents.

## Research questions

The work presented in this paper is considered as an exploratory design (Singh, 2007) to obtain and analyze a first set of data from the first implemented course and to redesign it to be applied in another institution. The specific research questions that will be studied are:

- RQ1. The role played by question-answer maps in teacher education: Do they help lecturers describe, analyze and design inquiry and modelling processes and the involved knowledge?
- RQ2. Does the course empower lecturers to identify the dynamic and collective nature of the lived SRP in contrast to the static, individual and compartmentalized dominant conception of knowledge?

## Course description

The engineering school where the course was implemented keeps a four-hour time slope with no teaching for all lecturers all Wednesdays: they use this time for professional development, meetings, pedagogical courses or activities. In fact, it is a Salesian university with a special concern about teaching and learning processes, as well as students' personal evolution. The course was structured in six two-hour sessions during three weeks, and the central question to be partially answered was: "Could modelling be the main motivation of my subject? Which conditions enable and which constraints hinder this modelling activity?"

Because of the time restriction, the five-module structure of the SRP-TE had to be adapted. The six sessions appeared to us (designers and course leaders) as a short course. However, they finally seemed to be enough for the work planned. Of course the *true work* is to be carried out afterwards, when lecturers decide to introduce some new proposals in their subject based in the work initiated at the course. During this application phase teachers implementing SRPs asked for help to the researchers-educators, thus extending the real duration. We planned the course as follows:

- 1<sup>st</sup> session: Explicitly state the professional question  $Q_0$  and shortly present the ATD framework including the notions of praxeology, Herbartian schema and media-milieu dialectics, topogenesis, mesogenesis and chronogenesis (Barquero & Bosch, 2013). They seemed to be well understood and some of them were mobilized during the 4<sup>th</sup> session.
- 2<sup>nd</sup> and 3<sup>rd</sup> sessions: A SRP was proposed to be carried out in groups of up to three lecturers. "Taking into account the incidence index of the last 9 months of a dengue outbreak: could you forecast the incidence index for the next 3 months (already known)?" (Figure 1)
- 4<sup>th</sup> session: Lecturers generated a question-answer map of the lived SRP including aspects such as media-milieu dialectics. One of the generated maps can be seen in Figure 2.
- 5<sup>th</sup> session: Lecturers are invited to create new small groups with the colleagues teaching the same subject. They are asked to design a SRP by choosing a generating question in their field trying to overcome some observed didactic facts such as the absence of *raison d'être*, the disconnections of topics or the poverty of the experimental work, among others.
- 6<sup>th</sup> session: Sharing some possible teaching proposals and conclusions of the course.

Figure 1: Data used for the lived SRP

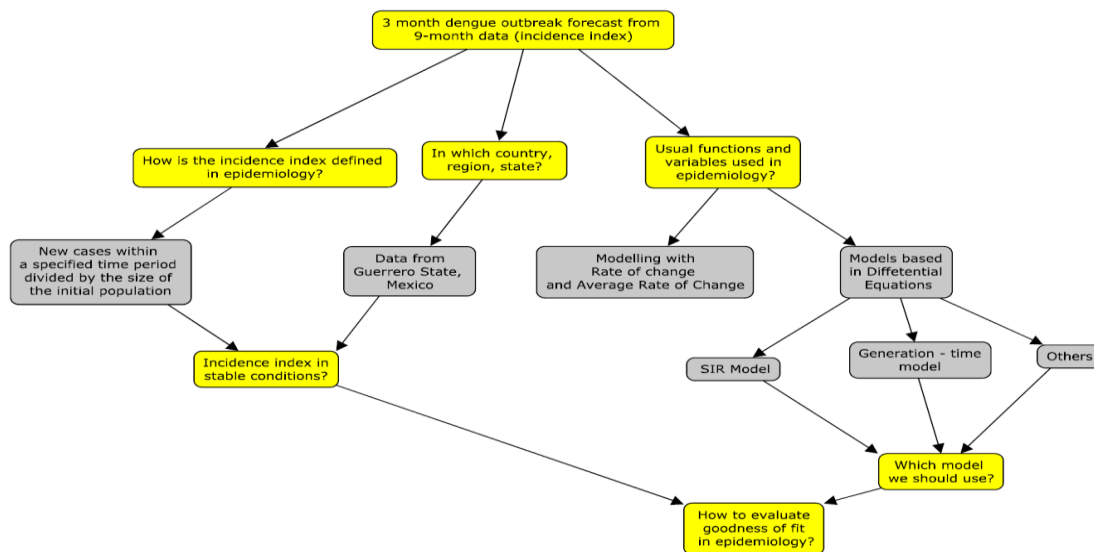

Figure 2: Question – answer map of one of the groups

In the introduction to the 5<sup>th</sup> session, lecturers were invited to identify didactic facts that they would like to overcome through the new didactic proposal. The goal was not to implement the inquiry by itself, but to identify how the *dominant epistemology* in the institution is related to these problematic phenomena and roughly propose new possible epistemological and didactic organizations to face them. The question-answer maps were the tool provided to lecturers to carry out this work. During the implementation of the course, some of the contents that we initially considered as difficult had an easier reception than expected (especially the notion of media-milieu dialectics) and, on the contrary, some basic notions were difficult to share with the participants, for instance the description of contents in terms of questions instead of topics.

In order to obtain data to evaluate the course, all the questions-answer maps of all groups, both from the analysis of the modelling lived activity and from the a priori design of the SRP, were collected. We have also obtained data from a final survey filled in by all lecturers attending the course. The survey was structured in three main blocks. The first block addressed general aspects of the course such as duration, balance between individual and team work, time structure, etc. The second block asked about content-related aspects of the course like the work developed with question-answer

maps and with the media-milieu dialectics. Finally, the survey asked the lecturers about the possible consequences of the course on their teaching activities: changes in the conception of knowledge, dynamics and collective aspects of activities, and availability of new designing and evaluating tools.

## Results and discussion

The question-answer maps regarding the dengue outbreak SRP shew up how the inquiry was capable to connect fields usually disconnected in the traditional curricular organization of contents. For example, the map of Figure 2 reveals that functions, differential equations, regression, average rate of change and epidemiological notions are deeply interrelated. An interesting fact emerged when analyzing different maps from different working groups: depending on their lecturing field, they approached the problem quite differently. For instance, Mathematics lecturers' work was centered on finding a mathematical model fitting the data, whereas Chemistry lecturers' work evolved around the epidemiological data, the notion of "incidence index" and searching scholar literature regarding other similar outbreaks. The different teaching fields of lecturers permitted to share different visions of the knowledge at stake in the proposed SRP. The use of the maps was a key factor to describe this connection of fields usually lacking in school institutions.

The second part of the survey about the content of the course reveals that the work developed by lecturers with the question-answer maps and the media-milieu dialectics was difficult for them (more than 70% of the teachers found it hard or very hard) but at the same time they identified this work as "easily applicable to design and manage new teaching and learning processes" (more than 70% of the lecturers found contents and tools of the course easy to use and to implement). Regarding the consequences of the course on the lecturers' teaching practices, the survey showed that it helped (more than 90% totally agreed) to change their previous conception of knowledge towards a dynamical-collective conception in terms of modelling activities.

The third source of evidence are the maps generated by the lecturers as a priori analysis for an SRP to be experienced in their subjects. In total, six maps were generated by lecturers, all of them with a generating question and making explicit the didactic facts intended to be overcome. Two of these a priori SRP designs were experienced during the spring semester, starting just after the lecturers' course. These two emerging SRP have been experienced and managed only by lecturers that followed the course and did not have any other didactic experience or training. This fact is especially interesting because with the analysis of these experiences a first set of data can be collected regarding the conditions of existence of SRPs at the university level led by lecturers with almost no direct connection with research in didactics. This first experience in lecturer education seem to preliminary validate Winsløw et al. (2013) hypothesis about the use of question-answer maps in teacher education and confirm Barquero et al. (2016) results. Lecturers have worked with the maps and have used them to both model a lived study process and a priori analyze their own designed SRP. Moreover, the maps have been used to compare the knowledge mobilized during a specific SRP and the school knowledge. The Q-A duplets appearing in the map were used as the elements to contrast with curricular requirements.

The course also appears as a good tool to empower lecturers to question and put under vigilance the *dominant epistemology* at the university. It produced a discussion (and thus enabled a reflection) on what knowledge has to be taught at the university and how the modelling activity with its dynamics

and collective aspects could be considered. Regarding the conditions of existence of a lecturer course based on the ATD, it seems that the described conditions make it viable and that some lecturers have taken it as an opportunity to redesign their teaching and learning activities. However, an important aspect to take into account is the fact that one of the leaders of the course is also a lecturer in the considered Engineer School, what certainly affected the good predisposition of the attendees due to his personal leadership in the institution. This particular condition has to be considered in new editions of the course and the question of its reproducibility remains open.

# High school teachers' choices concerning the teaching of real numbers: A case study

Laura Branchetti

Politecnico di Milano, Italy; [branchetti.laura@gmail.com](mailto:branchetti.laura@gmail.com)

*The goal of this paper is to present a case study in which a high school teacher with PhD in Mathematics was asked to answer a questionnaire concerning the teaching and learning of real numbers and then he was interviewed in order to investigate the interplay between his resources, goals and orientations in the decision-making process. As a main result, I show how some orientations concerning the epistemology of real numbers, the goals of mathematics education in the high school and the students' conceptions and difficulties lead him to choose a very intuitive approach to the teaching of real numbers and to leave aside all his expertise as a mathematician.*

*Keywords: Real numbers, teaching, high school, teachers, tertiary education.*

## Epistemological issues concerning real numbers and continuum

The relation between the continuum and the real numbers is often considered as something intuitive and to be taken for granted (Lakoff & Nunez, 2000), but as it is well known to the experts in history and epistemology of mathematics, this is one of the most complex issues to face dealing with the foundations of mathematics. This topic deals indeed with very relevant challenges. I will just highlight some aspects that are relevant to characterize the orientations of a teacher concerning the epistemology of real numbers and continuum. In *Continuity and irrational numbers*, Dedekind (1872, transl. 1901) stated: "In discussing the notion of the approach of a variable magnitude to a fixed limiting value, and especially in proving the theorem that every magnitude which grows continually, but not beyond all limits, must certainly approach a limiting value, I had recourse to geometric evidences. [...] For myself this feeling of dissatisfaction was so overpowering that I made the fixed resolve to keep meditating on the question till I should find a purely arithmetic and perfectly rigorous foundation for the principles of infinitesimal analysis. The statement is so frequently made that the differential calculus deals with continuous magnitude, and yet an explanation of this continuity is nowhere given; even the most rigorous expositions of the differential calculus [...] depend upon theorems which are never established in a purely arithmetic manner" (p. 1-2). Dedekind came to the construction of  $\mathbb{R}$  as the field of the rational cuts, stressing that the new numbers - irrationals - were creations necessary to identify the points of a line and the numbers and making explicit that the assumption of the property of continuity of the line is nothing else than an axiom. In this paper, I just report Dedekind's approach, since it's particularly relevant to analyse the case study I present here; for a complete dissertation see Bell (2014).

## Challenges with teaching and learning of real numbers and continuum

The topic of teaching and learning real numbers and continuum in the high school and the university have been investigated in several countries and nowadays a lot of results are available; in particular, the researches concern the difficulties of high school and university students and prospective teachers. In this paper, I report just some examples, but the literature is very rich (for a complete review see Voskoglou & Kosyvas, 2012). First of all, cognitive issues "resonate" with the very relevant epistemological issues: space-temporal intuitions and metaphors (Bolzano, 1817), and the formal

approach, based on static and rigorous should be clarified by teachers. Indeed, according to Lakoff and Nunez (2000), the identification between objects such as lines, points numbers and sequences, that is very usual at school and in the University, hide the intrinsically metaphorical nature of the relation between natural continuity and “formal continuity”. The main students’ difficulties reported in several studies concern: irrational numbers; infinity; points of a line; density and continuity; and, number line. Students from high school to university are often not able to define correctly the concepts of rational and irrational numbers, like if rational numbers in general remains isolated from the wider class of real numbers (ibid., 2012). In particular, students’ ideas concerning the relation between  $0.999\dots$  and 1 (Tall & Schwarzenberger, 1978) and, in general, concerning the meaning and the use of decimal representations (Margolinas, 1988) are usually very ingenuous and seem to be product rather of a spontaneous generalization from finite to infinite numbers than of a structured learning path. Tall (1980) observed a recurrent phenomenon, that was defined *dependence*: there are more points in a longer segment than in a shorter one, based on the generalization to infinite cases of what has been learnt of the biunivocal correspondence of finite cases. Tall (1980) also observed among the students an intuitive model of the line in which points are as much as they need to fill a segment with physical points, that are “non-overlapping marks” (p. 3) and the quantity of numbers is proportional to the length of the segment. This intuitive model, without a suitable elaboration, could influence the learning of properties like density and completeness if the model of real numbers considered is a line. Also, Bagni (2000) alerted from the false illusions concerning the introduction of properties of real numbers in the graphical domain. Bergé (2008) highlighted that in the transition from calculus to analysis in the university, it’s necessary first to change the conception of the number line. Fischbein, Jehiam and Cohen (1995) carried out research based on the assumption that the irrational numbers could be counterintuitive because of their high complexity but, contrary to what they had hypothesized, they found out that many high school students and prospective teachers overcame the barrier quite easily in suitable contexts, paying attention to the potential difficulties and presenting them to the students.

## Research problem and framework

In this work, I face the problem from the point of view of teaching in the high school, focusing the attention on high school mathematics teachers’ intended reported choices concerning the teaching of real numbers in the high school; in particular the focus is on what considerations and necessities guide their decisional process. Schoenfeld’s model (2010) provides a tool to distinguish between three main factors that may influence the teachers’ choices: *resources* (mathematical and pedagogical knowledge); *goals* (educational, instructional and social aims); *orientations* (beliefs concerning knowledge, concerning teaching-learning processes). I used this model to design a written questionnaire answered by the teachers in the first part of this research. Orientations may be very general (what mathematics is, what learning is) or more specific and may concern epistemological (what is the role of real numbers in the history of mathematics, what are real numbers necessary for), cognitive (what is difficult for the students, what is a good choice to help students) or ecological aspects of the didactical activities (what teachers must do within an institution, what are the aims of the teaching in high school). Some of these orientations act as criteria to make choices. Since real numbers and continuum both in the history and in the teaching-learning processes oscillates between the two poles of intuition and formalization, I owe special attention to the orientations concerning rigor and intuition.

## Methodology

This *case study* is part of a research carried out for a PhD dissertation concerning the teaching and learning of real numbers in the high school, in which I involved 89 Italian high school teachers with very different backgrounds. I will discuss in a *case study* the role of teachers' resources, orientations and goals in a teacher's decision making intended process, according to Schoenfeld's model (2010). In Italy, according to the national curricula, an introduction to calculus and some theorems of analysis are proposed to students in the end of high school. According to Bergé (2008) what characterize more the transition from calculus to analysis is the transformation of intuitive models of the line into a formal construction of  $\mathbb{R}$ . Usually, in high school, teachers are asked to introduce: limits, continuous functions and related theorems (Bolzano, Weierstrass), derivatives, Rolle and Lagrange theorems, examples of computations of limits and derivatives, Riemann integral, examples of integration based on Torricelli-Barrow theorem and examples of differential equations. Italian textbooks are usually based on formal definitions and intuitive examples that are not suitably connected each other. Usually intuitive approaches to the definition and use of real numbers are proposed in the first 4 years of high school (roots, points, decimal numbers). Then, in the last year, definition and procedures of calculus and theorems are introduced through formal expressions and using concepts such as limits, convergence towards a point and open intervals. The research question in this study is: *how does the interplay between resources, goals and orientations about teaching and learning of real numbers and continuum in the high school affect a high school teacher's intended choices?* I designed a study with a questionnaire and follow up interviews. The teacher first was asked to answer an online questionnaire structured in order to investigate his knowledge, goals and orientations. The first questions concerned the teacher's background and training. The teacher was asked to answer questions about the main properties of the set  $\mathbb{R}$ , the construction of  $\mathbb{R}$  starting from  $\mathbb{Q}$ , the definition of limit points. In the next section of the questionnaire the teacher was asked what they thought to introduce  $\mathbb{R}$  was necessary for and to comment on teaching materials or parts of lessons concerning real numbers and the line, from different points of view (construction of  $\sqrt{2}$ , correspondence between points of a line and numbers, algebraic and graphic approach to inequalities). Then the teacher was interviewed in order to make him declare his choices concerning teaching and learning of real numbers in depth and to follow the thread of his thoughts, in order to make the orientations emerge in relation to the epistemological, cognitive and institutional issues that were emerging time after time. The interview was a semi-guided one: a general question concerning the way the teacher introduces usually real numbers in the high school and the motivations of the choices; a particular question concerning the relation between numbers and points of a line; a particular question concerning the way the teacher presents the enlargement from  $\mathbb{Q}$  to  $\mathbb{R}$  in relation with the line; a general question concerning the relevance in the last year of high school (in particular for calculus and analysis) of the previous knowledge concerning real numbers and the way connect the two.

I identified the following *a priori categories*:

### 1. Resources

#### a. Mathematical knowledge

- i. The teacher knows the main properties of  $\mathbb{R}$  (complete, ordered, Archimedean field)

- ii. The teacher knows at least one construction of  $\mathbb{R}$  (Dedekind, Cantor, Hilbert, ...)
- iii. The teacher knows that a limit point of a set  $A$  can be defined in every dense set
- iv.  $\mathbb{R}$  as a complete ordered field is necessary for Analysis

## 2. Goals

### a. Institutional

- i. To introduce intuitively some real numbers, after providing some examples and proofs of irrationality of some numbers introduced in geometrical constructions
- ii. To formalize real numbers in order to give foundations to the theorems of Analysis

### b. Personal

- i. To construct a set in which it is possible to define the most used continuous functions (exponential, logarithmic, ...)
- ii. To construct a set in which it's possible to solve equations (but the ones with complex solutions) and inequalities
- iii. To construct a set in which it's possible to formulate some theorems of Analysis and to define limits, integrals and derivatives

## 3. Orientations

### a. Epistemological

- i.  $\mathbb{R}$  is complete in the sense of the continuity of the line
- ii. A theoretical construction of  $\mathbb{R}$  is not necessary to develop calculus and formulate theorems of Analysis, since it was constructed after the theorems
- iii.  $\mathbb{R}$  is a set of points of a line
- iv. The representations of real numbers (points, decimal numbers, ...) are all equivalent (framed in the same theory)
- v. A postulate is necessary in the constructions or axiomatization of  $\mathbb{R}$

### b. Cognitive

- i.  $\mathbb{R}$  is intuitive for students; students have preconceptions of real numbers
- ii. The construction of  $\mathbb{R}$  is too abstract for students
- iii. Students prefer simple and concrete things, even if they don't understand everything
- iv. It's important to make the lessons intuitive for students
- v. It's important to be rigorous and consistent during the lessons

### c. Ecological

- i. It's important to respect institutional constraints

I analyzed data of the questionnaire using *a priori* categories concerning the different dimensions of

the teacher's profile - goals, dimensions and knowledge - and then I looked for further emerging, unexpected phenomena to frame in this research background and to compare them with further literature review. Using a qualitative analysis, I labeled the relevant features concerning the three dimension and the declared choices. Then, I looked at the interview searching for sentences that could confirm the teacher's belonging to the categories I used in the questionnaire and to look for new relevant elements emerged in the interview. Finally, I looked for a relations between the different categories in order to interpret the teacher's choices in terms of the interplay between resources, goals and orientations.

## Data analysis

I report first the background and the teacher's answers in the first part of the questionnaire, to show that the teacher showed advanced mathematical knowledge. I label the sentences with the codes presented before.

*Background:* Master, PhD in Mathematics and National qualification for Mathematics and Physics high school teachers; 5 years of experience as a teacher

*He studied real numbers:* at the University in a course of Analysis and at school

*Properties:* two operations make real numbers a field (with characteristic 0); total order, compatible with the operations; complete [R-a-i]

*Construction:* Two equivalent constructions: 1) the method of Dedekind's cuts (separating elements of two sets whose union is  $\mathbb{Q}$  and that have no maximum or minimum in  $\mathbb{Q}$ , e.g.  $\{x \in \mathbb{Q} : x^2 < 2\}$  and  $\{x \in \mathbb{Q} : x^2 > 2\}$ ; 2) quotient of set of the Cauchy's sequences with convergent ones [R-a-ii]

*Limit point:* It's possible to define it also in  $\mathbb{Q}$ ; the set  $\{x \in \mathbb{Q} : x < 0\}$  has 0 as a limit point [R-a-iii]

Then, I report the most relevant results of the data analysis carried out in the second stage:

1. the properties of real numbers are necessary to introduce only differential and integral Calculus, sequences and series. [G-b-iii]
2. a video in which the graphic and algebraic solution of linear inequalities are presented as two different solutions should be changed because the solution is the set of numbers that satisfy the equation and only the representation may be graphic or algebraic [O-a-iv]
3. a tutorial in which a concrete problem involving measures of courtyard containment is used to present the "reality of irrational numbers" helps the student to create good images of real numbers, even if something is not convincing [O-b-iii]
4. a video in which the correspondence between  $\mathbb{R}$  and points of a line is showed using a point moving on a line, with the extreme indicated by a decimal number with one decimal digit, can't help to grasp the correspondence between real numbers and points of a line, because only an origin is fixed and not a unit and it's difficult to justify negative numbers [O-b-v]

In the interview, some further relevant aspects emerged concerning the teacher's knowledge and cognitive and epistemological orientations and goals. Since new categories emerged, I label the synopsis with a priori but also with a further category (NEW\_C\_i).

To present the following synopsis, I use a chronological criterion:

1. students have preconceptions of the relations between numbers and point of a line. He presents real numbers intuitively, as points of a line, and to base on this intuition all the definitions, also

- very formal (e.g. limits, Cauchy-Weierstrass continuity, decimal numbers, ...) [O-b-i]
2. this is enough to "do what we have to do", a "pseudo-mathematics" [NEW\_G\_1]
  3. real numbers are imagined as the real line, with an abuse of language, that makes a few damages at this level but may have many advantages [G-b-i&ii]
  4. it's important to be coherent with mathematics [O-b-v] without saying it to the students [O-b-iii]
  5. to introduce analysis "seriously" R is needed [R-a-iv]
  6. formal definitions are not useful but were only useful to clear "the conscience of Dedekind" and that "Euler did so many good things without formalizing R" [O-a-ii]
  7. history confuses students [NEW\_O\_1]
  8. students can't understand very much of real numbers in the high school [O-b-ii]
  9. asked to declare his choices concerning the introduction of continuous functions he referred to formal definitions (Cauchy-Weierstrass approach) that are traditional in Italy [G-a-ii]
  10. there is a "parallelism between geometrical and algebraic postulates" [O-a-iii]
  11. R and the line are the same object [O-a-iv]
  12. we live between two truths, the 'pure mathematical' and the 'operational' one [NEW\_O\_2].
  13. none really use R and the line is really strange; maybe teachers are disappointed because no one really knows what numbers are, thinking at infinite convergent sequences and the definition of new numbers (irrationals) that are limits of convergent rational sequences [NEW\_O\_3]
  14. he uses representations like decimal numbers, the line, the roots only in order to make operations with them [O-a-iv] but never deepen their meaning and mutual relations [O-b-iii]
  15. it's simpler for the students and for the teachers to "sneak off the theoretical crevices" [O-b-iii]

## Discussion and conclusions

The teacher is a PhD in Mathematics (Analysis) and attended teachers' training courses. The knowledge he showed about the topic is advanced. The pedagogical knowledge has never been taken in account by the teacher to support argumentations, while his orientations, reflections and experiences are used to motivate his statements during the interview. Also, he never quoted explicitly the institutional constraints. He declared to choose usually to avoid completely the formal introductions of real numbers and the historical issues and to simplify as much as possible. Even if he's aware also of some epistemological issues, his choices are very traditional and are suitable calculus but not for analysis (Bergé, 2008). Asked to declare his choices concerning the introduction of continuous functions he referred to formal definitions (Cauchy-Weierstrass approach) that are traditional in Italy. He declared to switch suddenly from intuitions of continuity and a set of numbers with different representations to a formal implicit meaning of R, used in the hypothesis of theorems without a contextualization and without stressing the epistemological implications of such a step. The teacher conflicted with the true relevance of formal constructions of real numbers: sometimes he said it's necessary, sometimes it seemed just a fancy of some mathematicians. He's convinced that some representations of real numbers can't be interpreted in high schools – even if he never considers not to use them – so he prefers the students to use them without being aware of their complexity. Moreover, he's convinced that not only the students have limitations dealing with real numbers but there is an epistemological issue: there are two truths, the 'pure mathematical' and the 'operational' one. Furthermore, he showed "epistemological doubts" concerning the deep meaning and the existence of irrational numbers. To sum up what could seem to be only didactical and cognitive

motivations (he wants the students to understand; simplifying and omitting is always better for students) hide – or at least are accompanied by – deep epistemological unsolved doubts and noisy ambiguities highlighted by the teacher, declared several times during the interview, both spontaneously and answering the interviewer’s questions, as confirmed by relevant sentences like “The line is... is perceptual. No.. it’s not perceptual, is stem from... you don’t see. But ... what is the line?”; “In practice is it useful for anything? It was useful for the purpose of a clear conscience for Dedekind but it’s not useful at all”; “I take this point, limit of a function. A bit an approaching to the border of the abyss, keep the feet ... approach something that doesn’t exist ... infinite rational paths doesn’t imply to be rational. It’s something that maybe we don’t understand very well too ...”. The teacher’s orientations concerning the cognitive aspects of teaching and learning real numbers (intuition and preconceptions) that seemed in the beginning the most relevant motivations towards an intuitive oversimplification, considered helpful for students, are thus deeply intertwined with his epistemological orientations. Firstly, his orientations concerning the uselessness of formal definitions do not motivate him to look for suitable teaching strategies and, on the contrary, act as factor that reinforces his naive orientations towards what is better to foster in students’ learning processes. Secondly, his epistemological doubts, hidden under perfect formal definitions, encourage him to keep the “Pandora’s vase” closed and to avoid to face his own uncertainties, thinking that for the students it’s absolutely better not to know them in order to keep on trusting him and let him going on presenting the “pseudo-mathematics” that is enough in the high school. His orientations and his decision to use a very traditional, internally disconnected and full of “theoretical crevices” approach to the teaching of real numbers have been proved to be unsuitable by a lot of researchers both from a general point of view and for the specific problem of real numbers. I can state that, in this investigation, it emerges that an advanced mathematical knowledge, even very significant, doesn’t imply the use of this knowledge in teachers’ choices: doubts and personal orientation can lead the teacher to use a trivial and sterile approach for all the complex issues that characterize real numbers and continuum from an epistemological point of view, taking the risk to create at least the same problems to the students that teachers with a weaker background in mathematics would create. The teachers, without suitable reflections and teacher training courses, could also reinforce their motivation towards such a choice mixing in their mind personal orientations and expected students’ cognitive features, justifying and hiding with the last ones the epistemological uncertainty. The main implications of the study are the following:

- 1) mathematicians, even with a PhD in Analysis, in their transition to a teaching profession may miss the opportunity to benefit from their knowledge by not being completely aware of the epistemological issues of the importance of formalizations into teaching;
- 2) mathematicians who become high school teachers, in order to become able to design good teaching and learning activities for their students concerning real numbers, should be trained not only from the disciplinary point of view, but also from the epistemological and the didactical one.

These observations are particularly relevant in the country in which I carried out my investigation, from an institutional point of view, where often the significance of the epistemological and the didactical background of teachers is a central in the debate between policy makers (and some teachers) and the community of researchers in mathematics education.

# Proof and formalism: The role of letters' logical status

Faïza Chellougui

Faculty of Sciences of Bizerte, University of Carthage, Tunisia; [chellouguifaiza@yahoo.fr](mailto:chellouguifaiza@yahoo.fr)

*In mathematical activity, especially in proof, it is a fairly common practice to change letters' logical status without giving any indication of these changes. Nevertheless, in some cases this practice is likely to hidden invalid steps in the proving process. In this paper, I show on an example that Copi's system for natural deduction provides a methodological tool that allows us both to anticipate where such invalid steps could appear and to analyse students' proof productions.*

*Keywords: Formalism, proof, letters' logical status, quantifiers, natural deduction*

## Introduction

Difficulties met by university students in the use of logical formalism are well documented in the literature (e.g. Selden & Selden 1995, Dubinsky & Yiparaki 2000, Chellougui 2009). An important issue on the development of formalism in university mathematics education is to reduce ambiguities conveyed by natural language, in order to foster the understanding of mathematical statements and to improve the development of proving skills. However, Durand-Guerrier and Arsac (2005) have underlined a rather common practise in mathematics textbooks of changing letters' logical status in a proof without giving any indication of these changes. This practice introduces additional ambiguities in the proving procedure. The aim in this paper is to address the conjecture that university students who are not able to cope with these ambiguities face difficulties with proofs.

In this paper I use the system for natural deduction (i.e. a formalisation of mathematical reasoning) suggested by Copi (1954) in predicate calculus (i.e. an extension of propositional calculus that deals with the internal structure of propositions, with symbols for properties, relations, quantifiers and individuals) as a tool for checking the validity of proof. A main interest of this system is to make explicit the difference between bound variables (i.e variables in the scope of a quantifier) and generic elements (i.e any individual element of the domain of quantification at stake)<sup>1</sup>. In the first part, I present the Copi system which has been used for both *a priori* and *a posteriori* analysis in my research. The second part focuses on the letters' status in a proof from the logic and didactic point of view. To this purpose, I present results demonstrating student's difficulties with letters' status at the beginning of their university studies. In the third part, I present results from first year university student's responses in a proof where the use of letters challenges the validity of the proof (Chellougui, 2009).

## Natural deduction system

I first introduce the natural deduction system proposed by Copi (1954) and show that this system provides tools to detect invalid steps in a proof by remaining as close as possible of the usual modes of reasoning of mathematicians (Durand-Guerrier & Arsac, 2005). In my work, I use this system in

---

<sup>1</sup> "[...] the proof of a universal statement, apart from the case of proof by induction, is always done by the method of the generic element: in order to prove a statement of the kind "for all  $x \in E$ ,  $P(x)$ ", you prove  $P(a)$  for a generic element  $a \in E$ , then after verifying that only properties of  $a$  that are common to all elements in  $E$  were used, you conclude that  $P(x)$  is true for every  $x$  in  $E$ ." (Durand-Guerrier and Arsac, 2005, p.153)

the frame of predicate calculus, where four rules for introduction and elimination of quantifiers are introduced. In Figure 1, I summarize a presentation offered by Durand-Guerrier (2005) of these rules completed by some specific restrictions needed for preserving validity.

*The first rule of inference concerns elimination of the universal quantifier; it is called Universal Instantiation (UI) and states that:*

"(...) any substitution instance of a propositional function can validly be inferred from the universal quantification. We can express this rule symbolically

$$\frac{(\forall x)\Phi x}{\Phi v} \text{ (where } v \text{ is any individual symbol)}^{1\text{'}} \text{ (Copi, 1982, p.50)}$$

This rule expresses that *what is true for all is true for any*.

*The second rule is the dual of the first one and concerns the introduction of the universal quantifier; it is called Universal Generalisation (UG) and states that:*

"(...) the universal quantification of a proposition can validly be inferred from a substitution instance with respect with the symbol  $y$ . Our second expression for this quantification rule is

$$\frac{\Phi v}{(\forall x)\Phi x} \text{ (where } v \text{ denotes any arbitrarily selected individual)} \text{ (ibid., p.51)}$$

This rule necessitates a restriction; you must be sure that no assumption other than the property expressed by  $\Phi$  has been done. Obviously, it is build "by analogy with a fairly standard mathematical practice"(ibid., p.50)

*The third rule concerns the introduction of the existential quantifier; it is called Existential Generalisation (EG) and states that:*

"(...) the existential quantification of a propositional function can be validly inferred from any substitution instance of that propositional function; (...) Its symbolic formulation is:

$$\frac{\Phi v}{\exists x\Phi x} \text{ (where } v \text{ is any individual symbol)} \text{ (ibid., p.52)}$$

*The fourth rule is the more delicate to use. It concerns the elimination of the existential quantifier; it is called Existential Instantiation (EI) and states that:*

"(...) from the existential quantification of a propositional function we may validly infer the truth of its substitution instance with respect to an individual constant which has no prior occurrence in that context. The new rule may be written as

$$\frac{\exists x\Phi x}{\Phi v} \text{ (where } v \text{ is an individual constant having no prior occurrence in the context)} \text{ (Ibid. p. 52).}$$

**Figure 1: Copi's rules (Durand-Guerrier, 2005, pp. 413-414)**

This system can be used to control locally the validity of mathematical proofs. It can act as an intermediate between the usual practice and the completely formalized system. The rules of introduction and elimination of quantifiers from Copi address the semantic dimension, because there is an introduction of letters referring to generic elements. In ordinary textbooks, most often, both operations of elimination and introduction of quantifiers are either absent or partial (Durand-

Guerrier & Arsac, 2005; Chellougui, 2009). By making explicit the rules of introduction and elimination of quantifiers, Copi's natural deduction system allows the identification of implicit steps, especially in cases of proof that use multi quantified statements where there is, at least once, each of both universal and existential quantifiers. In my research, I use Copi's natural deduction as a tool for *a priori* analysis in order to anticipate possible invalid steps in the proving process of a given statement and as a tool for *a posteriori* analysis of the proofs offered by undergraduate students. In a following section, I present an example of such analysis.

### The logical structure of mathematical statements: Changing letters' status

Durand-Guerrier and Arsac (2005) have investigated the letters' logical status in mathematics teaching. In their work, they refer to the predicate calculus in order to analyse quantified statements with a focus on the variables' dependence. They analyse a specific mistake which appears in proofs where one applies twice or more a statement of the kind "*for all X, there exists Y such that R(X,Y)*", abbreviated to AE statements, and a student may ignore that in that case, *a priori*, "*Y depends on X*". The misuse of AE statements in calculus have been demonstrated in an invalid proof of Cauchy's mean value theorem (Figure 2, Durand-Guerrier and Arsac, pp. 151-152):

**Theorem 1** (*mean-value theorem*). Let us consider two real numbers  $a$  et  $b$  such that  $a < b$  and a real function  $f$  defined on the closed interval  $[a; b]$ . If  $f$  is continuous on  $[a; b]$  and differentiable on the open interval  $]a; b[$ , then there is a point  $c$  in the open interval such that  $f(b) - f(a) = (b - a)f'(c)$ , where  $f'(c)$  is the first derivative of the function  $f$  at  $c$ .

**Theorem 2** (*Cauchy's mean-value theorem*). Let us consider two real numbers  $a$  and  $b$  such as  $a < b$  and two real functions  $f$  and  $g$  defined on the closed interval  $[a; b]$ . If  $f$  and  $g$  are continuous on  $[a; b]$  and differentiable on  $]a; b[$ , if  $g(b) \neq g(a)$  and if the first derivative  $g'$  of  $g$  is never equal to zero on  $]a; b[$ , then there is a real number  $c$  in  $]a; b[$  such that  $\frac{f'(c)}{g'(c)} = \frac{f(b) - f(a)}{g(b) - g(a)}$ .

**Figure 2: Two theorems: mean-value theorem and Cauchy's mean-value theorem.**

We can read:

"A proof rather often provided by first year science students consists of the following deduction of Theorem 2 from Theorem 1:

Function  $f$  satisfies the conditions for applying Theorem 1; hence there is a number  $c$  in  $]a; b[$ , such that  $f'(c)(b - a) = f(b) - f(a)$ . Also  $g$  satisfies the conditions for applying Theorem 1; hence there is a number  $c$  in  $]a; b[$ , such that  $g'(c)(b - a) = g(b) - g(a)$ . As  $g'$  is never equal to zero on  $]a; b[$ , then  $g'(c) \neq 0$ ; hence  $g(b) - g(a) \neq 0$ . The result follows from the quotient of the above two equalities.

This proof is invalid; one can prove it by considering two functions for which it is not possible to choose the same number  $c$ ." (Durand-Guerrier et Arsac, 2005, p.152).

According to the authors, the error from a logical point of view is the following: since  $c$  is a bound variable following an existential quantifier, it cannot denote a particular real number. However, the existential elimination that must be applied here allows to consider a real number  $r$  such that:

$$f'(r)(b - a) = f(b) - f(a).$$

When thus applying the same rule to  $g$ , it is necessary to consider a real number  $s$ , that may or not be equal to  $r$ , such as  $g'(s)(b-a) = g(b) - g(a)$ . It is important to notice that this logical analysis depends only on the logical structure of Theorem 1, and not on the mathematical meaning of the letters  $f$ ,  $c$ ,  $r$ , etc. The same reasoning allows us then to derive the quotients' equality:

$$\frac{f'(r)}{g'(s)} = \frac{f(b)-f(a)}{g(b)-g(a)}$$

but this does not provide a proof of Cauchy's mean value theorem (Durand-Guerrier & Arsac, 2005).

This example illustrates the difficulties linked with the logical status of letter in proof and proving. In the next section, I illustrate one example in Algebra how the use of Copi's natural deduction allow us to anticipate student's difficulties and to analyse their proofs.

### An example in elementary set theory

In the context of my PhD (Chellougui, 2004) conducted in Tunisia, I distributed a questionnaire to ninety-six mathematics students arriving at university in November 2001 (details on the analysis and main results can be found in Chellougui, 2009). In this paper, I focus on a specific example that I analysed in detail in order to highlight the methodological relevance of Copi's natural deduction for *a priori* and *a posteriori* analysis of proofs. In the Tunisian university, the first elements of elementary set theory including equivalence relation, order relation and binary relation, are taught at the beginning of the first academic year. The example I discuss here regards the proof that a given binary relation  $\mathfrak{R}$  is an order relation (Figure 3). My main objective was to identify precisely students' difficulties in the use of multi quantified statements in proof and proving.

We consider the set  $\mathbb{N}^{*2}$  endowed with the relation  $\mathfrak{R}$  defined by:  
 $\forall (p,q) \in \mathbb{N}^{*} \times \mathbb{N}^{*} (p\mathfrak{R}q \Leftrightarrow \exists n \in \mathbb{N}^{*}; p^n = q)$ . Show that  $\mathfrak{R}$  is an order relation.

**Figure 3: The exercise submitted to students**

I hypothesised that the students would be able to recall each of the three properties that an order relation checked: reflexivity, antisymmetry and transitivity, because they have met this type of questions in the course and in the series of exercises, although the formalisation of an order relation was new to them. The three definitions of the properties above were given to the students in the general case of a binary relation  $\mathfrak{R}$  as follows:

Reflexivity:  $\forall p \ p\mathfrak{R}p$ . Formulation containing one universal quantifier.

Antisymmetry:  $\forall p \forall q (p\mathfrak{R}q \wedge q\mathfrak{R}p \Rightarrow p=q)$ . Formulation containing two universal quantifiers.

Transitivity:  $\forall p \forall q \forall s (p\mathfrak{R}q \wedge q\mathfrak{R}s \Rightarrow p\mathfrak{R}s)$ . Formulation containing three universal quantifiers.

In this paper, I focus on the proof of *antisymmetry* for a binary relation whose definition involves an existential quantifier, leading to a rather complex logical structure as will be shown in the *a priori* analysis. I first present some elements of *a priori* analysis; then I present results from students' responses.

---

<sup>2</sup>  $\mathbb{N}^{*} = \mathbb{N} \setminus \{0\}$

### Mathematical and logical analyses of proof of antisymmetry

The definition of the binary relation  $\mathfrak{R}$  involves two universal quantifiers in the beginning of the formula and an existential quantifier in the second part of the equivalence.

In order to anticipate the difficulties that the students could meet in proving that the given binary relation owns the property of antisymmetry and to make explicit the steps needed for a complete proof, I provide (Figure 4) a mathematical and logical analysis, using the Copi's system for natural deduction (see Figure 1) with a specific focus on introduction and elimination of quantifiers

(1)	$\forall p \forall q (p \mathfrak{R} q \Leftrightarrow \exists n \in \mathbb{N}^* p^n = q)$	Premise <sup>3</sup>
(2)	$a \mathfrak{R} b \Leftrightarrow \exists n \in \mathbb{N}^* a^n = b$	UI on (1)
(3)	$b \mathfrak{R} a \Leftrightarrow \exists n \in \mathbb{N}^* b^n = a$	UI on (1)
(4)	$[ a \mathfrak{R} b \wedge b \mathfrak{R} a$	Auxiliary premise
(5)	$a \mathfrak{R} b$	Simplification on (4)
(6)	$\exists n \in \mathbb{N}^* a^n = b$	Modus Ponens on (2) and (5)
(7)	$b \mathfrak{R} a$	Simplification on (4)
(8)	$\exists n \in \mathbb{N}^* b^n = a$	Modus Ponens on (3) and (7)
(9)	$a^m = b$	EI on (6)
(10)	$b^k = a$	EI on (8)
(11)	$a^{mk} = b^k$	Property of the power
(12)	$a^{mk} = a$	Transitivity of the equality on (10) and (11)
(13)	$a=1$ or $m=k=1$	Mathematical properties
(14)	$a=b ]$	Consequence of (13)
(15)	$(a \mathfrak{R} b \wedge b \mathfrak{R} a) \Rightarrow a=b$	Introduction of $\Rightarrow$ on (4) and (14)
(16)	$\forall p \forall q (p \mathfrak{R} q \wedge q \mathfrak{R} p \Rightarrow p=q)$	UG on (15)

**Figure 4: Formalisation of the proof in the frame of Copi's natural deduction**

This formalized demonstration starts with a universal premise followed by four successive universal instantiations; twice in (2) with two different letters  $a$  and  $b$ , and twice in (3) with the two same letters  $a$  and  $b$ ; so, one works then with two generic elements. In (4) an auxiliary premise is introduced to express the antecedent of the property of the antisymmetry on the generic elements (this is a standard way to prove a conditional statement in the frame of Copi's natural deduction: proving  $B$  under hypothesis  $A$  provides a proof of  $A \Rightarrow B$ ). The two existential statements (6) and (8) are followed by two existential instantiations with two different letters:  $m$  in (9) and  $k$  in (10).

<sup>3</sup> A proposition upon which an argument is based or from which a conclusion is drawn.

The mathematical argument is developed in (11) to (14) using mathematical properties without the quantifiers. The passage from (13) to (14) does not appear in this demonstration. It can be expressed in the following way:

(13):  $a=1$  or  $mk=1$ ; First case:  $a=1$  then  $a=b=1$ ; Second case: if  $mk=1$ , with  $m \in \mathbb{N}^*$  and  $k \in \mathbb{N}^*$ , then  $m=k=1$ ; finally, in both cases,  $a=b$  (14)

Framing the proof in Copi's system allows us to anticipate potential flows likely to appear in students' responses from (6) and (8) to (9) and (10), respectively, in case the restriction rule for two successive existential introductions is not applied.

I provide an *a priori* classification of the answers that I will use for *a posteriori* analysis.

*Category 1*: answers for which two different letters are quantified existentially.

*Category 2*: answers for which the same letter is quantified existentially.

*Category 3*: answers for which the same letter is used without existential quantifier,

*Category 4*: answers where two different letters are used without existential quantifier.

### Classification of students' answers

Among the ninety-six students that answered the questionnaire 80 students have produced a proof of the antisymmetry property for the given binary relation.

1) There are 17 copies in category 1 (about 21%) with representative examples that illustrate this category (Figure 5).

<p>Student 1:</p> $\forall (p,q) \in \mathbb{N}^* \times \mathbb{N}^*; \begin{cases} p \mathcal{R} q \\ q \mathcal{R} p \end{cases} \Leftrightarrow \begin{cases} \exists n \in \mathbb{N}^*, p^n = q \\ \exists m \in \mathbb{N}^*, q^m = p \end{cases} \Leftrightarrow p^{nm} = p \Leftrightarrow \begin{cases} p=1 \\ \text{or} \\ nm=1 \Rightarrow n=m=1 \end{cases}$ <p>Then <math>\begin{cases} \text{if } p=1 \Rightarrow p=q=1 \\ \text{if } nm=1 \Rightarrow p=q \end{cases}</math></p>
<p>Student 2:</p> $\forall (x,y) \in (\mathbb{N}^*)^2 \begin{cases} x \mathcal{R} y \Leftrightarrow \exists n \in \mathbb{N}^* / x^n = y \\ \text{and} \\ y \mathcal{R} x \Leftrightarrow \exists n' \in \mathbb{N}^* / y^{n'} = x \end{cases} \Leftrightarrow x^n = y^{nn'} = y \Leftrightarrow x = y$
<p>Student 3:</p> $\forall p \in \mathbb{N}^*, \forall q \in \mathbb{N}^*; \begin{cases} p \mathcal{R} q \Leftrightarrow \exists n \in \mathbb{N}^*, n=m, p^n = q \\ q \mathcal{R} p \Leftrightarrow \exists m \in \mathbb{N}^*, m=n, q^m = p \end{cases} \Rightarrow n=m \Leftrightarrow p=q$

**Figure 5: Responses of Student 1, Student 2 and Student 3**

In the solution of student 1, the mathematical argument for step (11) to (14) is fully developed. This is not the case of student 2: the mathematical argument is absent, there is no mathematical justification for the equality of both natural numbers  $x$  and  $y$ .

Student 3 used two different letters in the existential statements, however student 3 declared them to be equal. In this case we can make the hypothesis that the student attributed the same value to  $m$  and  $n$  in order to satisfy the validity of the statement. Another hypothesis could be that student 3 thinks that the equality is necessary.

2) There are 27 copies in category 2, that I have subdivided in two cases:

(a) The existential quantifier is present twice (21 copies), see Figure 6.

<p>Student 4:</p> $\forall (p,q) \in \mathbb{N}^* \times \mathbb{N}^* \quad \left\{ \begin{array}{l} p \mathfrak{R} q \Leftrightarrow \exists n \in \mathbb{N}^* \quad p^n = q \\ q \mathfrak{R} p \Leftrightarrow \exists n \in \mathbb{N}^* \quad q^n = p \end{array} \right. \text{ for } n=1 \quad p=q$
<p>Student 5:</p> $\left\{ \begin{array}{l} p \mathfrak{R} q \Leftrightarrow \exists n \in \mathbb{N}^* \quad p^n = q \\ q \mathfrak{R} p \Leftrightarrow \exists n \in \mathbb{N}^* \quad q^n = p \end{array} \right. \Rightarrow p=q$

**Figure 6: Responses of Student 4 and Student 5**

In the production of student 4, there is a presence of both quantifiers, the student tries to construct the object  $n$  existentially introduced in such a way as to have the conclusion. So, to verify the property of antisymmetry and have the equality  $p=q$ , the student takes, for the natural number  $n$ , the value 1 which is a solution of the equation  $p^n=q$  of unknown  $n$ . Also for the student 5, where there is absence of universal quantification, the construction of the object  $n$  is implicit and the conclusion is immediate for the student.

(b) The existential quantifier is present only once (6 copies), see Figure 7.

<p>Student 6:</p> $\left. \begin{array}{l} p \mathfrak{R} q \Leftrightarrow \exists n \in \mathbb{N}^* \quad p^n = q \\ q \mathfrak{R} p \Leftrightarrow q^n = p \end{array} \right\} \Rightarrow p=q$
--

**Figure 7: Response of Student 6**

I notice with the student 6, that the existential introduction of  $n$  for the relation  $p \mathfrak{R} q$  is also considered for  $q \mathfrak{R} p$ . Let us note here that, on one hand, both variables  $p$  and  $q$  are not introduced and that, on the other hand, the elimination of the number  $n$  is not declared. This illustrates the fact that there are implicit arguments in the use of variables and in the steps required to prove the antisymmetry property.

3) There are 36 copies classified in category 3. I have considered in this category copies where the letter  $n$  is used for both statement and is not in the scope of a quantifier. I have considered it as an implicit existential introduction without taking in account the restriction rule. The example in Figure 8 is typical of answers in this category.

<p>Student 7:</p> $\forall p \in \mathbb{N}^*, \forall q \in \mathbb{N}^* : \left. \begin{array}{l} p \mathfrak{R} q \Leftrightarrow p^n = q \\ q \mathfrak{R} p \Leftrightarrow q^n = p \end{array} \right\} \text{ thus } p=q$
--

**Figure 8: Response of Student 7**

In the production of student 7, the variable  $n$  is the same in the two equivalences, and there is no mathematical argument supporting the conclusion. It is possible that the student wrote directly the conclusion  $p=q$  to fulfill the antisymmetry property; another possibility is that he considered that it was obvious that both equations  $p^n=q$  and  $q^n=p$  allow to conclude that  $n$  is 1 and to deduct the equality.

4) There is no copy in category 4, provided that we consider that the existential introduction may remain implicit.

These results confirm my hypothesis that the complexity of the logical structure on the side of quantifiers is likely to create an obstacle for the students to provide a correct mathematical argument. In particular, it is noticeable that the only students that provide sound mathematical

arguments are those in category 1, i.e. those who take in account the restriction rule for existential introduction.

These results also highlight the fact that in case of two successive applications of an existential definition that *a priori* requires the use of different letters, many students use the same letter. In other words, they do not respect the restrictions on the names of objects associated with the rule of existential instantiation. We could suppose that the symmetry in  $p\mathcal{H}q$  and  $q\mathcal{H}p$  triggers the choice of the same letter; however in line with other results (e.g. Durand-Guerrier et Arsac 2005) we would say that this students' practice could be found in various other contexts.

## Conclusion

In this paper, I aimed to illustrate the relevance of our methodology relying on Copi's natural deduction that allowed detailed *a priori* analysis of proofs and *a posteriori* analysis of students' productions. From the *a priori* analysis of the proof of the antisymmetry property of the binary relation at stake, I identified possible invalid steps. The *a posteriori* analysis of the proofs provided by students has shown that such invalid steps appeared in many answers and that in some cases, this invalid steps prevent the students from identifying the mathematical property required for providing a valid proof.

# A mathematics educator and a mathematician co-teaching mathematics – Affordances for teacher education

Jason Cooper<sup>1</sup> and Orit Zaslavsky<sup>2</sup>

<sup>1</sup>Weizmann Institute of Science, Israel; [jasonc2107@gmail.com](mailto:jasonc2107@gmail.com)

<sup>2</sup>New York University, USA; [oritath@gmail.com](mailto:oritath@gmail.com)

*Prospective secondary school teachers are required to take undergraduate courses in mathematics, which may be of limited relevance for their teaching. In this study, we investigate affordances of co-teaching for achieving such relevance. This is a qualitative study of an undergraduate course on Mathematical Proof and Proving, co-taught by a professor of mathematics education and a professor of mathematics. Analyzing an episode critiquing three different proofs, we show that the mathematician was concerned mainly with the written proof and its “correctness”, whereas the mathematics educator showed a sensitivity to the person behind the proof, and to pedagogical aspects of proof and proving. We propose that such a course may help students reconcile conflicts between how mathematics is taught and practiced in university and in high school, and suggest such co-teaching as a model for achieving relevance for teaching in mathematics courses.*

*Keywords: Mathematical proof and proving, teacher education, undergraduate mathematics.*

## Background and setting

The study reported herein was carried out in the context of an undergraduate course on mathematical proof and proving (MPP) taught at a major university in the USA<sup>1</sup>. Typically, such courses are the responsibility of mathematics departments, yet this course was conceived and designed through collaboration between the university’s department of teaching and learning and its mathematics department, and was co-taught by a professor of mathematics education – the second author of this paper, herein MEI (Math Educator Instructor) – and a professor of mathematics, herein MI (Mathematician Instructor). The goal of this collaboration was to capitalize on the two departments’ complementary fields of expertise – mathematics education and mathematics. This setting provides a unique opportunity to investigate differences and interactions between these two different types of mathematical expertise. Some preliminary findings were reported by Sabouri, Thoms, & Zaslavsky (2013) and by Zaslavsky & Cooper (2017), where some aspects of the co-teaching were discussed.

The course was open to a wide range of students, but the majority of participants were enrolled in teacher preparation programs, for which it was a required course. Accordingly, we situate our study in the context of the mathematical preparation of pre-service secondary-school teachers. These students have two different needs for MPP. In the short term, they must be proficient in university routines of proving in order to succeed in their mathematics courses. The notion of formal proof is new for many university students, and the transition to the kind of mathematical proving that is required in undergraduate courses is known to be difficult (Harel & Sowder, 2007). In the longer term, the majority of these students will become secondary school mathematics teachers. As such, they will be expected to teach MPP in their classrooms and to assess students’ proficiency in and understanding of mathematical proving. Thus they are faced with the challenge of two transitions,

---

<sup>1</sup> Data collection was supported by the National Science Foundation under Grant No. 1044809.

first from high school to university MPP, and then back to high school. One way of addressing this challenge is to offer two separate courses, taught in mathematics departments and in schools of education, leaving it up to students to reconcile differences between MPP in the two contexts. Our study suggests an alternative; perhaps a course that is co-taught by professors of mathematics and of mathematics education will help reconcile the different, sometimes conflicting notions of MPP at high school and undergraduate levels. This is the overarching question that guides our study.

## **Literature review and research questions**

Secondary school teachers are usually required to take some university level mathematics (ULM) courses in their pre-service training; in some contexts, they are even required to hold an undergraduate degree in mathematics or in a related field. Yet many ULM courses, taught in mathematics departments, deal with advanced mathematical content whose relevance for teaching is not immediately obvious. A number of researchers have investigated affordances of ULM courses for teaching, using a methodology of teachers' self-reporting (e.g., Adler, et al., 2014; Even, 2011; Zazkis & Leikin, 2010). Such methodologies have been found to be of limited value; teachers tended to report on general affordances of learning mathematics from mathematicians, however, Zazkis & Leikin (2010) found that teachers were generally unable to specify in what ways they made use of ULM in their teaching. In our study we utilize a different methodology for revealing affordances of the MPP course for teaching, in analysing the teaching in this unusual setting.

According to Harel & Sowder (2009), mathematicians teaching undergraduate courses are not fully aware of student difficulties in learning MPP. The conception of co-teaching in our context was similar in some aspects to the way it is utilized in special education (Friend et al., 2010), letting the mathematician and the mathematics educator share the responsibility for the content, while leaving it up to the educator to attend to students' "special needs". Thus, we hypothesize that the mathematician will take responsibility for epistemic aspects of the course, while the educator will take responsibility not only for addressing the students' mathematical difficulties, but also for the course's relevance for teaching. This hypothesis is consistent with Cooper's findings (2016) in his study of a professional development course for primary school teachers taught by research mathematicians, where the mathematicians took responsibility for the mathematical content, while the participating teachers themselves took responsibility for achieving relevance for teaching. Accordingly, our research questions are:

1. What are the instructors' views on MPP? In what ways are their views similar or different?
2. What are the affordances of different views on MPP for the students as future teachers?

## **Theoretical framework and epistemic analysis**

We join researchers such as Nardi et al. (2014) in taking a Commognitive approach (Sfard, 2008). Mathematical "knowledge" is conceived as a particular community's established modes of communication, called discourses. These are constituted in commonly used keywords (e.g., "proof", "given"), in narratives that are endorsed or rejected by the community (e.g., proofs), in visual mediation that is considered useful (e.g., two-column format of a proof), and in repetitive routines (e.g., proving). The very different mathematical discourses of two communities - research mathematicians and researchers in mathematics education - differ in their use of common keywords, in the types of routines they engage in, and in the rules and norms that determine which narratives

will be endorsed and which will be rejected, and these differences are grounded in the communities' activities – mathematical research on the one hand and mathematics education on the other.

Proof is a *genre* in mathematical discourse, a type of narrative that is expected to adhere to a community's conventions. It usually includes text, and may employ a variety of means to visually mediate its mathematical ideas. A proof may be endorsed or rejected based on the metarules of a community's mathematical discourse. Proving is a routine in mathematical discourse, with the goal of producing a proof. Ideally, the prover should take responsibility for producing a “valid” (i.e. endorsable) proof, which may subsequently be endorsed or rejected by a teacher or by peers (classmates or fellow researchers). Routines of proving, and the proofs that are produced, are governed by very different metarules in school and in university.

## Method and data

The study reported herein is part of a larger study, for which extensive data were collected, including video recording and field notes of each of the 13 lessons taught in 2013, audio recording and field notes of weekly meetings held following each lesson, email exchanges among members of the teaching team, and students' written homework with TAs' comments and grading. The rich data offers insight into the instructors' intentions, however, in the current analysis we are concerned with affordances of the co-teaching as it played out, and thus focus our attention on the video recordings of the lessons, and, in particular, on a single episode from lesson 8, selected for being rich in interactions between the MI and MEI. We assumed that the two instructors referring to each other's ideas, possibly disagreeing with each other, would reveal their tacit norms and ideas about MPP, and highlight differences between them.

## Analysis

In the following episode, MI and MEI discuss a homework assignment, where an exemplary proof had been provided for the claim  $|x \cdot y| = |x| \cdot |y|$ . Three other responses (also ostensibly proofs) were included in the assignment, and students were asked to critique them. These “proofs”, labeled 2.1, 2.2, 2.3, were copied onto the board, and were discussed.

Format: we present one or more utterances followed by a short annotation raising points that we later elaborate in the discussion. For brevity, utterances not relevant for our analysis were omitted.

### Sample proof 2.1

MI One thing I told you in the very first lecture is to do what? Write the “given” and write RTP [remains to prove] ... This is a mistake that is commonly made because people confuse what is given and what you need to prove.

MI considered proof 2.1 unacceptable, since it begins with what needs to be proven, and manipulates it to obtain the incontrovertible  $a \cdot b = a \cdot b$ . He believes that following a simple rule of writing the given and writing RTP at the outset can help students avoid this common mistake.

2.1  
 CASE 1: LET  $x = -a$ ,  $y = -b$   
 $|-a \cdot -b| = |-a| \cdot |-b|$   
 $a \cdot b = a \cdot b$   
 CASE 2: LET  $x = -a$ ,  $y = b$   
 $|-a \cdot b| = |-a| \cdot |b| \Rightarrow -a \cdot b = a \cdot b$   
 CASE 3: LET  $x = a$ ,  $y = b$   
 $|a \cdot b| = |a| \cdot |b| \Rightarrow a \cdot b = a \cdot b$

Figure 1: Proof 2.1

MEI [Where] we provided proof [in the HW], we actually wrote the given and what you have to find, and if the people who wrote this proof [2.1] started by saying: “given”, then there would be no confusion of what should the last line be. The last line being verifying this.

MEI elaborates MI’s point, but soon after gives a different perspective on this rule of thumb:

MEI It's more than writing what's given and what you have to prove. It's also accounting in each line ... what is the status of what you wrote. Is it given, is it a known fact that you bring from some other place, which is fine. You have to annotate and write where it comes from, how you got to there... If we can infer the following [line], we have to say it... We need these words to make sense of what the status of each line is. Because you'll suddenly ask what is this? How do I know it? It's a mean of communication, but it's also a means of sort of control of what you're doing... We need to know [where it came from], not just us to follow you, but mainly for you to produce a correct proof. If you skip and don't account for each line, you're more likely to make a mistake.

MEI stresses the importance of accounting for everything that is written. The most obvious reason, stressed by MI earlier in the lesson, is that these are the norms of the genre; this is the way you communicate with others within the mathematical community. However, MEI’s words suggest additional considerations. First, in her words “we need to know... not just to follow you” she appears to be conscious of the pedagogical setting, where instructors need to follow the student’s thinking in order to assess their work. Additionally, she sees the written proof not only as a means of communicating with others, but also for communicating with oneself (i.e., thinking). Her word “control” alludes to metacognitive aspects of proving, and MEI seems to be suggesting that following norms of writing a proof may contribute to the process of producing a valid proof.

### Sample proof 2.2

MI The proof started by saying... this  $[(xy)^2 = x^2 \cdot y^2]$  is correct, right? Does [it] imply  $[\sqrt{(xy)^2} = \sqrt{x^2 \cdot y^2}]$ ?

MEI The thinking of this person was that they're taking what we need to prove and squaring it and getting there

For MI, it is the proof that is “saying” something, whereas MEI draws attention to the thinking of the person behind the proof.

Figure 2: Proof 2.2

MI I'm asking you simply does anyone in this room disagree up to this step?

The implication of MI’s question (“does anyone disagree”) is that the proof may be correct (at least “up to this step”) regardless of the thinking of the person who wrote the proof (e.g., squaring the RTP instead of beginning with the given).

MEI This would be ok without this [striking through lines in the parentheses “square both sides and get rid of the absolute value”]. Because what it says here, that you took this as given in a way, and squared it and got this.

In spite of MEI’s previous attention to the prover, she is now showing how the written proof can be fixed by striking out the parts that were a consequence of the prover’s misguided thinking.

MI Sorry, I did not read that. I was just looking at the equations. Absolutely right, this is making the same mistake [starting with RTP instead of with Given].

MEI I do want to say very nicely that at least the logic of the thinking was clear here, because whoever did it provided the explanation, and this is easier to follow, and important.

MI, in assessing the correctness of the proof, had not read the text in parentheses. This further supports the suggestion that he is concerned with the proof as a mathematical product (i.e., the equations), and not with the prover's thinking, which is represented in the explanations. MEI, in contrast, values not only the mathematical correctness of the proof, but also the clarity of thinking that is revealed. Here again she is showing concern for pedagogical aspects of MPP.

MI Whoever wrote the proof had a very good idea at the beginning, and choked at this point [ $xy = xy$ ]

Here MI refers for the first time to the person who wrote the proof. However, his claim that this person “had a very good idea” is not justified. This claim was based on the fact that the first line on the board -  $\sqrt{(xy)^2} = \sqrt{x^2 \cdot y^2}$  - can serve as the beginning of a valid proof. In this he is ignoring the proving process and the thoughts of the prover, as reflected in the words that MEI crossed out.

### Sample proof 2.3

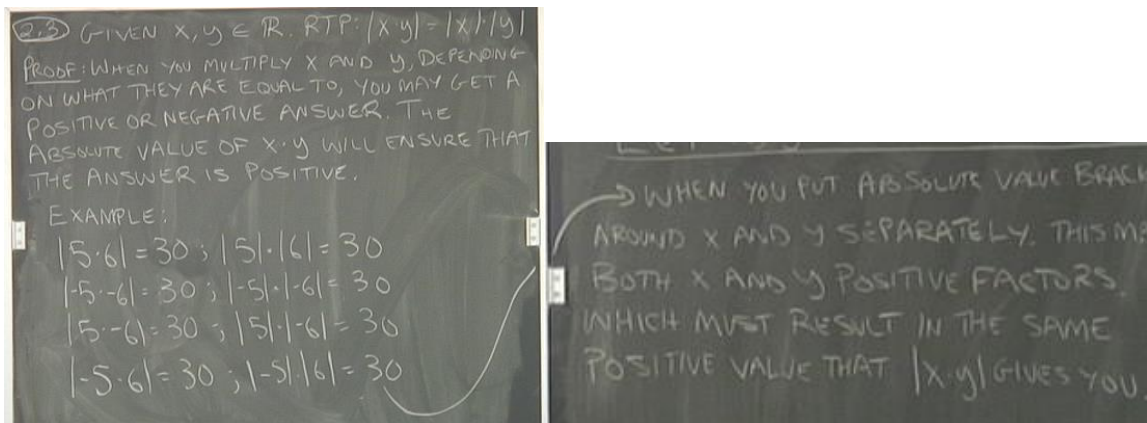

Figure 3: Proof 2.3

MI How many of you think this is a proof? How many of you don't think this is a proof?

MEI What do you think J's opinion is? Does he think it's acceptable or not?

In her question, MEI is allowing for the possibility that the students' opinion will be different from MI's, but she is suggesting that they should be coming around to seeing things Jim's way.

MI It is a proof. It's a badly written proof, but it is a proof. Whoever wrote this made a lousy job of writing [it]. That's the only mistake that person made... because they don't know how to write a proof. How to present it. So the mistake here is not in the content but in the presentation. The person ended up writing two paragraphs for two lines.

These words highlight three aspects of a proof in MI's discourse. There is the end product, what he calls the “presentation”, which in this case he considers “lousy” (Jim later rewrites the proof in two condensed lines of mathematical expressions). There is the “content” of the proof, the mathematical

ideas that underlie the presentation and are revealed in it, which in this case are valid. Finally, there is the thinking of the prover, which MEI is keenly aware of, but Jim appears to be ignoring.

## Discussion

In this section, we discuss findings from the analyzed episode, along with some additional findings from other episodes whose analysis we omitted for brevity. Regarding our first research question, we found, as hypothesized, that MEI and MI stressed different aspects of MPP. We present similarities and differences between their discourse, as it pertains to proof and proving.

### The human element in a mathematical proof

MI and MEI both held the view that a text purporting to be a mathematical proof must adhere to specific norms of communication. For Jim, the question of validity was central: does the proof begin with the given, end with what needs to be proven, and is each line in the proof mathematically justified. This is a consequence of the communicational role of proof in his discourse – to convince members of the community that a claim is valid. MEI, too, was concerned with the mathematical validity of arguments, yet she was also sensitive to pedagogical aspects of proving, and considered the prover's communication with a teacher, who is not only assessing the validity of a mathematical text, but also the nature of the mathematical thinking that produced it. There were also differences in the instructors' attitude to the prover's communication with herself. MI saw two distinct phases in proving, a draft phase (which he called a "scratch") where the prover does her thinking and is not accountable for what is written, and the final product which will be scrutinized by others. Thus, for MEI a student's proof should reveal the prover's underlying thinking, whereas for MI the final product should conceal thinking. MEI held a more integrated view regarding the phases of producing a proof, where the "accounting" in the final product could serve a metacognitive role in the process of proving, by "controlling" the flow and minimizing mistakes. These differences in the instructors' attitudes to proof and proving are evident in their use of language. MI spoke of what the proof "is saying", whereas for MEI it is a human agent who is "saying" something. Jim frequently asked if the students "agree up to this step", where he is referring to a step in the written proof. In sample proof 2.2 MI did not pay attention to the student's thinking, as reflected in the text in parentheses. It was MEI who suggested striking out these lines, but though this would "fix" the proof, she realized that it would not fix the thinking of the person who produced it. MI, on the other hand, when speaking of the process of producing proof 2.2, attributed a "good idea" to the prover, based on the fact that a valid proof could have begun with the first line. He felt that after this promising start the person had "choked", and this just a few seconds after he conceded that the prover had in fact made "the same mistake" as the prover in sample 2.1 - beginning with what needs to be proven.

In spite of MI's attention in sample proofs 2.1 and 2.2 to proof as a text, in proof 2.3 he suggested that this text may be a "representation" (i.e., a visual mediation) for something else. Though the proof was badly written, he felt that there was no mistake in the "content" of the proof. The nature of this underlying content and its relationship with its representation as a text is not clear. MI does not appear to be alluding to a human agent's thinking, but this point requires further analysis of his discourse, drawing on additional data.

## The role of proof in mathematical discourse

Later in the lesson MEI pointed out how the pedagogical context of the course may give a distorted view of the role of proving in mathematics: “Mathematicians do proof in order to establish theories... But what happens in this course, because the focus is on how to really construct proofs, sometimes we’re doing it about facts that may be trivial to you... we may be giving you a wrong message”. This may explain the importance MEI attributed to a comment from MI in lesson 6, regarding a proof of the claim: if  $n > 10$ , then  $n^5 - 6n^4 + 27 \geq 0$ . At MEI’s prompting, MI showed that a careful analysis of the proof reveals that the expression is not only greater than 0, it is in fact greater than 40,000! Why should this be important? Jim explained that “you might need [this “stronger” fact] later on in the proof”. MEI re-voiced this idea, but we suspect that for her it had a second role, in addressing “the wrong message” about the nature of proving. The task, given by some anonymous agent, was to prove “greater than 0”. In showing more than was required, MI and MEI were modeling proving as an investigation, where the prover has some agency in deciding what to prove.

## Affordances of the co-taught course for future teachers: Explicit and implicit goals

We hypothesized that a course on MPP co-taught by a mathematician and a researcher in mathematics education would have special affordances for futures teachers, in presenting and reconciling different aspects of MPP that are crucial for teaching. Our analysis has demonstrated some affordances.

The explicit goal of the course was transitional – to help students learn the mathematics department’s norms of MPP, and to develop proficiency in university level routines of proving. This goal was addressed by both instructors, with Jim taking a leading role. MEI accepted and encouraged Jim’s role as the mathematical authority, in calling on him to take over when crucial mathematical issues were at stake. It was MI who modeled the kind of proving that will be expected in advanced university courses. Furthermore, if students internalize MI’s discourse, they may eventually bring a commitment to mathematical precision and rigor to their own classrooms. MEI did not disagree with Jim. However, in stressing other aspects of MPP, we feel that she was modeling not only how to produce an acceptable proof, but also how to teach MPP. In her attention to the thinking behind students’ proofs she was modeling how these future teachers should be concerned not only with what their students are writing, but also with the mathematical thinking that drives their work. She was further concerned with some meta-level issues, such as the investigative nature of mathematical activity, and the development of metacognitive skills of self-monitoring the process of proving.

Thus, students were exposed to two different perspectives on MPP, both of which they will need to internalize as teachers. However, MI and MEI by and large taught in the *one teach, one observe* approach (Friend et al., 2010), and their points of view remained disjoint. In fact, being aware of their differences and wishing to present a unified front, they often tried to resolve them at the planning stage of lessons (Sabouri, Thoms, & Zaslavsky, 2013). Had they taught in the *teaming* approach, described as “representing opposite views in a debate, illustrating two ways to solve a problem, and so on” (Friend et al., p. 12), there may have been opportunities to openly discuss differences, encouraging students to reconcile different aspects of MPP relevant for their future teaching.

# The organization of study in French business school preparatory classes

Lynn Farah

American University of Paris, France; [lgf00@mail.aub.edu](mailto:lgf00@mail.aub.edu)

*This paper presents parts of a doctoral research pertaining to the study of mathematics in French business school preparatory classes. In what follows, we identify the main features of the institutional devices designed and implemented by two mathematics teachers in their respective classrooms in order to influence and transform the working habits of their students. To do so, we rely on qualitative analysis of data collected mainly through interviews and questionnaires. Our conceptual framework borrows constructs from the Anthropological Theory of Didactics as well as several works in the sociology of education field.*

*Keywords: Mathematics learning, preparatory classes (CPGE), organization of study, teaching devices, teachers' practices.*

## Context

Student failure in mathematics during the first university years is a widespread problem in many countries including France, but it does not seem to affect in the same way students of all French higher education institutions. In fact, there are in France alternative institutions such as the *Classes Préparatoires aux Grandes Écoles* (CPGE in what follows) students achieve much better results in mathematics than those enrolled in regular French universities, as is reported in official statistics provided by the ministry of national and higher education and research<sup>1</sup>. The CPGE prepare students over two academic years after obtaining the French baccalaureate to enter the *Grandes Écoles*, which are mainly business schools or engineering schools, by passing the *concours*, national competitive written and oral exams specific to each type of school which students take by the end of the second preparatory year. In the French educational systems, the two preparatory years at the CPGE are equivalent to the first two years of undergraduate study at university and do not lead to obtaining a degree. The CPGE have three streams, scientific (S), business and economics (EC) and literary (L), which each have different tracks.

Our study focuses on the CPGE in the continuation of the work of Castela (2011). These institutions differ widely from regular French universities in elements commonly considered as the main causes of student failure (Farah, 2015b, chap.II, section 4). They are known for their selectivity in recruiting students who have obtained exceedingly above-average results throughout high school and in the French baccalaureate, as well as their supportive culture, which fosters student collaboration and provides them with close follow-up, in a relatively rigid high-school-like system within stable moderate-sized classrooms. In fact, these institutions resemble more the European and North American universities than the French universities in terms of teaching methods and student-teacher relationships. Therefore, it is important to point out that although our study is conducted in a

---

<sup>1</sup> Source: <http://www.enseignementsup-recherche.gouv.fr/cid75181/reussite-et-echec-en-premier-cycle.html>

specific environment, its results help us to understand more general issues that concern other institutions in France and in other countries.

With the change of institution, from high school to CPGE, students face a significant rift with respect to the work they have to complete in order to succeed in mathematics. In fact, in the CPGE, students are expected to develop without teacher supervision and in addition to the tasks that are prescribed to them, significant autonomous personal work in mathematics that is not necessarily in the continuity of what ensured their prior success in high school. Moreover, assessment in the CPGE is entirely conditioned by the nature of the examinations of the *concours*. In mathematics, it is cumulative, covering the content of both preparatory years, which is never the case neither at university nor even in high school. In this paper, we are interested in the ways these institutions shore up their students and help them develop a new working mode in mathematics, geared towards the CPGE requirements, during the first year of scientific track business school preparatory classes (ECS). Therefore, we focus on the relationships that exist between institutional and students' personal organization of study in mathematics.

## Conceptual framework

We are mainly interested in the institutional dimension and its impact on students' learning in mathematics. We claim that through their ways of functioning, the CPGE institutions help their subjects (the students) construct a new working mode in mathematics adapted to the CPGE requirements. We refer to the foundations of the Anthropological Theory of Didactics (ATD) to examine the weight and action of these institutions (Chevallard, 2003). We endorse Chevallard's (2003) description of an institution as a social system that allows and imposes on its subjects, that is people who occupy different positions within the institution, ways of doing and thinking. Subjects are hence submitted to collective constraints and expectations that regulate their actions and thus subjugate them (in French, *assujettir*). For our study, we consider first, at a global level, the CPGE institution within which individuals occupy the positions of student, teacher, and administrative staff... At a local level, we focus first on the teaching of mathematics in the broader sub-institutions, the EC stream then the ECS track. Next, we consider the teaching of mathematics in the school institution. Lastly, we examine the institution of the mathematics classroom of each teacher, with two main positions: teacher and student.

Regardless of the level of institution in question, it is important to bring forward the idea of organizational stability emphasized by Darmon (2013) and Rauscher (2010). Darmon identifies institutional devices that are shared among CPGEs, which put students to work while supervising them. In accordance with the ATD hypotheses, Rauscher advances that subjects of the CPGE institutions occupying the teacher position (per discipline, hence in mathematics in particular) predominantly share common experiences and background traits. They thus form a distinctive social group, as a result of several interacting mechanisms, and take decisions as a team, or a tribe (*tribu*) as Chevallard (2003, p.89) would refer to it. The hypothesized continuity and stability within the CPGE, as to the norms of the teacher profession and the study organization created by each teacher, enables us to foresee the influence of the global CPGE institution on the students' work.

The work of Darmon (2013) in sociology allows us to clarify certain important aspects of the functioning and role of the CPGE institution, through which it exerts its subjugation actions and the

resourcing of students' personal work. Darmon defines a specific type of institution based on the socializing functions of the CPGE and examines it as an institution where a specific type of person is manufactured. According to her, these “*enveloping institutions*” (p.10) shape and transform the students through preparatory institutional socialization processes. Therefore, she analyzes the different daily functioning devices that make it possible for the institution to exert its effects on the students (“*surveillance, sanction, examination and pressuring techniques*” p.16). It appears that this subjugation process is undertaken by taking into consideration the individuals involved; this is far from common in higher education practices in France and sounds highly paradoxical. In fact, Darmon puts forward the fact that the CPGE strives to soften the preparatory violence. She describes the institution as being powerful but not totalitarian, violent but concerned about the well-being of its members, it operates by individualizing to the extreme rather than homogenizing, thus reinforcing its take over the individuals which are its members (2013, p.28). Her findings converge with those of Daverne and Dutercq (2013) who put forth the regretted yet accepted pressure to which CPGE students are subjected as well as the personalized adaptation of teaching.

Furthermore, we sought to develop the institutional dimension of our research from the point of view of the teachers. We hence considered two levels: the first one pertains to the way teachers are subjected to the CPGE institution; the second one is related to the mathematics classroom of each teacher, the local institution s/he creates thanks to stable devices which we seek to identify. We believe that the subjugations to the CPGE generate an environment in which each teacher enjoys a given autonomy and can freely express his/her individuality within the boundaries of the common CPGE teacher culture highlighted by Rauscher. Using Darmon's work, we bring forward the CPGE institutional functioning analysis in order to explore how the socializing function is exerted.

Therefore, based on the different didactical and sociological elements of our conceptual framework, we address the following research question in this paper: which institutional devices lead to the transformation of the students' personal work mode in mathematics, at both levels of an institution, ranging from the global CPGE institution to the local teacher classroom institution?

## Methodology

A first phase of our study, which is beyond the scope of this paper, was entirely centered on students' personal work in mathematics. Using questionnaires and interviews of first year students from two ECS track preparatory schools in Paris (see Farah, 2015a), we gathered data about the organization of mathematics courses, the teaching methods, the assessment tools and the resources provided by the teachers to put students at work and accompany them in the study of mathematics. Based on this, we sought to approach the practices of the teachers by examining the teaching devices they design and implement in their classrooms as well as their meta discourse (Robert and Robinet, 1993, p.1). We must clarify that the word “discourse” refers to verbal expression, i.e. the use of words to exchange thoughts and ideas. It is not a theoretical construct borrowed from a conceptual framework. As for the word “meta”, we refer to Robert & Robinet's definition (1993) whereby a teacher's discourse contains meta elements, i.e. about mathematics and about the ways of doing and learning mathematics. The second phase of our research followed from this.

To answer the research question addressed in this paper, we relied on qualitative analysis of data collected from two mathematics teachers of the schools involved in our study. We started with data

obtained through semi-structured interviews conducted with each of the two teachers about the devices instituted in their classrooms. Then, we designed and had each teacher complete two questionnaires. The first one, inspired from Rauscher's thesis (2010), is about their career path and their choices with respect to teaching in the CPGE, which we believe determine their position and impact their subjugation within the CPGE institution. The second one, inspired from Darmon's book (2013), is about the assessment and pressuring devices the teachers implement in their respective classrooms to put the students to work, as well as their ways of softening preparatory violence in terms of the support and comfort they bring to the students.

We used Qualitative Content Analysis of the interview transcriptions and questionnaire answers to put together a description of institutional devices implemented by each teacher (local) and those common across the different institutional levels (global). The narratives were analyzed thoroughly, manually, line by line, in a search for keywords and vocabulary terms constituting the teachers' discourse about the ways students should study mathematics, while focusing on anything pertaining to institutionalization, regularity, and insistence on specific actions by the students or the teachers. Our search was structured around the following themes that determined the analysis rubrics of our content analysis: taking notes in class, managing work and revisions overall, studying between two mathematics sessions, using resources, preparing for an exam, the *colles*<sup>2</sup>, collaboration between students, student difficulties. We then resorted to triangulation to confirm the information obtained from the teacher-designed instruments by comparing it with what we had gathered in the first phase of our study through the students. We must clarify that, besides the things that converge with the information gathered from the students, we had very few elements that would allow us to determine the propinquity between the teachers' statements and what actually takes place in their classrooms. In fact, one could be surprised that, in an analysis of teaching practices, there have been few filed observations. This limit is due to practical constraints in terms the duration of a doctoral thesis. The final output of our analysis is presented in the form of a description of the different institutional devices that organize and shape students' personal work in mathematics.

## Main findings

The findings show that the teachers seek to put their students to work and mold their study methods in mathematics through numerous collective devices instituted in their classrooms. In addition, they closely follow-up on each student's work in mathematics through customized individual devices. Thanks to the latter, the teachers develop and apply diverse pressuring techniques in order to ensure the students' intellectual training and their successful passing of the *concours*. We provide below a description of the main devices, which are either dictated by the global organization of mathematics study in the CPGE institution and thus revealing how the teachers are subjugated to their institution, or specific to one of the more local sub-institutions (for more details, see Farah, in press).

---

<sup>2</sup> A *colle* is an assessment tool specific to preparatory classes. In mathematics, it classically takes the form of a one-hour bi-monthly oral examination, in groups of three students working individually but simultaneously, answering lesson questions and/or solving problems on the board, managed by a *colleur* who is present to supervise and grade the work.

## The teacher's course and the follow-up beyond

The mathematics course organization and progression are the first aspects of guidance to students' work. For both teachers, when they explain a mathematics lesson, their first priority is to retain the students' attention while encouraging them to actively participate by regularly asking questions. The lesson is completed and illustrated through examples and exercises, which are solved in class or at home, then corrected in class. During regular classroom sessions, if needed, teachers wrap up the work that they have previously started during practical solving sessions (called *Travaux Dirigés* or TD). These special sessions give students room to work on exercises in small groups, thus fostering discussions with the teacher as well as classmates.

Both professors involved in our study use a handout as the baseline for the lesson explanation; they distribute it to students either systematically or occasionally. Depending on the teacher, the class or the chapter, this handout can be exhaustive or having blanks to complete, and teachers modify it regularly in order to tailor its contents to the level of the students and their capabilities (concentration, understanding, note taking ability) and the course pace is slowed down or increased accordingly. The main objective behind the use of such a device is to save note-taking time in class and ensure that students don't make mistakes in copying key elements. A typical handout contains mathematical definitions and notations, propositions and theorems with occasional short proofs, lesson examples and application exercises. During the lesson, the teachers spend most of the time completing the missing proofs then provide additional examples. They explain to students that the proofs are the basis of mathematics, and repeatedly underline the practical and generic aspects to be extracted. On the contrary, little importance is given to statements of theorems. This is an example of a specificity of mathematics teaching in this CPGE stream as opposed to the insistence on academic knowledge in universities. In addition, the teachers formulate several remarks that are not solely about theoretical mathematical knowledge. In fact, in addition to the mathematical content, the teachers make comments related to practical knowledge. These are part of their meta discourse which contains technological elements (Castela, 2011) used to bring forward the know-hows linked to the mathematical content, thus allowing them to accompany students in their study.

In addition to the time dedicated to lesson explanation, exercises solving and correction, both teachers ensure to always be available to assist the students in the learning of mathematics outside the classroom. They are willing to answer questions, provide explanations, recommend and even correct additional work despite believing that the workload they assign is already enough (regular exercise sheets and occasional extra exercise sheets with their correction for some chapters). They usually encourage students not to look for more resources (textbooks, online) and focus on what they provide due to time constraints. Moreover, the teachers hold weekly tutoring sessions to ensure that students are getting all the needed help within the institution. Through their extended availability and individualized follow-up, the teachers are ensuring that all their students are provided with the necessary assistance for their learning, while they control and organize their study. They are thus softening the preparatory violence through surveillance and examination. This is one important manifestation of the CPGE teacher culture that is absent in French universities.

### **The recurring discourse about the ways of studying**

The teachers encourage their students to regularly study their mathematics lessons and solve the assigned exercises (for both the regular sessions and the TD) and they always explain to them how they should proceed to do so. The teachers emphasize the importance of reading a mathematics lesson actively and critically. The objective is learning the keys lesson elements while thinking about them and asking the right questions to first understand then memorize. According to both teachers, validation of the learning should be done by playing-back important lesson contents mentally, then preferably in writing.

In addition, they both stress the crucial role of decontextualizing in mathematics learning. To do so, they underline the significance of both the results brought through proof and the use of generic components of reasoning, in addition to the techniques used in standard exercises which students must be able to acquire and plough back in other situations. In fact, they preach strategic exercise solving whereby students are expected to identify standard problems and recognize methods, techniques and tricks that can be used to solve them, which can also be applied to other problem situations. Thus, according to both teachers, students should have a transfer-oriented approach to exercises rather than one that favors only practice or reproduction (Castela, 2011), the latter are dominant among successful university students but are deemed ineffective in the CPGE. The teachers also insist on the necessity of doubling efforts until mastery is attained when facing difficulties in solving an exercise.

We can refer to the notion of constructive help proposed by the teachers to guide students in studying the lesson, solving exercises and decontextualizing proof and exercises, when working on a daily basis between two mathematics sessions, as well as when preparing for an exam. In fact, we have identified several features of help common to both teachers in their discourse, about expected ways of studying mathematics and practical knowledge pertaining to the techniques which could help students gain know-hows relating to the awaited tasks. These illustrate the convergence of learning methods regularly repeated by two different teachers of the same stream and track.

### **The assessment tools**

In order to ensure that the students are completing the assigned work (lesson and exercises) and to identify their weaknesses and difficulties in mathematics before the graded exams, teachers use personalized informal evaluation techniques during classroom sessions (both regular and TD). They often resort to oral interrogations about the lesson notions by randomly calling on students or choosing those who are inattentive or fall behind. Also, while the students are solving exercises in class, the teachers go around to check what they have done, they assess their understanding and help when needed. Then, the teachers encourage the students to engage in discussions about the exercises' solutions before correcting them or asking a student to do so. One of the two teachers gives special care to exercises preparation by the students prior to class. In order to push students to maintain regular work, he periodically calls students to the board and collects notebooks without prior warning whenever he notices that the work has not been fully done, without necessary grading any. These are all examples of surveillance and sanction techniques that allow the institution to monitor and redirect the work of the students' work.

The teachers have several types of more formal assessment devices, institutionalized at the global CPGE level, which allow them to evaluate the degree of investment and understanding of their students. Firstly, they use all sorts of written evaluations. Teachers mainly resort to short quizzes focused on the mathematics lesson content (definitions, theorems...) at the beginning of the school years to push the students to study, however they state that they cannot maintain them throughout the year due to time constraints. They also have monthly exams (called *Devoirs Surveillés* or DS), and bi or triannual mock *concours* which are summative and are conducted in conditions similar to the official *concours*. One of the teachers quizzes his students about the correction of previous DS exams thus allowing the students to detect and address their weaknesses. In addition, teachers assign and grade homework sets (called *Devoirs Maison* or DM) on a monthly basis and they usually invite students to work on those in small groups. All of the above are examination and pressuring techniques used across the CPGE institution, with specificities of each sub-institution.

Last but not least, the *colles* are the most important assessment tool that teachers use to evaluate their students in a highly customized manner. We summarize the main perks they list about this institutional device, which are for most specific to the case of mathematics *colles* in the ECS track, since their organization and functioning changes across disciplines, tracks and streams. The *colles* impose on the students a work and study regularity, which is certainly stressful and tiring for some, but the pressure is eventually seen as beneficial for the majority. Mathematic *colles* sessions are described as similar to private tutoring sessions where students can discover their weaknesses, ask questions, obtain additional explanations and a new point of view, and practice by solving additional exercises. Further to these mathematical learning related aspects, the *colles* are characterized by their interpersonal feature and the know-hows and social skills they teach (stress management, oral presentation, self confidence) which go beyond the scope of the classroom or even the school. Therefore, the *colles* are viewed as a summary of the best things the CPGE have to offer in terms of learning environment for their students (Daverne and Dutercq, 2013, p.182). They are to many teachers the secret to students' success in CPGE (ibidem, p. 182), despite the difficulties and constraints they are subjected to.

## Discussion and conclusions

On one hand, we can conclude that the teachers who took part in our study are heavily involved in their students' learning. To accommodate the needs and level of a "*new population*" (ibidem, p.7) of CPGE students, more diversified in terms of academic and social backgrounds, teachers redefine their teaching modalities and pedagogical devices and adjust the level of their expectations. Daverne and Dutercq state that if some young students have good working habits when they enroll in the CPGE, none yet have the general culture nor the confidence needed to face the *concours*, which requires from teachers a high level of commitment towards them and a constant care for their moral (ibidem, p.8). Hence, the teachers participate in the didactical and pedagogical organization of their students' autonomous study thanks to the advice they provide and the devices they institute and regularly adapt according to their needs and capabilities. They are therefore clearly dedicated to their students' success. This is also reflected through the closeness in the student/ teacher relationships, which we do not tackle in this paper (for more information, see Farah, 2015b).

On the other hand, although the use of the varied pressuring techniques in mathematics differs among teachers and depending on the students' dispositions, the techniques themselves remain redundant across teachers and classes. This brings forward their generality and continuity within the EC stream of the CPGE institution, of which they become a specificity. As a matter of fact, we find in the teachers' discourse common features underlining the coherence in the practices of teacher tribes per class as well as the stability of practices within each preparatory school, within the ECS track, and even within the entire EC stream. Regardless of the level of the institution, the devices used are specific to the teaching and learning of mathematics, even though we do not examine them with respect to a specific mathematical content in this paper. We conclude that the coherence of practices noted between the two teachers involved in our study concurs with what the sociological studies of Rauscher (2010), Darmon (2013), and Daverne and Dutercq (2013) have identified.

# How mathematicians conjecture and prove: An approach from mathematics education

Aurora Fernández-León, Rocío Toscano-Barragán and José María Gavilán-Izquierdo

University of Seville, Department of Didactics of Mathematics, Seville, Spain

[auroraf1@us.es](mailto:auroraf1@us.es), [rtoscano@us.es](mailto:rtoscano@us.es), [gavilan@us.es](mailto:gavilan@us.es)

*This work makes a contribution to the research line that studies the mathematical practices of research mathematicians, when developing their research, with the aim of improving the teaching and learning of such practices in an educational context. To be precise, we focus on the mathematical practices of conjecturing and proving in order to identify their characteristics as a basis to formulate a model. To address this problem, we consider Rasmussen, Zandieh, King and Teppo's (2005) theoretical constructs (horizontal and vertical mathematizing) and report results from a case study of a research mathematician.*

*Keywords: advancing mathematical activity, conjecturing, proving, research mathematicians.*

## Introduction

Freudenthal (1973), in relation to mathematics and its learning, asserts that

there is no doubt that pupils should learn mathematizing [...] There is no mathematics without mathematizing [...] This is what follows from the interpretation of mathematics as an activity. (p. 134)

On the other hand, Dreyfus (1991) points out the relevance of mathematizing by highlighting the processes through which mathematical knowledge is constructed (discovering, defining, proving, modelling, etc.). These processes are relevant research focuses in mathematics education by the importance of its teaching and learning. In this sense, assuming mathematics as an activity, Rasmussen, Zandieh, King and Teppo (2005) also note the significance of considering mathematical practices developed in a learning setting.

From the mathematics education perspective, mathematicians have been seen as study subjects. In fact, Tall (1991) already points out that “we are cognizant of the fact that it is essential to understand the nature of the thinking of mathematical experts to see the full spectrum of mathematical growth” (p. 3). In this regard, several researchers study mathematical practices of mathematicians with the aim of proposing models that describe such practices. For instance, Ouvrier-Buffet (2015) proposes a model that describes how mathematicians develop the mathematical practice of defining. Weber and collaborators focus on aspects of mathematician's work associated to the process of proving (Mejia-Ramos & Weber, 2014; Weber, Inglis & Mejia-Ramos, 2014; Weber & Mejia-Ramos, 2011). Furthermore, Weber and Mejia-Ramos (2011) devise “a model for how mathematicians read the proofs of others” (p. 341). These inquiries lead us to consider the study of the mathematical activities that take place when research mathematicians generate conjectures and proofs.

In our study, conjecturing and proving refer to those activities carried out to generate conjectures and proofs respectively. For us a conjecture is a statement that can be true or false, appears reasonable, “has not been convincingly justified and yet it is not known to be contradicted by any examples, nor is it known to have any consequences which are false” (Mason, Burton & Stacey, 1982, p. 58). On

the other hand, we consider Weber and Mejia-Ramos's (2011) definition of proof: "the socially sanctioned written product that results from mathematicians' attempt to justify why a conjecture is true" (p. 331).

For two reasons, we consider the practices of conjecturing and proving as two sides of the same coin. Firstly, for reasons related to mathematics, Peirce's contributions (1997) on the three type of reasoning: abduction, induction and deduction, applied to mathematics, justify the joint consideration of both processes (Fernández-León, Toscano & Gavilán-Izquierdo, 2016). Specifically, abduction refers to the provisional adoption of a hypothesis, deduction traces out the probable and necessary consequences of a hypothesis and induction is the verification of a hypothesis by experiments (Peirce, 1997). Secondly, from mathematics education, Alibert and Thomas (1991) point out that "[t]he formulation of conjectures and the development of proofs are two fundamental aspects of a professional mathematician's work" (p. 215).

This work contributes to the research line that studies the mathematical practices of research mathematicians, when developing their research, with the aim of improving the teaching and learning of such practices in an educational context. To be precise, we focus on the mathematical practices of conjecturing and proving in order to identify their characteristics as a basis to formulate a model.

### **Mathematisation: Theoretical perspectives**

In the last decades, the specific meaning of the term "advanced mathematical thinking" has been a subject under discussion. Tall (1992) associates this expression with the formal use of definitions to describe concepts and the logical deductions of theorems based upon them. He points out that such grade of sophistication is the highest level of mathematical thinking, but not the activities to reach it. With this in mind, Rasmussen et al. (2005) propose an alternative characterisation of advanced mathematical thinking, called "advancing mathematical activity", that mainly focuses on general mathematical practices (defining, classifying, conjecturing, etc.) instead of on particular mathematical contents. They emphasise the progression and evolution of students' reasoning in relation to their previous activity when participating in a variety of different socially or culturally situated mathematical practices.

Rasmussen et al. (2005) also suggest that each mathematical practice can be described by using two different dimensions, the so-called horizontal mathematising and vertical mathematising. These two terms are firstly used by Treffers (1987) to describe what he calls "progressive mathematising". Treffers refers to horizontal mathematising as the activities of "transforming a problem field into a mathematical problem" (p. 247) and to vertical mathematising as those proper activities of the process of reorganisation within the mathematical system itself. Notice that the idea of mathematisation is originally formulated by Freudenthal (1973), who understands mathematics as a human activity. This author indicates that "there is not mathematics without mathematizing" (op. cit., p. 134). He defines mathematisation as the activity of organising matter from reality and within the mathematics discipline. Freudenthal (1991) assumes Treffers' dimensions, although expressing their meanings in the following way:

horizontal mathematisation leads from the world of life to the world of symbols. In the world of life one lives, acts (and suffers); in the other one symbols are shaped, reshaped, and manipulated, mechanically, comprehendingly, reflectingly; this is vertical mathematisation. (Freudenthal, 1991, pp. 41–42)

For him, these two forms of mathematisation are not separated worlds, have the same status in practice and can take place at all levels of mathematical activity.

In our research, we assume Rasmussen et al.'s (2005) approach about horizontal and vertical mathematising. These authors also slightly adapt and modify Treffer's constructs. For them, horizontal mathematising refers to those activities used to formulate a problem situation in such a way that it can be mathematically addressed subsequently. Thus, horizontal mathematising also includes problem situations that are properly mathematical and is mainly related to initial or informal ways of reasoning. On the other hand, vertical mathematising refers to those activities built on horizontal activities with the aim of creating new mathematical ideas or realities. They use these constructs to characterise the practices of symbolising, algorithmatising and defining. An important coincidence they find among these three mathematical practices is the relation between "creating" and "using". They argue that both actions occur when these practices are carried out, although with a different role in each dimension. In particular, in horizontal mathematisation, people create (definitions, algorithms, etc.) "to express, support, and communicate ideas that were more or less already familiar" (Rasmussen et al., 2005, p. 70) and products of this dimension are used within their mathematical problematic situation. On the other hand, in vertical mathematisation, new mathematical realities are created and using promotes "movement from the particular to the more general and in some cases the more formal" (op. cit., pp. 70–71). The authors state that vertical activities often give rise to other horizontal activities. Vertical mathematisation may be the setting for a new horizontal mathematisation, which subsequently can lead to vertical mathematisation, and so on, creating a chain of progressive mathematisations.

Our study aims to identify characteristics of the practices of conjecturing and proving of research mathematicians to describe and explain how they develop them. For this purpose, horizontal and vertical dimensions proposed by Rasmussen et al. (2005) are considered. Thus, the research question behind this study is: Can horizontal and vertical mathematising constructs describe and explain the mathematical practices of conjecturing and proving of research mathematicians?

## **Methodology**

In this research, we assume a qualitative methodology. In particular, we have adopted a case study methodological approach. With the aim of answering the research question above, we consider an inductive analysis, that is, the different categories emerge from the data. In this work, we discuss one case of a research mathematician.

## **Participant and context**

The participant (Anna, pseudonym) is a research mathematician, understanding as such those who have a Ph.D. in mathematics and have published research papers also in mathematics. Specifically, Anna is a teacher that researches in mathematical analysis (functional analysis) and has more than five years of experience in university teaching. The case study of Anna presented here is part of a larger research study which aims, among others, to refine and thus improve the analysis shown below. The results reported in this paper are based only on this participant's case.

## The research instruments

The data for our study are obtained from different sources: interviews, working documents and research reports. Four semi-structured interviews are conducted. The first of them aims to obtain basic information from the researcher; the following interviews revolve around the mathematical research carried out by Anna. Specifically, we discuss her research results collected in different research reports (papers, posters and beamer presentations in conferences). We also talk about the personal working documents used in the development of her research. Some of these documents are related to situations that led to successful outcomes and some others to situations which were less successful.

## Data analysis

The analysis process (interpretative analysis) considers the dimensions horizontal and vertical mathematising from Rasmussen et al.'s (2005) approach to organise the mathematical activities that take place when conjecturing and proving. Specifically, this process identifies relevant events in the data and assigns meanings according to the theoretical framework: first, they are classified as actions linked to the mathematical practices of conjecturing or proving. These actions are subsequently linked to the horizontal or vertical dimension of the corresponding practice, according to the characteristics of these two dimensions. For instance, when proving, the activity of *Detecting patterns in examples* (see description below) is considered horizontal since when detecting patterns in examples one systematically expresses or formulates (based on experimentation) how certain property (the problem situation) holds in such a way its generalisation can be addressed in the vertical category *Formalising findings with examples*. Once that double assignment is finished (conjecturing-proving and horizontal-vertical), taking the nature of the events in consideration, the categories emerge in such a way that each event is seen as an “example” of a category.

## Results

In this section, categories of activities that emerged from the analysis of the data are presented. Consequently, the offered classification is not based either on the content of the research (geometry, analysis, etc.) or the mathematical method considered in each practice (proof by contradiction, etc.). Although space prevents the exemplification of each given category, we provide several excerpts from Anna's answers and documents to illustrate some of them. Specifically, we denote each example by “Example x.y”, where “x”, that may be 1 or 2, refers to the mathematical research situations in which the example arises and “y”, that varies between 1 and 6, indicates the precise moment (in the temporary sequence) of the mathematical research situation in which the excerpt appears.

Although conjecturing and proving are closely related practices (Fernández-León et al., 2016), we describe them separately for expository reasons. Notice that the informal character of horizontal mathematising and the almost simultaneity of these two mathematical practices make complicated to differentiate if the features of the researcher's informal activities are linked to the construction of a proof or, on the contrary, of a conjecture.

## How mathematicians conjecture

Three categories of horizontal nature (C.H.a, C.H.b, C.H.c) and two of vertical one (C.V.a, C.V.b) have been characterised during the analysis of Anna's case. These categories do not describe a linear

process, but they are interconnected many times. We begin by describing the activities that characterise the horizontal component of the practice of conjecturing.

**C.H.a) *Detecting patterns.*** Experimentation with mathematical objects (a triangle, a number, a Hilbert space...) and in relation to a certain characteristic or observable property. To be more precise, logical reasoning and informal activities with mathematical objects involved in detecting a certain pattern in a concrete mathematical context.

**Example 1.1- Anna:** When dealing with the research question about whether all complete CAT(0) spaces satisfy the (Q4) condition, we started to check what happened to spaces with constant curvature, since the other two extreme cases had already been checked by the authors of the paper (Hilbert spaces and R-trees). Firstly, we checked that the hyperbolic space, with curvature -1, satisfied property (Q4). That conclusion led us to a conjecture.

**Example 2.1- Anna:** We considered the analytic expression of the modulus of convexity of the sphere, a geodesic space that is not linear:  $\delta(r, \varepsilon) = 1 - \frac{1}{r} \arccos\left(\frac{\cos r}{\cos \frac{\varepsilon}{2}}\right)$ ; and tried to prove its monotonicity with respect to “r” through the first derivative. We did many calculations but no conclusion could be established. Many experiments with the software Mathematica were also done to see if the modulus of convexity of the sphere was monotone with respect to the variable r. However, we couldn’t derive any conclusion from hand calculations, which was the necessary for any future publication.

**C.H.b) *Testing conjectures.*** Verification or rejection of a certain conjecture by specific examples.

**Example 1.3- Anna:** We started to checked property (Q4) in more CAT(0) spaces, specifically, on gluing CAT(0) spaces. These experiments allowed us to reject the conjecture “every CAT(0) space has property (Q4)”.

**C.H.c) *Modifying statements.*** Experimentation with the components of an already existent conditional proposition (proved or not, that is, a proved proposition or a conjecture) consisting in modifying its hypothesis or conclusion.

The activities that characterise the vertical component of the practice of conjecturing are given next.

**C.V.a) *Formalising patterns.*** Generalisation and formalisation of a certain pattern observed in horizontal mathematising activities. Specifically, a pattern observed in the horizontal dimension is used to formulate what is known as a conjecture.

**Example 1.2- Anna:** We conjectured that “every CAT(0) space has property (Q4)”.

**Example 2.2- Anna:** After seeing many different plots with Mathematica of the cited function, we conjectured that “The modulus of convexity of the sphere is nonincreasing with respect to r”.

C.V.b) *Formalising modifications of statements*. Formalisation of the modifications of the hypothesis or conclusion of an already existent conditional proposition (proved or not) which gives rise to a conjecture.

Example 1.4- Anna: We changed the conjecture on the (Q4) property by formulating a new one that was more probable in the light of the example checked before (gluing CAT(0) space): “any CAT(0) space with constant curvature satisfies the (Q4) condition”.

### How mathematicians prove

Two categories of horizontal nature (P.H.a, P.H.b) and four of vertical one (P.V.a, P.V.b, P.V.c, P.V.d) have emerged from the data. We start by describing the activities that characterise the horizontal component of the practice of proving.

P.H.a) *Detecting techniques or tools within proofs*. Careful study and examination of the characteristics and steps of other proofs related to the proof to be built. When dealing with the construction of a new proof, it is common to seek proof techniques, in other proofs, that may fit in well with the new proof. Notice that this description is consistent with the claim by Rasmussen et al. (2005) that many specific activities of this dimension are of organisational and clarifying type.

P.H.b) *Detecting patterns in examples*. Experimentation with specific examples that satisfy the hypotheses of a given conjecture with the aim of detecting patterns that could be extended to more general settings for the proof in process.

Example 1.5- Anna: After formulating the new conjecture, we considered another space of constant curvature, the sphere, to see which pattern was followed when checking the (Q4) condition in such space. We observed that it was very similar in both spaces.

In the sequel, the activities that characterise the vertical component of the practice of proving are given.

P.V.a) *Selecting and applying demonstration methods*. Selection and application of demonstration methods (direct, by contraposition, by contradiction, etc.).

P.V.b) *Using proof techniques*. Use of proof techniques or tools found in the horizontal dimension.

P.V.c) *Applying known results*. Application of known results to build chains of logical implications.

P.V.d) *Formalising findings with examples*. Extension and formalisation of the findings and calculations with examples in the horizontal dimension.

Example 1.6- Anna: After revising those examples, we extended the calculations in the examples to general cases and proved the conjecture. In fact, what was done was the following: we wrote the proof in the hyperbolic space and wrote what to do in the general case. This type of reasoning is very common in our papers if the extension is very easy and useless.

Results of this study may show the still strong influence of formalism on mathematical research.

## Conclusions

In this research, different categories are identified (and organised through the constructs horizontal and vertical mathematising) to describe and explain the mathematical practices of conjecturing and proving. These categories are consistent with previous results of other studies, for instance, inductive reasoning described by Peirce (1997) is closely related to our category *Testing conjectures*. The “Examples x.y” shown in the previous section corroborate, for both practices, the interrelationship between horizontal and vertical mathematising activities. Notice that the identification of these different categories may contribute to elaborate a model that characterises both mathematical practices.

The categories identified may give information about instruction processes to improve students’ understanding of the practices of conjecturing and proving and of their products (conjectures and proofs). Such understanding highlights and emphasises the duality conjecturing/conjecture and proving/proof, so that it is consistent with what mathematics (as a product of mathematicians) reveals. On the other hand, Harel and Sowder (1998) identify three different students’ proof schemes: external conviction proof schemes, empirical proof schemes and analytical proof schemes. A tentative idea to develop in future works is to check whether the role we have identified induction to play in the horizontal dimension of the practice of proving, *Detecting patterns in examples*, may help us to facilitate the transition of students from empirical schemes to analytical schemes.

We characterise the results of this inquiry as exploratory. That is, the classification described above must be refined and validated, in future research, in other different contexts (with other mathematical contents, other mathematical cognitive levels, etc.).

# Students' interpretation of the derivative in an economic context

Frank Feudel

University of Paderborn, Institute of Mathematics, Germany; [feudel@math.upb.de](mailto:feudel@math.upb.de)

*The concept of derivative plays a major role in economics. One important competence for students of economics is to interpret values of the derivative in an economic context. In the study presented in this paper it was investigated how students of economics interpreted values of the derivative in an economic context before and after their Calculus course at university. Before the course only very few students were able to interpret these values adequately. After the course about half of the students were able to state an adequate economic interpretation of values of the derivative, mostly as amount of change of the function while increasing the output by one (marginal) unit, which is a common interpretation in economics. However, the data indicates that many of these students just identified the derivative with that amount of change without understanding the differences and the connection between these two different mathematical objects.*

*Keywords: Derivative, economics, concept image, economic interpretation, marginal cost.*

## Introduction and embedding of the research

In order to maximize their profit firms have to make many profound decisions, for example about possible investments. An important tool that aids economists to make optimal decisions is marginal analysis. Baumol and Blinder (2015) listed marginal analysis even as one of the most important ideas of economy. In marginal analysis the consequences of making relative small changes from the current situation are examined (Ruffin & Gregory, 1990). Typical problems are the effects on cost or revenue if the output is increased by a small amount (normally one unit), or the effects on the demand of a product if the price is increased by a small amount. Marginal analysis is closely connected with the mathematical concept of derivative, which serves as a tool to measure the effects of these small changes on cost or revenue. Therefore, students of economics should have a proper understanding of the mathematical concept of derivative and its use in marginal analysis, which is currently investigated in my PhD-Thesis (supervised by Prof. Dr. Rolf Biehler).

Unlike for students of engineering or physical science, whose understanding of the derivative has been examined more extensively (Bezuidenhout, 1998; Bingolbali & Monaghan, 2008; Çetin, 2009; Maull & Berry, 2000), only little research about the understanding students of economics have of this concept exists. Only two studies are known to the author dealing with the understanding of rate of change by students of economics (Mkhatswa & Doerr, 2015; Wilhelm & Confrey, 2003), and none of these involves the concept of derivative explicitly. To use the derivative in marginal analysis the students have to interpret calculated values of the derivative in an economic context. Interpreting values of the derivative in contexts is not easy for students, as shown by Bezuidenhout (1998) for students of engineering. He showed, for example, that many of these students could not interpret values of the derivative of a stopping distance function  $S(v)$  ( $v$  is the velocity of a vehicle) adequately. They overgeneralized that the derivative is the acceleration or the velocity, or they had problems with the unit, which shows that they did not have a profound understanding of the derivative itself as rate of change. The economic interpretation of the derivative has the additional difficulty that it does not directly correspond to any of the usual mathematical representations of the

derivative, which is explained in detail in the next section. Therefore, it can be expected that students of economics have even more difficulties in understanding this interpretation. To address this conjecture, the study presented in this paper is guided by the following research question: “How do students of economics interpret the derivative in an economic context before and after their Calculus course?” The results will extend the knowledge about students’ difficulties in the understanding of the derivative with a focus on students of economics, who have been rarely considered until now.

## Theoretical background of the study

### The economic interpretation of the derivative

In physical contexts, the derivative is often interpreted as rate of change (for example as speed), which directly corresponds to other representations of the derivative like the slope or the limit of the difference quotient. The common economic interpretation, however, represents a different mathematical object, which is now explained for cost functions. If  $C : [0; \infty[ \rightarrow [0; \infty[$  is a cost function and  $C(x)$  represents the cost of a given output  $x$ ,  $C'(x)$  (called marginal cost) is often interpreted as the additional cost while increasing the output by one unit (Schierenbeck & Wöhle, 2003). This additional cost, exactly calculated by  $C(x+1) - C(x)$ , differs from the derivative  $C'(x)$  in its numerical value and in the unit. Hence, this interpretation has to be connected to the students’ other knowledge of the derivative and needs to be justified. A typical justification is via the approximation formula  $C(x+h) - C(x) \approx C'(x) \cdot h$  for  $h$  close to 0 with the additional argument that  $h=1$  is really small in economic contexts. A more detailed description of the connection between the derivative and its economic interpretation as additional cost can be found in Feudel (2016).

Some books of economics add the word “marginal” to the unit when describing marginal cost. The marginal cost is then the cost that arises if the output is increased by a marginal unit and is written as  $C' = \frac{dC}{dx}$  (e.g. in Reiß (2007)). In economic literature the term “marginal unit” is often used as a

synonym for a very small, but finite, unit. In Dyckhoff (2002), for example, the term is used to emphasize that one unit is small enough and that the derivative  $C'(x)$  can be used as approximation for the difference quotient  $\frac{\Delta C}{\Delta x}$  for  $\Delta x = 1$ . Reiß (2007) emphasizes furthermore that it depends on

the context whether a unit can be considered as marginal or not (example of the book: if water utility is measured in cubic meters a marginal unit might be a cubic millimeter).

### Theoretical tools for the study

An adequate economic interpretation should be part of the students’ conceptual knowledge of the derivative, which can be described with the term *concept image* by Tall & Vinner (1981). The *concept image* describes the total cognitive structure that is associated with the concept. This includes all mental pictures, associated properties and processes. Concerning the derivative the students’ *concept image* should contain the different representations of it, the differentiation rules, connections to other mathematical concepts like monotonicity, and in the case of students of economics also an adequate economic interpretation of the concept. To understand this interpretation properly students should connect it to other knowledge of the derivative they already have from school. The process of making these connections, called synthesizing by Dreyfus (2002),

is a special challenge in the case of the common economic interpretation of the derivative as additional cost because this interpretation does not directly correspond to any of the other representations of the derivative, and, as described above, justifying it needs some argumentation.

### Knowledge about the derivative covered in the students' Calculus course

In the course the study took place in (University of Paderborn, Germany), the derivative concept itself was covered in two lectures. In the first lecture the definition of the derivative as limit of the difference quotient, which was also visualized by secant lines “converging” to the tangent line, and the differentiation rules were presented. Afterwards the unit of the derivative in comparison with the unit of the original function was discussed in the case of a cost function  $C$ . In the second lecture the economic interpretation was presented and justified. Two possibilities were given in the course:

#### 1. Approximation of the additional cost of the next unit

This interpretation was justified in the course via the above mentioned approximation formula  $\Delta C \approx C'(x) \cdot \Delta x$  that was derived by deencapsulating the limit in the definition of the derivative and using the limit as an approximation of the difference quotient.

#### 2. Additional cost of the next marginal unit

It was illustrated in the lecture with the help of the tangent line in the case of a convex function that the error between  $\Delta C$  and  $C'(x) \cdot \Delta x$  in the approximation  $\Delta C \approx C'(x) \cdot \Delta x$  becomes smaller, the smaller  $\Delta x$  is. It was explained that the limiting process  $\Delta x \rightarrow 0$  results in a fictional equation  $dC = C'(x)dx$ , in which  $dx$  was called a marginal unit.

Some lectures later, after the introduction of the concepts of monotonicity and convexity, the connection between the derivative and these two concepts was discussed. In a last step the derivative was used as a tool to solve optimization problems.

Besides the lectures the students had to solve problems referring to the content of the lectures. The problems were solved by the students in small groups. One week later the solutions were presented on the board in the lecture hall. Relevant for this study is that the problems also included a task to interpret the value  $C'(5)$  of the cost function  $C(x) = 8x^2 + 10x + 700$  in an economic context.

## Methodology of the study

### Data Collection

Students of economics at the University of Paderborn were administered a pre-test addressing their previous knowledge of the derivative concept in September 2015 in a voluntary bridging course before their math courses. The pretest contained the following task, to check if an adequate economic interpretation was part of the students' *concept image*:

A company produces pens. The cost (in euro) for the production of a number of  $x$  pens can be described with a cost function with the following equation:

$C(x) = \frac{1}{30000}x^3 - \frac{1}{100}x^2 + 2x, x \geq 0$ . It can be determined that  $C'(200) = 2$ . Interpret this result in the above context.

After their Calculus course in February 2016 the students had to take an exam to finish the course successfully. In the exam the students also had to answer a similar task:

Let  $P: [0; \infty[ \rightarrow \mathbb{R}$  be a profit function of a company, which manufactures a product in an unlimited and indivisible amount. The profit is measured in units of money, the output measured in units of quantity. It is known that the derivative function  $P'$  is called marginal profit. You get to know that  $P'(73) = 0.2 \frac{\text{GE}}{\text{ME}}$  (GE = units of money, ME = units of quantity).

State an economic interpretation of this value.

As described in the previous section, the students were familiar with that type of task.

### Data analysis

The answers to the two tasks were categorized by the author with quantitative content analysis. Besides two categories given by the interpretations “additional cost of the next unit” and “additional cost of the next marginal unit”, which were derived from literature in economics (see “Theoretical background”), the categories were created inductively because it was not clear what answers the students might state. This led to a system of 10 categories for the task in the pretest (other answers, which were all wrong, were given by less than 3% of the students). The answers in the first three categories were adequate economic interpretations (detailed descriptions in Figure 1).

Category	Description	Prototypical Statement
1. Additional cost of the next unit	The students state that $C'(200) = 2$ means that the additional cost of the next unit (if 200 units are produced) is 2 euro (or round about 2 euro).	“It means that if the production is increased from 200 units by one unit, the cost increases by 2 euro.”
2. Additional cost of the next marginal unit	The students state that $C'(200) = 2$ means the additional cost of the next marginal unit is 2 euro or round about 2 euro. It was ignored if the units of money are also called “marginal”.	Not mentioned in the pretest. An example from the exam (interpretation of $P'(73) = 0.2$ for a profit function $P$ ) is: “At a production of 73 units of quantity the production of one more marginal unit would increase the profit by 0.2 units of money.”
3. Growth rate of cost	The students state that $C'(200) = 2$ means that the cost increases by 2 euro per pen (at a production of 200 pens).	“At a production of 200 pens the cost increases by 2 euro per pen.”

**Figure 1: Adequate response categories for the task to interpret  $C'(200) = 2$  for a cost function  $C$  in an economic context**

The answers in the categories 4-10 were not adequate economic interpretations (detailed description in Figure 2): the answers in categories 4-5 contained at least a correct idea, the answers in categories 6-8 were wrong economic interpretations, and the answers in categories 9-10 were no economic interpretations and therefore were wrong answers to the task as well.

Category	Description	Prototypical Statement
4. Gradient of cost at the point	The students state that $C'(200) = 2$ means that the cost increases by 2 euro at a production of 200 pens.	"At a production of 200 pens the cost increases by 2 euro."
5. Cost per unit	The students state that $C'(200) = 2$ means that the cost per pen is 2 euro.	"The cost per pen at a production of 200 pens is 2 euro."
6. Total cost	The students state that $C'(200) = 2$ means that the cost for 200 pens is 2 euro.	"At a production of 200 pens the cost is 2 euro."
7. Cost doubles or halves at the point	The students state that $C'(200) = 2$ means that the cost doubles or halves at a production of 200 pens.	"At this point the cost doubles for each pen further produced."
8. Other wrong interpretation	Another wrong interpretation is stated or the answer does not make sense.	"The 201st pen costs exactly the same like the 200th pen."
9. Slope at the point	The students state that $C'(200) = 2$ means that the slope of the cost function is 2 at $x = 200$ . There is no connection to economics.	"Slope at the point 200 is 2."
10. No valid answer	The students state a (maybe) right answer, which does not have to do anything with the task, or state no answer or answer fragments.	1. "No idea." 2. "If $C'(x)$ positive, then the profit"

**Figure 2: Not adequate response categories for the task to interpret  $C'(200) = 2$  for a cost function  $C$  in an economic context**

After the development of the category system the data was re-coded by a student to check inter-rater reliability. The reliability coefficient Cohen's Kappa was  $\kappa = 0.82$ , which is good.

The 10 categories mentioned above were also used to categorize the answers to the task in the exam to interpret  $P'(73) = 0.2$  for a profit function  $P$ . However, three additional categories that contained more than 3% of the answers had to be added (Figure 3). In addition, the category "cost doubles or halves" was adapted to "Increase of profit by 20%".

Category	Description	Prototypical Statement
11. Marginal profit at the point	The students state that $P'(73) = 0.2$ means that the marginal profit at a production of 73 is 0.2 units of money per unit of quantity.	"At the point $x = 73$ the marginal profit is 0.2 units of money per unit of quantity."
12. Growth of marginal profit	The students state that $P'(73) = 0.2$ means that the marginal profit increases by 0.2 either at a production of 73 units or if the production is increased by one (marginal) unit.	"If one changes the production from 73 units by a marginal unit, the marginal profit increases by 0.2 marginal units."
13. Extreme point at the point	The students state that $P'(73) = 0.2$ means that the profit has an extreme value at 73 units of quantity or that 73 units is the optimal output.	1. "The company has a maximal profit at the output of $x_{opt} = 73$ ." 2. " $x_{opt}$ is located at 73."

**Figure 3: Additional response categories for the task to interpret  $P'(73) = 0.2$  for a profit function  $P$  in an economic context**

## Results

The students' answers to the task to interpret  $C'(200) = 2$  for a cost function  $C$  in an economic context before their Calculus course are shown in Figure 4.

**Figure 4: Students' answers to the task to interpret  $C'(200) = 2$  for a cost function  $C$  in an economic context before their Calculus course (N = 143)**

As can be seen in Figure 4, the economic interpretation of the derivative of a cost function  $C$  as the additional cost of the next unit was not known by the students from school, and is not as intuitive that the students stated it spontaneously. Instead, some students tried to use their knowledge about the derivative being the slope at a point (category: Gradient of cost at the point) or the rate of change (categories: Growth rate at of cost or Cost per unit). Others had misconceptions.

The students' answers to the task to interpret  $P'(73) = 0.2$  for a profit function  $P$  in an economic context in the exam after their Calculus course are shown in Figure 5.

**Figure 5: Students' answers to the task to interpret  $P'(73) = 0.2$  for a profit function  $P$  in an economic context in the exam at the end of their Calculus Course (N = 821)**

As can be seen in Figure 5, more than half of the students knew the common economic interpretation of the derivative of a profit function as additional profit of the next (marginal) unit after the course (but still various misconceptions occurred). Thus, an adequate economic interpretation of the derivative was part of their *concept image* for about half of the students. However, the data indicates that many of these students did not really integrate their economic interpretation of the derivative with the rest of their concept image, i.e. they did not fully understand the differences between the derivative  $P'(x)$  and its economic interpretation as profit of the next unit (differences in the numerical values and in the units). Of the 422 students who interpreted the derivative as additional profit, 100 students (23.7%) mentioned "unit of money per unit of quantity" as corresponding unit, which is the right unit of the derivative but not of its interpretation as additional profit. Furthermore, of the 103 students who interpreted the derivative as the additional

profit of the next unit, only 20 students (19.4%) mentioned in their interpretation that the value of the derivative  $P'(x)$  is just an approximation of the additional profit  $P(x+1) - P(x)$ , although the lecturer had emphasized that this has to be stated explicitly in the interpretation (and had shown graphically the error on the board). This indicates that many students probably did not understand the differences between the derivative  $P'(x)$  and its economic interpretation. They just identified both objects, which leads to an incoherent *concept image* of the derivative (Tall & Vinner, 1981).

### Limitations of the study

Due to organizational problems it was not possible to match the students in the pretest and the exam. So it is not possible to investigate the progress of individual students with the data. It is just possible to compare the amount of students giving certain answers before and after the course.

### Discussion and conclusions for further research

The study shows that an adequate economic interpretation was not part of the students' *concept image* of the derivative (with few exceptions) when entering university. Hence, this interpretation should be introduced in the course with caution and connected to the rest of their *concept image* of the derivative concept. After the course an adequate economic interpretation of the derivative as the additional cost/profit of the next (marginal) unit was part of their *concept image* for about half of the students. However, the data indicates that many of these students did not understand the differences between the derivative as a mathematical concept and its economic interpretation. For example, one quarter of the students who interpreted the derivative as additional profit gave the wrong unit (a unit of rate). They did not distinguish between the derivative being a rate of change and its economic interpretation being an amount of change, which is also documented in literature (Mkhatshwa & Doerr, 2015). Furthermore, the data indicates that many students were not aware that the value of the derivative is just an approximation for the additional cost/profit of the next unit. Students having these problems probably did not connect the economic interpretation of the derivative to their *concept image* of the derivative as a pure mathematical concept properly.

To find out to what extent the students really integrated the economic interpretation of the derivative as additional cost/profit into their *concept image* as intended in their Calculus course (i.e. that they know the differences and the connection between these two different mathematical objects, and can justify the identification of them), further research is necessary. Therefore, in spring 2015, an interview study addressing this identification directly was conducted to find out to what extent the students really integrated the economic interpretation of the derivative into their *concept image* of the derivative concept (and not just memorized it) and what cognitive obstacles occur during the justification of the economic interpretation of the derivative in the way it was done in the course.

The above mentioned research, however, only takes a cognitive perspective into account. There are more factors influencing the way students interpret the derivative in an economic context like institutional practices of the two institutes involved in their education (institutes of mathematics and economics). Taking these institutional influences into account, which has great potential for further research, would, however, require other theoretical perspectives like ATD (Bosch & Gascón, 2014).

*Flipped Classroom approaches to teaching are becoming increasingly popular in higher education, but there is a lack of empirical research. We present here a study performed during an engineering course for 20 students at a Norwegian university, on student appropriation towards Flipped Classroom through interviews, questionnaire, video/quiz usage statistics and classroom filming. We approach this research through an activity theoretical framework, focusing on tensions experienced as the students try to tackle the demand of video preparation and active learning in class. In line with much of the recent research on the topic, we find that most students seem to appreciate more collaboration with peers and teacher. However, there is also evidence that the new form of teaching creates various tensions; a minor part of the cohort demonstrates conflicting beliefs about mathematics learning, resisting the active learning part of Flipped Classroom.*

*Keywords: Activity theory, flipped classroom, tensions.*

## Introduction

Flipped Classroom (FC) is most commonly known as a method that arranges the lecturing part of the teaching as homework through videos. This is considered the out-of-class part of the FC. When students come to class, the stage is set for learning in a student-centered manner, using various problem-solving activities (Bergmann & Sams, 2012). This is considered as the in-class part of FC. Both are vitally important for the FC learning model to work. The out-of-class video learning “primes” the students for the crucial in-class active phase (Seyfedine, Kadry & Hami, 2014), where hopefully the active “learning-by-doing” understanding and adaptation takes place. The idea is that through well-designed activity sets in class, the teacher has the opportunity to challenge the students at both a collaborative and conceptual level in this phase (Wan, 2015).

In this paper, we describe a study that was conducted in the spring term of 2016 at a Norwegian university, where students in their first year of engineering studies were exposed to several interventions of the FC way of teaching. The teaching setup in this university is well suited for flipped teaching. It is a small campus, with only 20-30 students per-year in a 3-year long bachelor study in computer engineering, allowing for a tight integration between the students and the teacher.

Many studies on the implementation of FC seem to indicate that motivation might increase among students in mathematics (Franqueira & Tunnicliffe, 2015; Kadry & El Hami, 2014; Roshan, 2015). However, there are also research studies that indicate the opposite. Wasserman, Quint, Norris, and Carr (2015) found that students in a flipped calculus III class were critical to the use of class time for group work. Strayer (2015) reports that students felt “lost” and disengaged with the material sooner than students in the traditional classroom did. Ramaglia (2015) did a comparative study between

flipped and non-flipped high school and middle school mathematics classes in her PhD thesis, but failed to find consistently increased peer-to-peer activity among students. Referring to these mixed results from other studies, it seems interesting to gain more insight into what kind of tensions, strains and possible resolutions of these can be observed in a FC realization. Based on this background, our research questions are formulated as follows:

**Research Question:** What are the tensions that emerge from students' attempts to appropriate change towards FC facilitated by videos and quizzes?

## Theory

We believe that learning can best be understood when considered as a common enterprise among students and teacher, emerging as culturally negotiated in an environment based on constructive criticism. Turning to Cultural Historical Activity Theory (CHAT) (Engström, 1994), we have a rich theoretical basis to put FC in a broader perspective.

**Figure 1: The CHAT triangle adopted to the Flipped Classroom from a student's perspective**

The primary part of the activity system in this study is the student as a subject in her object-oriented activity to learn engineering mathematics. In attempting this, she uses various instruments. The most important ones are Campus Inkrement (a virtual learning environment used for distributing videos and quizzes), classroom discourse and curriculum literature. The dominant new rule governing FC compared to “traditional teaching”, is the video preparation part, forming the out-of-class component of FC. The mathematics in the video should form a common ground of knowledge for the community consisting of students and teacher. For the division of labor, we consider how students attain various roles in their collaboration to solve tasks in-class.

In any activity system there exist tensions and contradictions. Engström (1994) summarizes activity theory in five principles, and among these, he mentions contradictions as one of the leading sources for change and development. Basically, contradictions can be defined as a misfit within elements of an activity system, between them, and between different activity systems. Engström (1987) argues that four levels of contradictions are present in an activity system, and identified tensions in interactions within and between activity systems. The contradictions can be identified at four levels: primary, secondary, tertiary, and quaternary. If we apply this model in the context of FC, we can describe the contradictions as follows:

1. The primary contradictions occur within the elements or components of FC as an activity system, e.g. within the community of students and teacher.

2. Secondary contradictions arise between the elements of FC, or when two or more elements of FC conflict with one another, e.g. between the community and subject (for example between the class and the individual student), between the object and the community, or between the rules and the community, etc.
3. Tertiary contradictions arise when a new and advanced method or artefact is used to achieve an objective, e.g. when videos are introduced as a new artefact to teach mathematics.
4. Quaternary contradictions occur between FC (as activity system) and another activity system.

## Methodology

We performed two separate periods of FC teaching during the second semester of study year 2015/2016. We performed data collection by issuing an anonymous questionnaire, doing three semi-structured interviews and two rounds of classroom filming. In addition, students' usage statistics of video and quizzes were collected through the Campus Inkrement software. As our theoretical stance is in the socio-cultural field, an interpretative research paradigm was chosen. The questionnaire and the interviews were performed after the students' first encounter of FC teaching, informing us on student impressions on pedagogical and technical impressions with the learning platform chosen for distributing video/quizzes, the in-class group work activities and the quality of interaction with the teacher and the other students. Episodes relevant for the enlightenment of the research questions of the paper, tensions and student appropriation towards FC, are highlighted in the results section.

### Campus Inkrement (CI) as a mediating artefact

Preceding each in-class session, a corresponding out-of-class session of videos and quizzes was presented to the students in CI, which is a web-application fulfilling the role of the out-of-class component of FC. Built from the ground up to be consistent with the FC teaching design, the teacher/researcher also has the capability to highlight video watching statistics and quiz results for the individual student. From a student perspective, CI brings the opportunity to give feedback on how well the student understood the current topic on a scale 1-5. In addition, self-perceived effort can be reported on a similar scale. The student also has the opportunity to ask for further guidance from the teacher on specific topics. This opens up for an out-of-class possibility for students to prompt the teacher for assistance without revealing their uncertainty to peers in-class.

### FC implementation

In this class, there were 20 students following the course. Before attending the spring term, these students had all background from a 10 ECTS (European Credits) calculus based Math-1 course with traditional lecture-based teaching. The course in the spring term that was subject for FC teaching was labelled Math-2, consisting of 10 ECTS containing series, Fourier and Laplace transform, recursion equations, proofs and optimization on functions with two variables.

After having informed the students thoroughly about the new form of teaching in the beginning of the term, we started out the term with one month of FC teaching in January. The topic for this first round of FC teaching was sequences and series, studying criteria for convergence, and in the end Taylor expansions and Maclaurin series. Although we did not influence the curricula, obligatory assignments and exam, we could plan and implement FC as we saw fit, including the teaching performed in-class. The teaching consisted of two or three 90-minutes sessions each week. To prepare

each in-class session, 3-4 videos each of 8 to 15 minutes in length were available for the students. In between the videos, quizzes directly related to video contents were given. The videos presented the mathematics in a chalk-and-talk fashion, screen-capturing teachers writing using a tablet, including some demonstrations made in geogebra. We produced 12 of the 36 videos, the rest were collected from online resources mainly from Khan Academy (<https://www.khanacademy.org>). The videos were procedural in content, in the sense that there was little time to go into proofs or elaborate on deeper concepts. This choice was intended to make the video homework manageable in length for the limited out-of-class time. In line with FC ideas, in-depth understanding should be elaborated in an in-class setting.

After this first attempt at FC teaching, we spent the middle of the course teaching traditionally with other teachers involved. The reason for this shift was the necessity for collecting feedback through interviews with a representative selection of students, in addition to an anonymous questionnaire. This to inform us on potentially needed adjustments in the second phase of FC. At the end of the term, we ran two more FC teaching weeks on the introduction of functions with several variables, linearization of these, partial derivatives and optimization. On most occasions, specially adopted task sheets were prepared for in-class active learning to provoke discussion and in-depth conceptual reflection about the mathematics, the purpose being to raise the abstraction level.

## Results

These three sources of data, the questionnaire, the interviews and the filming, provide the possibility for us to triangulate findings. As this is a paper investigating tensions in the CHAT sense, we have been actively looking for excerpts where such qualities are prominent.

### Questionnaire

At the beginning of March, we invited all students participating in the class to answer an anonymous questionnaire. Here we asked the participants to agree or not on fifteen statements, in a 5-point Likert scale fashion, about various features of our FC implementation. The purpose of this was primarily to inform us towards the next iteration of FC. Additionally, the questionnaire contained three open-ended questions, prompting the students to express their opinions about the method with their own words.  $n=15$  out of  $N=20$  students responded.

We have chosen to highlight three responses to the open-ended question: “What did you feel was most inconvenient with this method of teaching and learning mathematics?” While other questions highlighted the positive sides of FC, the three statements below are representative for most of the answers to this question, and are important for the analysis of tensions:

“Personally, it works better for me when I spend time on my own with the tasks. Thus, the session in the classroom became wasted for me. I believe I should learn new things in the class, and then work on my own with the topic afterwards, and then turn to the videos for assistance.”

“I got “pushed away” from the classroom using this method, since I do not like to work on tasks in groups. I feel that group work is difficult since many do not understand the topic 100%, which means that many just do not participate in the discussions.”

“Group work was unsuitable, since mathematics is a more “individualistic” subject.”

## Interviews

In addition to the questionnaire, we performed interviews with a representative set of students in a semi-structured fashion. Due to time constraints, we had to limit the sample to three persons. This group of students was chosen as a representative sample according to gender and age, but also due to observed willingness to make critical remarks about the teaching. The interview tried to dig a bit deeper into topics of engagements, impressions about videos, group work and interaction with the other students and the teacher and lasted for about 30-40 minutes. With respect to our consideration of tensions, we present interview excerpts from students with positive and negative views on FC.

The first interviewee was an engaged student in mathematics, with almost 100% attendance in class. He favored learning by videos over traditional learning, and liked the fact that the teacher was more available for questions than traditional lecture-based teaching. As the problematic part of all the group work, he pointed at troubles with fluency in using new mathematical vocabulary. However, he noted that by trying to communicate verbally the task with the others in the group, it became easier to understand how to solve it for himself.

The second interviewee had most of his career from offshore industry but turned to engineering studies for health reasons. He had been away from mathematics for a long time and sometimes struggled to keep up with the pace in the group work

Student: I did not like the specially adopted tasks we got for the class session, and the way we worked in the groups was very inefficient for me. Because many in the class are above me, I am stuck behind the rest during the work.

Interviewer: Ok, but you liked to prepare using the videos?

Student: Yes, I liked that very much.

Interviewer: But you think it would be easier for you to find the answer to the tasks if you were all by your own solving them?

Student: Not easier, but it would have been a better way for me to understand them, since I would be alone to think it over, instead of the others in the group just working fast through them.

Interviewer: So you weren't able to engage in the conversation and participate with your own thoughts?

Student: Not to the degree I wanted.

Both interviewees 1 and 3 expressed concerns about using specially adopted tasks for the in-class work. They worried about the tasks not having sufficient relevance for the final exam, and would rather spend time solving tasks from the textbook. I chose to not include excerpts from the third person being interviewed, since there were little indications of tensions in this interview.

## Classroom filming

During the second FC intervention period, we filmed two in-class sessions. We filmed several of the groups, primarily motivated by how the out-of-class teaching affected in-class group work. Two or three students worked together solving problems related to the videos, but on a slightly higher level

than the examples used in the videos. One episode in particular caught our attention. One student in a pair (let us call her Silvia) attended class seemingly well prepared and brought notes with her that she had taken from the videos. The other student in this pair (let us call him Nick) seem to be quite unprepared. A study of CI usage statistics confirms this impression. He did not bring notes, and barely spoke during the beginning of the episode. Silvia on the other hand expressed interest in how the formula of linear approximation for functions in two variables came about. The formula referred to is the well-known linearization

$$\Delta f = \frac{\partial f}{\partial x} \Delta x + \frac{\partial f}{\partial y} \Delta y$$

The first author hinted that this formula was based on an extension of the single variable case that was derived in the video, but Silvia was clearly not satisfied with this, wanting to know more. In addition, she was the dominant speaker in the group: In the 22 minutes that the episode lasted, we counted 488 words spoken by Silvia, whereas Nick spoke 236. He did catch up in the last third of the episode though, speaking almost as much as Silvia does then. We observe from the videos that this occurs after he had listened carefully to her struggles with the problems and the conversation that she had with the teacher in connection with this.

It was evident from the CI user statistics that many students had not prepared in the last period of FC teaching. This was influencing their progression in-class, although many seemed to use other means of catching up with the topic. They used other resources such as the curricula book, discussions with more knowledgeable peers like prepared students and the teacher, and even to some extent looking at the videos in-class on their own laptop.

## Discussion and summary

As previously discussed, activity theory can be used to depict tensions in the FC teaching. Studying the activity triangle in Figure 1, one of the most prominent changes in FC compared to traditional teaching are the rules. These undergo a radical change in FC, enforcing video preparation for in-class active learning.

There are two important observations we would like to highlight. Firstly, the second statement from the questionnaire excerpts hints towards a lack of understanding among several group members (the community) about the mathematical topic at hand. It seems that many members in the group had not grasped the mathematics in the videos, or they simply had not watched them, leading to a breach in the quality of student group collaboration.

The filmed episode of Silvia and Nick confirms this impression. Nick appeared to struggle to follow the arguments of Silvia, although there were evidence that he somehow changed from being an ‘eavesdropper’ of her struggling and collaboration with the teacher to becoming an active participant. However, Nick was not playing as the part of a collaborating peer, and thus failing to support Silvia in the discourse. We believe that this was due to his lack of preparation using the videos.

Classroom discussion is considered a vital instrument of learning in FC, and it constitutes a major tension if this is not taking place inside a group. We consider this as a secondary contradiction between rules and community. As previously explained, the major rule to consider in the student FC activity is the necessity to arrive at the in-class session being ‘primed’ by the out-of-class session. If

a major part of the group has failed to do this, the in-class discourse, considered a CHAT instrument, is hampered. Thus, this contradiction could also be seen as a secondary contradiction between rules and instrument.

Considering the data excerpts, we can also mention the tensions below, even though not substantiated through triangulation as the one already mentioned:

1. Tension in expectations/beliefs/rules: Students expect to be “taught” by the teacher, but FC rules and division of labour directs students towards learning through collaboration with peers (subject – division of labour tension), (secondary contradiction).
2. Students disagree with the new rule that tasks should be solved during class time. Preference towards solving them in solitude (object – rules tension, students feel this is not the best way to learn math), (secondary contradiction).
3. Students need to adopt to a new paradigm of work: Preparation through video lessons requires discipline, which results in tension, especially when a heavy workload is expected in courses taken in parallel (subject – rules tension), (tertiary contradiction).
4. Fluency in discourse. Problems expressing the mathematical problems verbally to other students. (subject – instrument (discourse) tension), (tertiary contradiction).
5. Students failing to keep up with the others during group-work (subject – community tension), (secondary contradiction).

As we discussed earlier on, in the filmed classroom episode with Silvia and Nick there is indication that students who have prepared by engaging in the out-of-class work seem to express themselves fluently in the mathematical problems, and in addition seem eager to learn more about the concepts behind the procedural mathematics shown in the videos. This provides empirical evidence (though only a single case) of the potential of FC to motivate students to strive towards a higher level of abstraction.

### **Validity and reliability issues**

This paper must be viewed in the context of a report on a pilot study. More elaborate studies will be carried out during 2016/2017 and 2017/2018 with engineering students in the same institution. Thus, there is little rigid design according to how data have to be collected to obtain optimal analysis and results. Handpicked excerpts from the data material were chosen to highlight the findings. There is also the issue of the researcher being present as the teacher, a classical objectivity dilemma found in many small-scale educational research settings. However, as we are presenting the data using several methods, both quantitatively and qualitatively, we can to some degree state that we have made valid triangulation of the findings.

### **Conclusion**

Our analysis of the data collected in this study, shows evidence that there exist several tensions in FC; some of these could be expected from the outset, while others are surprising. Data seem to point towards various aspects of the *active learning* being the most problematic part for many students towards a FC realization. Considering the activity system of the student, a secondary contradiction or tension materializes between the rules and the community, since many students was not adhering properly to the out-of-class part of FC. This is also seen to hamper the in-class discourse, considered to be an important instrument of learning.

# A micro-model of didactical variables to explore the mathematical organization of complex numbers at upper secondary level

Imène Ghedamsi

University of Tunis, Tunisia; [ighedamsi@yahoo.fr](mailto:ighedamsi@yahoo.fr)

*When complex numbers are introduced, there may be some mathematical choices that go beyond the learning processes requirements. Research highlights the necessity to take into account the epistemological aspects of complex numbers in order to cope with students' potential difficulties with these numbers. In this paper, we analyze the contents of the mathematical organization planned by the upper secondary institution to introduce these numbers by using a micro-model of didactical variables. Our results underline a lack of organization and put forward some learning criteria that could be deployed to design tasks for introducing efficiently complex numbers.*

*Keywords: Didactical variables, complex numbers, mathematical organization.*

## Introduction

One of the most useful approaches to introduce the complex numbers postulates the existence of the solution ( $\sqrt{-1}$  or  $i$ ) of the equation  $x^2 + 1 = 0$ , and enlarges by the same time the set of real numbers by including such solution in a way that the sum and product rules could be naturally generalized (Ghedamsi & Tanazefti, 2015). Yet, the real number and the complex number are utterly unlike, specifically because the former is associated to a concrete measuring process. Some pioneer research on complex numbers (Artigue & Deledicq, 1992; Rogalski, 2002; Rossel & Schneider, 2003) underline the complexity of learning these numbers by emphasizing the gap between the epistemological aspects of these numbers and the mathematical organization chosen to introduce them. Three fundamental epistemological aspects are highlighted by these researches and may give some details about this gap:

- In history, imaginary numbers are firstly used as a tool by the Italian algebra school to resolve cubic equations; they appeared as the square root of a negative number in the numerical expression given by the formula of the real solution ( $\sqrt[n]{a + \sqrt{-b}} + \sqrt[n]{a - \sqrt{-b}}$ ) with no more mathematical meanings.
- Imaginary numbers were being used by mathematicians long before they were first properly defined as complex numbers. The progress of the imaginary from the statute of a simple tool towards a mathematical existence as an object was supported by their efficiency to solve geometrical and infinitesimal calculus problems. Mathematicians made free use of them by applying the permanence principle which consists on generalizing real number rules to these numbers.
- The manipulation of imaginary numbers in history evolved through the use of several mathematical and semiotic representations. The use of several procedures, particularly those related to the multiplication of vectors, led to a geometric representation of imaginary numbers in the Argand (or complex) plane by identifying them to both a vector and a point. This kind of representation is not the first one; mathematicians started thinking about trigonometric representations of imaginary numbers along with their emergence by using infinitesimal calculus rules. The key role of these semiotic and mathematical representations reinforced the utility of imaginary numbers and putted forward the necessity to firmly entrench them as a mathematical object.

Many researches emphasize the major role of the organization of mathematical activities in the teaching and learning of mathematics as it shaped what could be taught and how this could be done (textbooks, syllabus, etc.). For instance, the study of the mathematical organization of Calculus concepts in the transition between secondary school and university highlights several problems in the way used to introduce mathematical topics that could potentially affect students' process of learning (Bressoud, Ghedamsi, Martinez-Luaces & Törner, 2016). This paper seeks to analyze this phenomenon in the case of complex numbers taking into account the epistemological aspects mentioned above, especially through their connection to the development of students' work with these numbers. We build on a networking of frames in order to identify the didactical variables - defined as the parameters that influence students' work (Bloch & Ghedamsi, 2005), related to complex numbers. Then, we use these variables to give a global vision of the choices of the mathematical organization related to the introduction of these numbers.

### Theoretical frames

Sfard (1991) argued that three phases shaped both the historical and the cognitive development of a mathematical concept. She particularly underlined subtle differences between historical and cognitive phases by means of the example of complex numbers. From the historical point of view, the three phases are defined as follow: “1) *the preconceptual stage, at which mathematicians were getting used to certain operations on the already known numbers [...] manipulations were treated as they were; as processes and nothing else [...]; 2) a long period of predominantly operational approach, during which a new kind of number begun to emerge out of the familiar processes [...], at this stage, the just introduced name of the new number served as a cryptonym for certain operations rather than as a signifier of any "real" object [...]; 3) the structural phase, when the number in question has eventually been recognized as a fully-fledged mathematical object [...].*” (Sfard, 1991, p. 14). These three stages are firmly consent with the history of complex numbers. In adequacy with these phases, the cognitive development of students is categorized into three stages: 1) *interiorization* where students become aware of the processes that gives rise to the concept; 2) *condensation* where students start combining and generalizing processes; 3) *reification* where the concept achieves the status of mathematical object by unifying the various processes in a structure. In this sense, the mathematical organization of complex numbers should cope with activities that enable students to first build skills of computation with square roots through active involvement of processes including those related to number representations; and secondly to realize through a huge variety of cases the practical perspective of these numbers (Sfard, 1991).

The object level of this concept is closely linked to the algebraic structure (or mathematical category) of the set of complex numbers. Each category or structure refers to one mathematical representation. In the language of category theory, the establishment of an isomorphism between sets of the same algebraic structure allows a person confronted to a new set to detect similarities and connections to familiar objects or sets, and to organize efficiently the new set. For instance, the isomorphism of fields  $\varphi : (\mathbb{C}, +, \cdot) \rightarrow (\mathbb{R}^2, +, \cdot)$ ,  $a + ib \rightarrow (a, b)$  permits to link the abstract representation of the complex numbers to a more concrete one. Furthermore, the use of functors to transit from one category to another permits to translate a difficult problem from one mathematics area into an easier problem in another area; this is the case of the trisection problem which is just solved by using complex numbers. This knowledge thus permits to orientate and to organize mathematical thinking.

At the transition from the end of secondary school to university, two categories of mathematical structures are implicitly used in the teaching of complex numbers: the category of Euclidian space and the Field category. To achieve the object level, these categories (and more) should become “*the ultimate base for claims on the new object's existence.*” (Sfard, 1991, p. 20). Of course, this could not be done at the transition between secondary school and university! To do so requires some foundational notions that are actually not taught at these levels. Nevertheless, the study of the mathematical organization of complex numbers by means of category theory provides information about the mathematical representations concerned by the institution and their design as well as those involved in a process of conversion between two mathematics areas. These information are associated to the mathematical culture of complex numbers, and they are useful for the teachers as they become aware of substantial details that influence the development of the learning process. Thus, the investigation of the upper secondary mathematical organization by using categories should not be outlawed simply because of the lack of mathematical notions at this level. However, it is fundamental to stress the distinction between the semiotic representations of an object as signifiers - that are organized into semiotic registers, and what is signified thus the mathematical representation. In the case of complex numbers, one semiotic representation may evoke more than one mathematical representation and vice versa. For instance,  $z, \bar{z}, |z|, \arg(z)$ , etc. constitute the elements (or the scripts) of what we called the intrinsic register; students' work with complex numbers in the category of Euclidean space could be done by using both the intrinsic scripts and the geometrical ones. This is the case of the representations of three collinear points: A, B and C are collinear points, if there exists a real number  $\alpha \neq 0$  such that  $z_B - z_A = \alpha(z_C - z_A)$  which is equivalent to  $\arg\left(\frac{z_C - z_A}{z_B - z_A}\right) \equiv 0(\pi)$ . Further study on the semiotic registers involved in the same category or in the transition between two categories is unavoidable. A switch between two semiotic registers is a conversion which refers to the same signified being in the same category. This conversion creates a new semiotic representation that does not involve the formation of a new object. In the case of the translation from one category to another, this switch engages a process of creation of a new mathematical representation of the same object. The process of conversions between semiotic representations as well as between mathematical representations performed the cognitive flexibility of the students and enabled the enlargement of the representations field of these numbers (Duval, 1995).

This theoretical synthesis highlights the impact of at least three didactical variables on the learning process of complex numbers. These variables lead to a micro-model that we use to investigate the institutional mathematical organization of complex numbers: DV1: The use of the permanence principle which concerns the generalization of real numbers rules (in the categories of field and Euclidian space) to the complex numbers; DV2: the use of the process-object duality; and DV3: the use of the semiotic and mathematical representations. We classify the mathematical organization in terms of practical blocks containing types of tasks and techniques to solve these tasks (Chevallard, 2006). This classification gives an overall patent description of the institutional requirements that permits to analyze the mathematical organization of complex numbers by involving the three variables of the stated micro-model. In this paper, we investigate this mathematical organization by means of two didactical variables that are DV2 and DV3.

## Empirical context

Complex numbers constitute one of the most important topics introduced in algebraic courses at the end of the secondary school in Tunisia for 16/17 years old students. Courses follow the contents of the unique official textbook used by the teachers as their own syllabi; almost all mathematics teachers adhere strictly to this textbook. The mathematical organization concerned by this study is taken from this textbook.

The modeling of the whole mathematical organization of complex numbers into praxeologies underlines the existence of 14 types of tasks designed T1 until T14; each one can be solved by using more than one technique. These techniques are generally algorithmic and indicated in the terms of the questions. For instance, to solve the type of task *T7: Determine an argument of a complex number*; students have the possibility to simply employ the property of the argument of the product of two numbers, they can also use cosine and sinus properties. Each task is a block formed by the type of tasks and the involved technique. The frequencies of these tasks (each task can occur more than once) in the whole organization are as follows:

T1: Determine the cartesian representation of a complex number	20
T2: Solve an equation using complex numbers	5
T3: Determine the conjugate of a complex number	2
T4: Determine the affix of a point or a vector	7
T5: Determine the modulus of a complex number	12
T6: Spot points in the complex plane	16
T7: Determine an argument of a given complex number	5
T8: Determine the trigonometric representation of a complex number	11
T9: Determine the kind of a quadrilateral (rectangle, square, etc.)	2
T10: Determine a set of points of the complex plane	11
T11: Determine the kind of a triangle (isosceles, equilateral, etc.)	1
T12: Prove that three points are collinear	1
T13: Determine the position of two lines (parallel, secant, etc.)	1
T14: Determine the sinus and the cosine of an angle	1

**Table 1: Types of tasks and frequencies**

The tasks are organized according to the categorization of the course into three sections: 1) the first section concerns the introduction of complex numbers via the traditional approach mentioned in the beginning of this paper; T3, T2 and T1 are the tasks used in this section particularly to prove and to exemplify the proprieties of the product and the sum of complex numbers and of their conjugates, by using the cartesian representation; 2) in the second section, the affix and the image notions, and the modulus and its proprieties are introduced with no details about the necessity to draw on the complex plane; T6, T5 et T4 are the tasks involved in this section; 3) the third section introduces the argument and its proprieties, and the trigonometric representation of complex numbers; T7 and T8 are mostly studied here. The tasks T9 to T14 are not concerned by a specified section, they are considered as integrative tasks that permit to use a variety of techniques. Using this classification, we can now

analyze the mathematical organization of complex numbers with a particular focus on the micro-model of the selected didactical variables.

## Some results

### Pseudo operation level of complex numbers

In opposition to the cognitive development principles as highlighted by Sfard (1991), the mathematical organization focus from the beginning, on the object level of complex numbers in way that: 1) the *reification* phase is “imposed” to the students with no tasks that allow the unification of the processes into a structure; 2) the *preconceptual* level of these numbers is missing, and the *interiorization* phase is limited to the manipulation of several representations of the object which is already introduced via one of them, this manipulation is mainly guided by the questions; 3) the *condensation* phase, which is supposed to illustrate the operation level of these numbers, is mostly neglected. It is important to precise that the same type of tasks could be associated to more than one level of complex numbers: preconcept, operation, or object. Specifically, the frequencies of the tasks referring to these levels are as follows:

	Objet	Preconcept	Operation
T1: Determine the cartesian representation	20	0	0
T2: Solve an equation using complex numbers	5	0	0
T3: Determine the conjugate of a complex number	2	0	0
T4: Determine the affix of a point or a vector	3	4	0
T5: Determine the modulus of a complex number	11	1	0
T6: Spot points in the complex plane	5	11	0
T7: Determine an argument of a given complex number	5	0	0
T8: Determine the trigonometric representation	10	1	0
T9: Determine the kind of a quadrilateral (rectangle, etc.)	0	0	2
T10: Determine a set of points of the complex plane	1	8	2
T11: Determine the kind of a triangle (isosceles, etc.)	0	0	1
T12: Prove that three points are collinear	0	0	1
T13: Determine the position of two lines (parallel, etc.)	0	0	1
T14: Determine the sinus and the cosine of an angle	0	0	1

**Table 2: Complex numbers levels and frequencies**

About 2/3 of the whole tasks concerns the object level of complex numbers, and only deals with algorithmic computation in the field category or the Euclidian space category of  $\mathbb{C}$ . The only process, referring to the supposed *preconceptual* level of complex numbers, consists on the strict manipulation of complex numbers representations by “juggling” from one to another. These manipulations are isolated, indicated in the statements, and do not probably lead to any kind of *interiorization*, this is the case, for example, of the geometric interpretation of the cartesian representation and vice versa. Only two tasks from those related to the operation level could actually be considered as an effective training to combine and unify processes that show the practical perspective of complex numbers (tasks T13 and T14). Tasks T9 to T14 should clearly highlight the role of complex numbers to

overcome complex computations of the geometrical problems, but with a certain choice of data, the students can simply apply geometric rules with no reference to these numbers. But the mathematical organization that is investigated in this paper does not permit to underline the role of complex numbers in simplifying extremely complicated computations; the data associated to the tasks T9 to T12 are not thought to take advantage of the operation level of these numbers.

### The amalgam of complex numbers representations

Four kind of semiotic representations structured into four registers intervene in the mathematical organization of complex numbers: 1) intrinsic register (In.,  $z, \bar{z}, |z|, \arg(z)$ , etc.); 2) cartesian register (Ca., scripts using  $a + ib$ ); 3) trigonometric register (Tr., scripts using  $r(\cos\theta + i\sin\theta)$ ); 4) graphic register (scripts using cartesian coordinates G.a.c., or polar coordinates G.a.p.). These semiotic representations are employed in several ways by mean of the two mathematical categories of  $\mathbb{C}$  used in this mathematical organization: field category and Euclidian space category. The analysis of the tasks using complex numbers representations is structured into three levels depending on the conversion process: 1) no conversions between semiotic representations as well as between mathematical representations; 2) only conversions between semiotic representations; 3) conversions between both semiotic representations and mathematical representations. In the case of this mathematical organization, each conversion between mathematical representations is followed by a conversion between semiotic representations. Depending on the techniques used, the same type of tasks could be associated to any of the three levels mentioned above: object, preconcept and operation. For instance, the tasks related to *T1: Determine the cartesian representation of a complex number* can be solved in the same register (computing powers of  $i$  in the cartesian register), or by moving into another register (from the graphic register to the cartesian one). Some techniques used to solve tasks referring to T8, T3, T2, T1 and T10 do not require conversions, the frequencies of these tasks are shown in the table below:

Mathematical category	Semiotic register	Occurrence
<b>Field</b>	Cartesian	26
	Intrinsic	1
	Trigonometric	2
<b>Euclidian space</b>	Cartesian	1
	Intrinsic	5
	Graphic/cartesian coordinates	1

**Table 3: Frequencies of tasks with no conversions**

About 1/3 of the whole tasks (26 out of 95) of the mathematical organization concerns the work on the Field category using the Cartesian register. These tasks involve simple computations by the mean of the properties of the operations in the  $\mathbb{C}$  field. Tasks from almost all the types are concerned by the conversions between semiotic representations:

Mathematical category	Semiotic conversion	Occurrence
<b>Field</b>	$(Ca. \rightarrow Tr.)$	2
	$(In. \rightarrow Ca.)$	1
<b>Euclidian space</b>	$(Ca. \rightarrow In.); (Ca. \rightarrow Tr.)$	1; 6
	$(Ca. \rightarrow G.a.c.); (G.a.c. \rightarrow Ca.)$	24; 5
	$(Ca. \rightarrow G.a.p.); (G.a.p. \rightarrow Ca.)$	4; 1
	$(In. \rightarrow Tr.); (G.a.p. \rightarrow Tr.)$	6; 1
	$(In. \rightarrow G.a.c.); (In. \rightarrow G.a.p.)$	4; 2

**Table 4: Frequencies of tasks with semiotic conversions**

The most important tasks that require semiotic conversions within the Euclidian space are those related to the determination of the graphic representation of a complex number by interpreting geometrically a given relation with complex numbers. This interpretation is based on a standard employ of the properties given in the textbook. Finally, only two tasks need a double conversion: T13 (Euclidian space./G.a.p.  $\rightarrow$  Field/Tr.  $\rightarrow$  Euclidian space./G.a.c.), and T14 (Euclidian space/Ca.  $\rightarrow$  Fied/Tr.).

## Conclusion

The analysis shows that the mathematical organization of complex numbers involves some values of the didactical variables that are theoretically identified. This result corroborates their validity to examine students' learning expectations in the case of complex numbers. However, the approach used to introduce these numbers, firstly as object and implicitly as an element of a field set, avoids the possibilities to engage efficiently in tasks that deal with the operation level of these numbers as well as with valuable conversions of semiotic representations in the category of Euclidian space. Moreover, this approach makes it difficult to organize contents related to conversions between mathematical representations so that students can use them by their own in the future. But the role of the institutional mathematical organization is manifest to overcome the potential changes that should occur in the way students are required to work with complex numbers at university level. On the other side, the micro-model of didactical variables related to complex numbers reveals a high level of cognitive flexibility that is required for learning complex numbers specifically at the beginning of the university level: differentiate between real numbers rules and complex numbers ones; use conversions between mathematical representations to solve geometrical problems; make autonomously semiotic conversions; involve several categories of the set of complex numbers to solve problems outside and inside mathematics, etc. These requirements are a source of students' main difficulties with complex numbers (De Vleeschouwer, Gueudet & Lebaud., 2013 ; Ghedamsi & Tanazefi, 2015). Specifically, Barrera (2013) highlights students' difficulties to interpret the product of complex numbers by means of plane's transformations in the category of Euclidian space. The crucial question is then: how to design efficiently the introduction of complex numbers in ways that minimize transition issues to the university? This study leads us to conjecture how it is possible to tackle such question by means of the micro-model of didactical variables. More precisely, three criteria may be considered for designing efficiently the mathematical organization that aimed the introduction of complex numbers:

1) use several values of the didactical variables and specifically those related to the conversions between semiotic and mathematical representations; 2) highlight the distinctions between the different categories of the set of complex numbers; 3) focus firstly on the operational level of complex number and improve its use in the resolution of different kind of problems. Further studies on students' learning of complex numbers are needed to examine the efficiency of these criteria.

# How are Calculus notions used in engineering? An example with integrals and bending moments

Alejandro S. González-Martín<sup>1</sup> and Gisela Hernandes Gomes<sup>2</sup>

<sup>1</sup>Université de Montréal, Canada; [a.gonzalez-martin@umontreal.ca](mailto:a.gonzalez-martin@umontreal.ca);

<sup>2</sup>Université de Montréal, Canada; [gisela.hernandes.gomes@umontreal.ca](mailto:gisela.hernandes.gomes@umontreal.ca)

*Research has shown that mathematics courses in engineering programmes present students with a number of difficulties, some of which stem from a disconnection between mathematics course content and the professional activity of engineers. Using tools from the anthropological theory of the didactic (ATD), we examine how the drawing of bending-moment diagrams is introduced in a classic textbook used in engineering programs. Although the notion of integral is used to teach this topic, the techniques used rely mostly on geometrical considerations (and not on integral techniques or theorems), and the justifications provided are a mix of (incomplete) mathematical discourse and professional justifications, with implications for students' learning.*

*Keywords: Mathematics for engineers, ATD, praxeology, integral.*

## Introduction and background

Mathematics is an important subject in many scientific and technological fields, including engineering. However, the difficulties university students face in their mathematics courses can lead them to abandon their professional aspirations (Ellis, Kelton, & Rasmussen, 2014). Research in engineering and mathematics education has shown that these difficulties manifest themselves in at least two points in a student's learning pathway. First, researchers have stated that students find the progression from secondary to tertiary education to be very difficult, especially when it comes to mathematics (Rooch, Junker, Härterich, & Hackl, 2016), and that they possess unsatisfactory mathematical readiness for engineering courses (Bowen, Prior, Lloyd, Thomas, & Newman-Ford, 2007). Second, a disconnect between mathematics courses and professional courses in university engineering programmes has been identified. For instance, Loch and Lamborn (2016, p. 30) stated that "mathematics is often taught in a 'mathematical' way with a focus on mathematical concepts and understanding rather than applications. The applications are covered in later engineering studies." This disconnect may create a "gap in the students' ability to use mathematics in their engineering practices" (Christensen, 2008, p. 131). This gap can be aggravated by the fact traditional engineering courses are usually separated into two groups: basic science courses in the first two years (such as mathematics and physics), and technical courses specific to each area of engineering in later years. Regarding this, Winkelman (2009, p. 306) indicated that "the first 2 years are typically devoted to the basic sciences, which means that students may only encounter engineering faculty in the third year of study". Some effort has been made to bridge the gap between mathematical and engineering practices, for instance by linking basic mathematical methods to applications (Rooch et al., 2016) or by introducing courses on mathematical modelling and problem solving early on in engineering programmes (Wedelin, Adawi, Jahan, & Andersson, 2015). These initiatives seem to have positive effects on student learning.

Tertiary mathematics education research has identified a number of difficulties encountered by

Calculus students; however, there is a lack of research on how teachers of professional engineering courses consider and use the mathematical tools taught in prerequisite mathematics courses. In general, it is expected that students in second- or third-year professional courses have grasped the mathematical notions taught in their earlier courses. We are interested in studying how Calculus notions – which students are expected to master – are used in professional engineering courses; in particular, whether they are used in the same way as in Calculus courses. Specifically, our research analyses the presentation of Calculus notions in a classic engineering textbook. We anticipate that this analysis will help Calculus teachers in engineering programmes understand how the notions they teach are used in higher-year professional courses, which may lead to a reflection on the connections (or lack thereof) between the content of Calculus courses and that of professional courses. In this sense, we adhere to Castela’s (2016) position on the issue of choosing appropriate mathematics for professional-oriented programmes: “mathematicians need to take some distance with their own culture [...]. They have to reconsider the following questions: which mathematical praxeologies are useful for such engineering or professional domains? What needs would be satisfied? Which discourse makes the mathematical technique intelligible? This is actually an epistemological investigation that we consider as a prerequisite to the design of mathematics syllabi for professional training programs” (p. 426).

## Theoretical framework

Because we are interested in how mathematical notions are used in Calculus and professional engineering courses, we believe that an institutional approach is appropriate for our research. In particular, Chevallard’s (1999) anthropological theory of the didactic (ATD) provides useful tools for analysing mathematical activity, since it considers that human activities are institutionally situated, and, consequently, so is knowledge about these activities (Castela, 2016, p. 420).

A key element is the notion of *praxeology* (or *praxeological organization*), which is formed by a quadruplet  $[T / \tau / \theta / \Theta]$  consisting of a type of task to perform  $T$ , a technique  $\tau$  which allows the completion of the task, a discourse (technology)  $\theta$  that explains and justifies the technique, and a theory  $\Theta$  that includes the discourse. In analysing tasks, we identify the *practical block* (or *know-how*) which is composed of types of tasks and techniques. The *knowledge block* describes, explains and justifies what is done, and is composed of the technology and the theory. These two blocks are important elements of the anthropological model of mathematical activity that can be used to describe mathematical knowledge.

Our research identifies specific *praxeologies* present in professional courses; we analyse how Calculus notions are applied in these courses and whether this application reflects how the notions are usually presented in Calculus courses. In this case, analysing the *practical block* of these *praxeologies* allows us to identify specific tasks that require the use of Calculus notions, whereas analysing the *knowledge block* allows us to identify the justifications given in using these notions, and compare them with the justifications usually given in Calculus courses. We consider the work of Castela (2016), who identified that “when a fragment of social knowledge, produced within a given institution  $I$ , moves to another one  $I_U$  in order to be used, the ATD’s epistemological hypothesis states that such boundary crossing most likely results in some transformations of knowledge, called transpositive effects” (p. 420). Her model (p. 424) proposes that in the boundary-crossing process, some (or all) elements of the original *praxeology* may evolve, and it ascribes the same level of

importance to types of problems and techniques as to concepts and theories. However, unlike Castela, we do not analyse the same type of task in two institutions, but rather a single *praxeology* specific to engineering and the use of mathematical tools within it.

## Methodology

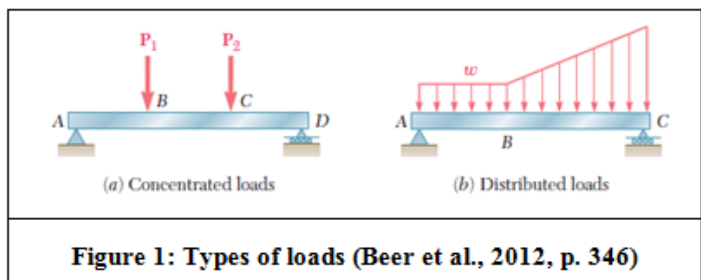

As we stated in the introduction (agreeing with Castela, 2016), in order to analyse how mathematics are used to solve problems in a given professional field, we must first understand and define these problems. We believe this is best achieved in collaboration with professional practitioners. To determine how Calculus notions are applied in professional contexts in engineering courses, we contacted an engineering teacher who holds Bachelor and Master of Civil Engineering degrees. Over the past 28 years this teacher has taught a variety of professional engineering courses at Brazilian universities, in engineering programs that meet international standards. He has also enjoyed a career in structural systems and reinforced concrete since 1986, developing projects and serving as a consultant. We interviewed him in March 2016 to understand how he uses Calculus notions in his professional courses. The interview and post-interview exchanges covered his way of teaching, the books he uses and the course notes he produces, focusing on his way of presenting different notions. For the purposes of this paper, we have chosen to analyse the introduction of shear force and bending moment and, specifically, how integrals are used to introduce this topic. At his university, shear force and bending moment are introduced in the second year of the programme, in the Strength of Materials for Civil Engineering course (students take Calculus in their first year). Three classic international textbooks are listed in the course syllabus (all translated into Portuguese), the main reference being the book by Beer, Johnston, DeWolf and Mazurek (2012).

The teacher indicated he primarily follows the structure of the main reference book in teaching shear force and bending moment. Therefore, this paper focuses on the book's content; we are currently analysing the complementary material provided to students, as well as the content of the interview, which will be the source of future papers. In analysing the textbook, we identified how notions are introduced, the type of tasks associated with them, and the type of *praxeology* developed, paying particular attention to the *practical* and *knowledge blocks* and the role of mathematical tools and discourse within these blocks.

It is also important to note that in the prerequisite Calculus course at this instructor's university, certain properties and results are proved while others are simply stated. For instance, the connection between the sign of the derivative and the monotonicity of the function ( $\theta_1$ ) is present and used in some tasks (such as the drawing of functions), as well as the connections between differentiability and continuity ( $\theta_2$ ).

### Shear and bending forces: a summary

The content introduced in this part of the course is related to the analysis and design of beams, an important aspect of civil and mechanical engineering. Generally, loads are perpendicular to the axis of a beam (*transverse loading*), which produces bending and shear in the beam. These

transverse loads can be concentrated (measured in newtons, pounds, or their multiples of kilonewtons and kips), distributed (measured in N/m, kN/m, lb/ft, or kips/ft), or both (Figure 1).

When a beam is subjected to transverse loads, any given section of the beam experiences two internal forces: a shear force ( $V$ ) and a bending couple ( $M$ ). The latter creates normal stresses in the cross section, whereas the shear force creates shearing stresses. Consequently, the criterion for strength in designing a beam is usually the maximum value of the normal stress in the beam.

Therefore, one of the most important factors to consider in designing a beam for a given loading condition is the location and magnitude of the largest bending moment. To determine this location, students are introduced to techniques for drawing bending-moment diagrams, defining  $M$  at various points along the beam and measuring the distance  $x$  from one end.

## Data analysis and discussion

Although the main reference book develops its theoretical content in a well-structured way – which allowed us to grasp the notions presented – is it possible that students do not read it. Research examining how engineering students use their mathematics books seems to indicate that students pay little attention to theory, focusing instead on tasks (Randahl, 2012). We are not aware of research that looks at the way engineering students use their textbooks in professional courses.

The content addressing the drawing of bending-moment diagrams is presented in Chapter 5 (*Analysis and design of beams for bending*) of Beer et al. (2012). The chapter starts by introducing the different types of beam and loads, and the notions of load ( $w$ ),  $V$ , and  $M$ . Section 5.1 introduces the relations between, and the directions of, the forces  $V$  and  $M$  in different sections of a beam, according to the type of load. In this section, calculations are made based on the idea that the sum of forces must equal zero, using formulae introduced earlier in the book. Sketches of bending-moment diagrams result in configurations such as the one shown in Figure 2. Obviously, someone with a background in Calculus could start to make a connection between the diagrams for  $V$  and  $M$ . However, this connection is not made in the textbook until section 5.2 (*Relationships between load, shear, and bending moment*).

The technique used in section 5.1 is quite rudimentary, but section 5.2 defines more explicitly (using derivatives and integrals – for this reason we focus on the content of this section) the relationships between  $w$ ,  $V$ , and  $M$  to facilitate the drawing of bending-moment diagrams, which is the type of task ( $T_E$ ) to solve. Section 5.2 presents a new *praxeology* (related to the one in section 5.1) that introduces the calculation of  $V$  and  $M$  at two adjacent points,  $x$  and  $\Delta x$ . Expanding on results from section 5.1, the authors arrive at  $\Delta V = -w \Delta x$  and state: “Dividing both members of the equation by  $\Delta x$  and then letting  $\Delta x$  approach zero:  $dV/dx = -w$ . [This] indicates that, for a beam loaded as shown in [the given figure], the slope

$dV/dx$  of the shear curve is negative” (p. 360). We have two remarks about this. First, the book avoids the writing of limits. Including limits could help make a connection with mathematical *praxeologies* present in the prerequisite Calculus courses (for instance, when defining derivatives and shifting from  $\Delta x$  to  $dx$ ). Even if the technology used to arrive at the final expression is based on content previously taught in a Calculus course, it is not certain that every student will make the connection, since tasks addressing the passage from  $\Delta x$  to  $dx$  are not very numerous in Calculus courses. Second, the book links  $dV/dx$  with the notion of slope, but (surprisingly) relates the latter to a single case (illustrated with a figure), rather than explaining it as a general principle using the technology  $\theta_1$  introduced in the Calculus course. This could lead some students to think that this connection between the slope of  $V$  and  $w$  applies only to the given figure. Although the notions (and their properties) introduced through  $T_E$  are defined using tools from Calculus, they are not explicitly linked to technologies (such as  $\theta_1$ ) derived from Calculus. Finally, the expression is integrated between points  $C$  and  $D$  to obtain: “ $V_D - V_C = - \int_{x_C}^{x_D} w dx$ ” and “ $V_D - V_C = -$  (area under load curve between  $C$  and  $D$ ).”

In general, although the textbook uses elements of Calculus, it avoids explicitly using the kind of notation and properties that have been institutionalised in Calculus courses (such as  $\theta_1$  and  $\theta_2$  mentioned above). For instance, the book states: “[ $dV/dx = -w$ ] is not valid at a point where a concentrated load is applied; the shear curve is discontinuous at such point” (p. 361). Here, the author avoids a clear statement about continuity and differentiability (available in  $\theta_2$ ). As Castela (2016) pointed out in a different context, we believe that the authors are seeking to develop another kind of knowledge, strongly correlated with a professional context. Employing techniques similar to those used to find  $V$  (and again, avoiding the writing of limits and saying instead “and then letting  $\Delta x$  approach zero”), the expression  $dM/dx = V$  is deduced and the authors state: “[this] indicates that the slope  $dM/dx$  of the bending-moment curve is equal to the value of the shear. This is true at any point where the shear has a well-defined value (i.e., no concentrated load is applied). [It] also shows that  $V = 0$  at points where  $M$  is maximum. This property facilitates the determination of the points where the beam is likely to fail under bending”. Interestingly, once again, the book’s authors avoid using explicitly a technology derived explicitly from Calculus ( $\theta_1$ ), making it less likely that students will make the connection. They finally deduce that: “ $M_D - M_C = \int_{x_C}^{x_D} V dx$ ” and “ $M_D - M_C =$  area under shear curve between  $C$  and  $D$ .”

We can see that the book avoids explicitly using properties previously institutionalized in Calculus courses, which leads to a kind of praxeology in which Calculus tools are written but geometric techniques are favoured. We do not mean to say these techniques are wrong; however, they could result in a knowledge gap, as some students may not recognise the same object (*integral*) that they

encountered in their Calculus course. For instance, the first solved example ( $t_1$ ) (Figure 3) presents a uniformly distributed load  $w$ . Using previous formulae, the reaction forces in the extremities are deduced (equal to  $\frac{1}{2}wL$ ), which allows the

deduction of  $V_A = \frac{1}{2}wL$  and  $V - V_A = -\int_0^x w dx = -wx$ , leading to  $V = V_A - wx = \frac{1}{2}wL - wx = w\left(\frac{1}{2}L - x\right)$ . Note that the

notation differs from that in the theoretical section, and the expression depends on the parameter  $w$  (introducing a technique  $\tau_1$  that differs from what was previously presented and that does not address the presence of  $w$ ); however, the latter is not highlighted, and a graph is drawn (Figure 3c), taking for granted that students can interpret a graph depending on a parameter (ignoring students' known difficulties with parameters; e.g. Furinghetti & Paola, 1994). The maximum value of the bending moment is obtained by calculating the area under the positive triangular region  $\left(M_{\max} = \frac{1}{2} \frac{L}{2} \frac{wL}{2} = \frac{wL^2}{8}\right)$ ,

and the curve is hand-drawn (another technique that does not address that  $M$  has been introduced as the integral of  $V$ ). The authors conclude with: "Note that the load curve is a horizontal straight line, the shear curve an oblique straight line, and the bending-moment curve a parabola. If the load curve had been an oblique straight line (first degree), the shear curve would have been a parabola (second degree), and the bending-moment curve a cubic (third degree). The shear and bending-moment curves are always one and two degrees higher than the load curve, respectively. With this in mind, the shear and bending-moment diagrams can be drawn without actually determining the functions  $V(x)$  and  $M(x)$ " (p. 362). A single case is used to introduce an important technological element ( $\theta_E$ ) that is helpful in solving  $T_E$  (drawn by hand), but this element is not justified in general, even though introducing  $V$  and  $M$  as integrals (showing that their coefficients can be deduced as primitives) would allow the use of a technology derived from the Calculus course for this justification. The book instead chooses to introduce a "rule" ( $\theta_E$ ) indicating that the student simply has to add one and two degrees, respectively, to draw  $V(x)$  and  $M(x)$ . The next solved problem has students calculate (again using formulae from section 5.1) the values of forces in extremities of intervals as well as areas using geometry. Students are asked to draw by hand the bending-moment curve (Figure 4), even for cubic functions. This way, given the original diagram (Figure 4-top), students can deduce the value of  $V$ , which will be constant at certain intervals, and deduce its value at  $D$  and  $E$  specifically, while simply linking them with a straight line. Once a student has drawn the graph for  $V$ , it is possible to calculate the areas under each segment to deduce the values of  $M$  in  $B$ ,  $C$ , and  $D$ , linking them by hand.

**Figure 3: Solved example (Beer et al., 2012, p. 362)**

In summary, the book introduces a *praxeology* to solve the problem of drawing bending-moment diagrams ( $T_E$ ); however, although related notions are introduced using mathematical tools such as integrals, the technologies rely on implicit mathematical results without clearly identifying them, favouring a more professional perspective. The techniques presented are limited to calculating certain points on graphs and linking them using geometric properties, which hinders students' ability to make connections with the techniques and notions introduced in their Calculus course. Notions are presented as integrals but this fact is not explicit in the book's techniques nor in the technology; because it is possible to ignore the book's explanations when focusing on techniques, it is not certain that students will connect this content with content previously studied in Calculus courses. The book introduces a *praxeology* in which the *practical block* is clearly presented [ $T_E$ ,  $\tau_E$ ], but where the *knowledge block* (mainly  $\theta_E$ ) mixes statements from mathematics and the engineering profession, leaving many facts implicit. Furthermore, this type of task does not justify all the content and techniques previously learned in Calculus courses regarding integrals.

### Final remarks

In this paper we analysed the process of boundary crossing (Castela, 2016) of content related to integrals, and examined how this content is used as technique and technology in a *praxeology* proper to civil and mechanical engineering. The literature has identified disconnections between mathematics and professional engineering courses (Christensen, 2008; Loch & Lamborn, 2016) and our research has allowed us to pinpoint one of these disconnections. Furthermore, we believe the tools provided by ATD allow us to study *praxeologies* and identify the connectivities and disconnectivities between the content in mathematics courses and professional courses.

It may be argued that the study of integrals in engineering programmes is motivated by the simple fact that “engineers use integrals”. However, we believe that the way integrals are taught in Calculus courses follows acknowledged *mathematics praxeologies* (those which are accepted and recognized by the institution of mathematics research; Castela, 2016, p. 421). These *mathematics praxeologies* ignore the use of integrals in professional courses. The crucial question, evoked in the introduction, of “what needs would be satisfied?” seems to be ignored by the *praxeologies* developed in Calculus courses, resulting in two different uses of *the same* object. We intend to analyse the entire content of the book related to shear forces and bending moments, as well as the course notes, to provide a more detailed portrait of the use of integrals in this content. This work will be followed by further analysis of other engineering-related content, which will allow us to better understand the use of Calculus content by engineers and pinpoint possible gaps experienced by engineering students.

**Figure 4: Solved example (Beer et al., 2012, p. 363)**

## Acknowledgments

The authors wish to thank Januário Pellegrino Neto, the engineer who participated in this project, for sharing his knowledge and experience and for making himself available for the interview and our many follow-up questions. The research presented here was funded by grant 435-2016-0526 of the Social Sciences and Humanities Research Council (SSHRC) of Canada's *Insight* program.

# Students' view of continuity: An empirical analysis of mental images and their usage

Erik Hanke<sup>1</sup> and Ingolf Schäfer<sup>2</sup>

<sup>1</sup>University of Bremen, Germany; [erik.hanke@uni-bremen.de](mailto:erik.hanke@uni-bremen.de)

<sup>2</sup>University of Bremen, Germany; [ingolf.schaefer@uni-bremen.de](mailto:ingolf.schaefer@uni-bremen.de)

*We investigate university students' mental images of continuity of real-valued functions by analyzing the answers of a questionnaire administered to Bachelor students at the University of Bremen. Our conception of mental images is based on concept images in the spirit of Tall and Vinner (1981) and the Grundvorstellungen (basic ideas) present in German subject-matter didactics (vom Hofe & Blum, 2016). For this purpose, we introduce the notion of "communicative simulacra." Furthermore, we catalog students' mental images of continuity that appear within this and preceding studies and demonstrate results on their acceptance in the study group. The used taxonomy and results are part of the first author's master's thesis (Hanke, 2016).*

*Keywords: Continuity, mental images, Grundvorstellungen, concept image, acceptance.*

## Introduction

More than 20 years ago Moore (1994) did an empirical analysis on the difficulties students face when they are required to give formal proofs. He identified among other factors that the students had little intuitive understanding of the concepts and their concept images were not adequate to perform certain proofs. Moreover, Selden and Selden (2013) argue that the ability to choose the right conceptual representation is a vital part in proving and generally in problem-solving activities.

In the context of analysis the concept of continuity is one of the most fundamental notions needed to do rigorous proofs. It is well known that students have difficulties with the notion (Tall & Vinner, 1981). This paper focuses on the mental images that future math teachers, pure math and applied math students have, which mental images they find acceptable and which they use to solve tasks. For the notion of continuity from the point of view of mathematics as well as mathematics education we refer to Tall (2013).

## Theoretical background

In the German tradition of subject-matter didactics the notion of *Grundvorstellungen* (regularly translated as "basic ideas") has gained much attention: The idea of Grundvorstellungen was extracted by vom Hofe (1995) after an analysis of related ideas of didactics of arithmetics and college-preparatory didactics by pointing out the importance of creating internal representations of mathematical notions in the learners' minds (vom Hofe & Blum, 2016). According to Kleine, Jordan and Harvey (2005) Grundvorstellungen link mathematics and reality by pointing out that modeling is a central mathematical process which fulfills requirements of mathematical literacy (application, structure and problem orientation): The authors argue that this is only possible after having acquired internal representations of mathematical concepts, so called Grundvorstellungen, which connect learners' experiences and mathematical knowledge with real life. Primary Grundvorstellungen are directly related to concrete objects and actions in the environment of the learners whereas secondary Grundvorstellungen consist of imaginative actions with mental representations (vom Hofe & Blum,

2016). The latter are particularly relevant for the notion of function and special classes thereof such as continuous real-valued functions.

We prefer to regard the essence of *Grundvorstellung*, using a subject-matter-didactical analysis, as a predominantly normative (or even prescriptive) approach to find internal representations learners should acquire in order to be able to recognize and use a mathematical notion in inner-mathematical or applied fields. But the idea of *Grundvorstellungen* is complemented by the wish of mathematical didactics specialists to observe actual mental models or images, respectively, that learners really develop (vom Hofe, 1995; vom Hofe & Blum, 2016; Kleine, Jordan, & Harvey, 2005).

The notions of *concept image* and *concept definition* by Tall and Vinner (1981) have been foundational for the existing literature on university students' conceptions of elements of analysis such as differentiation, integration but also limits and continuity. The concept image comprises "the total cognitive structure that is associated with the concept, which includes all the mental pictures and associated properties and processes" (Tall & Vinner, 1981, p. 152). Besides, the concept definition is a form of words to specify the concept and to communicate it. It can be *personal* or *formal*, thus individually shaped or widely accepted by the mathematical community (Tall & Vinner, 1981). A formal concept definition rather reflects a normative viewpoint on what is actually forced to belong to the concept. We argue that concept definitions are part of the overall of concept images of a mathematical notion. Contrariwise, if learners are confronted with an existing concept definition they develop *concept definition images*, a part of their concept images that expressly comprises their associations with the definition. Additionally, it is understood that learners enter their acquisition process of a newly introduced concept with preexisting concept images (Tall & Vinner, 1981), and that teaching persons and environments can influence the acquisition of concept images (Bingolbali & Monaghan, 2008).

Since both the idea of *Grundvorstellungen* and concept images lack a distinctive description of what actually counts as internal representations, a conceptualization of *mental images* (*Vorstellungen*) was developed in (Hanke, 2016) which seems more appropriate to address the subtleties of precise and distinguished research questions in the scope of mental images. Mental images are substantiated as *individual* constructions and therefore *reconstructions* of all kinds of mathematical notions. They are of *singular*, *regular* or *epistemological* nature, can be subdivided into *mental pictures* (*Vorstellungsbilder*) and *mental actions* (*Vorstellungshandlungen*) (Weber, 2007). Due to the premise of being able to be communicated, mental images can be shared as well as accepted, rejected or even imposed on somebody.

The most important idea for our study—and in general empirical research—is the fact that mental images cannot be observed. Thus, the only way to do empirical research about mental images is to study their *communicative simulacra*, the transformation of a potential inner world of a learner into observable entities such as spoken words, written solutions to exercises and so on (Hanke, 2016). In particular, communicative simulacra do not reflect normative assumptions on a notion as it is the case with *Grundvorstellungen*. In case of answers to a direct question on mental images (e.g. "What is *your* intuitive meaning of continuity?") we will speak of *exclamatory simulacra*. With this terminology we emphasize the fact that what is actually communicated by a learner depends on the occasion of communication and does not necessarily reflect the full entity of associations of the learner. We cannot even be sure that the learner is aware of the intentions of the researcher when

asked about mental images. Rather, we find blurrings of the actual mental images of learners that could potentially be sharpened by further qualitative analysis. In particular, exclamatory simulacra are shaped by the learner's understanding of the concept in question and are only a subset of communicative simulacra which, in turn, can be expressed by different forms of communication. Here we concentrate on descriptions of communicative simulacra.

Based on Moore's (1994) and Selden's and Selden's (2013) conclusions, we believe that the mere knowledge of definitions, the ability to reproduce them or the setup of mental images for a mathematical concept do not necessarily mean that the students are able to use the concept. Also, we believe that the more mental images students have the more they are able to apply at least some of these in inner-mathematical situations or in contexts. Moore's (1994) term *concept usage* is related to our idea of distinguishing between exclamatory simulacra of mental images and the usage of (probably different) mental images as required in the third section of our questionnaire. The second part of the questionnaire provides insight in the *acceptance of attitude* (Einstellungsakzeptanz) and *acceptance of usage* (Nutzungsakzeptanz) (Weber, 2007) (see next section).

The review of central papers (Bezuidenhout, 2001; Núñez & Lakoff, 1998; Schäfer, 2011; Takači, Pešić, & Tatar, 2006; Tall & Vinner, 1981) on concept images and related results on students' conceptions of continuity lead to the classification in Table 1 of eight possible mental images that are reported in the literature following Mayring's (2015) methodology of *qualitative content analysis*. We emphasize that these categories are representatives of communicative simulacra identified in the literature and we do not intend to judge about their formal or normative correctness.

Connections of continuity to the concept of integration is hardly ever noticed explicitly and therefore in case of appearance subsumed under miscellaneous. Likewise, the concept image of "pulling flat" the graph of a real-valued continuous function (Tall, 2009, p. 487) could not be found in any of the students' responses. It seems to be related to the rubber band metaphor often used in topology and usually is not part of standard German textbooks or lectures on analysis in one variable. Additionally, Schäfer's (2011) Grundvorstellungen for real-valued functions (controlled stability while wiggling at a point, possibility of approximation at a point and connectedness of the graph) are subsumed in the categories of Table 1.

#	Category	Example
I	Look of the graph of the function	"A graph of a continuous function must be connected"
II	Limits and approximation	"The left hand side and right hand side limit at each point must be equal"
III	Controlled wiggling	"If you wiggle a bit in $x$ , the values will only wiggle a bit, too"
IV	Connection to differentiability	"Each continuous function is differentiable"
V	General properties of functions	"A continuous function is given by one term and not defined piecewise"
VI	Everyday language	"The function continues at each point and does not stop"
VII	Reference to a formal definition	"I have to check whether the definition of continuity applies at each point"
VIII	Miscellaneous	

**Table 1: Categories for mental images of continuity**

## Setup of the study and methodology

Our research questions have been:

- 1.) What mental images do students express by exclamatory simulacra?
- 2.) What mental images do students accept and make use of in argumentation?
- 3.) Is there a difference between students who want to become teachers and those studying pure and applied mathematics with regard to mental images or concept usage?

We distributed a questionnaire to 54 Bachelor students (first-year pure and applied mathematics and second-year mathematics teacher students) in Bremen after the completion of a lecture with exercise classes on Analysis I (Hanke, 2016). The course covered approximately the content of Binmore (1982). The chosen methodology of the questionnaires is very similar to the one used often to investigate concept images (e.g. Tall & Vinner, 1981; Bezuidenhout, 2001; Nordlander & Nordlander, 2012). Our questionnaire, described in detail below, is an extended version of those described in Tall and Vinner (1981) and in particular Schäfer (2011). No questions concerning applications are given in order to identify students' conceptions of continuity solely related to the mathematics itself. New is the differentiation as described in the taxonomy of communicative simulacra and the comparative approach of acceptance of attitude and acceptance of usage, i.e. if students accept certain concept images and if they can apply those different images to some example functions.

To identify the different types of simulacra, the types of questions we provided different stimuli. In the first part of the questionnaire the students were asked to freely verbalize what the intuitive meaning of continuity from their point of view is. In the second part we probed the acceptance of attitude of the verbalizations of mental images presented to the participants in fictive statements on a 6-point Likert scale (totally decline (0), ..., totally accept (5)) (Table 2). Furthermore, the third part of the questionnaire focused on acceptance of usage of mental images since we asked to give arguments for whether the following functions in Table 3 are continuous at the respective locations with multiple mental images. We have chosen the functions because they have discontinuities of different kind: the right and left hand side limit of  $g(x)$  exist and do not coincide as  $x$  approaches 0, and the limits of  $f(x)$ , and  $h(x)$  respectively, do not exist as  $x$  approaches 1, or 0 respectively, while the graph of  $f$  is disconnected in every neighborhood of 1, whereas the graph of  $h$  is connected in every neighborhood of 0.

#	Description	#	Description
1	Having minima and maxima is characteristic for continuity	5	Controlled wiggling
2	Limit definition of continuity	6	Connection to differentiability ("a function is not continuous at a point if it cannot be differentiated at that point")
3	Weierstraß $\varepsilon$ - $\delta$ -definition / preimages of small open intervals contain small open intervals	7	Graph has no jumps
4	Graph has no holes	8	Graph does not swing too much back and forth

**Table 2: Mental images of continuity probed in the second part of the questionnaire**

1.) $f: \mathbb{R} \rightarrow \mathbb{R}, x \mapsto \begin{cases} 0 & \text{for } x \in \mathbb{R} \setminus \mathbb{Q} \\ x & \text{otherwise} \end{cases}$ at $x = 0$	2.) $f: \mathbb{R} \rightarrow \mathbb{R}, x \mapsto \begin{cases} 0 & \text{for } x \in \mathbb{R} \setminus \mathbb{Q} \\ x & \text{otherwise} \end{cases}$ at $x = 1$
3.) $g: \mathbb{R} \rightarrow \mathbb{R}, x \mapsto \begin{cases} 1 & \text{for } x < 0 \\ 0 & \text{otherwise} \end{cases}$ at $x = 0$	4.) $h: \mathbb{R} \rightarrow \mathbb{R}, x \mapsto \begin{cases} \sin(\frac{1}{x}) & \text{for } x \neq 0 \\ 0 & \text{for } x = 0 \end{cases}$ at $x = 0$

**Table 3: Different functions in the questionnaire**

Summarizing, we are interested in the threefold of mental images through communicative simulacra: exclamatory simulacra and the usage and acceptance of mental images observable in communicated outcomes. Due to page restrictions, we limit ourselves on an overview and provide some statistics. For instance, the flexibility of usage and acceptance of individuals will be preserved for an upcoming paper.

## Results and discussion

All answers to our questionnaires were categorized according to Table 1. Multiple responses of the students were not only possible but desired and multiple categorization of a single answer into the categories was also possible. The categorization of the answers to the first question “What is the intuitive meaning of continuity from your point of view?”—i.e. the exclamatory simulacra of mental images of continuity—led to the following: five students did not give an answer, 37 answers fell into only one category, eleven in two and the one remaining answer in three categories. Around 70% of the overall codes were found in “Look of the graph” (I) and all the other categories appeared in no more than 10% of the cases each.

The “Look of the graph” (I) is the dominant mental image among students when asked to give one. Nevertheless, some students are able to accept other mental images as well. Figure 1 illustrates this. While the items “Graph has no holes” (4) and “Graph has no jumps” (7) are accepted by the majority, items close to the limit (2) or Weierstraß definition (3) of continuity have 40% to 50% acceptance. The fact that the majority wrongly connects differentiability as a necessary condition for continuity may be a problem of the item in the questionnaire which included two negations. Based on the very high rejection rates for the items „Having minima and maxima is characteristic for continuity“ (1) and „Graph does not swing too much back and forth“ (8) in the second part of the questionnaire, it seems to be certain that these are not common misconceptions about continuous functions.

The functions  $f$ ,  $g$  and  $h$  in Table 3 were all known to the students and had been part of the course in analysis and also of the exercises. In contrast to Tall and Vinner (1981) we did not give a picture of the graphs. The functions  $f$  and  $g$  seem familiar to the majority of students so about 50% are able to give a correct answer. The function  $h$  seems more complicated and most students do not answer the question at all and about half of the answers are false. This item is one where there is a real difference between those who study to become teacher and those who want to work as mathematicians. In the latter group the percentage of a correct answers is about twice as high (Hanke, 2016).

**Figure 1: Acceptance of item on Likert scale from 0 to 5: Reject (0, 1), Neutral (2, 3) and Accept (4, 5) in percent of answers**

To identify group differences between the different study groups (pure and applied math students vs. future teachers), we counted the occurrences of every category in Table 1 in the answers of the students for each of the questions. Concerning the overall usage of certain mental images measured with the coding of all answers to all functions of the third part of the questionnaire Fisher's test on the resulting contingency tables did not yield a significant result. We interpret that there are no observable differences in the acceptance of usage of the different study groups. Using the Kruskal-Wallis-Test, we could not find statistically significant differences except for the acceptance of the limit definition (2) in part two of the questionnaire ( $p < 0,03$ ) where teachers students tended to express their acceptance with higher values on the Likert scale than the others.

Comparing the results with Schäfer (2011) we identified more detailed mental images via their exclamatory simulacra (categories 4 to 7). While the concept image of "look of the graph" (I) was dominant here as well, it was not so dominant in Schäfer's study (2011). We see a more diverse pattern in the argumentation for the three functions instead.

The most interesting part of the empirical results is that the same mental image is used by the students either to justify a wrong or a correct answer (based on their judgment whether the given function is continuous or not; cf. Figure 2): The look of the graph (I) was used most frequently for a correct but also for a wrong answer. For example, the graph of function  $h$  is connected (i.e. has no jumps) but the function is discontinuous at the origin. Among the answers to this function we found e.g. "Yes [ $h$  is continuous], since [it is] going through, without gaps or jumps," or "The function looks continuous, since it does not 'jump'." General properties of functions (V) were even used more often for a wrong than for a correct judgment of continuity. Again, for the function  $h$ , some students argued it is "discontinuous because of a pole," but also  $h$  is "continuous at  $x=0$ , since it lies in the domain of the function." For this function we could also find various different justifications for (dis-) continuity like "it gets area-like at the origin" or "it wiggles too much." This is also the function where more wrong than correct answers were justified with mental images.

**Figure 2: Numbers of correct and incorrect answers per category summed up for all four functions**

## Outlook

In this study we provided a taxonomy that guides empirical research related to mental images of mathematics students in several directions. We pointed out that communicative simulacra of mental images of real-valued continuous functions depend on the context in which mental images are used: Figures 1 and 2 show that the spectrum of mental images used or accepted by the students we investigated is broader than the spectrum of explicit exclamatory simulacra. We also found out that in the overall of justifications of (dis-) continuity a single mental image does not exclusively help or misguide. A first step into mental images of metric space-valued continuity is also given in (Hanke, 2016).

We believe that future research on teachers', doctoral students', tutors' or university lecturers' conceptions of continuity will provide insight into similarities and differences between social groups in the overall process of teaching and learning of a particular mathematical notion. This will be of particular importance for the teaching of real-valued continuity in today's university classrooms. Since continuity is disappearing from the curricula in secondary schools in Germany, it would be interesting to find out how the teaching of continuity in secondary schools implicitly or explicitly influences the mental images of beginning university students. Particularly, the question on the stability of mental images arises. Focusing on the analysis courses taught at secondary schools, an upcoming research area are teachers' judgments of the adequacy of teaching continuity in schools as a prerequisite for important facts on differentiability and integration such as the fundamental theorem of calculus.

# Using the theory of instrumental genesis to study students' work with a digital tool for applying integrals in a kinematic simulation

Ninni Marie Hogstad<sup>1</sup> and Ghislain Maurice Norbert Isabwe

University of Agder, Norway; <sup>1</sup>[ninni.m.hogstad@uia.no](mailto:ninni.m.hogstad@uia.no)

*Digital tools are increasingly becoming part of mathematics in Higher Education, some of which are used pedagogically. An example is Sim2Bil, a digital tool that offers mathematical tasks about a simulation of cars. Students can solve the tasks using integrals. Applying the theory of instrumental genesis, in which techniques are analyzed in light of epistemic and pragmatic value, we studied the tool when used by groups of engineering students. We observed the students applying techniques such as instrumented and pen & pencil for solving the tasks. The techniques required the combination of understanding integrals kinematically (as distance travelled), graphically (as area under a graph) and as a calculation with symbols (finding the anti-derivative). In fact, the mathematical tasks provided opportunity for students to address at least one task, and we had students solving the most demanding ones.*

*Keywords: Digital tool, engineering students, instrumental genesis, epistemic value, pragmatic value.*

## Introduction

Solving mathematical tasks involves using different tools. These tools might be compasses and rulers, but also language, symbols, gestures, and digital tools. From a didactical point of view, it is important to study how such tools function, how students work with these tools and how the tools can be incorporated into educational practices. Within education, tools not only serve to do mathematics, such as carrying out calculations quickly, but they can also be pedagogical instruments for learning mathematics (Artigue, 2002). In our study, we focus on digital tools. Examples of digital tools for doing mathematics are Mathematica ([www.wolfram.com/mathematica/](http://www.wolfram.com/mathematica/)) and MatLab ([www.mathworks.com](http://www.mathworks.com)), which are numerical computing environments used in academia and industries. Examples of digital, pedagogical tools for mathematics are Geogebra ([www.geogebra.org](http://www.geogebra.org)) and MIT Mathlets (<http://mathlets.org>).

Our research is positioned within the education for engineers. The integral is one of the mathematical concepts to be learned. It can be perceived in many different ways, for example as an object (as a function or as an area) or as a process (calculating the anti-derivative or taking the limit of a Riemann sum). Researchers have found that students have difficulties conceptualizing the integral (e.g. Jones, 2013; Swidan & Yerushalmy, 2014). Derouet (2016) has focused on the relation between integral, area and probability, in which the integrand is the probability density. We take an approach where we study the relation between integral, area and distance in which the integrand is the velocity. We are representing the integral as a mathematical model for making objects move under certain conditions.

There are several digital tools used for the learning of integrals. On the internet one can find applets, in which the integral is demonstrated with the Riemann Sum with an interactive slider for showing the limiting process. Berry and Nyman (2003) used a different tool, namely one that can record

displacement of an object and then graphically display both a displacement-time graph and a velocity-time graph. These kinematical graphs were meant to assist students in visually making a connection between the function and its anti-derivative. Yerushalmy and Swidan (2012) describe another tool that, given a function and its graph, generates graphically an accumulation point graph. Further on, Swidan and Yerushalmy (2014), presented the Calculus Integral Sketcher, which allows students to construct and drag a primitive graph when a function graph is given. In all cases, students' learning is supported by graphical means. We want to extend the research on pedagogical, digital tools for learning the concept of integrals by combining graphical and kinematical approaches with dynamic animations. Therefore, we considered a tool aiming to engage students to (1) combine different topics of their curriculum, such as calculus and kinematics, (2) calculate and interpret graphs etc, and (3) collaborate.

We studied Sim2Bil which can be used for groups within higher education where integrals and kinematics are part of the curriculum (students in the natural sciences, engineering, etc.). The tool requires users to work with velocity functions, of which the integral represents the distance travelled. The tool's name comes from a Norwegian word for car, 'bil', derived from automobile. The tool consists of mathematical tasks connected to dynamic animations. In addition to studying this tool, we want to study collaborative work between students, because inter-personal mediation is considered an important aspect of future education (Lowyck, 2014).

Figure 1 shows the interface of Sim2Bil. The top left part shows an animation of two cars driving in a straight line from a starting line to a finish line. This is the simulation area. The lower left part shows two separate graphs for the velocity-time function of both cars. The areas under the graphs represent the distance travelled by the cars. This is the graph area. The bottom right part is the space for the velocity functions of the cars. A user can set in parameters for polynomial velocity functions. This is called the formula area. Also, within this area there are buttons to click on. 'Formula1' and 'Formula2' give the generalized kinematical formulae for average and instantaneous velocity, and displacement, which include the integral symbol. Other buttons can hide/show the cars and graphs. When pressing the Start button in the bottom right corner, an animation starts showing the cars run, and at the same time the areas under the graphs are animated: the grey areas increase with time.

The tasks in the top right area were especially designed for the animations. In connection with the animations of cars driving by taking over each other and finishing at the same time and the graphs, the tasks were about making these cars run under certain conditions. Without the tasks, the animations of moving cars will not be very meaningful, and vice versa.

In the study presented in this paper, we investigate how Sim2Bil is used by groups of students. We use the theory of instrumental genesis to analyze our data. Our research question is: what forms does the instrumental genesis of students working with Sim2Bil take?

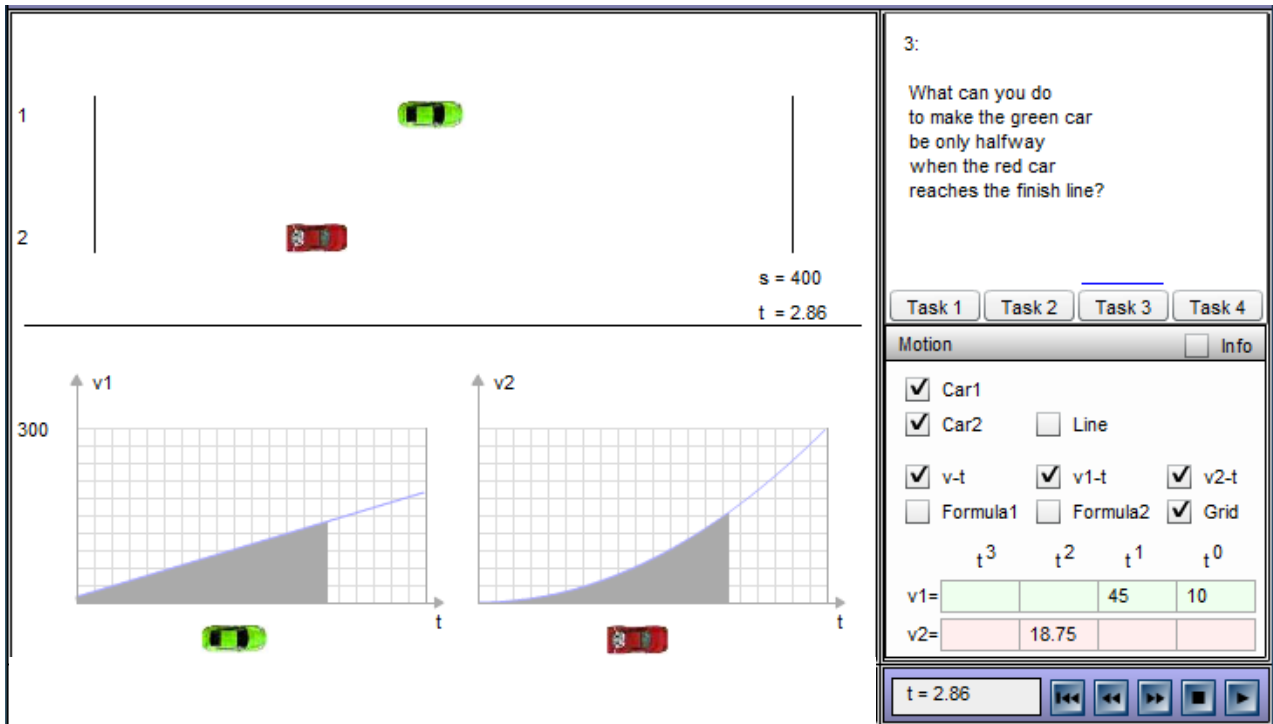

Figure 1: Interface of Sim2Bil.

## The theory of instrumental genesis

The theory has assisted researchers to study students' activities in CAS environments (e.g. Drijvers, 2003; Guin & Trouche, 1999) and dynamic geometry environments (e.g. Alqahtani & Powell, 2016). First, we will explain the constructs instrumentalisation, instrumentation and technique which play an important role in the theory. Further, we will explain how techniques can have epistemic or pragmatic value.

Any artifact, a physical object, will remain a bare artifact for a person if the person does not know what to use it for. However, an artifact might turn into an instrument if there exists a meaningful relation between the person and the artifact (Rabardel, 2003). Drijvers and Trouche (2008) give a good example of how a hammer, an artifact, is turned into an instrument if a person has skills and experience of how to use it properly. The distinction between artifacts and instruments does not lay in a physical change of the objects, but a transformation of the way a person thinks about and practically uses the object.

This transformation process is a learning process and it is called instrumental genesis. The transformation process works in two directions as explained by Trouche (2004): towards the artifact and towards the user. The first direction involves the user learning to use the artifact. This embraces the activities in which an artifact becomes an instrument for a user, and about how the action influences the user's activity and knowledge. This direction is called *instrumentalisation*. The other direction concerns the user using the artifact meaningfully for tasks. This is called *instrumentation*. As Artigue (2002) points out, this process involves developing ways for solving tasks.

We will analyse students' work with Sim2Bil. Our intention is to understand how students are appropriating the tool and the transformation process of the tool becoming an instrument. Since

there exists a dialectic relationship between an artifact and a user (Gueudet & Trouche, 2009), we will look into both directions described above for the investigation.

### Epistemic and pragmatic value of techniques

While doing mathematics, students can use several techniques, which may involve doing calculations and making drawings. A technique within the theory of instrumental genesis means “a manner of solving a task” (Artigue, 2002, p. 248). Artigue distinguishes between instrumented and paper & pencil techniques. Techniques yield a result and, therefore, they have a value. The value can be epistemic or pragmatic. Epistemic value involves that the technique has a meaning for the students related to the mathematical objects involved. We observe this, for example, when students find solutions to symbolic equations by creating a graphical representation with a graphing tool to use the zeros of the graph instead of solving the equations algebraically or numerically.

A technique might also have pragmatic value. Artigue (2002) explains that we can observe pragmatic value when a technique is applied by students who are focused on the productive outcome of that technique (e.g. to have a quick answer). Further, she states that epistemic value might be less recognizable than pragmatic value since the latter concerns the appearance of immediate results. We observe this, for example when students are randomly guessing an equation.

### Methods

To investigate students’ work with Sim2Bil we needed to observe students interacting with this digital tool. Hence, we created an environment in which students use the tool (tasks, animations), and other resources such as calculators, pens and paper.

As a default setting, there are two velocity functions given in the interface so that a student can press the Start button, see the cars run and the areas under the graphs grow. The two default velocity functions make the cars finish simultaneously. In this way, the forthcoming tasks were framed, which all have requirements on how the cars should finish. With a total of four tasks, Sim2Bil integrates tasks and animations.

The first task requires students to press the Start button and explain what the shaded areas represent. This task gives a visual introduction to the tool offering an association to distance as represented by area under a graph. After Task 1, there are Tasks 2–4, in which students are asked to find velocity functions that fulfill different requirements for the running cars. In Task 2, students are asked to find other functions so that the cars run with different velocities and arrive at the finish line at the same time. This will require students to translate the kinematics into mathematics and find functions  $v(t)$

so that  $\int_0^4 v(t) = 400$ . In Task 3, they are asked to make the green car be only half way when the red car reaches the finish line, thus  $\int_0^4 v(t) = 200$ . In Task 4, they are asked to make one car have half the velocity of the other when they arrive at the finish line simultaneously.

Our study was carried out at two different universities, at each of which we worked with one group of three students. All were within their first year of engineering studies. Group 1 comprised three boys, while Group 2 included one boy and two girls. All the six participants were not familiar with

Sim2Bil. In their lectures, the students of Group 1 might have seen a similar tool as Sim2Bil, including a button to press on screen for making an animation run. All volunteered to participate in this study outside regular lectures. The groups sat in a room with a table and one laptop with the tool in front of them. They were informed that we would study how they interact with the tool, and that they would not be assessed. Both groups were given an unlimited time for group work, and it turned out that Group 1 spent 45 minutes and Group 2 used one hour.

There are some differences in how the groups were treated, with regards to parts of the interface and how the tasks were given. In the interface, the top right area showed an unused menu for Group 1 and they received the tasks on paper. For Group 2, the Tasks 2–4 were given on screen. In the formula area, the students of Group 1 could write in parameters to make up to third degree polynomials (see Figure 1). Group 2 students could write in any expressions. Since Task 1 has a different nature than the others, as it does not ask for mathematical expressions, we gave this task orally to Group 2, at about three minutes into the session. In this way, we could see whether the Start button would be quickly found. The data collection consisted of video recordings of the students' group work. The first author was present with both groups and two cameras were used at different angles to capture students' writings, gestures, and screen activity. The video recordings were transcribed fully for Group 1 and largely for Group 2, and analyzed in light of instrumental genesis. In particular, techniques the students used to solve the tasks were identified by going through the videos and transcriptions, and analyzed in terms of epistemic and pragmatic value.

## Results

By analyzing the students' group work regarding the process of *instrumentalisation*, we observed that Group 1 easily found the Start button at the beginning. They saw the cars driving to the finish line and arriving together, the growing graphs and the increasing shaded areas. Then they read Task 1. They related the areas under the graphs with the distance covered by the cars.

Group 2 was not asked to press the Start button at the beginning. They started by explaining to each other what they saw on the screen:

Dana: We are going to work with the relationship between velocity and time. (...) I'm thinking we are supposed to come up with functions like this (points at the formula area) related to the graphs (points at the graph area). Isn't it?

Jeff: Mhm... Okay, it looks like we have the formula for the velocity of the first car... and for the second car. So, uhm....

In the episode above the students related velocity functions to the graphs and velocity to the cars. After this, Jeff turned to the researcher and asked: "Excuse me, what are we supposed to find out here? We are supposed to...". The researcher asked them to press the Start button. Then, they pressed Start and saw the animated cars and graphs, and they related the areas under the graphs to distance covered by the moving cars. Thereafter, they started working on the remaining tasks.

Based on the observation of Group 2, we saw that guidance of finding the Start button was needed. At first sight, the screen offers much information, so this button can be overlooked. By pressing Start, they were introduced to the tool's functionalities and to the conditions of the tasks. The animation showed two cars running differently but finishing simultaneously. We interpret that once

the Start button was found, it enabled the appropriation of (1) the operations of the animations and (2) the conditions of the tasks.

In regards to the process of *instrumentation*, the students used several techniques. For example, they set parameters in the formula area and pressed the Start button and watched the cars run. Another instrumented technique was to insert parameters and notice how a graph of a function looked like, dismissing it when it went too low. These techniques were applied by both groups within each task. On some occasions, we observed some students set in parameters seemingly at random in the formula area. Then, the graphs were noticed or they saw the cars run. On other occasions, the instrumented techniques were done as a final check whether their paper and pencil solutions were correct (paper & pencil techniques are explained below). These instrumented techniques had pragmatic value, since it was a quick check to see whether inputs were correct. The students might have reasonably guessing parameters, and on some occasions, the students explained why the animations appeared the way they did connecting it with algebraic expressions of the functions. The techniques connect symbolic, graphical, and kinematical representations. Therefore, it can be argued that the techniques also had epistemic value.

We observed both groups use paper & pencil techniques for the tasks 2–4. They calculated the integral as anti-derivative, but knowing that they calculated the area under the graph and that it was the distance covered by the cars. In task 4, Group 1 also used a technique consisting of making rectangle and triangle drawings and making area calculations based on the fact that one area needs to be equal the other one. The techniques have a pragmatic value since the focus was on the productive potential (finding velocity functions) and it was a way of checking their answers. It can also be argued that these techniques, inherent symbols, had an epistemic value, since integration can be regarded as anti-derivation and an area can be regarded as distance travelled.

Both groups discussed how to solve each task. Also, one group occasionally used gestures to visualize the cars and graphs in a way they could not visualize through instrumented techniques (e.g. get a specific graph). Also, gestures were used to support their imagination in discussions on the requirements. When one group started on task 4, they used their hands to gesture the run of the cars, mimicking the cars take over each other and finish together. Especially, the use of gestures occurred when the students faced challenges in finding parameters to solve the tasks.

For creating polynomial velocity functions, the tool included a hint for the problem-solving process. We observed some students being “stuck” while doing calculations and clicking around on possible buttons for a clue. The formula buttons confirmed to them, that they needed an integral, but it did not help them in calculating the integral or in mathematizing the requirements of the tasks.

At the end, the one group related their answer ( $v_1=100$ ,  $v_2=-25t+150$ ) to different parts in the areas on screen:

Erik: Can we prove that the answer is correct? Yes, by the calculations again. (...) But we can also see it here that it stops on half of the other (point at the screen). So, it stops on 40. So, you can see that on the graph, actually.

Sam: Oh, yes and you can see that it is a relation between the area under the graph...which is the integrated of the velocity.

This episode shows that the students were reasoning on how they can check whether their answer is correct. Erik mentioned the *paper & pencil* technique (calculating the triangle and rectangle, area), and the *instrumented* technique (notice the graphs on screen including the equal areas and the velocity of the red car is half the velocity of the green car). Sam repeated the relation between areas and distance.

## Discussion and conclusion

Research has focused on different approaches for learning the concept of integral. In some studies, the integral was visualized as Riemann sum. In our contribution, we have taken another approach: we investigated how students work with Sim2Bil, which is a digital tool designed for university level engineering studies that include mathematics and kinematics. Two groups of students were offered tasks and animations to make cars fulfill different requirements. They needed to collaboratively understand the distance travelled as an area under a graph.

The theory of instrumental genesis allowed us to investigate students' activities in a technological environment as previous studies have shown. In particular, focusing on particular aspects of the theory such as instrumentation, instrumentalization and technique, we were able to analyse the ways students used Sim2Bil.

In the theory of instrumental genesis, a distinction is made between learning to use a tool, and using the tool for solving tasks. For learning to use the tool, the Start button played a dominant role. By pressing the Start button, students observe how the velocity functions make the graphs appear and the cars run. Thus, students were introduced to the functionalities of the tool and the conditions of the tasks. However, if students weren't told to press Start, it could take long before they discover the dynamic animation. For using a tool for solving tasks, also known as instrumentation, Artigue (2002) distinguishes between two types of techniques, *instrumented* and *paper & pencil* techniques. In tasks 2–4, our students needed pencil and paper for calculating the integral as anti-derivative, and making drawings of areas which they also calculated. Their instrumented techniques consisted of generating cars running and generating graphs. In both groups, the instrumented techniques were always the final activity in each of the tasks 2–4. With this technique, they could check whether the functions they had found met the conditions of the task.

Several techniques were used to solve the tasks. The instrumented techniques in the groups played a role as a check whether solutions are correct. Thus, they had pragmatic value. At the same time, the instrumented techniques had epistemic value because integration can be regarded as anti-derivation, and an area can be regarded as distance travelled. With task 1, our students learned the operations of the animations and the conditions of the tasks within only a few minutes. The Start button was included to get the cars running. This framed the forthcoming tasks. The challenge laid in finding functions for solving the remaining tasks. To overcome these challenges, the students used several techniques as explained above supported by gestures and discussions.

The study has some limitations. Sim2Bil is different from other tools in which students can construct mathematical objects (drag triangles, construct families of parabolas, etc). It is more of a question generator, the animation “explains” the task, and the students can use the animations or the graphs to check their answer. Additionally, the findings of this study may not be generalizable to larger groups of students since we have only observed two groups of students using the digital tool.

# Investigating the discursive shift in the learning of Group Theory: Analysis of some interdiscursive commognitive conflicts

Marios Ioannou

University of the West of England (Alexander College); [mioannou@alexander.ac.cy](mailto:mioannou@alexander.ac.cy)

*This study aims to investigate undergraduate mathematics students' learning experiences in a first course on Group Theory. I have used the Commognitive Theoretical Framework to examine incidences of interdiscursive commognitive conflict that emerge due to incommensurabilities with other areas of mathematics, such as Set Theory. Data is comprised of students' coursework, interviews and other secondary data. Analysis suggests that incidences of incomplete mathematical learning emerge when students need to cope with the notions of set, group, subgroup, and their elements in the same mathematical task. In addition, analysis suggests that students can often successfully produce a technically valid proof, without necessarily having full grasp of the involved concepts, indicating a ritualistic participation in Group Theory discourse.*

*Keywords: Group theory, theory of commognition, discursive shift, commognitive conflict.*

## Background

Unlike other areas of university Mathematics, such as Calculus and Analysis, the learning of Abstract Algebra, and Group Theory in particular, has been investigated to a significantly lesser extent. The first studies focusing on the learning of Group Theory emerged in the early nineties, adopting, mostly, an acquisitionist<sup>1</sup> perspective and within the Piagetian tradition of studying cognitive processes and errors (e.g. Dubinsky et al., 1994; Asiala et al., 1998). Other studies investigated issues such as difficulties students face with the level of abstraction of this particular mathematical subject (Hazzan, 1999), students' reaction to the semantic abbreviation and symbolisation (Nardi, 2000), the importance of visualisation (Ioannou and Nardi, 2010; Zazkis et al., 1996), and novice-students' difficulty with the process of proof (Weber, 2001).

These studies have highlighted the pedagogical challenges that students, as well as educators, face in the learning of this particular course, mostly due to its abstract nature, the often unclear, to the novice students, *raison d'être* of the fundamental concepts, as well as the consequent tension due to historical decontextualisation of these concepts (Nardi, 2000). Leron and Dubinsky (1995, p. 227) suggest that “[t]he teaching of abstract algebra is a disaster, and this remains true almost independently of the quality of the lectures.”

Far more scarce are studies in this particular area that analyse learning from a participationist<sup>2</sup> perspective and in particular through the lenses of Commognitive Theoretical Framework (Nardi et al., 2014). Ioannou (2012), among other issues, investigated the intertwined nature of object-level

---

<sup>1</sup> Acquisitionists consider human development “as proceeding from personal acquisitions to participation in collective activities”. (Sfard, 2008, p.78)

<sup>2</sup> According to participationism, “patterned, collective forms of distinctly human forms of doing are developmentally prior to the activities of the individual.” (Sfard, 2008, p. 78)

and metadiscursive level of mathematical learning in Group Theory, focusing on the *intradiscursive*<sup>3</sup> commognitive conflicts (see Ioannou (2016) as an example) but also on the *interdiscursive* commognitive conflicts, namely in relation to the incommensurability with other areas of mathematics. This study is a ramification of the second category. In particular, the aim of this study is to investigate incidences of commognitive conflict that emerge due to the incommensurability between various mathematical concepts in other mathematical fields towards the learning of Group Theory. For instance the notion of a set, as this has been learned in secondary mathematics education, or in the introductory course of Set Theory, and the newly introduced notion of group, focusing both on these notions as well as their elements.

## Theoretical framework

As mentioned above, Commognitive Theoretical Framework (CTF) by Anna Sfard (2008) adopts a participationist perspective on learning and teaching. This fact sets CTF apart from Behaviourism and Cognitivism, in an ontological, epistemological and methodological level. Unlike the acquisitionist perspective, Commognition considers the object of developmental change to be the human activity and not the individual. Moreover, by using CTF, one should not aim to analyse the students' skills or the mental schemas of the various concepts but the discourse itself, as the principal object of attention. In fact this last characteristic of CTF is what distinguishes it from the other participationist approaches (Sfard, 2008).

Focusing on mathematical discourse in specific, unlike other scientific discourses, objects are discursive constructs and form part of the discourse. Mathematics is an *autopoietic system* of discourse, i.e. "a system that contains the objects of talk along with the talk itself, and that grows incessantly 'from inside' when new objects are added one after another" (Sfard, 2008, p. 129). CTF defines discursive characteristics of mathematics as the **word use** (the mathematical vocabulary, including the keywords that are used, not always exclusively, in schools and academia), **visual mediators** (the visible objects that are used as part of communication), **narratives** (any sequence of utterances that describe objects, relations and process, such as definitions, theorems and proofs), and **routines** (repetitive patterns characteristic of mathematical discourse) with their associated metarules, namely the *how* and the *when* of the routine.

A useful notion of CTF, especially for this particular study, is **commognitive conflict**, which is defined as a "situation that arises when communication occurs across incommensurable<sup>4</sup> discourses" (Sfard, 2008, p. 296). Commognitive conflict is considered "a gate to the new discourse rather than a barrier to communication, both the newcomer and the oldtimers must be genuinely committed to overcoming the hurdle" (Sfard, 2008, p. 282). Therefore, an aim of this study is to identify these

---

<sup>3</sup> These are conflicts that emerge within the particular mathematical discourse, e.g. a conflict that may occur for concepts such as subgroups and normal subgroups (both within the discourse of Group Theory).

<sup>4</sup> Incommensurable discourses are the discourses that differ in their use of words, visual mediators, routines or their rules of substantiation. In addition, they may allow the endorsement of seemingly contradictory narratives, due to the fact that they do not share criteria for deciding whether a given narrative should be endorsed or not. (Sfard, 2008)

situations in the undergraduate mathematics students' attempts to solve problems, which involve the newly introduced notion of group.

Other important notions within the CTF that are important for this study are the **rules of discourse**, namely the object-level and the metalevel rules. **Object-level rules** are defined as “narratives about the regularities in the behaviour of the objects of the discourse” (Sfard, 2008, p. 201). In other words these are rules that are directly related to the definition of the various objects, e.g. group, subgroup, coset, etc. **Metalevel rules** “define patterns in the activity of the discursants trying to produce and substantiate object-level narratives” (Sfard, 2008, p. 201). In other words metarules govern the process of proof of new (to novice students) mathematical results.

Consequently, Sfard (2008, p. 254) describes two distinct categories of learning, namely the object-level and the metalevel learning. Moreover, **object-level learning** “expresses itself in the expansion of the existing discourse attained through extending a vocabulary, constructing new routines, and producing new endorsed narratives; this learning, therefore results in endogenous expansion of the discourse”. In addition, **metalevel learning**, which involves changes in the metalevel rules of the discourse “is usually related to exogenous change in discourse. This change means that some familiar tasks, such as, say, defining a word or identifying geometric figures, will now be done in a different, unfamiliar way and that certain familiar words will change their uses”. In the context of this study, object-level rules could be considered the rules governing the elements of the set  $X$  or the group  $G$ , whereas metalevel rules could refer to the proof that an algebraic structure is indeed a subgroup.

## Methodology

This study is a ramification of a larger research project, which conducted a close examination of Year 2 mathematics students' learning experiences in their first encounter with Abstract Algebra. The module was taught in a research-intensive mathematics department in the United Kingdom, in the spring semester of a recent academic year.

The Abstract Algebra (Group Theory and Ring Theory) module was mandatory for Year 2 mathematics undergraduate students, and a total of 78 students attended it. The module was spread over 10 weeks, with 20 one-hour lectures and three cycles of seminars in weeks 3, 6 and 10 of the semester. The role of the seminars was mainly to support the students with their coursework. There were 4 seminar groups, and the sessions were each facilitated by a seminar leader, a full-time faculty member of the school, and a seminar assistant, who was a doctorate student in the mathematics department. All members of the teaching team were pure mathematicians. The module assessment was predominantly exam-based (80%). In addition, the students had to hand in a threefold piece of coursework (20%) by the end of the semester.

The gathered data included the following: Lecture observation field notes, lecture notes (notes of the lecturer as given on the blackboard), audio-recordings of the 20 lectures, audio-recordings of the 21 seminars, 39 student interviews (13 volunteers who gave 3 interviews each), 15 members of staff's interviews (5 members of staff, namely the lecturer, two seminar leaders and two seminar assistants, who gave 3 interviews each), student coursework, markers' comments on student coursework, and student examination scripts. For the purposes of this study, there have been analysed the staff and student interviews, and the coursework solutions. The interviews, which covered a wide spectrum of themes, were fully transcribed, and analysed with comments regarding the mood, voice tone,

emotions and attitudes, or incidents of laughter, long pauses etc., following the principles of Grounded Theory, and leading to the “Annotated Interview Transcriptions”, where the researcher highlighted certain phrases or even parts of the dialogues that were related to a particular theme. Furthermore, coursework solutions were analysed in detail, after the data collection period, using the CTF, and mostly focusing on issues such as students’ engagement with certain mathematical concepts, the use of mathematical vocabulary and symbolisation, and the application of discursive rules.

Finally, all emerging ethical issues during the data collection and analysis, namely, issues of power, equal opportunities for participation, right to withdraw, procedures of complaint, confidentiality, anonymity, participant consent, sensitive issues in interviews, etc., were addressed accordingly.

## Data analysis

This study focuses on the application of object-level and metalevel rules that govern the mathematical concepts under study, namely, groups, subgroups, sets and their elements, investigating also the emerging commognitive conflicts. A priori analysis suggests that there are two likely commognitive conflicts: the first is related to sets (in school mathematics, sets come with a binary operation, whereas, in university mathematics, sets such as  $X$  in  $Sym(X)$  do not); the second is related to functions (in school mathematics, functions operate on algebraic structures, whereas in Group Theory they play a double role, namely, operating on sets, and being themselves members of a set with a binary operation). Such commognitive conflicts have appeared in five of the thirteen students’ solution of the following task: Suppose  $X$  is a non-empty set and  $G \leq Sym(X)$ . Let  $a \in X$  and  $H = \{g \in G: g(a) = a\}$ . Prove that  $H$  is a subgroup of  $G$ .

Interestingly, students, despite their problematic application of object-level rules of the involved concepts, were often able to apply the involved metarules correctly, and produce a valid proof (e.g. for the claim that  $H$  is a subgroup of  $G$ ). This fact possibly indicates that proving, as assessed in this course, may not always require an explorative participation in the proof process and complete grasp of the involved mathematical notions, but rather can rely on a ritualistic<sup>5</sup> performance of new routines. Moreover, successful application of metalevel rules does not necessarily imply that all the involved mathematical concepts have been fully objectified<sup>6</sup>. Due to limited space, below there will be demonstrated two examples of students’ responses.

The first example of interdiscursive commognitive conflict, as this has been suggested in the a priori analysis above, appears below in the solution of Student A. The student has not grasped the fact that the operation refers to the group  $G$  and not to the set  $X$ . Apparently, he seems to have tried to apply it to  $a \in X$  in an effort to prove inverses. He has not realised that  $X$  is a set and not a group, and therefore there is no defined binary operation on  $X$ .

---

<sup>5</sup> Rituals are defined as “sequences of discursive actions whose primary goal (closing conditions) is neither the production of an endorsed narrative nor a change in objects, but creating and sustaining a bond with other people” (Sfard, 2008, p. 241)

<sup>6</sup> Objectification is defined as the “process in which a noun begins to be used as if it signified an extradiscursive, self-sustained entity (object), independent of human agency” (Sfard, 2008, p. 300).

$a \in X$       let  $g \in G : g(a) = a$   
 So  $a^{-1}$  has no meaning as no operation is defined on  $X$ . The only group we have is  $G$  which is a permutation on  $X$ .  
 $g^{-1}(a) = a^{-1} = a \quad (a \in X)$   
 $g^{-1}g = e$   
 $\Rightarrow (g^{-1}g)(a) = e(a)$   
 $\Rightarrow g^{-1}(g(a)) = a$   
 $\Rightarrow g^{-1}(a) = a$   
 So  $H$  is subgroup of  $G$   
 Why is  $H$  non-empty?  
 ②

**Figure 1: Example of commognitive conflict of Student A**

In Figure 1, one can identify a commognitive conflict that emerged due to the discursive shift from the secondary school mathematical discourse, where all mathematical sets have algebraic structure, and in particular a binary operation with some properties. The notion of a set without an operation is new for these students. Furthermore, it proves to be particularly confusing to deal with this new kind of object in the context of a course on Group Theory, where some structures, namely groups, do have a binary operation, and others do not. In addition, another commognitive conflict is related to changes in acceptable notation. In particular, the notation  $gH$  is possibly confused with  $g(X)$ . This “abuse” of notation, where  $gH$  stands for “the set of all  $gh$  for  $h$  in  $H$ ” may contribute to the confusion. An underlying commognitive conflict is due to the fact that in a university mathematics discourse, abuse of notation is often acceptable where it does not cause mathematical ambiguity. However, notation that is mathematically unambiguous may nevertheless be pedagogically confusing.

The second example, related to the second commognitive conflict of the a priori analysis, appeared in Student B’s attempt to solve the aforementioned mathematical task, as seen in Figure 2. Although her solution demonstrates that she has a structural understanding of the required proof, yet she is still unable to practically do it. She applies accurately the routine for a set to be a subgroup, nevertheless there is an inaccurate application of object-level rules of the concepts of set and group and consequently several inaccuracies in her attempt. The first one is related to the expressions  $g(a_1), g(a_2), \dots$  and  $a_1, a_2, \dots$  where  $a$  is used to signal an element of  $H$ , and which is possibly a result of a deep confusion regarding the elements of the groups,  $G, H$  and  $Sym(X)$  versus the elements of the set  $X$ , as well as the operation of the permutation on a set versus the composition of permutations. This inaccuracy may be considered as a result of a commognitive conflict regarding the notion of function. In the old mathematical discourse functions operate on algebraic objects, which are usually numbers. In Group Theory, functions (such as permutations) play a dual role – they operate on sets as in the old discourse, where often these sets have algebraic structure, but, in addition, they are also themselves objects of an algebraic structure (in this case group), where there is a binary operation (function composition). This dual role contributes to the incommensurability of the discourses.

2i)  $H = \{g \in G : g(a) = a\}$   
 $H$  is non-empty because the identity,  $e$ ,  $\in H$  as  
 ~~$G$  is a subgroup~~  $\cdot g(e) = e$ .  $\text{Sym}(X)$  is a group  
 and  $g(e) = e \Rightarrow e \in H$ .

If  $a_1, a_2 \in H$  not correct use of notation  $g(a_1), g(a_2)$  are elements of set  $X$  and we have no multiplication defined on this set.  
 $g(a_1)g(a_2) = a_1a_2 = g(a_1a_2)$   
 $\Rightarrow a_1a_2 \in H$

So is closed under  $\cdot$ . Also  $H = \{g \in G : g(a) = a\}$   
 So  $H$  is the set of  $g \in G$  such that  $g(a) = a$   
 So if  $a \in H$  then  $a \in X$  must have an inverse say  $a^{-1}$

so  $g(aa^{-1}) = g(e) = e$  and  $e \in H$   
 $\Rightarrow a^{-1} \in H$

again if  $a \in H$   $a \in \text{Sym}(X)$   
 and  $a \notin X$

You have misunderstood the definition of  $H$ .  
 $H$  is a set of permutations on the set  $X$ .

**Figure 2: Example of commognitive conflict of Student B**

Moreover, Student B uses the incorrect expressions  $g(a_1), g(a_2)$ , referring to elements of the set  $X$ , but under operation that is not applicable in  $X$ . She does not have a clear view of what is  $X$  and what is  $H$ , i.e. that  $X$  is a non-empty set and that  $H$  is a subgroup of  $G$  with a certain condition. At some point she also writes  $a \in H$ , which is not true since  $a$  is an element of  $X$ . Student B's incomplete object-level learning is also revealed in the following statement:

I found it quite hard, because... I got a bit confused with this um...  $\text{Sym}(X)$  and stuff, but – so I don't – I started it but then I weren't sure, whether I was doing it right, so I kind of have stopped, and I'm gonna go ask for help. To like – because I – I don't like, if I'm doing something and I'm not sure if it's right, I don't like to carry on because I don't want to do it all wrong.

The Lecturer, with the statement below, reinforces the claim that a number of students had an incomplete object-level learning regarding the elements of groups and sets.

It is interesting, you know you have got a set in the group and somehow separating out in their minds the different roles of the elements of the setting up around and the group which is acting, is something that, you know, somehow they don't have a picture in their mind of – so they – you know writing a string of symbols round like  $g_1g_2(a)$  its – the sort of – the distinction between the elements of the group and the elements of the set is something that is not necessarily clear.

Lecturer's opinion highlights the importance of examining students' object-level learning of the relevant mathematical concepts as well as their efficiency with the process of proof, something that can be investigated using CTF. It also reinforces the claim of unresolved commognitive conflicts as these occur in the discursive shift from the secondary education mathematics discourse to the formalism of Group Theory discourse. In particular, this study is in agreement with the Lecturer about

the fact that in the discourse of Group Theory there coexist structures with and without an operation, a new feature that is particularly confusing for novice students.

Interestingly, Lecturer's view is in agreement with the Seminar Leaders and Assistants', as this has been expressed in their final report on the 78 students' performance, as seen in Figure 3.

Q2(i) - At times a poorly done question. Many people were confused by the definition of  $H$ . The thing to note is that  $X$  and  $Sym(X)$  (the permutations of the set  $X$ ) are two separate entities and elements of one are not elements of the other. So here  $H$  is a subset of  $G \leq Sym(X)$  and in particular  $H$  is the subset of those  $g \in G$  which leave some fixed element  $a$  in  $X$  unmoved. So we are fixing  $a$  and looking for the permutations that do not move  $a$ , not a set of elements of  $X$ . Importantly we have no operations defined on the elements of  $X$  only on the elements of  $G$ , so  $g_1(a) \cdot g_2(a)$  as some wrote is undefined since  $g_1(a)$  and  $g_2(a)$  are elements of  $X$  an arbitrary set.

**Figure 3: Markers' comments on the 78 students' performance**

Similarly, Markers' comments highlight students' difficulty to distinguish the various algebraic structures that coexist in the discourse of Group Theory. Students' confusion is due to the fact that they often cannot distinguish the elements of the set and the elements of the group, but also they cannot always successfully attach the binary operation to the appropriate structure.

## Conclusion

This study's aim was to identify incidents of incomplete mathematical learning in the context of Group Theory, focusing, when possible, on interdiscursive commognitive conflicts, related, in particular with the concepts of set, group and their elements. In agreement with other studies, Group Theory is a demanding subject, both from an object-level (Dubinsky et al. 1994; Nardi, 2000) as well as from a metalevel (Weber, 2001) perspective. The analysis above suggests that a frequent incidence of incomplete mathematical learning emerged during the discursive shift from a set (as students have learned in the secondary education mathematical discourse) to a group (new introduced concept in the discourse of Group Theory) and it also involved their elements. The first example of commognitive conflict emerged when Student A applied object-level rules relevant to the concept of group on set  $X$ , in which there is no defined binary operation. A second example of commognitive conflict, related to the first, was revealed through problematic use of notation, that displayed Student B's unclear view of what is  $X$  and what is  $H$ , i.e. that  $X$  is a non-empty set and that  $H$  is a subgroup of  $G$ . Finally, the analysis above suggests that students may have a structural understanding of the required proof, yet they are still unable to practically do it, indicating a ritualistic participation in the Group Theory discourse.

# Theorising university mathematics teaching: The teaching triad within an activity theory perspective

Barbara Jaworski<sup>1</sup>, Despina Potari<sup>2</sup> and Georgia Petropoulou<sup>2</sup>

<sup>1</sup>Loughborough University, Loughborough, UK; [b.jaworski@lboro.ac.uk](mailto:b.jaworski@lboro.ac.uk)

<sup>2</sup>University of Athens, Athens, Greece; [dpotari@math.uoa.gr](mailto:dpotari@math.uoa.gr), [enaprosena@yahoo.gr](mailto:enaprosena@yahoo.gr)

*We draw on our recent research to inspect again some of the theoretical perspectives we have been using to analyse data and to characterise teaching-learning in university settings. We focus particularly within a sociocultural perspective on Activity Theory (AT) and the construct ‘the Teaching Triad (TT)’, seeking to embed the TT within an AT perspective. To achieve this, we relate the Teaching Triad with aspects of the sociocultural setting both in and beyond direct interactions in face to face teaching. While this is mainly a theoretical paper, an example is taken from observations of teaching in university lectures in a Greek university to show how these theoretical perspectives have provided insights to the institutional and cultural complexities involved.*

*Keywords: University mathematics learning and teaching; teaching triad, activity theory, didactical triangle and tetrahedron.*

## Introduction to University Mathematics Teaching (UMT)

By University Mathematics Teaching (UMT) we refer to any or all the teaching of mathematics which takes place at university level. In our own corpus of work we are particularly interested in face to face teaching in lectures and tutorials in which teachers design their teaching for the benefit of students who attend their sessions. We are interested in uncovering relationships between teaching and learning within the full sociocultural context of university life. This includes the institutional setting as well as the cultures from which teachers and students make sense of the interactions in which they engage. In particular, we seek to know more about “what teachers do and think daily, in class and out, as they perform their teaching work” (Speer, Smith & Horvath, 2010, p. 99). Our research addresses:

What is it that mathematics teachers do and think as they perform their teaching work in a university setting, and how does this relate to the mathematical meaning making of their students? (Jaworski, Mali & Petropoulou, 2016)

This question takes us into the didactical thinking of teachers who consider how best to enable students to think mathematically and develop understandings of mathematical topics; it includes teachers’ pedagogic thinking in the ways in which they interact with students and use resources to promote students’ engagement with mathematics; it includes also the ways in which teachers work within university affordances and constraints, the norms and expectations of university culture and their own educational histories, their views of mathematics and of what it means for students to learn mathematics and so on.

In our work to date we have used a number of theoretical perspectives to analyse data from teacher-student interactions in university mathematics teaching. Largely we have taken a broad sociocultural perspective in which we aim to address both micro and macro aspects of teaching. In

some of our work we have more specifically used Activity Theory to examine relationships and issues in teaching (e.g., Jaworski & Potari, 2009; Jaworski, Robinson, Matthews and Croft, 2012). Within some of this work we have used a theoretical construct, the Teaching Triad to address *micro* aspects of teaching while Activity Theory has addressed *macro* aspects, as we explain below.

In this paper our aim is to zoom in on connections and inter-relationships between these areas of theory as they apply in our research into teaching mathematics at university level. In order to contextualize these theoretical ideas, we include below an example from university lecturing. Since our focus is on the *theories* we are using in relation to the *activity of teaching*, we do not try to analyse the actual meaning-making of the students in our example.

## Introduction to the Teaching Triad (TT)

The Teaching Triad (TT) is a theoretical construct developed from earlier research into the teaching of mathematics at secondary school level. It offers a way of characterizing mathematics teaching by acting as a tool for analyzing teaching data from classroom situations; it has also been used by teachers as a developmental tool (Jaworski, 1994; Potari & Jaworski, 2002). More recently it has been used to characterize mathematics teaching at university level and as an analytical tool at this level (Jaworski, 2002; Jaworski, Mali & Petropoulou, 2016).

Although NOT a triangle, the TT comprises *three* inter-related elements or domains of teaching: Management of Learning (ML); Sensitivity to Students (SS) and Mathematical Challenge (MC). These have been interpreted in terms of the interactions that take place within a classroom setting and, as such, focus on the *micro* aspects of teaching, without overt focus on the broader situational and cultural focuses, the *macro*. Briefly, *Management of Learning* describes the

**Figure 1. The Teaching Triad (Jaworski, 1994).**

teacher's role in the constitution of the classroom learning environment by the teacher and students. It includes classroom groupings; planning of tasks and activity; use of textbooks and other resources, setting of norms and so on. *Sensitivity to Students* describes the teacher's knowledge of students and attention to their needs, affective, cognitive and social; the ways in which the teacher interacts with individuals and guides.

group interactions. *Mathematical Challenge* describes the challenges offered to students to engender mathematical thinking and activity; this includes tasks set, questions posed and emphasis on metacognitive processing. These domains are closely interlinked and interdependent (Jaworski, 1994). Research has shown that a good balance between SS and MC is needed for effective teaching: a lot of SS, but little MC can lead to good teacher-student relations but low mathematical progress; a lot of MC but little SS can result in students feeling stressed or unable to succeed. When challenge and sensitivity are well balanced, the result is "harmony" – students are suitably challenged and stimulated while supported to achieve (Potari & Jaworski, 2002).

The TT is associated with another familiar construct, the Didactic Triangle (DT) which links Teacher (T), Students (S) and Mathematics (M) and draws attention to relationships

Teacher $\leftrightarrow$ Student; Teacher $\leftrightarrow$ Mathematics; Student $\leftrightarrow$ Mathematics and links between these pairs (e.g., Rezat & Strässer, 2012). The TT expands the “Teacher” node of the DT, illuminating the links Teacher $\leftrightarrow$ Student and Teacher $\leftrightarrow$ Mathematics through the constructs SS and MC respectively while extending the DT to the wider classroom context through the construct ML. This wider context includes the resources a teacher uses in mediating between students and mathematics as expressed in the idea of a Didactic Tetrahedron in which there are 4 planes: the original DT linking TSM and the planes linking TSR, TRM and SRM (R=Resources/artifact; see Figure 2).

**Figure 2 . The Didactical Tetrahedron (DTetra) (Rezat & Straesser, 2012)**

**Figure 3. The Expanded Meditational Triangle (EMT) (Engestrom, 1999)**

### Embedding the TT into the sociocultural perspective

In this paper we re-examine the TT as a construct used within a sociocultural perspective and particularly its relationships to and within an Activity Theory analysis of teaching data. As a backdrop to AT we take Vygotskian perspectives involving particularly mediation, tool use, scientific concepts and the zone of proximal development (ZPD). Briefly, we see teaching as a process of mediation between teacher, students and mathematics (relationships are expressed simply in the DT and expanded in the TT). Teaching can be seen as mediating between student and mathematics: this is not a simplistic relationship but one with several dimensions which the TT serves to accentuate. The resources that a teacher brings to teaching (examples include mathematical symbolism, dynamic software, display media) are tools used in the teaching process; tools to facilitate learning (indicated by the extension of the DT to the DTetra). Scientific concepts are those distinguished by Vygotsky as involving theoretical learning in contrast with spontaneous concepts which arise from empirical learning (examples are mathematical concepts which need to be introduced by someone – they are not naturally occurring in everyday interactions). Daniels (2008, p. 314) cites Hedegaard (1998, p. 120) to suggest that “the teacher guides the learning activity both from the perspective of general concepts and from the perspective of engaging students in ‘situated’ problems that are meaningful in relation to their developmental stage and life situations”. These words capture importantly the basic ideas of ML and SS in the TT of which we say more below. Daniels emphasizes the important relationship between the idea of scientific concepts and the ZPD as involving a teacher in bringing general theoretical knowledge to her interactions with students, while engaging students in concrete tasks from which scientific concepts can be abstracted. This suggests important relationships between a teacher’s didactics and pedagogy – expressed simply, the former involving the transformation of mathematical concepts into tasks and activity for students and the latter involving the organization of the social setting to enable students’ engagement with mathematics (together these form the basis of ML in the TT). Within the

ZPD, student engagement with a teacher's theoretical input can achieve better learning outcomes than would be achievable by a student's engagement with empirical tasks alone.

The concepts expressed extremely briefly above fit with the sociocultural perspective of A. N. Leont'ev, who makes the following point "in a society, humans do not simply find external conditions to which they must adapt their activity. Rather these social conditions bear with them the motives and goals of their activity, its means and modes." (A. N. Leont'ev, 1979, pp. 47-48). Here we focus particularly on Leont'ev's three layers of human action which constitute *Activity*. The outer, or top layer is labelled 'Activity' which according to Leont'ev (1979) is *always motivated*, although the motive might not be explicit. Within Activity, the second layer consists of the 'actions' of humans engaging in Activity. *Actions* are *goal-directed*, such that the goals are always explicit or conscious. In the third layer, actions include 'operations', which depend on the 'conditions' within which actions take place. In earlier research we have used Leont'ev's layers to explain issues and tensions which have emerged from analyses between teachers' and students' perspectives on mathematics teaching and learning (Jaworski & Potari, 2009; Jaworski, Robinson, Matthews and Croft, 2012).

If we think of the *Activity* of a university teacher teaching mathematics, within a university setting, subject to all the sociocultural forces within which the Activity takes place, we might think of the *motive* of this activity to be the mathematical learning of students participating within the complexities of this setting. *Actions* here are the *teaching actions* which take place as the teacher engages in the teaching process in relation to the mathematics which is the focus of teaching. Such actions are *goal* directed and relate to ways in which the teacher thinks about her teaching and acts in relation to her students. Thus, teacher intentions and theoretical perspectives form *goals*, and didactical and pedagogic processes form *actions* in this activity setting. The *operations* within this role, with which the teacher engages, are closely related to the practicalities of the role; for example, setting exams, creating VLE pages, assessing students' work. These operations must take place within the affordances and constraints of the university system which impose *conditions* on the operations.

Another model which is used very commonly to represent an Activity System, is the *Expanded Mediation Triangle* (EMT) from Engeström (e.g. 1998). This developed originally from Vygotsky's (simple) mediational triangle (the top part of the EMT) linking a subject with the object of her activity via the resources (tools, artefacts) employed in mediation. Engeström recognized the important mediational functions of other aspects of the sociocultural setting, such as 'rules', 'community' and 'division of labour' which expanded the roles of tools/artefacts, and which he added overtly in the EMT (see Figure 3). The 'rules' include university procedures and constraints, community includes both student and academic communities, and division of labour recognizes differences between student and teacher roles within the academic setting.

### **Example: Teaching in a lecture course in calculus with first year undergraduates**

This example comes from the study of university lectures in first year calculus teaching in a four-year mathematics programme in the mathematics department of a Greek University (see Petropoulou, Jaworski, Potari & Zachariades, 2015). The lecturer is an established mathematician,

with extensive teaching experience, who is very popular among the students in this department. The teaching takes place in an amphitheatre with more than 200 students. The course is compulsory and its focus is theoretical with an emphasis on proofs; in this example, the mathematical focus is the convergence of series. The approach is new for the students who have previously experienced calculus in high school as a set of methods and computations. Students' expressed opinions and the very low success rate in the course examination suggest that this course is experienced as one of the most difficult during the four year programme. A large number of students take more than four years to complete their studies (the average time is 6.5 years) and some of the students have part time jobs in order to support their studies financially.

The lecturer is aware of these sociocultural issues and takes them into account in his teaching, as our analyses show. For example, he says, "I do know that students get lost in their first year and that most find mathematics too difficult...if you don't *pay attention as a teacher*, the average duration of their studies could easily become 7 or 8 years". (In analysis we see here SS in cognitive, affective and social dimensions as we explain below).

The lecturer's teaching appears rather traditional as he is seen mostly standing at the front of the room, writing at the board, "telling" or "explaining" the mathematics with rare interaction with students. Nevertheless, we see many elements of sensitivity, taking into account students' learning needs. By scrutinizing his teaching actions and goals, we see that his main teaching *goal* is to make the content relevant to students, with associated *actions* providing comprehensive explanations, highlighting subtle points that cause students' difficulties, linking informal and formal representations, making connections with students' prior school experiences, emphasizing the importance of the specific content in mathematics, in the course exams and in other courses.

At the beginning of this episode the lecturer reminds students that they know they can add a finite number of terms of a sequence i.e. they know that the sum of a finite number of terms always exists. He points out that a central question is whether the sum of an infinite number of terms exists.

He establishes the importance of this question by saying that this is exactly what we mean when we say that if it exists then the series converges. He also highlights that the "big difference here" is that the number of terms is infinite. By relating the convergence of the series to the existence of a sum, he attempts to help students to make sense of the meaning of convergence (which may still be difficult however). This can also offer a mathematical challenge that is possibly not appropriate for the students to respond to at this stage. It acts more as a situated problem for introducing the relevant theorems about the convergence of a series.

He sympathizes with the students, through a personal story about a teacher he had at school for whom the convergence was of great importance. We might say that this story supports their comfort zone, offering affective sensitivity. He then formalizes a basic proposition related to the necessary

condition for a series to converge: "If a series  $\sum_{k=1}^{\infty} a_k$  converges, then the sequence  $a_k \rightarrow 0$ ".

Here we see SS-cognitive in alternative expressions of the meaning of convergence, helping students to make sense of the concept of series convergence. We categorise the personal story as SS-affective/social, encouraging students in the lecture to have rapport with the lecturer and feel empathy with his approach to teaching them. These are pedagogic strategies which enable the

lecturer to proceed to a more formal didactic stage in his explanation in which he acknowledges a problem they might find in a text book on the topic. “The books write ‘consider the sequence  $S_{n-1}$ ’. But what is the sequence  $S_{n-1}$  if  $n=1$ ? Is it  $S_0$ ?  $S_0$  is not defined! Ok?”. His solution to this problem is to introduce a second sequence  $t_n$ : “Now, I define a second sequence  $t_n$  as follows – I am going to write down for you the terms of this sequence. First, I set something... let’s say  $t_1$ , to be equal to 0. Then I set the 2nd term of  $t_n$  to be equal to  $S_1$ , the 3rd to  $S_2$ ... Ok? ... the 4th to  $S_3$  etc. Namely I set  $t_1$  to be 0 - you can set everything you want. So let  $t_n$  be  $S_{n-1}$ , if  $n \geq 2$ .” He concludes this proof and then he offers a second proof based on the formal  $\varepsilon$ - $\delta$  definition. He compares the two ways by characterising the first way of proving ‘the quick way’ and the second  $\varepsilon$ - $\delta$  proof ‘the slow way’. He provides all the details in both of these proofs highlighting the problem solving strategies that are usually used in proofs about series such as for example the use of partial sums.

These steps challenge students to engage with the mathematics of series in a more formal way. Perhaps this MC is scaffolded by the sensitivity observed in the earlier considerations. We see again the lecturer’s drawing of students into his confidence in encouraging them to be critical of the text book, and in involving them in his reasoning for introducing the new sequence. We might see these careful steps on the part of the lecturer as his sensitivity in “paying attention as a teacher to his students’ potential difficulties”.

The lecturer subsequently takes the opportunity to remind students of the harmonic series  $\sum_{k=1}^{\infty} \frac{1}{k}$  the sequence of which tends to 0 but the series itself does not converge, and he uses this to justify that the inverse of the above proposition does not hold. He draws students’ attention to the usefulness of this example in the forthcoming exams.

Further actions include providing resources and materials to students for their individual studying especially for those students who cannot attend the lectures, the structuring of the content, the teaching tools (board, supportive resources) and the traditional communication norms. In the analysis, Mathematical Challenge (MC) is often difficult to distinguish, appearing to be integrated into the SS. It is usually addressed through problem solving heuristics that are presented by him in explaining general mathematical strategies in specific cases of problems and theorems (e.g., the use of partial sums for proving the convergence of series) and by emphasizing metacognitive processes (e.g., comparing different solution strategies).

By referring to the EMT, we identify some links to the TT. SS is related to the lecturer’s attention to the students’ community (e.g., offering supportive resources for the students who do not attend the lectures, the delay for completing their studies). ML is related to the lecturer’s attention to the university community (e.g., the tools that the lecturer uses and develops, the institutional rules such as examinations, large cohorts of students,) On the other hand MC is related to the community of mathematicians and to the mathematical practices that the lecturer brings into the classroom.

## Discussion

In this example, the Activity is the sociocultural setting of teaching and learning. Seeing the teacher as *subject* (in the EMT) with the *object* of enabling students to make sense of the mathematical topic, mediators are the various artefacts/resources (such as the lecturer’s board writing; his provision of on-line resources) as well as the cultures of students or teachers (student community).

academic community), differing roles of students and teachers (division of labour), and the expectations of university lectures/tutorials and the four-year programme (rules). In Leont'ev's terms the Activity is the whole, the lecturing, with the motive of enabling the students to learn basic concepts and theorems of calculus by taking into account their learning needs. We see actions and goals particularly in the activity of the lecturer: what he does to achieve the main goal of making the content relevant to the students, such as explaining mathematics at the board to ensure that students are provided with clear accounts of mathematical concepts with which they can work further, providing on-line resources to help students who must work to support their studies.

The Teaching Triad cuts across the Activity Theory frameworks to interrogate the activity of teaching. It captures the teacher's actions as related to mathematics and to the students (MC and SS). Through ML, we see the teacher's use of artefacts: tasks and resources, pedagogic strategies to include and engage students, orchestration of the environment to facilitate learning. MC can be seen in the ways the teacher presents or provides access to mathematics, linking with what the students know and with what they are expected to do in the course exams.

SS links the affective, cognitive and social elements of student engagement, rationalizing conventions and norms within the constraints and affordances of the institution. The triad presents a framework in which we see all the aspects of Activity through its three dimensions.

Elaborating further the elements of the TT discussed above, we see a close link between SS and ML in the teaching of this lecturer. SS has a strong social dimension apparent inside and outside the amphitheatre. For example, we see his concerns for providing clear explanations without interaction with the students as the institutional context and the affective constraints do not allow it. He says, "In an audience of 200 students, if you discuss with 2–3 of them, these probably will be the strongest students and the others will feel bad. ... And finally nothing will remain on the board". He also takes into account students who cannot attend the lectures for various reasons (e.g., participating in social associations; socializing after the hard entry examinations; or having to get a job for financial reasons) by providing supportive online resources and materials. The lecturer teaches within the sociocultural setting described above. He engages with mathematics and with students: the fundamental relationships expressed in the DT. He uses a range of resources with which to engage students as expressed in the DTetra. The TT enables us to inspect these relationships in more depth, addressing the ways in which the lecturer engages the students and provides for their needs. We come to see that despite an approach that seems transmissive, he is nevertheless sensitive in social, affective and cognitive ways to what students need in order to make sense of the mathematics he offers. These needs relate strongly to elements of the sociocultural context in which the activity takes place including the number of students, the financial provision for their studies, and their struggles with mathematical formalism. We see lecturer's goals and actions, through which he demonstrates challenge and sensitivity, to relate fundamentally to his recognition of these contextual demands. While the AT frames (EMT and Leont'ev's layers) characterize teaching activity in its relation to context, the TT zooms in on the goals and actions to specify qualities of sensitivity and challenge and their management within the given context.

*The importance of studying structuralist praxeologies has been highlighted by Hausberger (2016). In this communication, we illustrate it on the case of ideals in Ring Theory. We provide a detailed study of a proof extracted from a textbook in Abstract Algebra showing that structuralist praxeologies involve interplay between intertwined algebraic, set-theoretic and logical praxeologies, revealing a hidden complexity.*

*Keywords: Mathematical structuralism, structuralist praxeologies, ideals in Ring Theory, logic.*

## Introduction

Hausberger (2016), with the introduction of the notion of *structuralist praxeology*, underlined the importance of *praxeological analysis* in the didactical study of phenomena related to the teaching and learning of Abstract Algebra at University level. His work is based on an epistemological investigation of algebraic structuralism that showed that mathematical practice in Abstract Algebra may be interpreted as an application of the *axiomatic method*, structures being used as tools by mathematicians in order to prove statements on objects. In the Anthropological Theory of the Didactics (Bosch & Gascon, 2014), a method is a *set of techniques*. In fact, ATD poses the general model that every human activity may be described by quadruples  $[T, \tau, \theta, \Theta]$ , called *praxeologies*, which correspond to the organisations it sets up: these combine a praxis (a type of tasks  $T$  and a set of techniques  $\tau$ ) with a logos that include two levels of description and justification of the praxis: the technology  $\theta$  and the theory  $\Theta$ . Hausberger (2016) made the assumption that clarifying the *structuralist techniques* may illuminate practices in Abstract Algebra, make their rationale more visible and ground them as a coherent whole. Hausberger (2016) described common tasks and techniques in the arithmetic of abstract rings and studied the structuralist praxeologies developed by students on a mathematical forum online. By contrast, the empirical data presented here is an extract of the solution of an exercise on Noetherian rings proposed by teachers in a textbook. The central mathematical notion at stake is the notion of *ideal*. By a detailed study of this example, we will develop the argument that structuralist praxeologies involve interplays between algebraic, set-theoretic and logical praxeologies, thus revealing a hidden complexity.

## Structuralist praxeologies as intertwined algebraic, set-theoretic and logical ones

### The notion of structuralist praxeology

Structuralist techniques are the by-products of the complete rewriting of classical algebra operated by Noether's school in the 1920s (Hausberger, 2013 & 2016). They are based on the now standard structuralist constructs: sub-structures, homomorphisms, isomorphism theorems, products or sums of structures, quotients, etc. Hausberger (2016) stressed that common tasks in Abstract Algebra may often be solved using elementary techniques. Whenever its logos block contains a theorem on structures, the praxeology may be called structuralist. Nevertheless, a gradation of its structuralist

dimension (loc. cit.) may be observed. In fact, structuralist praxeologies reflect the concrete-abstract and particular-general dialectics that are at stake in Abstract Algebra: tasks involving concrete and particular objects are completed by using abstract and general considerations on structures. Examples will be given in the sequel. The particularity of structuralist praxeologies that will be investigated in this article is that they often involve sub-praxeologies of algebraic, set-theoretic or logical type.

### Algebraic and set-theoretic praxeologies

Noether qualified her own work of “set-theoretic foundation for algebra” (Hausberger, 2013), following Dedekind. On an epistemological point of view, it is characterised by the transition from thinking about operations on elements to thinking in terms of selected subsets and homomorphisms. The distinguished subsets are the kernels of homomorphisms, hence the normal subgroups in Group Theory and the ideals in Ring Theory. Noether uncovered the importance of the chain condition on ideals that led to the definition of Noetherian rings (see below). In other words, set-theoretic operations on ideals are connected to algebraic properties on elements. We will present below this connection by means of a “dictionary”. It explains the intertwining of algebraic praxeologies (on the level of elements) and set-theoretic praxeologies (on the level of structures), but it leads also to the use of logical praxeologies, notably for the descent from the ideals toward the elements at stake.

### Logical praxeologies

Many tasks in Abstract Algebra involve proof and proving, thus logical praxeologies. Durand-Guerrier (2008) has enlightened that the natural deduction developed by Copi (1954) provides a powerful tool to analyse and check mathematical proofs. In particular, it allows identifying those steps where mathematical arguments are silenced, supporting the claim that mathematics and logic are closely intertwined in proof. We will rely on Copi’s natural deduction to describe logical praxeologies likely to appear in proof and proving: elimination and introduction of implication, universal quantifiers and existential quantifiers, restriction of the domain of quantification. The theory is the First order logic (Predicate calculus) and the technologies are logical theorems (i.e. statements true for every interpretation in any non-empty domain). In Copi’s natural deduction, one deals with a generic non-empty universe, and some aspects need pragmatic control in order to ensure validity, as we will see below. The following table details common logical praxeologies that can be involved in a proof and hence in the study of structuralist praxeologies.

We provide triplets (type of tasks, technique, technology):

index	Type of tasks	Technique	Technology	Example of use
L1	Elimination of an implication	Asserting the antecedent – asserting the consequent	$[(P \Rightarrow Q) \wedge P] \Rightarrow Q$	Deduction based on a conditional theorem
L2	Introduction of implication	Recognizing that $Q$ has been proved under the hypothesis $P$ , and assert “ $P \Rightarrow Q$ ”	$\neg(P \wedge \neg Q) \Leftrightarrow (P \Rightarrow Q)$	Conclusion of the proof of a conditional statement
L3	Elimination of a universal quantifier	Deleting the quantifier, introducing of a generic element of the universe, assigning this element to every occurrence of the variable in the open statement.	$[\forall x (F(x))] \Rightarrow F(y)$	Using a universal statement in a proof by generic element.
L4	Introduction of a universal	Given a true statement involving a generic element of a domain $U$ ,	No logical theorem. Need to control that the	Conclusion of proof by generic element.

	quantifier	assert the corresponding universal statement	element is actually a generic element of $U$ (no other assumption on this element has been done)	
L5	Introduction of an existential statement	Given an element of the universe $U$ satisfying an open sentence, assert that the corresponding existential statement is true.	$F(y) \Rightarrow \exists x F(x)$	Conclusion of the proof of an existential statement.
L6	Elimination of an existential statement	Given a true existential statement, introduce an element satisfying the corresponding open sentence.	No logical theorem. Need to control that the name of the element has not been used prior in the proof	Using an AE statement (“For all, Exists”) in a proof.
L7	Restriction of the domain of quantification	Given a universal statement true in a domain $A$ , assert it on a subdomain $B$ of $A$ .	$[(\forall x (A(x) \Rightarrow F(x)) \wedge (\forall x (B(x) \Rightarrow A(x))) \Rightarrow [(\forall x (B(x) \Rightarrow F(x))]$	Fitting the statement with the antecedent of a conditional statement
L8	Transformation of a statement preserving its truth value	Substitute an equivalent statement to a given statement	In the case of implication: $[(\forall x (P(x) \Rightarrow R(x)) \wedge (\forall x (Q(x) \Leftrightarrow R(x))) \Rightarrow [(\forall x (P(x) \Rightarrow Q(x))]$	Using the dictionary of properties elements/structures (cf. table 2)

Figure 1: List of a priori logical praxeologies according to Copi

## The case of ideals in Ring Theory

### The notion of ideal and its ecology

An *ideal*  $I$  of a ring  $(A, +, \cdot)$  is, by definition, a subset of  $A$  with these properties: (i)  $I$  is a subgroup of the additive group  $(A, +)$ ; (ii) if  $a \in A$  and  $x \in I$ , then  $a \cdot x \in I$ . As part of her Master’s degree dissertation, the first author conducted an epistemological and didactic study of the concept of ideal in order to explore the ecology, including the *habitats* and *niche* (Artaud, 1997) of this concept in French university education. This epistemological study started with the creation of ideal numbers by Kumer in 1847 and it enhanced the rise towards abstraction leading in the 1920s through the work of Noether to the concept we use today (Jovignot, to appear). As far as the ecology of the concept of ideal is concerned, the epistemological study allowed the identification of the following *a priori* main *habitats*: general Ring Theory (quotient rings and isomorphism theorems), arithmetic of abstract rings and elimination theory. Bearing on those results, Jovignot developed an analytical framework to identify *habitats* and *niches* of the notion of ideal in algebra textbooks addressed to undergraduates and Master’s students. A first study of 3 textbooks has led to improve this grid, that was then applied to a sample of 7 French textbooks that were considered as representative of the ecology of the concept of ideal and of its use in the different post-secondary institutions in which this concept is taught in France. This study confirmed general Ring Theory and arithmetic of abstract rings as major *habitats* of the concept of ideal, but it also allowed the exhibition of *habitats* that had not been previously identified, such as the theory of modules and algebraic geometry, which suggests the importance of leading a complementary study in contemporary epistemology. Finally, elimination theory appeared, in our sample, only in the specialized computer algebra manual.

## Ideals and structuralist praxeologies in the arithmetic of abstract rings

Arithmetic of abstract rings as a mathematical domain is characterized by a mathematical structure in “Russian dolls”: it involves Euclidean, principal ideal domains (PID) and unique factorization domains (UFD), which generalize properties of the ring of integers, and mathematical theorems that state inclusions from the former class to the latter. Common tasks consist in proving that a given ring, for instance Gauss’s ring of integers  $\mathbb{Z}[i]$ , belongs to a class or the other. More abstract tasks, such as the one that will be analyzed below, involve making new connections between such classes. The central notion is the notion of ideal. In fact, the class may be defined directly by a property on ideals (such as PIDs) or by properties on elements (such as UFDs) which may be related to properties of ideals by means of the following “dictionary” which was already mentioned above. This dictionary will be useful to understand used praxeologies in the task studied below.

index	Conditions of validity	Level of elements	Level of structures
D1		$a$ divides $b$	$(a)$ contains $(b)$
D2		$a$ and $b$ are associates	$(a) = (b)$
D3	$p \neq 0$	$p$ is a prime element	$(p)$ is a prime ideal
D4	$A$ is a principal ideal domain	$p$ is irreducible in $A$	$(p)$ is a maximal ideal of $A$
D5	$A$ is a unique factorisation domain	$d$ is a $gcd$ of $a$ and $b$	$(d) = (a) + (b)$

### The task under study

In the next section, we will present the praxeological analysis of an exercise involving the concept of ideal which is extracted from a book addressed to Master’s degree students preparing the French *Agrégation*<sup>1</sup>: Francinou, S. & Gianella, H. (1994). This book is widely used by university students in France. The authors sampled classical exercises in Algebra and provided proofs. In the chosen exercise, students are requested to establish a connection between Noetherian integral domains endowed with an extra property and PIDs. We clarify that this praxeological analysis is not a tool for teaching but could help us later for the design of experimentation with students.

The exercise is the following (our translation):

Let  $A$  be a Noetherian integral domain. We assume that every maximal ideal of  $A$  is principal.

- 1) Show that  $A$  is a unique factorization domain.
- 2) Show that every non-zero prime ideal is maximal, principal and of the form  $(p)$  where  $p$  is irreducible.
- 3) Show that  $A$  is a principal ideal domain. (loc. cit. p.57)

We will restrict our study to question 1. The authors introduce the following classical criteria, in which  $E$  designates the property of existence of a factorization and  $U$  the property of unicity:

$A$  is a UFD if and only if:

- a) every increasing chain  $(a_1) < (a_2) < (a_3) < \dots$  of principal ideals is stationary (equivalent to  $E$ )
- b) every irreducible element is prime (equivalent to  $U$ )

<sup>1</sup> Competitive exam for prospective teachers for secondary and tertiary education

The proof provided by the authors is the following (our translation from French):

Since  $A$  is Noetherian,  $A$  satisfies (E). To establish that  $A$  is a unique factorization domain, it suffices to prove that if  $p$  is irreducible, the ideal  $(p)$  is prime. Let us consider a maximal ideal  $M$  containing  $(p)$ . By hypothesis  $M$  is principal generated by  $a$ . Thus  $a$  divides  $p$ . Since  $a$  is not a unit (because  $M \neq A$ ),  $p$  and  $a$  are associates and  $(p) = M$  is maximal. In particular  $(p)$  is prime.

## Praxeological analysis of the task

### Supplementing the proof

Reading the proof of the authors, it appears that a lot of steps remain implicit. In order to be able to study the full set of praxeologies involved in the proof, either explicit or implicit, we have supplemented it. We consider that the proof is complete when all the statements are obtained by natural deduction from previously established results or standard theorems in Abstract Algebra. We do not examine in detail in this paper the question of which of these supplements should be taught, but we will provide hypothesis that will be studied in further steps of this research. The steps of the proof presented in the textbook are numbered, our supplements appear in italic and are designated by letters whenever several steps are involved. The supplemented proof reads as follows:

1. Since  $A$  is noetherian,  $A$  satisfies (E).
  - a. Indeed,  $A$  is Noetherian so every increasing chain of ideals is stationary by definition.*
  - b. In particular, every increasing chain of principal ideals is stationary.*
  - c. So, thanks to the criteria,  $A$  satisfies (E).*
2. To establish that  $A$  is a UFD it suffices to prove that if  $p$  is irreducible, the ideal  $(p)$  is prime.
  - a. Indeed, we need to show that every irreducible element is prime (criteria, b)*
  - b. And “ $p$  is prime” is equivalent to “ $(p)$  is prime”*
  - c. In fact, we will show that  $(p)$  is maximal. It is enough since every maximal ideal is prime in a ring.*
3. Let  $p$  be an irreducible element of  $A$  and  $M$  a maximal ideal containing  $(p)$ .
  - a. If there aren't any irreducible elements, we are done. In fact, irreducible elements exist since  $A$  is Noetherian, except if  $A$  is a field.*
  - b.  $p$  is not a unit, so  $(p)$  is proper and  $M$  exists according to Krull's theorem.*
4. By hypothesis  $M$  is principal. Let  $a$  be a generator of  $M$ .
5. Thus  $a$  divides  $p$ .
  - a. Indeed,  $(p)$  is included in  $M$  and  $M = (a)$ , so  $(p)$  is included in  $(a)$ .*
  - b. And  $(p)$  is included in  $(a)$  if and only if  $a$  divides  $p$ .*
6. Since  $a$  is not a unit (because  $M \neq A$ ),  $p$  and  $a$  are associates - *indeed,  $a|p$  so there exists  $b$  in  $A$  such that  $p=ab$ ; moreover,  $p$  is irreducible so, since  $a$  is not a unit,  $b$  must be a unit and  $p$  and  $a$  are associates -*
7. and  $(p) = M$  is maximal *since two principal ideals are equal if and only if their generators are associates.*
8. In particular  $(p)$  is prime.

### Praxeological analysis

We present the praxeological analysis as a tabular; in the column labelled “steps”, we are indicating in which steps of the proof the studied praxeology appears. Only tasks, techniques and technologies are mentioned; the theory in the sense of ATD is Ring Theory. We note S structuralist praxeologies and A algebraic ones.

steps	Type of task	Technique	Technology
1 – 8 (S1)	Show that a ring is UFD	Use of the criteria	Equivalence between the criteria and the definition of a UFD
1	L7		
2	L8		
2 b – 8 (S2)	Show that an element $p$ is prime	Associate to $p$ the ideal $(p)$ and show that $(p)$ is prime	The dictionary of properties elements/structures (D3)
2 c – 8 (S3)	Show that an ideal is prime	Try to show that the ideal is maximal	Every maximal ideal is prime
2 c	L1		
3 - 7 (S4)	Show that an ideal $I$ is maximal	Take a maximal ideal $M$ containing $I$ and show that $M=I$	Krull's theorem
3 a	L6 (making explicit the two existential statements permitting the introduction of $p$ and $M$ )		
4 - 7 (S5)	Show that two principal ideals are equal	Show that two generators of those ideals are associates	The dictionary of properties elements/structures (D2)
5 (S6)	Show that $a$ divides $b$	Show that $(a)$ contains $(b)$	The dictionary of properties elements/structures (D1)
6 (A1)	Show that two elements $a$ and $b$ are associates	Show that $a$ divides $b$ ; it is enough to conclude whenever $b$ is irreducible and $a$ is not a unit	Definition of units, irreducible elements and associates; $a$ and $b$ are associates if and only if $a \mid b$ and $b \mid a$

**Figure 3: praxeological analysis of the task**

### Conclusions of our analysis

This praxeological study allows us to highlight significant characteristics of the praxeologies used by the authors that we summarize below.

The dictionary elements/structure is used along the proof; indeed the proof involves relationships between properties of elements of the ring (being an irreducible or a prime element) and properties of subsets (being a principal, maximal or prime ideal). Moreover, the algebraic notion of generator and the dictionary of properties elements/structures allow the replacement of common set-theoretic praxeologies (such as proving an equality of two sets by double inclusion) by more powerful algebraic praxeologies (involving A1). This cultural shift that is characteristic of structuralist algebra may be pointed out as a potential obstacle (previous praxeologies hindering the use of the new praxeologies to be acquired).

The structuralist praxeology S1 decomposes into several sub-praxeologies S2-S6, A1, L1, L7, L8. In the authors' proof, only structuralist steps of the proof are given; the steps involving algebraic and logical praxeologies are nearly systematically hidden. We may hypothesize that these authors see structuralist steps as the architecture of the proof and expect students to be able to reconstruct the missing elements by themselves. On the contrary, we will argue in favour of setting out the non-structuralist praxeologies and elaborate on their role in connection with structuralist praxeologies.

The nearly systematic omission of logical praxeologies raises the following issues and comments. First of all, the proof deals with generic objects, which is due to the level of generality of the statement of the exercise. It is already explicit in the statement itself, therefore both rules of elimination (L3) and introduction (L4) of a universal quantifier on the ring are not needed. In the sequel, the ideal  $M$  is introduced (step 3) without justification of its existence (Krull's theorem). The introduction of the generator of  $M$  is allusive and could be misinterpreted, letting think that this element has already been introduced. In both cases, the elimination of the existential quantifier (L6) remains implicit, letting thus implicit the statements themselves. The generic element  $p$  that plays a central role in the proof is not introduced, while it is a delicate step. Indeed, a classical way to prove a conditional statement by generic element is to introduce an element satisfying the antecedent, under the implicit assumption that such element exist; indeed, if not, there is nothing to prove (step 3.a). In addition, letting silent the restriction of the quantification domain (L7, step 1) hides the fact that this rule does not apply for existential statements, which might not be clear for some students. Finally, the substitution rule (L8) is a key for using the dictionary elements/structure by substituting a property of elements for a property of structure and vice-versa.

Giving such a proof requires the availability of the praxeologies cited above and a suitable understanding of their interrelations, or enough experience on the structuralist methodology in order to apply these praxeologies *en acte*. We hypothesise that the textbook's proof does not permit the appropriation of the structuralist praxeologies at stake. A didactical strategy to reach this goal may include, for instance, a "meta-discourse" on the crucial role of the dictionary elements/structure, together with making explicit the logical praxeologies whose role has been underlined above.

The particular construction of the proof (related to the decomposition of S1 into S2-S6-A1) can be understood by analysing the interplay between the blocks of the praxis and that of the logos of the different praxeologies engaged in the proof. However, the technological elements are seldom present in the proof written by the authors. For example, the properties of the dictionary are used but barely cited. Even if the students own in their praxeological equipment those technologies, the proof doesn't offer them the opportunity to identify those technologies in the context of the proof and thus build the associated structuralist praxeologies in order to be able to use them by themselves in another proof situation.

## General conclusion and perspectives

Our praxeological analysis has highlighted the complexity of the chosen exercise. This complexity comes, in particular, from the decomposition of structuralist praxeologies into several structuralist sub-praxeologies and their interrelation with logical and algebraic praxeologies. These are fundamental in order to make the structuralist technologies practically operative. A sketchy proof which restricts to the structuralist steps, although it is seen as a clear and synthetic account by mathematicians, may therefore appear quite inadequate for self-learning by students who are not familiar with the structuralist methodology. In other words, our study contributes to break the "illusion of transparency" behind proofs that may be found in Abstract Algebra textbooks.

We aim to record and analyse the work of students who attempt to reconstruct the proof as we did, or to write a proof from scratch. In this forthcoming empirical study, our praxeological analysis will serve as an *a priori* analysis. It may also be used as a starting point in order to prepare clues for the

students and other types of didactical intervention, as well as to lead semi-structured interviews. Moreover, we intend to interview the authors of the book in order to get insights in their goals and motivations for the choices they made when writing down the proof. More generally, it is expected from these praxeological analyses, conducted on a larger scale, a deeper understanding of structuralist praxeologies with a view to setting up didactic engineerings dedicated to the teaching of structuralist concepts and in particular the ideal concept.

# University students' understandings of concept relations and preferred representations of continuity and differentiability

Kristina Juter

Kristianstad University, Sweden; [kristina.juter@hkr.se](mailto:kristina.juter@hkr.se)

*The aim of the study reported in this paper is to investigate how students understand continuity and differentiability during and after a calculus course. The students' choices of representations, both claimed and acted, were also studied. The study is part of a larger study of four student groups taking a calculus course. 207 students answered a questionnaire during the course and of them, 11 were interviewed after the course (the ones in this paper). Answers in questionnaires and interviews were categorised and compared. All students who preferred formal theoretical representations, and only those students, were able to produce formal proofs. The students' stated and acted preferences of representations were quite coherent, with only a few inconsistencies.*

*Keywords: Calculus, continuity, differentiability, understanding, representations.*

## Introduction

Learning means adaption of, building on and sometimes rejection of prior knowledge. Calculus at university level comprises numerous new things to learn for many students and the actual learning may take place a while after the teaching occasion or even the examination. Differentiability and continuity, the topics studied in this paper, are closely linked to limits that have been proven difficult to learn (e.g. Juter, 2005, 2012; Tall & Vinner, 1981). Nagle (2013) concludes, in her overview of research on transitions to formal limit conceptions, that there is a consensus in the results about the students' insufficiently developed concept images that do not allow them to formally understand limits. The transition requires students to go from a dynamic, discrete way of perceiving limits as processes to a static, continuous viewpoint where limits are regarded as formal objects. Nagle suggests an alternative introduction to calculus where more time is spent on informal conceptions to ease the transition to a formal definition. Raman (2002) found that students learning calculus do not seem to develop abilities to coordinate formal and informal aspects of mathematics unprompted, due to too little experience of such activities. It is therefore important to learn more about how students use formal and informal representations, deliberately or not, when they study mathematics. Exams also influence students' studying strategies. Bergqvist (2007) found that a vast majority of tasks from 16 university exams in introductory calculus from four different universities in Sweden only required imitative reasoning skills to pass. Mathematics learning is then endangered to become reduced to remembering routines rather than understanding concepts, processes and relationships, since students' strategies for learning are influenced by exams. The study in this paper further investigates formal and informal representations used by students to argue for relational properties of continuity and differentiability during a calculus course, and how they have developed after the course. The students' exams were divided in two, where the first part was a written routine problem solving exam and the second an oral exam where definitions and proofs were assessed. The students' preferred types of representations were also investigated and compared to their used types of representations and understandings to further explain how the students' use of formal and

informal representations compare to their learning processes. The research questions addressed in the paper are:

- How do students' relational understandings of continuity and differentiability during a calculus course compare to their understandings after the course?
- How do students' claimed preferences of representations match their actual use of representations?
- How do students' understandings and preferences of representations, spoken and acted, correlate?

## **Theoretical frame and some prior results**

Students' understandings of mathematical concepts are reflected in their solutions, reasoning and other actions as traces (Juter, 2005) of their concept images, i.e. the total cognitive representation of a concept that an individual has in his or her mind (Tall & Vinner, 1981). Tall and Vinner define a person's concept definition for a concept as the words or symbols used to define the concept. Understanding a concept and being able to solve tasks involving the concept may be regarded as synonyms for some students, particularly if being able to solve tasks through imitative reasoning is enough to pass exams. The two ways of dealing with mathematics can however be distinguished according to their core features. Hiebert and Lefevre (1986) defined conceptual knowledge (p. 3) as a web of pieces of information well linked together with meaningful connections. Relations between concepts are abundant and significant. They defined procedural knowledge (p. 6) as knowledge requiring an input which the learner recognises and is able to perform a linear procedure on to obtain an outcome. No relational understanding is required for the process to be carried through. Strong and valid connections between concepts, i.e. conceptual knowledge, help learners to understand more as new information is embedded in, and supported by, their existing knowledge (Hiebert & Carpenter, 1992). Rich connections between concepts also reduce the burden of remembering pieces of knowledge and makes transfer within the concept image easier. Students are often unaware of the quality of links between concepts in their concept images, particularly if irrelevant or untrue links are mixed with true ones (Juter, 2011). A large number of links enables students to explain what they think determines a concept or a relationship between concepts. This can give a false sense of understanding if the links are incorrect, which in turn may lead to a situation where the student is unaware of any need for further work with the concept.

Connections between different representations of the same concept, as well as connections between different concepts, are important to create strong concept images. A function can for example be represented in different ways algebraically, by a graph, or in words. Santi (2011) addressed the issue of students understanding different representations of the same mathematical phenomenon or concept, e.g. tangents. He compared the limit process of a derivative in calculus with a cognitive perspective to a more embodied Euclidean approach of the tangent touching the curve in one point. Some students showed difficulties in seeing those representations as the same object. In a study of university students learning limits of functions (Juter, 2005), another example of incoherence in representations of a concept was apparent. Several students interpreted the formal theory as stating that limits are unattainable for functions, but when limits were used in problems they could see that sometimes functions could attain limit values (e.g. linear functions). When both these perceptions

were evoked simultaneously, the students became confused. Students meet different definitions and representations, depending on the context, e.g. intuitive descriptions, informal definitions and formal definitions (Jayakody & Zazkis, 2015). Jayakody and Zazkis presented two definitions of continuity based on limit definitions used at university courses. They concluded that students should investigate different definitions and their consequences to better understand the purpose of them. When investigating a function for continuity, the results may differ depending on definition choice, particularly if the definitions are learned intuitively rather than formally. An intuitive representation is here regarded as a perceived self-evident mental representation of a concept or phenomenon, as described by Dreyfus and Eisenberg (1982). An intuitive representation often lacks the benefits of formal strictness that can be useful in particular situations, e.g. determining if a function is continuous in a neighborhood of a given point. Developing conceptual knowledge may be difficult based mainly on intuitive perceptions. In the example with attainability of limits (Juter, 2005) some students misinterpreted the strict inequalities in the formal definition to mean that the function never can attain the limit value. The intuitive interpretation of that part of the definition overthrew the formal definition leaving the students with an incoherent concept image. Intuitive representations and other informal representations work as support for learning in many cases, but sometimes they are obstacles, particularly in a procedural learning approach where there are few opportunities to understand relations from deductive reasoning. In this study students formal and informal (including intuitive) representations of continuity and differentiability are studied and compared to the students' stated and acted preferences of representation forms.

## **The study, methods and sample**

The 11 students focused on in this study were part of a larger study of 207 students enrolled in their first calculus course at university level. The course was not given in one particular program, so the students were from different disciplines, such as physics or mathematics. Their understandings of continuity and differentiability, and proving strategies of statements regarding the concepts, were examined (for prior results see Juter, 2012). The students were from four different groups taking the same course (different semesters). The duration of the course was 10 weeks and included basic calculus with limits, continuity, derivatives, integrals, differential equations and Taylor's formula. The students wrote an individual exam with focus on problem solving, mainly with calculations, at the end of the course and if they passed, they took an individual oral exam covering the theory of the course a couple of days later. The students answered a questionnaire when they had covered continuity and derivatives in the course. The 207 students in the study were all answering the questionnaire, which was more than 90% of the students attending the lectures. They filled it out after a lecture and had as much time as they wanted (they used up to about 30 minutes). The aim was to learn more about the students' understandings of the concepts and the relation between them, but also how they expressed their responses, e.g. formally or informally. The questions were for those reasons openly formulated. The first five questions were about what features continuous functions and differentiable functions have and what the concepts are used for. The questions relevant for the part reported here followed and they are:

1. Are all continuous functions differentiable? Justify your answer.
2. Are all differentiable functions continuous? Justify your answer.

The aim with these two questions was to see what types of representations the students would select to argue for their hypotheses. Before the data collection, they had seen examples and proofs that would enable them to answer both questions even though they were differently formulated than in the course. After the course, 11 of the students were individually interviewed. The students volunteered by indications in their questionnaires and were selected from their questionnaire answers to exemplify conceptual understanding, procedural understanding, formal use of theory and informal use of theory. The selected students are described after Figure 1. Each interview lasted about 30-45 minutes and was audio recorded. The questions were about the questions from the questionnaire and the students' answers to them, proving, examination forms and attitudes to mathematics. They were particularly asked if they agreed to their former statements in the questionnaire or not. The analysis of the interviews were tightly connected to the questionnaires and the students' development from them. Representation forms as well as mathematical content were analyzed and categorized.

## Results and discussion

Figure 1 shows the students' answers to the two questions in the questionnaire (Q), if they agree or disagree (correctly or incorrectly) to those answers at the interview (I) after the course, and if the students managed to prove their statement in the second question (if so, in the questionnaire, Q, or the interview, I).

<i>Stud.</i>	<i>Continuous implies diff. Q</i>	<i>Diff. implies continuous Q</i>	<i>Agrees (I) correctly/incorrectly</i>	<i>Disagrees (I) correctly/incorrectly</i>	<i>Proves formally, Q or I</i>
Jonas	No, $ x $	Yes, small change in $x$ causes a small change in $y$	Correctly but he wants something added about intervals		Yes, I
Jack	No, $ x $	Yes, no actual reason	Correctly explaining why $ x $ is not differentiable		Yes, I
Jim	No, not $ x $ and endpoints of $[a,b]$	Yes, differentiability is a stronger feature than continuity	Correctly		Yes, I
John	No, $ x $	Yes, correct formal proof using the definitions of continuity and derivative	Correctly		Yes, Q
Felicia	No, $ x $	Yes, same left and right limit, slope independent of chosen point in the neighbourhood of the point	Correctly agrees with first question and explains why $ x $ is not differentiable	Correctly clarifies her answer to the second question. Thinks it was messily formulated	No
Fred	No, $ x $	Yes, no reason	Correctly (some confusion)		No
Fay	Yes, no jumps in a neighbourhood of an undefined point so same limits form left and right	No, a function may be differentiable on an interval, but not in the actual jump		Correctly but a bit vaguely justified in a formal attempt	No
Clara	No, only if defined for all points in an interval	No, no reason	Incorrectly		No

Carly	Yes, since they always have a slope	Answers that continuous implies differentiable again	Incorrectly on the first question, not really addressing the second	No
Celia	No, $ x $	Yes, no actual reason	Agrees but adds error: In $(0, 0)$ is $ x $ not continuous	No
Carl	No, at peaks there are many different tangents. States that continuous implies diff. in another question	No, not a stair function	Correctly agrees on the first question	Correctly disagrees to his statement that continuous implies differentiable but unable to clarify the second question

**Figure 1: Students' understandings of continuity and differentiability from questionnaires during the course (Q) and interviews after the course (I)**

The students in Figure 1 are categorized in three groups, separated by different first letters in their fictitious names, depending on their responses to the two questions in the questionnaire and the interviews. In the first group (all names start with J), the four students correctly answered the questions in the questionnaires and interviews and came up with correct formal proofs. All four students used  $|x|$  as a counter example to show a continuous non-differentiable function in the questionnaires. Three of the four students (all but John) did not prove their answers to the second question in the questionnaires, but they were all able to do so in the interview. Jim did at first not think he was able to prove his statement in the interview, but when he got started he was able to take it deductively step by step through knowledge about the concepts revealing a conceptual (Hiebert & Lefevre, 1986) approach to mathematics in this area. Jack had a similar task to prove at his oral exam and showed confidence in procedurally proving it in the interview, even though he was unable to prove it during the course in the questionnaire. In the second group, with three students, all names start with F. The students either answered correctly at the questionnaire and agreed with their answers in the interview (Fred and Felicia) or answered wrongly at the questionnaire and then disagreed in the interview (Fay). Felicia and Fred both used  $|x|$  as a counter example the same way the students in the first group did. The students in the second group could show some confusion or small mistakes, but they answered correctly in a large sense after the course. The students did not produce any proof of the second question, but Fay made an attempt to do so when she was asked to try. She was however unable to see it through after she had written the definition for continuity where  $x$  tends to  $a$  and the definition for derivative where  $h$  tends to 0. It would probably work better for her if she had used a definition of derivative where  $x$  tends to  $a$  so she could combine the definitions easier; the lack of such flexibility could be due to her concept definitions. Comparisons of various definitions, as suggested by Jayakody and Zazkis (2015), could have helped her adjust her concept definitions to work together. She also thought that a limit is not an exact value, which can lead to problems understanding that a tangent in a point is unique if it exists, as Santi (2011) found. The third group comprises four students, all names starting with a C. These students were unable to correctly answer and/or justify their answers in the interviews. Carl and Carly both stated that continuous functions are differentiable in the questionnaire (Carl wrote it as an answer to another question where he was asked what features continuous functions have, so he gave two opposing answers in the questionnaire since he answered 'no' to question 1 above) and

Carly kept that opinion in the interview whereas Carl changed to a correct standpoint. He was however not able to correctly answer the second question. Carly thought that all continuous functions have a specific slope in all points and are hence differentiable. In the interview she thought that all differentiable functions are continuous in an open interval since the tangent does not fall over the edge at the endpoints. Carly had an intuitive (Dreyfus & Eisenberg, 1982), non-formal, way of explaining her thoughts as this example indicates. Celia got the answers correct but added erroneous explanations that did not seem founded in any conceptual knowledge, e.g.  $|x|$  is not continuous at  $(0, 0)$ .

There were various kinds of confusion in all groups, but in the first group it was only Jonas who lacked something about intervals in his own reasoning in the questionnaire, and this was sorted out in the interview. The other two groups showed more serious errors and confusion as described. The clarity in representation varied in the students' responses to questions in the study and the students used different types of representations to argue for their hypotheses. Figure 2 show the students' preferred representation styles as they described it and as they acted when answering the questionnaire (Q) and in the interviews (I). The category called "F theory" means students using formally expressed definitions and theorems. "Pictures" is a category for students using diagrams or other figures to explain. "Words" is a category for descriptions in words, including theoretical (but not formally theoretical), and informal (including intuitive) descriptions. The categories "F theory" and "Words" complement each other in the sense that formal representations are in the first category and informal representations in the second. The categories can be combined, e.g. "Theory" and "Words" in John's description where he formally stated a proof of the second question using formal definitions of derivative and continuity and explained the definition of continuity using words and not formal theoretical notation. John specifically stated that he did not use pictures ever, Clara stated that she read the formal theoretical parts, but did not use that way to express herself and Celia described her learning intentions to be shallow with no focus on formal theory. The categories for these three students are specified according to this in Figure 2. These are only narrow timespans to look at the students' mathematics representations so they may of course vary from what is reported here.

<i>Students</i>	<i>Says to prefer in interview</i>	<i>Preferences in action</i>
Jonas	F theory	F theory I, Words Q
Jack	F theory	F theory I, Words Q
Jim	F theory	F theory I, Words Q
John	F theory, Not pictures	F theory I, Q, Words I
Felicia	Pictures	Pictures I, Words Q
Fred	F theory	Pictures I, Q, Words Q
Fay	Pictures	Words I, Q, Pictures Q, F theory I
Clara	Reads F theory	Words I, Q
Carly	Pictures	Pictures I, Words Q
Celia	Not F theory	Words I, Q
Carl	Pictures	Pictures I, Q

**Figure 2: Students' outspoken and acted preferences of representation forms in interview (I) and questionnaire (Q)**

There is a rather good correlation between what representations the students said they preferred and what they used in this study. Fred's statements and actions were most apart as he said that he preferred formal theory, but showed no traces of it. Instead he used pictures and words as did Felicia and Fay in the same group. Only students in the second and third groups, i.e. students with names not starting with a J, stated that they preferred to use pictures in their reasoning. The tendency was also apparent in their actions. Carly, who was very visual in her explanations, preferred representations as pictures. Her mathematical development was not conceptually strong as her representations were vague and erroneous. Fay also preferred pictures, but she turned to formal representations when she was urged to try to conduct a proof (as afore described). Male students had a stronger focus on formal theory throughout, but this is a small sample so it may be a coincidence. All four students in the first group (names starting with J) said to prefer formal theoretical representations and correspondingly used formal theory. John even emphasized that he did not use pictures, which he also did not do in this study. No other student than these four both said to prefer formal representations and used formal representations in justifying claims. The four students were the only ones who could prove that differentiable functions are continuous (Figure 1). Three of them were unable to prove it in the questionnaire (or did not do it for other reasons) even though they had just covered the topic in the course, but managed to prove it in the interviews. One reason may be that many students learned the theory after the course for the oral exam since the theory was examined then. If so, they did not use much of the theory in problem solving or in making sense of mathematics during the course.

Celia stands out from the other students in Figure 2, as she showed traces of a concept image with quite weak connections. She was aware of the weaknesses since it was her strategy to learn mathematics shallowly and she kept on learning that way on purpose. Her stated approach to mathematics was procedural and she had no attempt to learn anything conceptually. This was also very clear in her responses in the interview and the questionnaire (see Figure 1). Celia had a representation of  $|x|$  not being differentiable, but she did not know why. She had an intuitive sense of how it should be and kept that standpoint even though she had no means available in her concept image to justify or explain it. When she tried to explain she came to the wrong conclusion that  $|x|$  is not continuous at  $(0, 0)$ .

## Conclusions

The changes in students' understandings of continuity and differentiability from the time right after they have learned the concepts (Q) to after the exams (I) were mainly correct adjustments. Some added errors occurred but the main type of changes were improvements of the concept images. It appears as if the students' conceptual understanding and use of theory had matured and small mistakes could be clarified deductively after the course. Students with more serious misunderstandings or insubstantial learning strategies during the course did however not show evidence of understanding the concepts better after the course (e.g. Clara and Carly). Most students' descriptions of what types of representations they used agreed with their actual usages in the data sample. A clear result is that all students in the first group claimed to prefer formal theoretical representations, all used them and all (and only they) were able to correctly prove the statement in the second question. The results of this study imply that further development of conceptual understanding after the learning situation may depend on students' preferred representation style.

Formal representations seem to be most useful for developing conceptual understanding of the concepts.

# Engineering mathematics between competence and calculation

Birgit Griesse<sup>1</sup> and Michael Kallweit<sup>2</sup>

<sup>1</sup>Paderborn University, Germany, [birgit.griesse@math.upb.de](mailto:birgit.griesse@math.upb.de)

<sup>2</sup>Ruhr-Universität Bochum, Germany, [michael.kallweit@rub.de](mailto:michael.kallweit@rub.de)

*This study continues our previous research about the relationship between learning behavior and examination outcome in first-year engineering courses. So far, our findings have stressed the importance of making (continuous) effort and processing the weekly assignments (Griesse, 2016; Griesse & Kallweit, 2016), but learning behavior related to understanding was found to have little relevance. In this paper, we examine a consequent cohort of 458 students, and investigate the relationships between examination outcomes and deep learning strategies. This approach is better suited to assess competence rather than calculation routines, in accordance with the SEFI (Société Européenne pour la Formation des Ingénieurs) curriculum (Alpers, 2016). To reach this goal, variations of traditional exercises are planned to be gradually introduced in a mathematics lecture (and the appertaining assignments) for engineering first-years.*

*Keywords: Engineering, mathematics, curriculum, competence, assessment.*

## Introduction

There is a general awareness of “the struggle students endure in Service Mathematics courses” (Liston & O’Donoghue, 2009, p. 10), and of an orientation of future engineering education towards competencies (<http://www.teaching-learning.eu>; Alpers, 2011, 2016), following analogous developments in secondary education. This, however, is not intended to mean less skill in the handling of symbols, formulae, and operations, as the deficiencies in this area are often lamented. Rather, the notion is to keep “higher-level learning goals” (Alpers, 2011, p. 107) in mind: thinking, reasoning and modeling mathematically, posing and solving mathematical problems, as well as communicating in, with, and about mathematics (Alpers, 2011, p. 103f.), while not neglecting the traditional skills. This change must necessarily involve reforms in teaching and assessment (Entwistle & Entwistle, 1992), albeit gentle ones. Our research prepares the ground for a planned development study in this area.

## Theoretical background and research approach

When introducing curricular innovations, it is advisable to investigate the initial situation as thoroughly as possible, so that changes can be researched adequately. This applies to the current state of teaching and assessment in engineering mathematics, as well as to predictors of success or failure. For mathematics majors, Rach (2014, p. 219) identified, among others, mathematical competence and school qualifications as predicting as much as 38% of academic success (in terms of passing a first-year module in calculus), whereas other researchers (Eley & Meyer, 2004) focus on aspects of the learning process (e.g. “systematic and principled use of examples”, p. 449). The role of affective factors was investigated in depth by others (e.g. Andrà, Magnano, & Morselli, 2011; Liston & O’Donoghue, 2009), stressing the importance of enjoyment of mathematics, the individual’s mathematical self-concept, beliefs, and motivation. Personality, or more specifically, interest in mathematics, is also an important factor (Alcock, Attridge, Kenny, & Inglis, 2014; Liebendörfer & Hochmuth, 2013). When aiming at competence-oriented learning of mathematics for first year

engineering students, their specificities and level of understanding is worth investigating (Entwistle & Entwistle, 1992; Khiat, 2010), and should be supported not only by an appropriate choice of tasks, but also by innovations in both teaching and assessment, such as “small group activity, a variety of forms of questioning, an assessed group project” (Jaworski & Matthews, 2011, p. 178) or journal writing (Glogger, Schwonke, Holzäpfel, Nückles, & Renkl, 2012).

We are interested in what learning behavior is promoted for first-year engineering students, who are confronted less with proofs, but who have to deal with formal notations and who are expected to draw the connection between abstract theorems and calculation routines when aiming to succeed (see also Griesse & Kallweit, 2016). Findings could also shed a light on how much conceptual understanding is required in service mathematics. We phrase our research objectives as follows:

RQ1: How do specific teaching practices relate to student learning behavior in first-year engineering mathematics courses?

RQ2: What clusters of students indicating specific learning behavior can be identified?

RQ3: What are the relationships between student learning behavior and academic success?

## Methodology

### Questionnaire

For our current survey we opted for items covering learning behavior under six aspects: weekly assignments (a1 to a8, 8 items), lectures (l1 to l5), tutorials (t1 to t4), deep learning (d1 to d8), surface learning (s1 to s4), and effort (e1, e2). The items were taken from Wild and Schiefele (1994), Himmelbauer (2009) as well as from Trautwein, Lüdtke, Schnyder, and Niggli (2006), via Rach (2014), and were slightly reworded to distinctly refer to mathematics. All items were rated on a 4-point Likert scales with extreme points (1) *not true* and (4) *true*. The survey was conducted three weeks before the end of the first semester. So, students had had ample experience (> 12 weeks) with academic work, had overcome the Christmas break, and the written examinations were looming. The mathematics lecture for students of civil, mechanical, and environmental engineering was addressed in the academic year 2015/2016, as well as the more advanced one for students of electric engineering and IT security, yielding a total of 458 data sets, complementing the 508 from our previous study (Griesse & Kallweit, 2016).

### Data analysis

In order to explore the structure of the questionnaire, we employed descriptive statistics, conducted explorative factor analysis (principal component analysis with orthogonal, i.e. varimax rotation) and calculated Cronbach's  $\alpha$  for internal reliability.

Then, k-means cluster analysis was employed to identify different learner types who might show different patterns of academic success. Here, standardization of scale scores proved helpful for the characterization of the clusters. The average examination scores of the clusters were calculated.

Multiple linear regression was chosen to explore the influence of the different categories of learning behavior on academic success. For each participant, the items of one scale were combined by determining their means. These were used as predictors to calculate their influence on the outcome variable, *academic success*, represented by assessment points. Predictors were entered into or

removed from the linear model by means of the forward, backward and stepwise methods. Constants, coefficients  $b$ , their standards errors, standardized coefficients  $\beta$ , their significance values,  $R^2$  and  $\Delta R^2$  were calculated. Missing data was eliminated pairwise in all analyses.

## Results

### Sample description

Out of the 458 students having answered our questions, 382 (83.41%) are enrolled in an engineering course (the rest gave no answer or were attending other courses). 74.61% of these are male, although the percentage varies over the different engineering courses (from only 49.35% males in civil engineering up to 90.23% males in machine engineering). The average age is 20.75 years ( $SD=3.30$  years, median = 20 years), which means that the vast majority enrolled at Ruhr University almost directly after leaving school. About one quarter (25.57%) have a mother tongue different from German. About two thirds (67.42%) gained their general qualification for university entrance at a grammar school (German *Gymnasium*), and 70.05% attended an advanced course in mathematics when at school. 69.02% went to the preparation course offered by our university. Considering that 37.31% of the students state they got no more than average marks in mathematics at school, there may be a notable share of students facing problems with tertiary mathematics.

The sample of 262 data sets from students of machine, civil, and environmental engineering (who attended the same mathematics lecture) was chosen as it fit the sample from the previous year. 192 data sets could initially be matched via their individual codes to results from the written examination, and a further ten were matched by completing exactly one blank (out of the five defining a code). In order to avoid wrong matchings, this was only done in unambiguous cases. The resulting 202 data sets were then used for further explorations (meaning 60 questionnaires were eliminated for the purpose of research question three).

### Exploration of items and factor structure

Some items showed prominent descriptive values. The items with the highest scores are  $I_1$  and  $t_1$  ( $M_{I_1}=3.69$ ,  $SD_{I_1}=0.75$ ,  $M_{t_1}=3.58$ ,  $SD_{t_1}=0.85$ ) which cover regular attendance of lectures respectively tutorials. Item  $I_4$  (see below) scored lowest, followed by  $t_3$  ( $M_{t_3}=1.94$ ,  $SD_{t_3}=0.86$ , *I prepare for the math tutorials*).

The results of the explorations of the factor structure are presented here, complementing the outcomes from the year before, see Table 1. In summary, in 2014/2015, the theoretically implied six factors were identified with only one slight renaming of *effort* into *continuous effort*, but the internal reliability was compromised in three of the six scales (Cronbach's  $\alpha < 0.6$ ): *surface learning*, *deep learning*, and *tutorials*. This was acceptable only because the factors relevant for academic success, *weekly assignments*, and *continuous effort*, had  $\alpha > 0.7$ . The explorations for the new data from 2015/2016 finally resulted in the same six scales as before (with a root mean square residual of 0.07). The similarities between the two years are notable, and as before, the total variance explained sums up to 48%.

Factor	Items 14/15	$\alpha$ in 14/15	Items 15/16	$\alpha$ in 15/16
Weekly assignments	a1, a2, a4, a5, a6, a7, a8	0.75	a1, a2, a5, a6, a7, a8	0.74
Continuous effort	e1, e2, d4, d7, d8, t3, l5	0.72	e1, e2, d4, d7, d8, t3, l5	0.63
Lectures	l1, l2, l3	0.72	l1, l2, l3	0.48
Surface learning	s1, s2, s3, s4	0.57	s1, s2, s3, s4	0.59
Deep learning	d1, d2, d3, d5, d6	0.56	d1, d2, d3, d5, d6, a4	0.61
Tutorials	t2, t4, a3	0.53	t1, t2, t4, a3	0.61

**Table 1: Factors and their internal reliabilities, data from two years**

Item a4 (*I only hand in the solutions of weekly assignments that I authored myself*) has changed its loading from *weekly assignments* to *deep learning*, and indeed it can be understood both ways, as a strategy for handling the weekly assignments, and as a deep learning strategy. The factor *continuous effort* shows only an acceptable internal reliability which does not improve when items are deleted or added. Item l4 (*During or after the mathematics lecture I ask questions if something is unclear to me*) again showed its inadequacy and was not entered into further calculations, so this item (with  $M_{l4}=1.80$ , which is the lowest value observed, and  $SD_{l4}=0.91$ ) is not expedient. Item t1 (*I regularly attend math tutorials*), which was eliminated in 2014/2015 due to unilateral scores, now loads (in compliance with its conception) on *tutorials*, without worsening the internal reliability. The scale *lectures* has lost its cohesion due to the fact that it contains both the lowest and the highest scoring item (l4 and l1). The scoring may be connected to some changes in teaching style, thus addressing RQ1. Mostly, the internal reliabilities of the scales are within the range of acceptability or better (apart from *lectures* with  $\alpha = 0.48$ ) and allow the use of five out of the six factors for further investigations.

Scale	A	E	L	S	D	T	# Students	Average assessment points
Cluster 1	0.55	0.54	0.21	-0.46	0.55	0.53	64	84.52
Cluster 2	-0.63	-0.62	-0.25	0.52	-0.63	-0.61	56	50.84

**Table 2: Cluster analysis (k-means) for two clusters, standardized score values**

Concerning RQ2, the data fitted best into two clusters, whose average standardized scale scores are presented in Table 2. The students in the first cluster show superior learning behavior under all the six aspects represented by the factors; they even employ less *surface* and more *deep learning* techniques (as pointed out by the pattern of algebraic signs), which consequently correlates to a higher number of achievement points in the written examination.

The scales (named with capital letters) show varying average scores, indicating the relevance students assign to them. *Lectures* (L), *tutorials* (T), and *weekly assignments* (A) score highest ( $M_L=3.55$ ,  $M_T=3.43$ ,  $M_A=3.26$ ,  $SD_L=0.57$ ,  $SD_T=0.54$ ,  $SD_A=0.52$ ), while *deep learning* (D), *continuous effort* (E), and *surface learning* (S) score medium ( $M_D=2.87$ ,  $M_E=2.82$ ,  $M_S=2.31$ ,  $SD_D=0.48$ ,  $SD_E=0.43$ ,  $SD_S=0.60$ ).

Predictor	b	SE for b	$\beta$	Sig.
(Constant)	-33.10	30.50		0.280
Weekly assignments	17.18	5.88	0.27**	0.004
Continuous effort	-3.43	7.02	-0.04	0.626
Lectures	5.27	5.25	0.08	0.318
Surface learning	-12.71	4.57	-0.24**	0.006
Deep learning	2.97	6.55	0.04	0.651
Tutorials	17.06	5.65	0.27**	0.003

$R^2=.38$ , \*\*\* for  $p<0.001$ , \*\* for  $p<0.01$ , \* for  $p<0.05$

**Table 3: Regression model with six predictors and outcome variable academic success**

For answering RQ3, concerning the relationship between learning behavior and examination outcomes, linear modelling was employed. The correlations between the resulting six factors were limited to 0.45, allowing this method. The purpose of a linear model is to identify the factors (predictors) connected to an outcome variable (*academic success*, measured in achievement points in the written examination), as well as the direction (via the algebraic signs of  $b$  and  $\beta$ ) and the strength of their influence (via the absolute value of the standardized  $\beta$ ). In linear regression, the aim is to predict values of an outcome variable via a linear model of one or more predictor variables. Correlation between the predictor and the outcome variables is a condition for linear regression, but must not be interpreted as causality without further information. It can (but need not) mean causality in both directions (or even a common cause for both observations). Linear regression, however, has the advantage of distinguishing between predictors and outcome. It also provides estimates for the significance and the strength of the influence of each predictor on the outcome variable.

Predictor	b	SE for b	$\beta$	Sig.
(Constant)	-35.40	26.94		0.192
Weekly assignments	16.54	5.61	0.26**	0.004
Surface learning	-9.81	4.35	-0.18*	0.026
Deep learning	6.10	5.78	0.08	0.293
Tutorials	16.65	5.12	0.27**	0.001

$R^2=.38$ , \*\*\* for  $p<0.001$ , \*\* for  $p<0.01$ , \* for  $p<0.05$

**Table 4: Regression model with four predictors and outcome variable academic success**

In our case, the direction of the influence (learning behavior on examination performance) is unsuspicious, even though we are aware of the fact that other variables (e.g. general intelligence, education before university) influence performance, too. As a first step, all six factors were entered into a linear model, resulting in the parameters presented in Table 3, showing the importance of *weekly assignments*, *tutorials*, and of avoiding of *surface learning* techniques.

The forward, backward, and stepwise methods for entering predictors into the model, respectively removing them, were employed, resulting in the four-predictor model shown in Table 4, which additionally comprises *deep learning* strategies (which, though not significant, increases the  $R^2$  considerably from 25%), and explains 33% of the variance of *academic success*. The algebraic signs of the (significant)  $\beta$  values indicate the direction of the supposed impact of the predictors on the outcome variable: The more students engage in working on their *weekly assignments*, the more they actively partake in the *tutorials*, and the less they employ *surface learning* behavior, the more successful they are in the written examination.

## Summary and discussion

The highest average scale scores were found for *lectures* and *tutorials*, thus pointing out their central role in university teaching (in spite of new digital tools for distance learning). Again, the item on asking questions during or after lectures scores consistently lowest and loads unsystematically. Obviously, hardly any students dare to ask questions in the huge lecture hall comprising more than 800 seats. This item need not be used again in comparable courses. There is no scale with a mean score below 2.3 (all average scale scores are medium or high), which can be understood as an indication for the fact that our questionnaire covers only the learning behavior students report to engage in regularly; it may also be understood as a weakness of the questionnaire, as learning behavior *not* engaged in might also provide interesting revelations.

Some parameters of the new sample indicate a more competent cohort (e.g. the smaller share of students with a weaker educational background), although other findings show hardly any difference (e.g. gender, mother tongue  $\neq$  German). The high scores for the items from the *lectures* scale are striking, it now has a distinctly higher average score ( $M_L=3.55$  in 2015/2016;  $M_L=2.35$  in 2014/2015) and has gained the top position, hinting that the students from this cohort attended the lectures more often and engaged in preparations or follow-up work more regularly. One reason for this may be a very different teaching approach in 2015/2016, which (among other features) involved the upload of script with gaps *before* lectures, as contrasted to uploads of complete scripts *after* lectures in 2014/2015. This distinct difference impacts on learning behavior and addresses RQ1.

Regarding RQ2, in the cluster analysis, two opposing groups of almost equal size emerge: one showing sensible, continuous, and diligent learning behavior (and consequently attaining more assessment points); the other is characterized by superficial and irregular learning or procrastination (and less points). It is remarkable, though, that their standardized scores for *lectures* are more similar than the scores from the other scales, which (apart from the fact that it reveals the weakness of this scale) allows the interpretation that the engagement in *lectures* is a less distinctive feature than other learning behavior. Considering how irregular the items from this scale score over the years, and the personality factors involved, this scale will probably stay problematic in future.

Concerning RQ3, the linear modeling stresses the relevance of working with the *weekly assignments* (as in the previous year) and attending *tutorials*. Again, *lectures* play no quantitatively relevant role, despite the high average score assigned to them now; but for reasons pointed out above this scale must be interpreted with care. The fact that *surface learning* techniques have a significant (and negative) impact in the final model is remarkable in view of the task types engineering students face in their first year. This may be hinting at an already changed assessment focus, but that would have

to be supported by a detailed and comparative analysis of the tasks from several years. *Deep learning* techniques were kept in the model as a complement and because they increase the explained total variance, although it can be argued that their contribution is weak and not significant. In contrast to other findings, (*continuous*) *effort* now does not contribute relevantly to explaining academic success, which is another indication of a change in assessment. On the whole, the more recent model paints a clearer picture of what is relevant or not in order to succeed in the examination than in the year before, when multiple choice tasks were involved.

## Outlook on further research perspectives

The results form the basis for further research in which the tasks from the weekly assignments and the exercises in the written examination are examined more closely with the goal to gradually change them towards more competence-orientation, according to the suggestions by Alpers (2016). This would involve, for example, finding, describing, and correcting different types of mistakes in the calculation of an inverse matrix, instead of doing the calculation itself. The results gained from the explorations presented in this and a previous paper (Griese & Kallweit, 2016) will then supply the background against which the expected changes can be compared.

*Arguments have been made that one purpose of learning mathematics successfully is for students to develop mathematical identities. Thus, since students are frequently evaluated with grades in university mathematics courses, a relevant question is how mathematical identities are associated with average grades. This study has measured engineering students' mathematical identities and compared these measures with grades in university mathematics courses, and a Welch's ANOVA conclude that the mean average grade amongst students with high mathematical identities is significant, and about one grade higher than students with low mathematical identities. Moreover, the variance is greater amongst students with low mathematical identities, which indicates a strong association between mathematical identity and average grade only when mathematical identities are high.*

*Keywords: Mathematical identity, Rasch, ANOVA.*

## Introduction

The transfer of mathematical knowledge from university to the world of work seems problematic. Specifically, evidence has been provided that “attainment” in university mathematics courses is poorly transferred. One example is an experiment that illustrated how 17 students and researchers all failed a mathematics examination they had previously passed, even the students who had recently passed the original exam with an “A” (Rystad, 1993). Moreover, selected studies illustrate how the mathematics is often hidden in “black-boxes” (e.g. Williams & Wake, 2007) in the world of work, and consequently, arguments have been made that the world of work seeks more general mathematical characteristics than what is typically assessed in standard exams (e.g. Hoyles, Wolf, Molyneux-Hodgson, & Kent, 2002). On a general note of education, Wenger (1998) argued that learning is about developing identities in communities of practice. In general, over the last decades, there has been an increased attention towards the construct of identity, and mathematical identity in particular (e.g. Axelsson, 2009; Black et al., 2010; Wenger, 1998). Thus, if the world of work seeks general characteristics of working mathematically, a relevant question is how mathematical attainment in university mathematics courses, as represented by average grades, is associated with mathematical identity. This paper addresses this question.

This study has examined the association between self-reported mathematical identities and average grades in university mathematics courses. From a Rasch calibrated instrument, previously validated in Kaspersen (2015), the students were categorised as having a “low,” “medium,” or “high” mathematical identity, and the paper will illustrate how the mean average grade of students with high mathematical identities was significant and about one grade higher than students with low mathematical identities. Moreover, the variance amongst students with low mathematical identities was higher than amongst students with high mathematical identities, although the difference was not

significant ( $p=0.06$ ). The paper concludes that high mathematical identities are associated with high average grades in university mathematics courses. However, the same conclusion is not true amongst students with lower mathematical identities.

## Theoretical framework

The construct of identity suffers from a lack of consensus on general philosophical issues (Cote & Levine, 2014). Specifically, identity is defined differently across different studies and paradigms, such as “a certain kind of person” (Gee, 2000, p. 99), “those narratives about individuals that are reifying, endorsable and significant” (Sfard & Prusak, 2005, p. 44), and “self-perceived mathematical knowledge, ability, motivation and anxiety” (Axelsson, 2009, p. 387).

This lack of consensus is typical in pre-paradigmatic fields (Kuhn, 1970). Unlike firm paradigmatic fields where well-established theories tend to guide the analyses, research in pre-paradigmatic areas has a more dialectical relationship between data and theory (Kuhn, 1977). This description is a fair representation of how the theoretical perception in this study was chosen. That is, no ready-made theory was chosen on pure faith. Rather, a definition of identity was established that was consistent with measurement (i.e., consistent to conclude some persons to have stronger mathematical identities than others), yet, influences by fragments of multiple existing theories. The following theoretical perspective and a wider discussion on practical significance has been provided in more detail in Kaspersen, Pepin, and Sikko (2017).

On another note, we do not regard theories as mirrors of some true reality. Thus, we do not believe that some theories *are* true, and that others *are* false. When we propose the following theoretical perspective, therefore, we are not refusing other perspectives, for instance, a narrative view on identity. Rather, we claim that *if* we choose the following perspective, then the practical consequence is that mathematical identity can be measured.

The perspective of mathematical identity relies on two assumptions. First, we assume that identity (originated from the Latin *idem*) is about sameness and distinction. As such, the position in this study juxtaposes perspectives that consider persons to have their unique identity. That is, persons are indeed unique. However, they can be defined as identical with respect to a set of characteristics, just like mathematical objects can be identified by certain characteristics while remaining unique on others. Moreover, since there exists an infinite number of characteristics, identities have a varying degree of complexity. That is, mathematical identity can be binary, linear, or multidimensional, and we argue that there is no ontological limit to the number of dimensions. Consequently, there exists no set of criteria that dictates when researchers have arrived at the final dimension. Hence, the choice of complexity can be nothing but pragmatic, and in this study, we have chosen a one-dimensional perspective on mathematical identity, whereby persons are distinguished on a continuum from having a low to having a high mathematical identity within the engineering education context.

Furthermore, if we accept that persons participate and contribute in multiple activities, a consequence is that each person has multiple identities, a position that is shared by many authors, for example Black and colleagues (2010) who, inspired by Leont'ev (1981), presented the idea of “leading identity.” Since there is no limit to how many ways persons can be distinguished, we argue that there exists no limit to the number of identities, although the number of identities that individuals are consciously aware of is likely to be finite. Moreover, in this study, we take no definite position on the

relationship between identities. Thus, when we later will conclude that selected persons have (more or less) the same mathematical identity, we do not make claims about how these are related to the multiplicity of identities—for instance, whether they are central/leading or peripheral identities.

Second, we assume that identity is relational by nature. That is, persons can be concluded to be identical relative to a set of characteristics, only if the structure of these characteristics is person-independent. Thus, in quantitative studies, we reject the assumption that persons with the same score on some test or questionnaire are identical unless statistical evidence is provided that the items stay invariant across relevant subgroups. Hence, there likely exist contexts that are so different that comparisons of identities across these contexts do not make sense. Consequently, we argue that the methods that are applied to capture identities should also capture the level of invariance.

In conclusion, we define mathematical identity to be *where persons position themselves relative to the social structure of being mathematical within the activity in which they participate and contribute*. From a one-dimensional perspective, “the social structure of being mathematical” is a person-independent set of characteristics and their internal structure (i.e., their relative distance) that distinguishes persons on a continuum from having a “low” to having a “high” mathematical identity. “Where persons position themselves” is persons’ positions relative to the social structure.

## Method

To test the relationship between engineering students’ self-reported mathematical identities and average grade in mathematics courses, a convenience sample consisting of Norwegian engineering students ( $N=361$ ) was selected. 47 students attended an “Introductory course in mathematics,” 71 students attended a “Calculus 2” course, 113 attended a “Calculus 3” course, 11 a “Cryptography” course, and 119 were students from a variety of courses in their normalised final year of education. The participants responded to a Rasch-calibrated instrument (Rasch, 1960), previously validated in Kaspersen (2015), that measures persons on a continuum from having a low to having a high mathematical identity relative to 20 uni-dimensional characteristics. The items in the instrument were collected from three sources: the literature, other related instruments, and from persons contributing in mathematical activities (e.g., students and lecturers). The validation of the instrument will not be discussed in depth, as details can be found in Kaspersen (2015). The person reliability, analogous to Cronbach’s alpha, was 0.87. Moreover, from principal component analysis of residuals, the instrument was found to be sufficiently uni-dimensional for the purpose of measurement with a 1.99 unexplained variance (in Eigenvalue units) in a second contrast. Furthermore, the mean of the squared standardised residuals (outfit mnsq) and the information-weighted version (infit mnsq) (see e.g., Bond & Fox, 2003, p. 238 for a detailed description) indicated a sufficient data-model fit, with Item 6 and Item 15 as the most underfitting items (Table 1).

Rasch measurement requires additivity, uni-dimensionality, and invariance, and the probability of an observation is a function of the difference between a person’s measure and a characteristic’s measure (e.g. Wright & Stone, 1979). Thus, most response strings follow a Guttman-like structure with most deviations around the measure of the person. Consequently, persons with approximately the same measures, except those with large misfit, have, not only the same measures but also approximately the same combination of self-reported characteristics (and thus concluded to be identical with respect to these characteristics).

After the validation of the instrument, the respondents were categorised as having either low (measures lower than -1), medium (measures between -1 and 1), or high (measures above +1) mathematical identities (all measures are in logit units). The distance from the “low”/“medium” to the “medium”/“high” thresholds was about the same distance as one response category. Consequently, persons with “high” mathematical identities were expected to respond at least one category higher on each characteristic than persons with “low” mathematical identities. Subsequently, a one-way ANOVA was conducted to compare the association between mathematical identity and the self-reported average grade in mathematics courses at the University (from grade F=1 to grade A=15). However, since the Levene’s (1960) test barely accepted the null hypothesis of homogeneity of variances ( $p=0.06$ ), and the sample sizes across categories were unequal, the Welch’s ANOVA was chosen since it is more robust to unequal sample size and variance.

Moreover, the assumption of normality was violated, and the grades were ordinal as opposed to interval measures. Since Welch’s ANOVA assumes normal and interval measures, 10,000 simulations were made in R (R Core Team, 2015) to assess how these violations affected the robustness of the analysis. To ease this part of the analysis, we considered a transformed data set which had no difference in the mean across groups but was otherwise identical to ours—the assumptions of Welch’s ANOVA were violated equally in the empirical study and the simulated studies. This transformation eased the interpretation since we could compare the results with the statistical ideal situation (perfectly normal interval data, equal sample size and variance). If our data set was as good as the ideal situation, we would expect the Welch’s ANOVA to show a significant difference in about 5% of the simulations.

Specifically, from the empirical data frame,  $M$ , a new data frame,  $M'$ , was made whereby each grade in the medium and high groups was shifted so that the mean of all three categories in  $M'$  were equal (i.e., keeping the sample sizes and distributions, but aligning the means). From  $M'$ , 10,000 data frames,  $M_1 - M_{10,000}$ , were randomly sampled whereby the sample sizes in the three groups were equal to the original  $M$ . Subsequently, Welch’s ANOVA was conducted on each simulated data frame. Since the result showed that 5.2% of the  $p$ -values in the simulations were less than .050, it was concluded to ignore violations of Welch’s ANOVA’s assumptions since they had only a trivial negative effect on the robustness.

## Result

### Mathematical identities

Due to the Guttman-like response strings, a rough interpretation of Table 1 is that most students with low mathematical identities (measures lower than -1) agreed with characteristics much lower than -1, and disagreed with those much higher than -1. That is, students with low mathematical identities often keep trying when they get stuck, but they rarely study proofs until they make sense (to them), they rarely like to discuss mathematics, they rarely derive formulas, etc. Likewise, students with medium mathematical identities (measures between -1 and 1) frequently keep trying, connect new and existing knowledge, and can explain why their solutions are correct, but rarely take the initiative to learn more than expected, rarely take the time to find better methods, etc. Students with high mathematical identities (measures above +1) agree with most characteristics in the instrument. A more thorough discussion is discussed in Kaspersen, Pepin, and Sikko (2017).

*Item statistics: Measure order*

Measure	INFIT MNSQ	OTFIT MNSQ	Item
1.91	.81	.83	1. Takes time to find better methods
1.58	1.08	.99	2. Takes the initiative to learn more
1.24	.91	.86	3. Thinks of times when methods don't work
.55	1.22	1.20	4. Struggles with putting problems aside
.51	1.05	1.07	5. Derives formulas
.45	1.36	1.37	6. (x) Likes to be told exactly what to do
.41	.96	.95	7. New ideas lead to trains of thoughts
.32	1.05	1.05	8. Likes to discuss math
.20	1.07	1.07	9. Makes his/her own problems
.05	.99	.99	10. Studies proofs until they make sense
.04	.86	.88	11. Moves back and forth between strategies
-.10	.87	.86	12. Tries to understand formulas/algorithms
-.20	.72	.74	13. Considers different possible solutions
-.26	1.03	1.05	14. Pauses and reflects

**Table 1: Characteristics of mathematical identities amongst Norwegian Engineering students**

Moreover, it is evident from Table 1 how the identities in this study were situated amongst the engineering student context. That is, persons with measures, say, around 0.5 in other contexts would be identical to engineering students with the same measures, only if the same set of characteristics were proven to be invariant (i.e., calibrated to have the same structure) in both contexts.

### **The relationship between self-reported mathematical identities and average grade**

Figure 1 illustrates the relationship between self-reported mathematical identity and average grade in university mathematics courses. The Welch's ANOVA showed that the association between mathematical identity and self-reported average grade was significant,  $F(2, 110.79)=31.966, p=0.000$ . Moreover, the mean of the self-reported average grade amongst students with high mathematical identities was about one grade higher than those with low mathematical identities. The Games-Howell test showed that the difference was significant between all groups with low-medium as the least significant ( $p=0.001$ ).

**Figure 1: The relationship between self-reported mathematical identity and average grade in university mathematics courses**

The unequal variance is also illustrated in Figure 1. Specifically, the variances decreased with the increase of mathematical identity. That is, high mathematical identities are associated with high self-reported average grade. However, there seems to be no limit to how low mathematical identities students can have and still get high grades.

## Conclusion and discussion

In this paper, we have argued that the average grade in university mathematics courses amongst students with high mathematical identities is about one grade higher than amongst students with low mathematical identities, and the difference is significant. Moreover, we have shown that the variance of self-reported average grades amongst students with low mathematical identities is higher than amongst students with high mathematical identities. That is, students with high identities get, for the most, high grades. However, the grades of students with lower identities are more uncertain.

We have in this study examined the association, and not the causal relationship, between self-reported mathematical identities and average grades, and therefore we argue that the significance of the result is that it points the direction for future research. Specifically, we suggest future research to address the following:

First, replicates of this study should seek more precise measures. That is, the precisions of the mathematical identity measures can be improved by including more response categories (as long as they are sufficiently validated) and more items, particularly near the “gaps” (e.g., between 0.5 and 1.2 logits). Moreover, the precision of the average grade would most likely be improved if self-reported average grades were substituted with actual average grades.

Second, future research should seek a more causal relationship between identities and grades. Specifically, this study does not conclude that an increase in mathematical identity infers an increase in attainment.

Third, future research could study the significance of mathematical identity versus the significance of attainment. For instance, students can be categorised as having “low identities and low grades,” “low identities and high grades,” or “high identities and high grades,” and subsequently studied with respect to other variables, for example, in the transition from university to the world of work.

Fourth, we argue that future research can transfer the design of this study to other samples and forms of testing students’ attainment. For example, relationships between mathematical identity and measures on international standardised tests, such as PISA and TIMSS, can be tested. Accordingly, we argue that future research can nuance the debate on the significance of these tests. If some districts/countries are “teaching to the test,” then one might hypothesise that a relatively great proportion of students in these districts/countries are in the “top left corner”—that is, students with low mathematical identities, yet, high measures of attainment.

# A praxeological approach to Klein's plan B: Cross-cutting from calculus to Fourier analysis

Margo Kondratieva<sup>1</sup> and Carl Winsløw<sup>2</sup>

<sup>1</sup>Memorial U. of Newfoundland, Canada; [mkondra@mun.ca](mailto:mkondra@mun.ca)

<sup>2</sup>University of Copenhagen, Denmark; [winslow@ind.ku.dk](mailto:winslow@ind.ku.dk)

*In our previous work on Calculus–Analysis transition we independently explored the reasons of students' difficulties with studying analysis and observed that the problem is related to the discontinuity of students' experiences leading to their inability to interpret the (formal and more rigorous) ideas learned in analysis courses in terms of (practical) knowledge acquired in calculus courses, and vice versa. In this paper we continue and combine our work with two new contributions: a theoretical formulation of Klein's idea of a “Plan B” for teaching mathematics, applied to the transition in question; and a concrete student activity attempting to give flesh to this “plan” for the special case of introductory Fourier Analysis.*

*Keywords: Calculus, Fourier analysis, transition, praxeology*

## Introduction

Calculus and Analysis appear as related, but distinct subdisciplines in many contemporary university programmes. Calculus courses specialise in mathematical themes indicated by course titles such as “Integral Calculus”, “Functions of several variables” or “Ordinary differential equations”. Analysis courses, on the other hand, treat theoretical perspectives on these same mathematical themes, gradually moving from course titles such as “Real Analysis”, “Fourier Analysis” towards more abstract areas such as functional and harmonic analysis. In short, calculus courses can be roughly characterized as teaching students certain calculation practices related to real and vector valued functions, with little theoretical precision or justification – while analysis courses tend to present “formal theory with little practice”. This division is a didactical construct which is related to historical and institutional conditions (see Klisinska, 2009, for an in-depth analysis of the case of the “fundamental theorem of calculus”).

The main reason for the division seems to be that the two types of courses cater to different student populations. While calculus courses are studied by a large cohort of students in natural and social sciences, much fewer students get to study analysis (mainly students of pure mathematics, theoretical physics and mathematical statistics). For these and other reasons, it may be difficult to change the course structure.

The transition from Calculus to Analysis presents mathematics students with several challenges (for examples, see Winsløw & Grønbæk, 2014). Here is a typical student formulation of some of these (interview with a student of the first author, summer 2016):

In calculus courses we learn methods, but usually the why questions are not explained or proved. (...) However, analysis courses felt as separate. They were more theoretical than applied. I never grasped them as well as Calculus. It was often unclear, what it was leading to. I wish we had a better sense of connection between the theory we covered in pure math courses and the methods shown in applied math courses.

We have explored this perceived lack of “connection” in earlier papers (Kondratieva, 2011, 2015; Winsløw, 2007, 2016). In the present paper, we use the notion of praxeology (Chevallard, 2006) to represent the general “connection” problem in more precise terms, and - as a theoretical case study - to present a new proposal for “connecting” Calculus and one of the basic theorems in Fourier Analysis. Our research results are thus basically theoretical.

## Theoretical framework

Chevallard (2006) defines a *praxeology* as a pair  $(P, L)$  consisting of a *praxis block*  $P$  and a *logos block*  $L$ . A praxeology is a minimal element of human knowledge,  $P$  representing the practical part - the “know how” - and  $L$  the intellectual part, the “thinking and explaining” – often called “know why”. The two are interdependent:

...no human action can exist without being, at least partially, “explained”, made “intelligible”, “justified”, “accounted for”, in whatever style of “reasoning” such an explanation or justification may be cast. Praxis thus entails logos, which in turn backs up praxis. For praxis needs support – just because, in the long run, no human doing goes unquestioned. (Chevallard, 2006, p. 23).

As we focus here on mathematical praxeologies taught and learnt at university, it is obvious that *praxis* (e.g. computing the Fourier series of a given function) is intimately connected to various forms of *logos* - from *ad hoc* explanations of standard techniques to theories involving general definitions, theorems and proofs. To compare and contrast the praxeologies developed in calculus and analysis courses, we consider that they represent various affinities with the praxeologies of present-day mathematicians, which we shall represent suggestively using Greek letters  $(\Pi, \Lambda)$ . We can thus, as a first naïve model, propose that praxeologies taught and learnt in calculus courses are of the form  $(\Pi_i, L_i)$ : the *praxis blocks*, including computational techniques, are identical to those used (for tasks of the same type) by professional mathematicians, while the logos blocks  $L_i$  are limited to informal explanations of smaller collection of practice blocks (like the various techniques for determining whether a series is convergent or not). On the other hand, analysis courses then focus on the scientific form of logos blocks. The taught and learnt praxeologies in such courses are therefore of the form  $(P_i, \Lambda_i)$  where each  $\Lambda_i$  constitutes a logos block consistent with the scientific model, while the praxis blocks  $P_i$  are didactic “afterthoughts” constructed to consolidate the acquisition of  $\Lambda_i$ . As mentioned in the introduction – such teaching practices often fail to motivate students for  $\Lambda_i$  and to provide them with a coherent, autonomous relationship with  $(\Pi_i, \Lambda_i)$ . Our research focuses on how this issue can be addressed.

Taken together, calculus and analysis courses in principle provide students with praxeologies  $(\Pi_i, \Lambda_i)$  which, taken individually, are close to the scientific model. For instance, convergence tests used in Calculus praxis on series are now supplied with a theory involving precise definitions and proofs of the “criteria” for convergence. However, because the number and technical complexity of these praxeologies is quite high and the  $\Pi_i$  were taught in other courses, typically years before, some effort and support may still be needed for students to “assemble” individual praxeologies  $(\Pi_i, \Lambda_i)$ . We can say that working along these lines corresponds to establishing complete but separate praxeologies within different small areas of mathematics, which is what Klein called “Plan A” for teaching: “Plan A is based upon more particularistic conception of science which divides the

total field into a series of mutually separated parts and attempts to develop each part by itself.” (Klein 1908/1932, p. 77, see also Winsløw, 2016) Within this approach two praxeologies are related only through strict logical dependency at the theoretical level and only within strictly confined areas (which, in terms of what students actually acquire, may be surprisingly small).

However as explained by Klein, the scientific practice (historically as well as currently) involves more than isolated or strictly dependent praxeologies. Klein (1908/1932, p. 78) recommended that also elements of “Plan B” be included in mathematics teaching both in schools and at university:

The supporter of Plan B lays the chief stress upon the organic combination of the partial fields, and upon the stimulation which these exert one upon another. He prefers, therefore, the methods which open for him an understanding of several fields under a uniform point of view.

In terms of the praxeological model above, we may thus summarize the two “plans” or strategies for developing and connecting students’ previous knowledge as follows:

Plan A. *assemble elementary praxeologies*  $(\Pi_i, \Lambda_i)$  from calculus and analysis elements, by establishing firm relations of type  $\Pi_i \leftrightarrow \Lambda_i$ . In fact, this is sometimes a possible function of the “fingertip” exercises, which constitute  $P_i$  in many courses and textbooks on analysis.

Plan B. *develop cross-cutting relationships among praxeologies* which could be of one of the following types (or combinations among them):

B1. Relating praxis blocks  $(\Pi_i \leftrightarrow \Pi_j)$  or logos blocks  $(\Lambda_i \leftrightarrow \Lambda_j)$

B2. Relating otherwise unrelated praxis and logos blocks  $(\Pi_i \leftrightarrow \Lambda_j)$

It may be more easy and common to develop relations of type B1, even if they certainly appear more often in “mathematician” praxeologies than in typical course teaching. We now present and analyse an example of student activity aiming at developing relations of the last type (B2): namely, that students connect a collection of praxis blocks  $\Pi_i$  (concerning trigonometry, integration and convergence) to a logos block  $(\Lambda_0)$  from Fourier Analysis.

## A logos block from Fourier Analysis

For a  $2\pi$ -periodic, piecewise continuous function  $f: \mathbb{R} \rightarrow \mathbb{C}$ , the Fourier series of  $f$  is defined as

$$\frac{1}{2}a_0 + \sum_{n=1}^{\infty} a_n \cos nx + \sum_{n=1}^{\infty} b_n \sin nx, \text{ where } a_n = \frac{1}{\pi} \int_{-\pi}^{\pi} f(x) \cos nx dx \text{ and } b_n = \frac{1}{\pi} \int_{-\pi}^{\pi} f(x) \sin nx dx.$$

In general the two infinite series may not converge at a point  $x$ . In 1829, Dirichlet gave one of the first sufficient conditions for pointwise convergence of a Fourier series. A version of this result which is usually formulated for *piecewise* continuous functions, is stated below in a special case to avoid technicalities. We refer to it as Dirichlet’s theorem, although we don’t use his original claim.

**Theorem** If  $f: \mathbb{R} \rightarrow \mathbb{C}$  is a continuous  $2\pi$ -periodic function with piecewise continuous derivative, the Fourier series of  $f$  is pointwise convergent to  $f(x)$  at every  $x \in \mathbb{R}$ .

Here we outline the main steps of the proof that appears in a typical formal course on Fourier Analysis (see e.g. Folland, 1992, pp. 30–36 for the wealth of computational details omitted here):

1. First, it is shown that under weaker assumptions, such as  $f$  being square integrable and  $2\pi$ -periodic, the coefficients  $a_n$  and  $b_n$  tend to zero as  $n$  tends to infinity. (In fact, one demonstrates this by showing that the series  $\sum a_n^2$  and  $\sum b_n^2$  are both convergent.)
2. Next, by direct computation, we rewrite the  $N$ th partial sum given by  $s_N(x) = \frac{1}{2}a_0 + \sum_{n=1}^N a_n \cos nx + \sum_{n=1}^N b_n \sin nx$  as:  $s_N(x) = \int_{-\pi}^{\pi} f(x+y)K_N(y)dy$ , where  $K_N$  is the *Dirichlet kernel* defined by  $K_N(x) = \frac{1}{\pi}(\frac{1}{2} + \sum_{n=1}^N \cos nx)$ . Clearly  $K_N(0) = (N+1/2)/\pi$  and  $\int_{-\pi}^{\pi} K_N(x)dx = 1$ . By clever use of the addition formulae,  $K_N(x) = \frac{\sin(Nx + x/2)}{2\pi \sin(x/2)}$  for  $x \neq 0$ .
3. Finally, let  $D_N(x) = s_N(x) - f(x)$ . Using 2., a straightforward set of computations yields

$$(*) \quad D_N(x) = \frac{1}{\rho} \int_{-\rho}^{\rho} g_x(y) \sin(y/2) \cos Ny dy + \frac{1}{\rho} \int_{-\rho}^{\rho} g_x(y) \cos(y/2) \sin Ny dy,$$

where  $g_x$  is defined by  $g_x(y) = \frac{f(x+y) - f(x)}{2 \sin(y/2)}$  for  $y \neq 0$ , and  $g_x(0) = f'(x)$ . In fact,  $g_x(y)$  is a continuous for  $y \neq 0$  and  $2\pi$ -periodic function. At  $y=0$   $g_x(y)$  may have a jump discontinuity if  $f'(x+0) \neq f'(x-0)$ . The functions  $g_x(y) \sin(y/2)$  and  $g_x(y) \cos(y/2)$ , notwithstanding the possible discontinuity of the latter at  $y=0$ , are bounded, and thus, square integrable. Formula (\*) shows that  $D_N(x)$  is simply the sum of  $N$ th Fourier coefficients of these two functions. Applying now 1., we conclude that the infinite Fourier series  $s_{\infty}(x)$  converges to  $f(x)$  because its partial sum  $s_N(x)$  can be written as  $s_N(x) = f(x) + D_N(x)$ , where  $D_N(x)$  vanishes as  $N \rightarrow \infty$ .

The key point of the proof is (\*): to rewrite  $D_N(x)$  as a sum of two Fourier coefficients, together with the fact that the coefficients tend to zero as  $N \rightarrow \infty$ . According to the distinction we made above, the general result (and certainly its proof) does not belong to the realm of Calculus. When students are presented with the theory in a somewhat more general form, - they may not realize that the proof almost entirely draws on the notion of series convergence and on techniques known from Calculus. To make them discover that is the aim of the design that we present in the next section, focusing on the following special case:

**Example.** Applying the above Theorem for  $f(x) = x^2$ , extended periodically from  $[-\pi, \pi]$  to  $\mathbb{R}$ , we get that the Fourier series converges to 0 at  $x = 0$ . Computing the Fourier coefficients, this gives

$$0 = \frac{\pi^2}{3} + 4 \sum_{n=1}^{\infty} \frac{(-1)^n}{n^2} \text{ so that } \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n^2} = \frac{\pi^2}{12}.$$

The latter - striking - result can be derived by other means, as a variant of the famous Basel problem (see e.g. Kondratieva, 2016). One such approach is at the root of the design presented below.

## Outline and *a priori* analysis of Student Activity

In continuation of earlier work of the first author (Kondratieva, 2016), we took the Example above as a point of departure for constructing a sequence of exercise-like activities that would lead

students through two approaches to computing the infinite sum considered in the Example: *part 1* consisting of a series of “calculus-like assignments” which, without saying so, go through the proof of Dirichlet’s theorem in the special case where  $f(x) = x^2$ ; *part 2* in which the students work directly with the result, as in the Example; and a *final reflection* in which the students are supposed to realize that the proof (known from a Fourier Analysis logos block  $\perp_0$ ) amounts to nothing more than a generalization of the sequence of calculus techniques drawn upon in part 1. We notice here that the numbering suggests that the praxis and logos blocks thus connected through the activity are not, *prima facie*, connected - and, thus, the connection established is really of type B.

*Part 1* begins with presenting the problem of determining the value of  $S = \sum (-1)^{n+1}/n^2$ . The praxis blocks acquired in calculus courses do not provide ready-made techniques to solve this problem; instead, students are invited to do so through “several preliminary problems”:

1. Compute the integral  $\int_{-\pi}^{\pi} x^2 \cos mx \, dx$  for any natural number  $m$  ( $\Pi_1$ : integration rules).

2. Show that  $\frac{1}{2} + \sum_{n=1}^m \cos nx = \frac{\sin(m+1/2)x}{2\sin(x/2)}$  ( $\Pi_2$ : trigonometric formulae).

3. Show that  $u(x) = \begin{cases} x^2/\sin x, & x \neq 0 \\ 0 & x = 0 \end{cases}$  defines a continuous function on  $[0, \pi/2]$

( $\Pi_3$ : techniques to compute limits, including the special result  $\lim_{x \rightarrow 0} x^{-1} \sin x = 1$ ).

4. Find  $u'$  and show this function is bounded on  $[0, \pi/2]$

( $\Pi_3$ , and  $\Pi_4$ : differentiation from first principles).

5. Show  $\int_{-\pi}^{\pi} x^2 \frac{\sin(m+1/2)x}{2\sin(x/2)} dx = 8 \int_0^{\pi/2} y^2 \frac{\sin(2m+1)y}{\sin y} dy = 8 \int_0^{\pi/2} \frac{\cos(2m+1)y}{2m+1} u'(y) dy$  ( $\Pi_1$ ).

6. Show that the integral in 5 converges to 0 as  $m \rightarrow \infty$  ( $\Pi_1$  and  $\Pi_3$ ).

7. Finally, combine the results above to find  $S$  ( $\Pi_1$ ).

The only slightly advanced praxis (technique) involved in the above appears in 6., where  $\Pi_1$  is supposed to include something like  $|\int f| \leq \int |f|$  – or, alternatively,  $\Pi_3$  should include a rule which permits to conclude that  $\lim_{m \rightarrow \infty} \int_I f_m = 0$  under appropriate conditions on  $(f_m)$ .

*Part 2* of the activity invites the students to compute the Fourier series of  $f(x) = x^2$  and engage in some concrete computations related to its convergence which are in fact very similar to 1.-6. above.

The final reflection is supposed to make them discover the close parallel between the two parts.

In case they do recall elements of the proof of Dirichlet’s theorem, they will recognize in Problem 2. the simplification technique of the Dirichlet’s kernel in step 2., and in Problems 3.-6. – a way to get the convergence result of step 3. Meanwhile, step 1 appears more indirectly in the concrete case, where both the Fourier coefficients of  $f$  and the auxiliary coefficients, appearing in (\*), can be computed or estimated directly. Indeed, many textbooks present Step 1 as a corollary of a more

general theorem on orthogonal sets in Hilbert space. This, together with the technicalities related to the possible non-continuity of  $f$ , contributes to the impression that the proof is way beyond simple techniques from Calculus. Nevertheless, comparing the proof with the proposed activity, the students could realize that in the special case  $f(x) = x^2$  the proof relies entirely on well-known praxis blocks  $(\Pi_i, i = 1, 2, 3, 4)$ . Certainly, this could establish a strong relation  $L_0 \leftrightarrow (\Pi_i, i = 1-4)$  which might in fact be prepared by students' working *Part 1* above *prior* to encountering  $L_0$ .

### Some experimental observations

To pilot and refine the above design before testing it with a larger group of students in a course on Fourier Analysis, we have done a preliminary study with five students who have completed at least 3 years of undergraduate mathematics program. These students were involved in summer research projects in mathematics at the Memorial University of Newfoundland. This involvement is an indicator of the students' high motivation and achievements in studying mathematics. The students volunteered to solve the problems from the activity (with no firm restrictions in time or access to any materials) and participate in a follow-up semi-structured interview. The students were asked whether they found the problems (a) familiar, (b) interesting, (c) easy/accessible; and whether they saw any connections between praxis and logos of parts 1 and 2. All students regarded problems 1-6 as familiar from their calculus courses, and they found them easy. In words of one student, "I loved that stuff when I was in my calculus courses, so I found these problems pleasant... And they are not difficult, too." While problems 1-6 were familiar to the students, they clearly indicated that no projects of nature similar to problem 7 were present in their study: "I think it is a cool layout. Nothing of this format was in my calculus courses, – when you need to use previous results to solve larger or more interesting problem." Students regarded the task of series evaluation as challenging but also most enjoyable: "The problems 1-6 were like baby steps... And they met together nicely in problem 7". So, at least these students were successful and appreciative of tasks in part 1. As for the accessibility of part 1 for an average student in a calculus course, we had overall a confirmative response: "I think it is accessible for a student who has done Integral Calculus.... if they are not confined to a very short period of time, then yes." Another student confirmed, "it could be a good exam sequence, more fun than just doing problems." However, a different perspective was also articulated: "...many students take this [Integral Calculus] course because it is a prerequisite for their programs, so maybe they would not be interested as much."

Among the five students only one had studied Fourier series in his courses, while others had heard the term but had very little familiarity with the subject. However, they all recognized the similarity in the technical praxis of parts 1 and 2, for example, that calculation of the Fourier series in part 2 resembles evaluation of integrals in problem 1 from part 1. Bridging the theory and connecting the idea of convergence of an individual series in part 1 and pointwise convergence of Fourier series was more challenging. This is where the role of an instructor might be critical: to help students to relate new theoretical constructs and ideas to familiar praxis. We realize that students' background makes a difference, however even learners previously unfamiliar with Fourier series seem to benefit from this activity. Students' responses based not on reproduction of known facts, but rather on reasoning related to their practical experiences, is an indication of establishing new mathematical relations. The following is an excerpt from an interview with students of the first author:

- M.K.: Is it always possible to replace a function with its Fourier series in calculations?
- Student 1: In my (applied) courses we were told that no (a function is not always equal to its Fourier series), but this was never proved. Now it kind of makes more sense.
- M.K.: Do you think that familiarity with part 1 would help to exemplify general theory related to Fourier series and their convergence?
- Student 1: Yes, definitely. I think it is more logical to go this way about discussing conditions of pointwise convergence of Fourier series. However, the experiences need to be close together in time, so that the second part occurs before students have forgotten the first portion.

The space available does not allow us to give the details of students' accomplishments and their impact on our design. We simply note that the sample students were by and large able to complete them and see the inner connections. Also, the students considered that building on the familiar computational tasks (1-6) on the one hand, and on new theoretical constructs (Example) on the other hand, organized around given problem (evaluation of the series  $S$ ) was stimulating: "Suppose someone has a theoretical solution and I have a computational solution and they look completely different, but they give the same answer to the same problem so they have to be the same somehow... then I want to go back and find out why they are the same. I found it very interesting."

## Conclusions

While calculus courses include praxis blocks  $\Pi_i$  compatible with those of professional mathematicians, their theoretical components are more informal and focused on algebraic computation. Moreover, these praxis blocks are often isolated from each other, as they occur within separate sections of textbooks and courses, and students typically don't get opportunities to apply them in combinations. When students meet Dirichlet's theorem, they are given a general and relatively complicated proof (in Analysis). In such courses, "simple applications" (such as the Example above) may be introduced as examples or exercises, to build an artificial practice block  $P_0$  corresponding to the much richer logos block  $L_0$ . The fact that the general proof ( $L_0$ ) is essentially linked to familiar praxis blocks from Calculus will then not appear. We propose that by replacing  $P_0$  by a sequence of computational auxiliary tasks (1-7), similar to the steps 2 and 3 of the proof ( $L_0$ ), two goals can be achieved. First, students will see how different praxis blocks ( $\Pi_1, \dots, \Pi_4$ ) from Calculus work together and combine to support  $P_0$  by themselves. Secondly, this special case might help to prepare for the various general theorems on Fourier series convergence ( $L_0$  and beyond) by relating it to the concrete and familiar elements  $P_1, \dots, P_4$ . This hypothesis will be investigated empirically. More generally, we hypothesize that situations which enable students to establish "cross cutting relations"  $\Pi_i \leftrightarrow \Lambda_j$  are precise and possibly partial interpretations of Klein's Plan B. At the same time, constructing integrated praxis blocks such as  $(\Pi_1, \dots, \Pi_4)$  above constitutes an essential complement to "Plan A" type courses. These constructions could emerge from detecting explicit links between different solutions of *interconnecting* problems (Kondratieva, 2011), as shown above. It will clearly necessitate a careful analysis of (central) theory blocks of more advanced courses, and resources found in reasonably well-established praxis blocks of previous

courses. So, while the general hypothesis may look fairly simply, realizing it in concrete cases - even theoretically - represents a non-trivial didactical research programme.

# The interface between mathematics and engineering – problem solving processes for an exercise on oscillating circuits using ordinary differential equations

Jörg Kortemeyer and Rolf Biehler

University of Paderborn, Germany; [kortemey@math.upb.de](mailto:kortemey@math.upb.de), [biehler@math.upb.de](mailto:biehler@math.upb.de)

*In our project, we investigate the mathematical skills that are required in first-year courses of technical subjects of engineering bachelor courses, i.e., we do not look at the courses on pure math. We analyze four exercises from an exam in electrical engineering, which is compulsory for first-years. To solve such exercises, students have to combine their knowledge in electrical engineering with their skills in mathematics. We introduce a theoretical approach consisting of three elements: a normative solution called “student-expert-solution”, “low-inferent analyses” for qualitative studies with students, and categorizations of written solutions. We describe the newly developed tools and details on one of the exercises and present the results from the analysis of the exercise in reference to the three concepts mentioned above. This provides insight into the interface between mathematics and engineering courses in the first year at university.*

**Keywords:** Engineering mathematics, competence, differential equations.

## Introduction

Engineering students at German universities are taught mathematical subjects as well as engineering subjects, which require some understanding of mathematical topics, at the same time. This leads to several challenges for the students: To begin with, the lectures on Mathematics for Engineering Students (MfES) and the Fundamentals of Engineering (FoE) are very often asynchronous. On the one hand, there is a deductive structure in the lectures on mathematics, which leads to a certain order of presentation of the different topics to assure understanding. On the other hand, there is also a standard way of presentation of the different engineering topics in the FoE-courses and because of that, mathematical topics are often needed earlier in the FoE-courses than they are presented in the MfES-courses. Moreover, there are different mathematical practices in MfES and FoE, for example in the use of vectors or differentials (see e. g. Alpers, 2015). There is a mismatch between the mathematics in MfES-courses, the mathematics at school level, and the “contextual mathematics” required in engineering tasks (see e. g. Redish, 2005).

At the beginning of the research, our central question was: how do engineering students solve tasks in basic engineering courses given this situation with two interconnected fields of competences - mathematics and engineering. We are interested in the modelling and assessing of explicit as well as implicit competences required and developed by students in this field. We investigate how students actually solve exercises in FoE-courses and which difficulties occur. Our focus is on four typical exercises of a FoE-exam after the first year at university. In this paper, we present a case study of these issues in the context of a single exercise on ordinary differential equations in the electrical engineering field of oscillating circuits. Our focus here is on the following research questions:

1. What are the expectations from students' solutions to an exercise on ordinary differential equations in a first-year electrical engineering course? 2. What are the characteristics of students' problem-solving processes (e. g. strategies, difficulties) in electrical engineering courses?

For the analysis of students' work we required a normative solution of the exercise, which was developed with engineering experts and which considers both fields of competences. This normative solution is based on relevant theoretical concepts that are presented in the next section.

## **Theoretical background**

In this section, we present the theoretical tools that were used to develop the newly constructed methodology for our investigations. As a first step, the approaches deal with modelling processes using mathematical methods and mathematical problem solving. Both theoretical approaches are relevant, as they combine inner- and outer-mathematical solution parts and describe their connections. Next, we also consider actual solving processes that help us to supplement normative solutions with the steps students use when solving an exercise.

The first approach is the modelling cycle by Blum and Leiss (2007), which is used to describe idealized modelling processes of real world problems that can be solved using mathematics. In a broad outline, it divides the modelling processes into two distinct parts, the so-called "rest of the world" and "mathematics". Our second perspective is mathematical problem solving by Polya (1949), who intended to give advice to students on how to solve mathematical problems as well as applied problems referring to mathematics. He divides the solving processes into four phases: understanding the problem, devising a plan, carrying out the plan, and looking back.

For the analysis of actual solution processes of students, we use theoretical approaches developed by Redish and his working group, i.e., by Redish and Tuminaro (2007) and Redish and Bing (2008), in addition to the normative solution. Their approaches discuss the role of mathematical resources and knowledge in solving processes by pairs of physics students. Redish and Tuminaro (2007) distinguish three framings in qualitative solving processes: quantitative sense-making, qualitative sense-making, and rote equation chasing (without understanding the underlying physical situation). Bing (2008) looked at mathematical justification strategies and found four distinct types of justifications: calculation (a correctly done algorithm gives a correct result), physical mapping (the physical behavior is described correctly by mathematical results), invoking authority (the result is consistent with the lecture) and math consistency (the same mathematical approach is used in a similar situation). The theoretical background is presented in more detail in Biehler, Kortemeyer, and Schaper (2015).

## **The newly developed methodology and its aims**

In order to do research in this interface of two interconnected competence fields, new theoretical approaches had to be developed. This section presents the three main approaches that were developed on the basis of the theoretical approaches mentioned above. As shown in Figure 1, the central theoretical tool is the SES, which builds on expert interviews and the theoretical frameworks of the modelling cycle and mathematical problem solving. The SES is our tool to answer the first research question, i.e., it gives idealized solution processes which we can expect from first-years. It is used to analyze and structure the video-graphed solving processes, which were transcribed using

LIAs, and the categorizations of written solutions. Details on the SES, the LIAs and the categorizations are presented in Figure 1:

**Figure 1: Diagram on the connection of the different elements of our analyses**

Initially we asked the task designer and the electrical engineering experts to solve the exercises from the perspective of students who understood the contents of the courses in the first year of studies well. Afterwards we interviewed them concerning their solution processes. The aim of the expert interviews was to identify the explicit and implicit competence expectations of instructors in electrical engineering courses. We conducted the interviews using the Precursor-Action-Result-Interpretation (PARI) method by Hall, Gott, and Pokorny (1995) which is a task-based interview technique. This solution was then subdivided using the language of the modelling cycle and mathematical problem solving, which in combination structured the normative solution of the exercise. The solving processes could be divided into three main phases: mathematization, math-engineering working, and validation and each main phase was subdivided by Polya's four phases. The expert interviews and the structure shown in Figure 1 were the basis of the student-expert-solution (SES), which was used to finally sharpen the theoretical description, and as a basis for the further analysis of students' work. SESs are represented by two columns: the first column provides a normative solution to the exercise in detail and is structured as mentioned above. The second column contains a division of the problem-solving process into phases, as well as remarks given by the experts on expected mistakes, alternative solutions, and learning goals for the different phases.

One of our main interests is to describe real problem-solving processes of students for the four exercises using both qualitative and quantitative methods. Those analyses are based on the SES. We conducted video studies of problem solving processes of three to four pairs of students per exercise, who were asked to solve the exercise and to think aloud during the solution processes. The videos were transcribed with additional remarks on the activities (especially gestures) performed. We analyzed the transcripts using our concept of the low-inference analyses (LIAs) with the aim of finding differences to ideal solutions (the SESs) and to identify students' difficulties. The LIAs consist of four parts: First, there is the connection of the phases in the SES and the phases in the problem-solving processes of the students. Second, the differences between the idealized solution parts in the SES and the actual solution paths of the students are described. The third part consists of commenting and interpreting of the differences, which forms the basis to conceptualize and describe problem-solving strategies, which are expected to be more general than just the process in the actual

exercise alone. Finally, we connect the strategies we found with the strategies described by Redish and Tuminaro (2007) in general, and Bing (2008) in particular, in order to find typical strategies and challenges at the interface between math and engineering.

In addition to these qualitative studies, we also scanned 92 anonymized “solutions” of students from their written exams. In order to analyze the solutions, the phases in the SES were subdivided into the particular activities that students have to accomplish in order to solve an exercise. For example, the phase of the math-engineering work was subdivided into the forming and the evaluation of the formula. Each student’s work was categorized using a partial credit system, i.e., they got two points if the activity was done correctly, or they got one point if it contains right parts (e. g. the solution would be correct if one multiplied it with a power of 10), or they got no points if the solution is completely wrong. The categorization “1” was subdivided into 1a, 1b, 1c etc. to distinguish different forms of mistakes. This provided quantitative results on the frequency of mistakes and – by combination of activities in contingency tables – the connection of successes in different activities. The results are used to confirm, refine, and enhance the results in the first two levels.

### **The SES for the analyzed exercise on ordinary differential equations**

This section presents the first part of one of the exercises of the exam to exemplify our method and present exemplary results. It answers the first research question, which asks what we can expect from students in their first year at university. The exercise deals with oscillating circuits and transients. We present the problem setting as well as a short overview of the solution. This solution is enhanced by the remarks of the experts, which were elicited in the third phase of the PARI-interview. For the first time, this paper presents our total approach for an exercise using methods from MfES. In this exercise, the oscillating circuit contains a resistor  $R$ , an inductor  $L$ , a capacitor  $C$  and an ideal voltage source  $U_0$ . In summary, the students have to read the sketch – taking into account conditions on the switches  $S_1$  and  $S_2$  - to be able to form an ordinary differential equation (ODE) and then to solve it. The exercise starts with the circuit diagram shown in Figure 2. It consists of eight subtasks. In this paper, we concentrate on the first five subtasks, which deal with the left part of Figure 2.

Initially, both switches are open, and the inductor and the capacitor are totally discharged. At the moment  $t=0$  the switch  $S_1$  is closed, while  $S_2$  remains open. In subtask 1 and 2 the students are to give the values of  $u_C(t)$ , the voltage at the capacitor,  $i_C(t)$ , the electric current in the capacitor, and  $i_L(t)$ , the voltage at the inductor, before and after opening  $S_1$ , i.e., before and after  $t=0$ . Solution: All three values are 0 before  $S_1$  is closed, because the components of the circuit are initially assumed to be discharged. After closing switch  $S_1$ ,  $u_C(t)$  and  $i_L(t)$  are still 0, as a voltage across a capacitor or an electric current through an inductor does not change discontinuously; a fact students learned in the lecture.  $i_C(t)=U_0/R$  directly after the switching of  $S_1$  due to Ohm’s law and then declines due to the charging of the capacitor.

**Figure 2: Sketch of an oscillating circuit containing the mentioned components**

In subtask 3 the students are to form an ordinary differential equation for  $u_C(t)$ . Solution: We have to apply Kirchhoff's voltage law on the left part, giving  $U_0 = u_C(t) + u_R(t)$ , and use the two component equations of the capacitor  $C u_C'(t) = i_C(t)$  and the resistor  $u_R(t) = i_C(t)R$ . The combination of those equations gives an ordinary differential equation (ODE) of first order, which is  $u_C(t) + RC u_C'(t) = U_0$ .

The ODE is to be solved in subtask 4. Solution: The solution can be done using either the separation of variables combined with a variation of constants, or alternatively, the solution can be found by superposition of the solution of the homogenized ODE, one particular solution of the inhomogeneous ODE and the using of the initial value  $u_C(0) = 0$ . The solution is  $u_C(t) = U_0(1 - e^{-t/(RC)})$ .

In subtask 5 the students are to sketch the voltage curve of  $u_C(t)$ . Solution: The graph of  $u_C(t)$  starting at  $u_C(t=0) = 0$  approaches an asymptote at  $u_C(t) = U_0$ , because  $e^{-t/(RC)}$  converges to 0 for  $t \rightarrow \infty$ .

## Developing the SES for this exercise

At first sight, the solving process can be divided into three phases: mathematization (the given circuit diagram, subtask 1 to 3), math-engineering working (subtask 4), and validation, which is partly done in subtask 5, at least, if the students know the physical behavior of the setting.

As stated in Biehler et al. (2015), there are differences to the modelling cycle in mathematization processes in exercises in basic courses of electrical engineering. Students do not construct a real model from a real situation – as suggested in the modelling cycle – but they need to have strategies to reconstruct the underlying real model – which was implicitly taught in the course (but usually not called model). This includes understanding conventionalized circuit diagrams. In contrast to the exercise on magnetic circuits that was presented in Biehler et al. (2015), the equivalent circuit diagram does not have to be produced by the students; they can use the given diagram directly for their mathematization. In both cases, students use implicit idealizations and are not necessarily aware that they are idealizations. The students have to “read” the diagram and recall and use its physical background in the first two subtasks. The didactic motive of the first subtasks is – as stated by the task designer – to remind students of applying Ohm's law. Then in subtask 3, the mathematization consists of two independent competences: either recognizing certain components and translating them into their equations, or alternatively the translation of the experiment set-up into mesh and node equations using graph-theoretical arguments in an application of Kirchhoff's laws. The result are three equations:  $U_0 = u_C(t) + u_R(t)$ ,  $C u_C'(t) = i_C(t)$ , and  $u_R(t) = i_C(t)R$ .

In the next step, there are similarities to the modelling cycle, except that physical quantities are used instead of numbers. The left part can be mathematized by the three equations mentioned and using them, an entering of the “world of mathematics of physical quantities” is possible. Students have to

do equation management (see Biehler et al., 2015) to combine the equations in order to get a formula, which also contains one unknown quantity (given by a function in this case), while all the quantities are given in the exercise or have already been calculated. The equation management includes equations with functions as objects and leads to an inhomogeneous ODE of order one. A further characteristic of the equation management is that, unlike in the solving of systems of linear equations, there are no methods to find out whether there are enough or too many equations to get a solvable ODE. Asked for typical mistakes the experts said that the students have some problems in applying mathematical methods to solve the ODE. He also said, that for some students, the application of Kirchhoff's laws is hard, as they do not obtain all the required equations.

Students have learned two different algorithms to solve such ODEs. In the MfES-courses, they solve the homogenous ODEs by separation of variables and – using the solution of the homogenous ODE – they subsequently solve the inhomogeneous differential equation. In the FoE-course, they retain a solution by using superposition of the homogenous and the inhomogeneous solution. In the interview, the expert said that most students are able to set up the differential equation, the following solving of the ODE, however, is quite difficult for many students, especially finding the inhomogeneous solution. As the students work with functions instead of numbers or quantities, there is no difference in the use of the solving algorithm for ODEs, which was presented in the MfES-course. So, in this case, the solving process can be divided analogously to the modelling cycle, i.e., there is a “real” world (given by a conventionalized sketch), its translation using three equations and the solving in the mathematical world with quantities.

The solution of the inhomogeneous ODE,  $u_C(t) = U_0(1 - e^{-t/(RC)})$ , describes the behavior of the voltage in the capacitor in such a setting. Students know the qualitative behavior of this function from lab courses, which are obligatory in the first year at university. The didactic motive of the task designer was to make students see the connection between their solution of the ODE and the physical mechanisms they know from the lab courses, and use this as a validation strategy. Possible variations of exercises on this topic, which were suggested by the experts, can be either done by using further components (as in the right part of the sketch, which leads to a second order ODE) or by changing the setting of the circuit from a series connection to a parallel connection.

### Analyzing the actual solution processes of the students

*Selected results of the analyses of the videos in the LIAs.* Three pairs of students worked on this exercise in our video studies. Each pair directly found the component equations using the concepts and the language of graph theory for applying Kirchhoff's laws was a bigger problem for two pairs: They were not sure whether one mesh equation would be enough to mathematize the setting, or if they also needed to have node equations, as there was a node between the two parts of the oscillating circuit. However, no pair started the equation management with an incorrect equation and they were also successful in combining them. In reference to solving the ODE, all three pairs used the superposition-method, i.e., they used the method presented in the FoE-course.

In subtask 5 the three pairs acted in different ways, which they described while thinking aloud. One pair found the solution of the ODE by inserting  $t=0$  and realizing that the function converges to  $U_0$ . Another pair remembered the behavior they had seen in the lab courses, i.e., they knew that the graph should start at  $u_C(0)=0$  (also known from subtask 1 and 2) and would converge to the value of

the ideal voltage source, so they applied their physical knowledge to get a mathematical representation of the result, i.e., they used the “mapping meaning to mathematics”-game (see Redish & Tuminaro, 2007). The third pair used both arguments, i.e., they drew the solution of the ODE and validated it with the physical behavior, saying it confirms the result of the ODE.

*Some results of the analyses of the written exams.* There is a connection between finding the component equations and the applying Kirchhoff’s law: 84 of 92 students either did both types of equations right or both wrong. Here, 77 students were able to find the correct ODE; 56 of them solved the homogenous ODE correctly, i.e., for about 73% of the students solving the rightly formed ODE was no problem. Table 1 shows that all students who were able to solve the homogenous ODE could also solve the inhomogeneous ODE. Eight students only solved the inhomogeneous ODE correctly by finding one particular solution using physical arguments, i.e., they were able to solve at least one part of the task without applying any mathematical methods to solve ODEs, by looking instead at certain values of  $u_C(t)$  that were known from the problem setting.

	Inhomogeneous solution: wrong resp. partly right	Inhomogeneous solution: right	Total
Homogenous solution: wrong	28	8	36
Homogenous solution: right	0	56	56
Total	28	64	92

**Table 1: Connection between homogenous and inhomogeneous solutions**

## Summary and discussion of results

*The solution processes of first-years (Research Question 1).* The SES shows that this exercise has more similarities to the modelling cycle than the one presented in Biehler et al. (2015). Although the exercise uses quantities rather than numbers, it contains three distinct parts, which are analogous to the modelling cycle: mathematization, math-engineering and validation. The mathematization part consists of finding equations for the involved components and the experiment set-up by applying Kirchhoff’s laws. In math-engineering these equations are combined in a purely mathematical way, they are solved using inner-mathematical algorithms. The validation part is attended to by a retranslation into the so-called real world by looking at the physical behavior.

*The analysis of students’ work (Research Question 2).* In the mathematization part, most students were able to find both kinds of equations, and in the video-studies the biggest hurdle was, whether they had the right number of equations to get a solvable ODE. The component equations were cited from the FoE-lecture, i.e., the students invoked authority (see Bing, 2008). The students in our studies could either find both the component equation and the equations by application of Kirchhoff’s laws or none of them. In contrast to the remarks of the experts, the same holds for the solution processes in the math-engineering part, i.e., more than 90% of the students who solved the homogeneous part correctly also solved the inhomogeneous part. Moreover, some students only solved the inhomogeneous ODE using physical arguments. The question remains is whether students realize that they can also apply another method from the MfES. In the validation part, students used different strategies, involving both mathematical as well as physical arguments, i.e.,

some students did all steps of the modelling cycle, while others argued using inner-mathematical arguments. They showed different justification strategies, analogous to justifications like calculation and physical mapping, as defined in Bing, 2008.

# Self-efficacy of engineering students in the introductory phase of studies

Ronja Kürten

University of Münster, Germany; [ronja.kuerten@uni-muenster.de](mailto:ronja.kuerten@uni-muenster.de)

*In this paper we investigate the self-efficacy (SE) of engineering students in the introductory phase of studies. We focus on changes occurring in the first weeks, reasons for those changes, and the effects of a mathematics preliminary course on SE. Based on results of interviews with first year students in 2014, the preliminary course was adapted in the following year. In 2015 we interviewed first year students and collected questionnaires on SE. In the analysis we focus on mathematics, social, and general SE.*

*Keywords: Self-efficacy, transitional programs, undergraduate students, higher education.*

## Introduction

The start of studies at tertiary education institutions marks a new stage of life for young people. Students often move to a new location, meet new people, learn new rules, and are required to become accustomed to new educational settings. These changes can influence the students' self-efficacy (SE) beliefs (Schunk & Meece, 2006), which can be defined as "beliefs in one's capabilities to organize and execute the courses of action required to produce given attainments" (Bandura, 1997, p. 3). In academic contexts these beliefs correlate with perseverance, persistence, and achievement (Pajares, 1996; Schunk & Pajares, 2001), and therefore mediate study-success (Fellenberg & Hannover, 2006). Depending on the given task, different SEs are of importance: Engineering students for example face mathematical, social, and course-specific tasks. For this reason mathematics, social, study-oriented, and course-related SEs may influence the study progress. In this paper we focus on mathematics and social SE, as it seems reasonable to assume that they might be influenced by a mathematics preliminary course.

Van Dinther, Dochy and Segers (2011) reviewed 39 studies investigating factors that affect SE at higher education level, which were conducted between 1993 and 2010. None of these studies considered effects of preliminary courses that are common measures at the introductory phase of studies. Fischer (2014) investigates the perceived change in SE occurring during a mathematics preliminary course in his dissertation and finds that students perceive only minor changes in SE caused by the preliminary course. This study, however, offers no reasons for existing or non-existing changes. Another educational transition, namely the transition from primary to secondary school, is well investigated concerning SE beliefs. "Young adults often experience declines in their competence and efficacy beliefs as they make the transition from elementary to middle school [...] [that] may result from changes in the school environment" (Schunk & Meece, 2006, p. 80).

The results of interviews conducted with first year students at the University of Applied Sciences Münster in 2014 suggested that several study-related SEs might change during the first weeks at university. The students reported rising uncertainty concerning the new style of teaching and learning at university and the finding and joining of a study group. Furthermore they feared to fail in their mathematics studies whilst being confident about success in other subjects. When asked for mastery experiences in mathematics during the first weeks they didn't report any preliminary course

experiences, and even improvement in the mathematics-tests didn't raise their confidence, as improvement was the least they had expected in a test that mostly differed only in numbers from the first one. As a consequence of these results, the preliminary course was adapted in 2015 to promote participation and cooperation of students.

In this paper the development of SE (mathematics and social) of engineering students at the start of studies is investigated. The study focusses on changes occurring during the first weeks at university, their reasons, and the role of the redesigned mathematics preliminary course regarding those changes.

## Theoretical framework

SE is "competence-based, prospective, and action-related" (Luszczynska, Scholz & Schwarzer, 2005, p. 440), as shown in items such as "*I am confident to solve the systems of equations with  $x + y = -7$  and  $x \cdot y = 30$* " (Zimmermann, Bescherer & Spannagel, 2011, p. 2137) or "*I am confident that I can start a conversation with someone I don't know very well*" (Hermann, 2005, p. 107). Efficacy beliefs are multi-dimensional, varying in level, generality, and strength (Bandura, 1997). Generality of SE can range from task-specific SEs as used in the original definition of Bandura (1997) to domain-specific SEs such as mathematics SE or social SE to general SE. "Mathematics self-efficacy expectations indicate the belief of a person in his/her own competence to solve mathematical problems and tasks successfully" (Zimmermann et al., 2011, p. 2136). Engineering students are confronted with a considerable amount of mathematics in their studies, although they usually don't choose their course of studies for that reason. Social SE can be defined as "an individual's confidence in her/his ability to engage in the social interactional tasks necessary to initiate and maintain interpersonal relationships" (Smith & Betz, 2000, p. 286). Students beginning their studies at university face these tasks daily. "General self-efficacy [...] reflects a generalization across various domains of functioning in which people judge how efficacious they are" (Luszczynska et al., 2005, p. 440). It can be defined as "the belief in one's competence to cope with a broad range of stressful or challenging demands" (Luszczynska et al., 2005, p. 439). We use this rather stable SE to control our results for testing effects.

SE beliefs influence goal-setting, motivation, or perseverance of people (Bandura, 1997). Empirical studies have shown that in academic contexts, low study-related SEs influence proneness to drop out of studies, whereas high SEs are supposed to promote study success (Fellenberg & Hannover, 2006). Pajares (1996) discovered that SE influences performance independently from and as strong as ability, and Schunk and Pajares (2001) showed that mathematics SE is a better predictor of achievement than self-concept, anxiety or prior experiences in mathematics. In general, SEs that slightly exceed actual skills are the most functional, as they "lead people to undertake realistically challenging tasks and provide motivation for progressive self-development of their capabilities" (Bandura, 1986, p. 394). SE can be developed through four main sources: enactive mastery experiences, vicarious experiences, verbal persuasion, and physiological and affective states. Enactive mastery experiences (failures or successes) are the most influential source, especially when they are attributed to personal effort. When no absolute measures of adequacy exist, social comparisons can function as source of SE. These vicarious experiences, i. e. observed experiences of models, are of greater influence when the observer perceives higher resemblance to the model. Verbal persuasion can be a third source of SE if significant others express faith or doubts in one's capabilities. This source is less influential than the first two. The last source mentioned by Bandura is that of

physiological and affective states. Stress reactions or feelings of joy in the face of certain tasks may influence one's SE if no other information is available. The way these sources influence one's SE is dependent on the cognitive processing, and therefore SE cannot simply be interpreted as the sum of prior mastery experiences (Bandura, 1997). Of these sources, enactive mastery experiences appear to be the strongest at higher education level (van Dinther et al., 2011).

## Research questions and methods

Based on the preliminary findings and open questions described above, this study aims to find answers concerning the following research questions:

1. Do mathematic and social SEs change during the first months at university and if so, how do they change?
2. How does the mathematics preliminary course affect mathematic and social SEs?

At University of Applied Sciences Münster each year in September before the start of the semester, a mathematics preliminary course takes place. It consists of twelve modules: The first one – “How to study” – addresses general differences between school and university and other study-related aspects, such as time-management or preparation for exams. The second module – “practicing mathematics” – gives an introduction into reading and writing mathematics, set-theory, propositional logic and proofs. The remaining ten modules focus on contents of school mathematics from lower and upper secondary level (Kürten & Greefrath, 2016).

**Figure 1: Time bar of the preliminary course and the accompanying surveys**

For the quantitative part of the study, three data collection points were chosen: At the day before and at the first day of the preliminary course (pretest), in the first two weeks of the semester (posttest) and in the first two weeks of January (follow-up test, see Figure 1). Participation in the first test was mandatory for all students taking part in the preliminary course and voluntary for the rest. Participation in the posttest and follow-up test was voluntary because of organizational reasons. Each mathematics test consisted of 19 items associated with the contents of the mathematics modules of the preliminary course, with items that vary from test to test only in the used numbers or the given context. After completing the mathematics test, the participants submitted a questionnaire on statistical data, such as the type of school qualification and the elapsed time since the end of school, and a SE questionnaire. This questionnaire, in 2015, was composed of the German versions of three category systems: general SE (Hinz, Schumacher, Albani, Schmid & Brähler, 2006), mathematics SE (Zimmermann et al., 2011), and social SE (Hermann, 2005). The general efficacy part uses a four level Likert scale, while the other two operate with a five level Likert scale. The results of the general SE test were used to complement the specific view of the other scales and provide an opportunity to

detect testing-effects. The other scales were chosen due to the results of prior analysis (2014), which suggested changes in mathematics and social SEs. This specific mathematics SE scale was chosen, as it presents tasks that can be solved using school mathematics, the only mathematics most of the students taking part in our survey knew when filling in the pretest. The reasoning behind the choice of social SE scale lies in its specific design for students at tertiary education. It was translated into German, and the translation was validated by retranslating the items back into English and comparing the two English versions. These scales were chosen because they were already tested for validity, objectivity, and reliability with satisfying results (e.g. Cronbach's  $\alpha$  between .80 and .94) (Zimmermann et al., 2011, Blömker, 2016, Smith & Betz, 2000).

For the qualitative part of the study we chose two data collection points: In the week before the preliminary course began (first interview) and during the third and fourth week of studies in October (second interview, see Figure 1). Participation in the interviews was voluntary. In the first interview 14 students were interviewed, and out of this group 8 were chosen for a second interview according to their department, their results in both mathematics tests, and their school-leaving qualification, to generate a heterogeneous sample and thus gather a large range of positions present in the population. The interviews were conducted using a semi-structured interview guide. The questions focused on mathematics and social SE as well as the students' motivation for studying and learning. In addition to the qualitative data gained in the interviews, the results of the SE scales were analyzed using t-tests to find changes in SE during the course, and semi-partial correlations to assess the relationship between attending the preliminary course and changes in mathematics SE. The interviews were transcribed and analyzed using qualitative content analysis according to Mayring (2014). As the interviews should be used to understand the quantitative findings, our focus lay on mathematics and social SE. To find reasons for changes and the perceived level of SE, inductive category formation was used conducting a summarizing content analysis (Mayring, 2014).

## Results

### Self-efficacy scales

In 2015 the SE questionnaire was completed by 409 students in the pretest, by 243 students in the posttest and by 135 students in the follow-up test. The downturn in the number of participants from pre- to post- and follow-up test can be ascribed to the change from mandatory to voluntary participation. 167 students completed the questionnaires in pre- and posttest and 54 students completed all three questionnaires. Comparison of the results of students taking part in the pre- and posttest ( $n = 167$ ) respective in all three tests ( $n = 54$ ) shows no significant differences in general SE and significantly higher results in the post or follow-up test for social SE (small effect size:  $d_{z\_post} = 0.20$ , resp.  $d_{z\_fu} = 0.40$ ) and mathematics SE (medium effect size:  $d_{z\_post} = 0.61$ , resp.  $d_{z\_fu} = 0.79$ ). To measure the relationship between attendance in the course and changes in mathematics SE we compute a semi-partial correlation of preliminary course attendance (as stated by the students) and mathematics SE after three months. We assume that for students not taking part in the preliminary course, mathematics SE didn't change in the weeks of the course. As those students neither took part in the course nor in the associated e-learning, we suppose they didn't engage in mathematics during this time. As we did not have results from those students in the pretest, we compare the first result of each student (whether it is from the pre- or posttest) with their results in the follow-up test. We found a significant correlation of .26 ( $n = 112$ ,  $p = .006$ ) between preliminary

course attendance and mathematics SE in the follow-up test, after partialing out mathematics SE-results of the first test.

## Interviews

In 2015 eight students taking part in the preliminary course were interviewed twice. They were of age 18 to 22 and studied chemical engineering (2), informatics (1), and electrical engineering (5). The qualitative content analysis resulted in six main categories: mastery experiences, vicarious experiences, verbal persuasion, goal setting, temporal effects, and type of teaching.

Pseudo-nym	School-leaving qualification		Last grade in mathematics	Test results		Mathematics SE		Social SE		Time since end of school
	Type	Grade		Pre	Post	Pre	Post	Pre	Post	
Dennis	ATC	1	1	81%	84%	80%	96%	59%	73%	0 years
Roman	A-level	3.3	4	68%	74%	72%	75%	53%	47%	1 year
Christoph	ATC	2.3	2	11%	61%	59%	72%	71%	80%	3 years
Leon	A-level	2.6	2.7	42%	95%	69%	80%	70%	72%	3 years

**Table 1: Statistical data of the interviewees cited in the article with German grades ranging from 1 (very good) to 6 (inadequate) and German school-leaving qualifications “Abitur” (A-level) and “Fachgebundene Hochschulreife” (advanced technical certificate [ATC])**

In the first interviews some students explained their perceived competence in mathematics by the time that has elapsed since their last studies of mathematics at school (Christoph, Leon) or by social comparison with students coming from more demanding schools (Dennis):

Christoph: Well, my mathematics are a bit rusty. I had in the advanced technical certificate/ I was quite good. [...] And now I haven't had any mathematics in the last three years apprenticeship. Really not a bit. (1<sup>st</sup> interview, translation by the author)

Dennis: If I now/ If I consider, I've been at a main school (Hauptschule), so surely there is something missing in maths compared with those of a middle school (Realschule) or a grammar school (Gymnasium). (1<sup>st</sup> interview, translation by the author)

In some of the answers the changes in the preliminary course are quoted as reasons for confidence in social or mathematical settings. The groupwork at the beginning of each tutorial offered possibilities to meet people and to solve harder tasks together. In the second interviews differences in school-leaving certification were of lower importance than mastery experiences in social tasks (finding a study group) as well as in mathematical tasks, and in the latter case the mastery experiences were attributed to personal effort:

Dennis: It worked out well. I met new people right after the preliminary course. It opened up with the groupwork. You have to talk to other people there. [...] And then groups formed right away and why should it worsen?! (2<sup>nd</sup> interview, translation by the author)

Roman: [...] I was first put off a bit by the exercises because I wasn't able to figure them out. But as I took the lecture notes, I understood it and I liked that a lot. Because I realized that I understand things I didn't understand before. And I could solve exercises I hadn't been able to solve and then I saw there is improvement. (2<sup>nd</sup> interview, translation by the author)

Christoph: That shows me that I'll be able to solve hard problems that I couldn't solve at first if I study for them. And it shows me concerning my studies that a 2.0 might be possible. Depending on how much I will knuckle down and then practice, practice, practice. (2<sup>nd</sup> interview, translation by the author)

The prediction of failure rates was mentioned by some students as a reason for their fear to fail in mathematics. These vicarious experiences didn't differ from those reported in 2014:

Interviewer: Okay. We get to the next statement: "I'm afraid to fail in my studies due to mathematics".

Leon: Well, I would say four. That's more like the case, there is a certain fear of course.

Interviewer: And can you explain why you put the cross at the four?

Leon: Well, if you look at the rate of the last year, there are many failing. And there is of course/ you fear a bit that you won't be able to make the cut somehow. (2<sup>nd</sup> interview, translation by the author)

## Discussion and perspectives

In the study presented here we show that students' mathematics and social SE did rise during the preliminary course, and that this effect was stable over a period of at least three months.

As participation in the interviews and the posttests was voluntary, and participation in the pretest only mandatory for those taking part in the preliminary course, the sample is probably not representative of the population of first year students. For example, motivation for learning or studying might influence the students' decision whether or not to take part in the course, the interviews or the tests. This is especially important for the quantitative analysis of the SE scales. Although the qualitative analysis of the interviews doesn't need statistical representativeness, it should be considered that certain interesting types of students (for example those with low motivation) were not included in our sample. Besides this limitation of the study, the results presented show that even in the first weeks at university study-related (mathematics or social) self-efficacies change, while general SE remains relatively stable. For ethical reasons we had no control group of students wishing to take part in the preliminary course, and for organizational reasons we weren't able to collect pretest results of those students not attending to the preliminary course. Therefore, the quantitative data does not reveal whether the perceived changes in SE are caused by the preliminary course or not. At that point the qualitative data help interpret the quantitative results, as their analysis suggests that experiences in the preliminary course influence changes in SE. Those experiences resulted partly from the redesign of the preliminary course in 2015, for example, the forced group work at the beginning of each tutorial that fostered social SE.

We did assume that for students not attending the preliminary course, no changes in mathematics SE occurred during the time of the course. However, some students might have used other resources to

prepare for their studies or just reflected on their competencies in comparison to the requirements of the University of Applied Sciences Münster. Again, the qualitative data help us justify our conclusions, as none of the students taking part in post- or follow-up tests stated other mathematical activities as reasons for not attending the preliminary course in the open ended questions of the survey. We feel therefore confident that our conclusion is valid for at least the bigger part of the students. Nevertheless, the correlation between course attendance and development of mathematics SE has to be treated with caution.

With regard to our first research questions we can say that in contrast to the findings of Fischer (2014), SE beliefs did change in the first months at university at least in the part of the population that attended the preliminary course. Social SE rose slightly and mathematics SE rose moderately during the preliminary course. These results are in contrast to the findings described in the introduction that predict a decline of self-efficacies during transitions (Schunk & Meece, 2006). The differences may be a result of different ages of the observed students, effects of the preliminary course, or other reasons. Another possible explanation is that the decline of SE takes place even before the preliminary course and is therefore missed by our survey. Further research could clarify this by assessing SE well before the move to tertiary education, as well as before and after a preliminary course. With regard to the second research question, we did find clues that there is a relationship between the changes in SE and the preliminary course attendance. Those students who reported mastery experiences (social or mathematical) in the second interview showed an increased value for the related SE in the second test as well. Further research should investigate changes in SE during a preliminary course in an experimental or quasi-experimental design to investigate whether the changes reported here are indeed caused by the preliminary course.

Of the students cited in this paper, those who had been out of school for a longer period showed lower mathematics SE than the others. As they also stated the elapsed time without mathematics training as a reason for their perceived mathematics ability, it might be interesting to evaluate the effect of time on mathematics SE.

## Q<sup>2</sup> game used in a task design of the double quantification

Thomas Lecorre

University of Grenoble-Alpes, department of mathematics, France; [thomas.lecorre@wanadoo.fr](mailto:thomas.lecorre@wanadoo.fr)

*This article deals with student's interpretation of multiply-quantified statements. The efficient interpretation of such statements is useful, for example, for those who try to understand and use the formalism of the definition of limit of a function. Literature points out some students' difficulties in the interpretation of double quantified statements. I am using the scientific debate methodology to design and implement tasks by means of two fundamental steps. In the first step, I draw on the results of a questionnaire to identify students' difficulties related to the order of quantifiers in the interpretation of such statements. The aim of the second step is to design the targeted tasks by considering the results of the first step; these tasks are based on a game called Q<sup>2</sup>. The implementation of the design shows that students understand that there are at least two kinds of interpretations, and that conventions of interpretations are needed.*

*Keywords: formalism, quantification, limit, scientific debate in class, game Q<sup>2</sup>.*

### Quantified statements problem

Mathematics formalism uses massively quantification and specifically multiply-quantification. Research shows that students have difficulties with the interpretation of multiply-quantified statements (Dubinsky & Yiparaki, 2000; Chellougui, 2009; Piatek-Jimenez, 2010). EA statements corresponding to "Exists...for all..." sentences must be distinguished from AE ones corresponding to "For all...there exists...". Dubinsky and Yiparaki (2000) study the impact of two main variables on the interpretation of double quantified statements. The first variable is the order of quantifiers (AE or EA) and the second one is the kind of statement, mathematical or non-mathematical. They show that the interpretation of non-mathematical statements is essentially correct but the interpretation of mathematical ones is difficult for students. For AE mathematical statements, the students' interpretation is very efficient, whereas their interpretation of EA ones seems to be done through an inversion: the EA statement is very often interpreted as the AE corresponding statement (the variables remain with their own quantifiers but the order of quantifiers are changed). Moreover, it is noticed that "the students did not appear to care of the syntax of a statement to analyze it [...] the student did not appear to be aware of having engaged in interpreting the questionnaire statements." (Dubinsky & Yiparaki, 2000, p. 53). The inversion of interpretation of an EA statement is also noticed by Chellougui (2009) when she asks students to define the upper bound  $M$  of a set  $A$  and when almost all of them answer by what she calls "a strange definition": «  $\forall x \in A, \exists M \in \mathbb{R}, x \leq M$  ». Piatek-Jimenez (2010) confirms the asymmetric perception and interpretation of those two kinds of double quantification in the mathematical field. There seem to be two different problems: the use of "strange" conventions and the unawareness to interpret statements.

To overcome these difficulties Dubinsky and Yiparaki (2000) presented a game based on the dialogical logic (explained below) and used it with students to make them aware that two kinds of interpretation can be used and that this depends on rules of interpretation linked to the places of quantifiers. Results have shown that the game seems to help sometimes students to understand such statements but in some cases, it does not, and in a few cases this has created more confusion.

I want to pursue this research by designing tasks to overcome the difficulties of the interpretation of double quantified statements using the methodology of scientific debate. This implies two related goals. The first one deals with the identification of students' difficulties related to the order of quantifiers in a double quantified statement. I specifically explore the role of some other potential variables: the set of quantification (familiar or not, finite or infinite), the semiotic representation of the quantified variables (formal or usual language) and the kind of relation involved in the predicate (familiar or not). The second goal is to design and to implement tasks by considering the results of the study related to the first goal. A new game called  $Q^2$  based on the interpretation of double quantified statements to determine a winning strategy will play a fundamental role in this design.

The aim of this paper is to study the following question: is there a domain of values of variables where students take into account the order of quantifiers and if yes how to take advantage of this domain to enlarge it? Specifically, how to make students aware that they are interpreting these statements and that they need rules for that?

### **The methodology of scientific debate: A tool for designing tasks**

The scientific debate (Legrand 2001) is a socio-constructivist approach to learning and teaching mathematics based on two main principles: 1) the need of new knowledge can be obtained by making one realize that his/her previous conceptions may lead to contradiction; 2) the organization of appropriate debates among students permits firstly to express and share previous conceptions about the targeted subject, secondly to encounter the limits of these conceptions, and thirdly to be able to understand the institutionalisation related to this knowledge that is made by the teacher. Three fundamental steps shape the design of tasks by means of the scientific debate methodology:

1) The first step consists on epistemological and cognitive studies of the targeted mathematical concept: the role of quantifiers in formal statements and the interpretation of double quantified statements that stands on the use of a convention of interpretation. For this interpretation, I have chosen the dialogical logic (Lorezen, 1967). In this paper, we mainly explore the cognitive aspects and we use a questionnaire for that purpose.

2) The second step concerns the design of the tasks, which is done by using mainly two kinds of questions to initiate the debate. The first kind of question concerns the truth of a conjecture: is it true or false? This conjecture can be given by the teacher or can come from the students after a call for conjecture. The second kind of question concerns the nature of an object for a conjecture or a property: is it an example, a counter example, or off topic (neither example nor counter-example) for this conjecture, and is it an example for a property? The example can come from the teacher or from a call for an example. A vote is made: do you think it is true, false or *something else* (an example, a counter example, off topic or *something else*)? The possibility of voting for *something else* is given to preserve the authenticity of the other votes (voting True or False must be a choice founded on convictions). Then a debate is organized by the teacher among those who have different view-points. The teacher never gives any opinion about what is debated but tries to maintain a level of interaction by emphasizing the contradictions between students.

3) The third step concerns the level of experimentation and its analysis: what actually happens is confronted to what was expected to happen. Specifically, this analysis leads to discuss the efficiency of the choices made in the two first steps.

The whole study is conducted according to the aforementioned three steps. In this paper, I show my findings from the study related to the first step and I give more details about the elaboration and the results of the two final steps. For the first step, I have chosen to use a questionnaire on a sample of 181 students in their last year of secondary school to identify students' difficulties with the interpretation of double quantified statements in formal and non-formal context. For the second step, the results of this questionnaire are used in a way that is aiming to make students aware that the lack of the rules of interpretation is not a problem in a certain domain but leads them to conflicts out of this domain. This design is based on a game, called  $Q^2$ , in which the interpretation of double quantified statements is crucial: the question that will initiate the debate concerns the way to win this game. For the third step, I experiment this design for students in their last year of secondary school in a scientific class composed of 29 students (experimentations at university are planned).

## Task design

### Background: The result of the questionnaire

I have mainly studied five variables in the interpretation of double quantified statements: place of quantifiers, kind of statements (mathematical or not), the set of quantification (familiar or not, finite or infinite), the semiotic representation of the variables (formal or informal language) and the kind of relation involved (familiar or not). In the questionnaire, words (for all, exists) are used instead of symbols because symbols are introduced after the game  $Q^2$  as a solution to the conflicts that appear about quantifiers and associated conventions. A questionnaire has been given to 182 students. We will only give the findings here (for more details see Lecorre, 2016a). The first finding is that the rule of “correct interpretation for AE statements and inversed one for EA statements” seems not so obvious: some EA statements are perfectly interpreted whereas some AE statements are interpreted through an inversion of the quantifiers and the variables. The second finding is that some other variables are correlated with difficulties in the interpretation (e.g. width of the quantified set, formalization of variables...). The third finding is that there exists a domain of correct interpretation for both EA and AE. This domain is made of non-mathematical statements quantified on a “small” finite set (less than ten values) without any formal variable and with a familiar relation. These findings are then used to design the tasks aiming at discussing the interpretation of double quantified statements.

### The game $Q^2$

The game presented by Dubinsky and al. (2000) is based on the dialogical logic of Lorenzen (1967) which gives a way to decide on the truth of quantified statements using a codified dialog between a proponent and an opponent. In this game, for example, if the sentence is “for All  $x$  there Exists  $y$  such that  $R(x;y)$ ”, the A-player chooses  $x$  and the E-player has to find a  $y$  such that  $R(x;y)$  is verified. If he/she fails to find such  $y$ , the A-player wins, otherwise the A-player can give another  $x$  (same kind of rule for EA). I call this game a direct game: given a statement and sets of quantification, you have to decide the truth. The  $Q^2$  game is an inverted game: given a statement and the truth, the players construct the set of quantification to make a statement true or false.

For the  $Q^2$  game I choose values of the variables that make it an easy game to play: non-mathematical field, small set of quantification, familiar relation. This choice is made to permit students to get into the game and into the interpretation of associated statements.

This is a two players' game. This game is given by four elements: a starting rule, a winning rule, a statement and a grid. For example, red player has to start (starting rule) and plays for the falsification (winning rule) of the statement S: "For all red letters, there exists the same black letter" and the given grid:

H	U	H
L	U	L
U	H	T

**Figure 1: A grid for the game  $Q^2$**

So red has, first, to circle one letter with his red pencil. Then the black player circles one letter and so on until all the letters have been circled. With the given elements of this example (starting and winning rule, statement, and grid) and the coloration of letters, if the statement S is false then the red player wins, but if it's true the black one wins. This game has, of course, many variants, beginning with the filling of the grid and the starting and winning rules. This game is the heart of a design which aims precisely to enlarge the domain of good interpretation. I am going to show that a smart use of  $Q^2$  in the design has the potential to reach such a goal by emphasizing the lack of the convention of interpretation.

### **"The $Q^2$ situation"**

The principle of the  $Q^2$  situation is to provoke conflicts of interpretations that will lead students to the need of the convention of interpretation. The situation  $Q^2$  is divided into four periods:

- The first period aims an appropriation of the game  $Q^2$  by playing.
- The second period deals with the concept of winning grid for the game  $Q^2$ .
- The third period targets a conflict of interpretation, in a way that students feel the need of conventions of interpretation. At that stage, the conventions are given.
- The fourth period is just an application of these conventions on the unsuccessful domain where the values of the variables lead students to difficulties of interpretation.

In the first period, a paper is given that contains eight games of  $Q^2$  to play (each game is defined by a statement, a starting rule and a grid). These games are designed for the two players to have opportunities to win and to start to have ideas on how to play to have good chances of winning. In fact, with such a game, with "good players", the winner depends only on the statement (EA or AE), the starting rule, and the grid given.

The second period aims at the definition of winning grid. The students are asked to give the winning grids for a given rule, then a debate is organized about these propositions: are they winning grids, or not? The contradictory opinions about the propositions should lead students to identify the lack of a definition of winning grid. A winning grid is, in fact, quite difficult to define in a mathematical way for pre-university students (double recursive definition). Here, a definition such as "a grid is a winning grid for red if when red plays "cleverly", he is sure to win, even if black also plays cleverly" is largely sufficient for this design. When the students show a need for a definition, the above definition is given.

The third period aims to highlight the lack of convention of interpretation. Once again, for a given rule, the students are asked to give winning grids. There should be no more conflicts about what is a winning grid in general, but new conflicts should appear about the propositions: is this grid really a winning grid with this rule? This should happen because the winning grids depend on the interpretation of the rule which is a double quantified statement. And the need for a convention should appear with the impossibility to find a common agreement (is it a winning grid or not?). The didactical principle which is used here is the following: it seems very difficult to organize a direct confrontation of the different rules used by students to interpret a double quantified statement, because this problem, taken as a general one, is too theoretical and depends on too many variables (findings of the questionnaire). On the contrary, it is much easier to create a conflict on concrete consequences of the interpretation of such statements. Here, the conflict holds about the question "is the grid a winning one or not?" Then, trying to understand each other, and trying to convince their peers, students are going to explain their own interpretation. And then it will appear that the implicit conventions used by students are contradictory. Students can realize that without common conventions, no agreement is possible. Deciding if a grid is a winning grid or not is possibly more complicated than the logical principles of deciding who won, but it leads students to materialize their own conventions through these grids and permit to confront these conventions.

Then these conventions are given in the manner of the dialogic logic (Lorezen, 1967), which is described above with the game of Dubinsky and Yiparaki (2000). At this stage, the game  $Q^2$  plays as a preparation to such rules by simulating a game between a proponent and an opponent. The design here aims much more the awareness of the need of convention than the "right rules". The aim is to make students aware of the necessity to check the validity of their interpretation relatively to the adopted conventions.

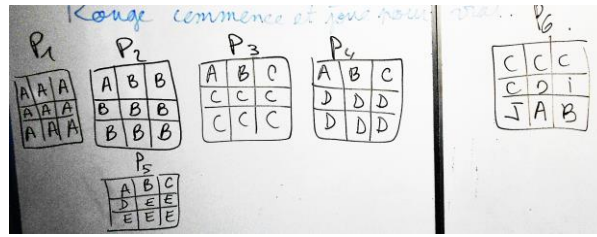

The fourth period consists in verifying, still using debates, that the given rules can lead to agreements, and even in the domain where students used to fail: the rules are helpful, efficient.

## Results

The first period of the situation  $Q^2$  (playing the game) shows a good appropriation of the game: the winning grids were almost always won by the one for who the grid was a winning one, which means that the students were playing "cleverly". Some strategies seemed to begin to be used. And, above all, almost all the decisions about who is the winner were correct. All this is coherent with the results from the questionnaire in terms of domain of interpretation.

The second period led to the question of the definition of a winning grid. The definition is given.

The third period begun with a question of the interpretation raised by students in a debate. I present an extract of the script of this debate to explain this unexpected acceleration. Student are asked to give winning grids for red for the game "There exists a red square such that all black squares have the same symbol" where red starts and plays for true. The given statement does not specify if black squares shall have the same symbol as the red one or not. So, after six winning grids had been given by the students in the second period, this lack of information was intensely discussed.

**Figure 2: The winning grids for red given by the students**

The grid P1 was put into debate and everyone agreed that it was winning grid for red. Then P2 was put into debate (28 votes for a winning grid for red and 1 for “something else”). Loïc who had voted “something else” changed his mind and explained why, for him, it was a winning grid for red:

Loïc: Because red starts and as he plays to win he takes the square A and...

Teacher: You're saying that “red plays A first” yes and what?

Loïc: Then black takes only B squares.

Teacher: Black only takes B squares. Why, in the end, red wins?

Loïc: Because....

Hadrien: Because Black has only B squares.

But Quentin disagreed with this explanation:

Quentin: And because red has it also (One B square)

But Hadrien and Louis did not agree with this addition:

Hadrien: No, he has A squares and B squares.

Quentin: Yes!

Louis: I think that I should just say that there exists a red square.

The sequence above shows that these students do not need to disagree on the fact that it is a winning grid or not to begin to explain their own interpretation: “the same symbol as the red square” (Quentin), or “the same symbol for all black squares” (Loïc, Hadrien). Then Fabio, in the same way, explained that nothing must be added contrary to the sayings of Quentin:

Fabio: I do think that what Quentin added is not necessary.

Then Quentin proposed a grid to strengthen the differences of interpretations:

**Figure 3: Quentin's grid (As in black and Bs in red)**

Leaving aside for a while the problem of the winning grid, the teacher asked whether the statement S1 was true or not, according to the grid of Quentin. Twelve students thought that the statement was true, ten false, while six students voted something else. Some conclusions were then raised :

Fabio: There are some, like me, that can think that all the black squares have got the same symbol is enough and some other, like Sébastien, who are thinking that there must be a red square that has got exactly the same symbol as any black square.

Mickaël: I'm asking: if you who think that only black squares have the same symbol is enough, this red square exists such that what?

This made Hadrien change his opinion, but Louis did not agree with this change:

Louis: There are two opposite opinions just because we're not thinking the same.

Teacher: Ok, you are not reading the same way... That is what Fabio said...

Louis: Exactly!

Juliette and Maxime then explained why they voted something else:

Maxime: That is exactly why, from the beginning, I voted Other.

Juliette: So do I.

These two interpretations are not directly linked to an EA/AE inversion but to the interpretation of the predicate. It would be interesting to investigate the role that the vernacular language (the linguistic subtleties that may eventually vary in French or English) may have played in leading students to interpret the two variables in the predicate as bound variables ("the same as red squares"), as shall be done in AE statements, where as it isn't the case in such an EA statement. In any case, the discussion among students led them to work on these interpretations and to get aware of the complexity of having a unique interpretation. The teacher then gave the conventions of interpretation of EA and AE logical statements. These conventions were then used successfully for the applications of the fourth period. One month later, the same students had to face double quantified statements in a situation aiming at the definition of limit. They experienced, once again, the need of conventions when they encountered another conflict of interpretation of these statements, so they checked the conventions to decide on their own (Lecorre, 2016b).

Later, another experimentation was realized with some other students using a "complete" rule ("...such that all the black squares have the same symbol as the red square") and this led students, with a grid of eight squares filled with symbols appearing twice, to the predicted conflict (EA/AE interpretation). A new didactic variable is then identified, the constitution of quantified sets (how they are filled relatively to the predicate), which raises an unexpected question: is the students' choice of convention between EA and AE convention for the interpretation more guided by the constitution of the sets of quantification than by the statement itself?

## Conclusion

The Q<sup>2</sup> situation, with the scientific debate methodology, were used to make the interpretation of the double quantified statement the main object of students' discussion. The contradictions that the lack of conventions of interpretation was bound to imply then emerged in that discussion. This lack which was invisible to students suddenly came into light with these contradictions.

More precisely, the questionnaire led to identify some variables playing a role in the interpretation of students. There is a domain of the value of those variables which gives a good interpretation.

This  $Q^2$  situation led students to be ready to receive the conventions of interpretation of double quantified statements. Indeed, they have experienced the need of shared conventions. The described situation  $Q^2$  mainly aims the recognition that there are two kinds of double quantifications that should be differenced according to the order of the quantifiers in the statement and the convention of interpretation of the predicate but the validation using variables defined in function of the other variable remains a difficulty.

*In university mathematics, support measures address diverse goals in terms of students' knowledge and abilities, motivation and beliefs, or institutional goals like the reduction of dropout rates. In order to facilitate the analysis of specific support measures' goals, their evaluation and comparisons with other forms of support, we aim at developing a taxonomy for these goals. To this end, we have analyzed documents of 44 innovative projects of mathematics support in Germany and conducted supplementary interviews with teaching staff. We present the method and intermediary results of this research and discuss its potential use for researchers, policy makers and teaching.*

*Keywords: Educational objectives, Mathematics support, Taxonomy, Tertiary education.*

## Background and aim of the paper

Mathematics support has become a common endeavor in many universities and both researchers and teaching staff are interested in identifying the “best way” of supporting their students. The research we present here is part of the ongoing WiGeMath project (Wirkung und Gelingensbedingungen von Unterstützungsmaßnahmen für mathematikbezogenes Lernen in der Studieneingangsphase; Effects and success conditions of mathematics learning support in the introductory study phase), which is a joint research project of the Universities of Hannover and Paderborn (Colberg et al., in press) led by Biehler, Hochmuth and Schaper. In a first phase, the research aims at identifying and structuring goals that have been pursued in selected Projects of Mathematics Learning Support (PMLS). This paper reports on the methodology and the research outcomes of this first phase, drawing upon the project proposal and the intermediate project report of the three project leaders.

In WiGeMath, we examine 44 PMLS in mathematics programs, teacher education and diverse engineering programs at 14 German universities. These projects all have in common that they are trying to help students acclimatize to university mathematics. We label them innovative as they aim at deviating from the formats of standard lectures or standard tutorials. The extent to which they can fulfill this deviation is part of the evaluation in WiGeMath. The PMLS are clustered into four types: bridging courses, mathematics support centers, redesigned lectures and support measures that parallel courses. In most German universities, bridging courses are offered shortly before the beginning of the first semester and aim to bridge the gap between school and university, dealing with school contents as well as university contents. Mathematics support centers are relatively new to German universities and have been implemented in rather few universities. They are designed as optional classes for students where they can go and seek help or work on their math problems under

the supervision of experienced tutors. Redesigned lectures are also relatively new and are offered particularly for preservice secondary teachers in order to support their transition from school mathematics to more abstract mathematical content. They focus more on study techniques like problem solving or reading and writing mathematical texts than on mathematical content. Support measures that parallel courses are diverse and include formats that provide online learning material as well as tutorials for special study groups (e.g. students at risk of failing the course), with a special focus (e.g., applications) or for a special purpose (e.g., exam preparation). Using a program evaluation approach (Chen, 1990), WiGeMath aims at evaluating different PMLS based on their own assumptions and comparing them. Therefore, we developed a taxonomy in the sense of a descriptive (non-normative), structured set of goals, features and conditions of the PMLS. In this paper, we focus on the taxonomy for the goals of PMLS. Here, the term “goal” is interpreted in the sense of any observable criterion that provides ground for the evaluation of a PMLS against its own initial conception. Existing taxonomies of educational objectives include cognitive and affective aspects of students’ learning (e.g. Krathwohl, 2002). However, they only describe learning outcomes of the individual. For evaluating the PMLS’ outcomes against their respective initial conception and comparing different PMLS, existing taxonomies have proved insufficient. We found, for example, that some PMLS have goals that cannot be assessed in terms of individual learning objectives, like the support of certain study groups.

## Method

We constructed a new taxonomy using an empirical approach consisting of two steps. In the first step, a document analysis was conducted based on documents from the partners’ PMLS. This step resulted in a first draft for the taxonomy. In a second step, this rough taxonomy guided interviews with teaching staff to check, refine and supplement the categories.

For the first step, we asked our partners to send us any document that might inform us about the projects, including self-descriptions and learning material. The kind of information greatly varied across the projects: some PMLS had been described in conference papers or posters; others sent us lecture notes or books, and in several cases, flyers or websites addressed at students were available. In the case of redesigned lectures, we also analyzed study regulations. Moreover, the depth of information varied as some projects had explicit descriptions of their goals, others only had learning resources and some PMLS were just in the making and could not give us any documents. We thus asked several partners to describe the goals of their projects either via email or in unstructured interviews and then included these emails or interview notes and transcripts in the analysis. In the following phase of the document analysis, we followed the typical steps of skimming the documents for relevant passages, reading them and interpreting them as an iterative process (Bowen, 2009). Following the principles of inductive category formation in qualitative content analysis (Mayring, 2015), we worked through the relevant passages line by line, either subsuming the goals under existing categories or constructing new ones. In this step, we also reconstructed goals that were not mentioned explicitly but were apparent in the documents. If, for example, learning material explicitly asked the students to consider mathematics as a process of trial and discovery, we assumed the change of students’ mathematical beliefs to be a goal. Due to the high diversity of materials and goals, we worked through all the material before reorganizing the

categories in a rough taxonomy. Here, distinctions from the literature were implicitly taken into account, like the distinction of cognitive and affective outcomes.

A limitation of document analyses may lie in insufficient details and a bias in the document selection (Bowen, 2009). Specifically, the teaching staff could have had goals that were not reflected in the documents. Thus, in the second step the rough taxonomy was used to guide eight interviews. Two interviews were held for each of the investigated designs, i.e., bridging courses, mathematics support centers, redesigned lectures and support measures that parallel courses. The interview guide first asked for the goals of the PMLS in general and then used the subcategories for deeper inquiry of each specific aspect. In the interviews, we found that some staff members did not mention all goals immediately. In reaction to a general question, only some goals were named. Explicit questions mentioning specific goal categories, however, led to additional goals named by the staff members. These interviews, taped and transcribed, were coded using the rough taxonomy as a coding scheme in order to see if each goal that was mentioned by the interviewees fit into one of our categories. This led to the refinement or reformulation of subcategories, but generally, all goals were covered by the taxonomy.

## Results

The goals we identified were split into two main categories of educational goals and system-related goals, each of which consists of several sub-categories. We proceed with a presentation and description of the emerged categories and sub-categories that are summarized in Table 1.

### Educational goals

The first main category of educational goals comprises learning outcomes with a focus on objectives regarding the individual learner. These educational goals are subdivided into knowledge goals, action-oriented goals and attitudinal goals. As these goals are more or less covered in existing taxonomies (e.g. Krathwohl, 2002) and space is limited, we omit a description and discussion of these goals. We only shortly mention the last category of **learning and working conduct**. It refers to learning rhythm (i.e., when do participants study), learning expenditure (i.e., how much do participants study), learning materials (i.e., which resources do participants use when studying), learning environment (i.e., where and with whom do participants study) and use of the PMLS' provision. This goal differs from the ones mentioned so far as it does not represent a final goal of studying but rather functions as a mediating partial objective that facilitates the fulfillment of other goals at a later point in the course of studies. Staff members explicitly mentioned that they wanted their students to work in specific ways they assumed to be most efficient.

### System-related goals

In our study, we found goals which do not focus on students as individuals but rather take into account the university as a broader organization and therefore decided to label them system-related goals. We specify how we understand each of these categories and which aspects they include. It is important to note that the system-related goals and the educational goals are not necessarily disjoint. When using the taxonomy to categorize the goals of a PMLS, these goals may fall into one category under educational goals and, at the same time, into another category under system-related goals. The difference lies in the focus on the individual learner versus the institution as a broader

organization which for example has to establish its own reputation, take into account questions of funding as well as maintain its societal position in providing studies that lead to certain certificates.

<b>Educational goals</b>	
Knowledge goals	<ul style="list-style-type: none"> <li>- school mathematics knowledge and abilities</li> <li>- higher mathematics knowledge and abilities</li> <li>- the language of mathematics</li> </ul>
Action-oriented goals	<ul style="list-style-type: none"> <li>- mathematical modes of operation</li> <li>- university modes of operation</li> <li>- learning strategies</li> </ul>
Attitudinal goals	<ul style="list-style-type: none"> <li>- beliefs</li> <li>- affective features</li> <li>- perceived relevance for the future job</li> <li>- perceived relevance for future studies</li> <li>- mathematical enculturation</li> </ul>
Learning and working conduct	
<b>System-related goals</b>	
Creation of prerequisites for knowledge/abilities	<ul style="list-style-type: none"> <li>- improvement of school knowledge and abilities as a prerequisite for university studies</li> <li>- requirements for lectures that exceed school knowledge</li> </ul>
Improvement of formal study success	<ul style="list-style-type: none"> <li>- dropout rates</li> <li>- passing rates/achievements</li> </ul>
Improvement of teaching quality	
Improvement of feedback quality	
Promotion of social contacts and connections relevant for the studies	
Making university study demands transparent	
Supporting of certain student groups	

**Table 1: Categories of the WiGeMath taxonomy**

As to the **creation of prerequisites for knowledge/abilities**, PMLS with this target would aim at qualifying students to participate successfully in subsequent university classes. This might be achieved via the *improvement of school knowledge and abilities as a prerequisite for university studies*, a category that we defined as a first sub-category. We refer to topics and methods that are not part of regular university lectures but should be familiar to students from their school background like doing arithmetic with fractions, sine, cosine, and solving systems of linear equations. The difference between this goal and the educational goal of fostering school mathematics knowledge and abilities is that the educational goal is only achieved when each and every student has gained the knowledge in focus, whereas the system-related goal is reached when the bigger part of students has gained this knowledge so that future teaching can take this knowledge as shared. In the latter case, it is inconsequential whether all students make use of the knowledge supply and integrate it into their own learning. It is well known, for example, that

students entering university often have gaps in their knowledge while lecturers want to give their lectures as if this knowledge was present. In one bridging course, asked for knowledge as a prerequisite in future lectures, a staff confirmed this (all quotations are own translations):

Staff member: Due to the fact that we refresh the students' school knowledge, there is something they can build on later [in the lectures] and certainly will. [...] If I look at a proof of continuity, I need absolute values and inequalities. If I do not know them, particularly now that they were removed from the school curriculum, then I have to learn them before.

Interviewer: That means, you try to compensate some deficits, in particular after changes through a school reform where some topics have been canceled from the curriculum?

Staff member: Yes, I would say.

Often, PMLS also aim at providing *requirements for lectures that exceed school knowledge*. In the innovative courses included in our study, examples may be seen in topics like groups, rings or fields that could be shifted from regular university courses, in which they would usually be discussed. Sometimes, bridging courses also cover topics that were considered school knowledge in the past but are no longer taught in schools today.

For some institutions, the **improvement of formal study success** also proved to be important. This relates to objectively measurable success criteria like *dropout rates*, defined as the number of students who withdraw from their studies, and *passing rates/achievements*, which can be measured via the final exam. For a support center, for example, this was central in the interview: "Clearly, I mean, the big credo was always to reduce the dropout rate." In German universities, dropout rates in mathematics and engineering programs exceed 30 % (Heublein, 2014). These criteria are of special interest as they may be used for an institution's quality evaluation. PMLS addressing dropout include tutorials for specific study groups with low success rates or students who already failed an exam twice and now make their final attempt.

The **improvement of teaching quality** is another goal of PMLS. The aim is to improve the teaching quality as perceived by the students and gain better evaluations from the participants. This may include changing the teaching styles and improving the communication with the students.

In our analysis, three more goals emerged, which all reflect the position that, the university on the one hand wants to provide an optimal environment for the students' learning, yet on the other hand does not take the responsibility for each individual student. The sub-category of **improvement of feedback quality** covers the aim to provide students with high-quality feedback on their state of studies that helps them improve their learning. Under **promotion of social contacts and connections relevant for the studies**, we subsume the support of social exchanges and conversations, technical aids, and stimulation to form study groups. For example, students may be offered specific hours for a specific lecture in a mathematics support center so that they may form learning groups on their own account. Also, the design of such centers may reflect this goal: "These workstations there have desks, where eight students may sit at a time. Students have increasingly come in larger groups. And it was clearly our goal, to foster this". A further category that some PMLS aimed at is **making university study demands transparent**. This includes giving insight

into demands of university education, especially with future orientation concerning preconditions and requirements in the course of further studies. Together, these aspects enable the students to make well-informed decisions on how to study according to their personal preferences.

Finally, some PMLS were designed to help certain students more than others, for example, students with a different language background, females, students with a sideline job or students with children. These aims would be encoded under **supporting of certain student groups**. For one support center, for example, the focus was on low and medium-achieving students, as we could see in the interview: “Our priority is on everyone but the high-performing students. So, from low-achieving to average. [...] If we have resources left, then the high-performers are also welcome”. In contrast, a redesigned lecture addressed the average-achieving students but not the low-achieving ones: “We have, so to say the very good students, a broad midfield and then the lower fifth part or so, where most of them will probably dropout from their studies, because they are not suitable after all. But they take part at the beginning and want to try it, anyway. And my objective during the development and conduction of this course was to address the broad midfield and in addition provide challenges for the very good students.” Another specific group that might be mentioned consists of students without “Abitur”. The German school system is split into schools for lower-achieving students where students attend nine/ten years and the so-called “Gymnasium” that adds another three years of school. Generally, only the students of the Gymnasium are allowed to attend university after they have passed the final exam called Abitur. Yet, there are exceptions where students without Abitur may attend university, a scenario that occurs particularly frequently in engineering programs. As engineering was one of the study fields we focused on, this category seemed especially relevant. This goal may reflect a special profile of the university or study program or societal goals and may come along with special funding opportunities.

## Discussion

### Methodological discussion

As mentioned above, the taxonomy at hand was developed in cooperation with university staff involved in innovative PMLS. Contrary to our expectation that the goals of PMLS were thought through and decided upon in advance, we found, in the course of our work, that many of their goals had remained implicit until our inquiry. This observation raises the question of whether important goals of innovative PMLS can be fully accessed from documents and interviews. Similarly, goals of traditional lectures might also be implicit, since some lecturers may be reproducing these long-established formats without further reflection. To be more specific, it seemed as if some PMLS aim at establishing a specific didactic contract (Brousseau, 1984). For example, students are to be offered a good learning environment in hope of thereby increasing success rates but the university does not take responsibility for the success of each individual. However, this aspect was not included in the taxonomy as we lacked clear evidence. The lack of reference to the didactical contract in the materials and the staff interview might be because of its implicitness in PMLS goals and to the less familiarity of staff to such theoretical terms.

### Discussion of the taxonomy

The educational goals in our taxonomy show similarities to the objectives of other taxonomies (Krathwohl, 2002). Whereas these models focus on individual learning outcomes, the WiGeMath

model aims at comparing and evaluating innovative measures as a whole, in particular following the program evaluation approach (Chen, 1990). This reflects in the new category of system-related goals. The system-related goals reflect three purposes: Some of the goals ensure the preservation of the institution. The creation of prerequisites for knowledge/abilities, improvement of formal study success, and improvement of teaching quality would fall into this category. Another set of system-related objectives consists of improvement of feedback quality, promotion of social contacts and connections relevant for the studies, and making university study demands transparent. These goals improve the environment for students' self-directed learning. Supporting certain groups of students is a goal of a third kind as it represents the societal goal of creating equal study conditions in higher education for a wide range of students. The taxonomy thus reflects the institutional framing, in particular goals related to the institutions' preservation as well as the preservation of the innovative PMLS, which mostly had no regular funding but were financed by federal grants for innovative support. Related notions can be found in classification systems for higher education institutions. However, these categories are intended to be strictly descriptive and can therefore not be reformulated as goals. An early example is provided by the Carnegie Classification of Institutions of Higher Education, which was created in the 70s for US institutions. Initially, it was mainly concerned with structural and organizational characteristics of institutions but has undergone major changes in 2000, strengthening the emphasis on teaching-related institutional characteristics (Bartelse & Vught, 2009). A shortcoming of the model is that it lacks a consistent theoretical framework. In following the program evaluation approach, we based its development on the individual language and paradigms of the PMLS and did not question them in their data. From a practical point of view, the model helps to highlight their similarities and specialties. From a theoretical point of view, a next step could be the consistent re-interpretation of their goals from a specific theoretical and epistemological stance, e.g. clarifying basic notions of knowing and learning. We should keep in mind, however, that such a taxonomy might not only be used for the non-normative exchange of ideas, but also be turned into a normative model.

### **Implications for research, policy and teaching**

It seems obvious that a model like the one developed above is never complete and could be expanded not only to fit more goals of innovative measures but also in order to serve regular courses or classes in other fields of study. So far in the first study phase of university mathematics education, we focused on innovative PMLS. We may thus have missed goals that are related to studies beyond the introductory year or to innovative measures integrated in the regular classes. An example for a possible system-related goal that was not mentioned in our study is the qualification of future staff or PhD-students.

Since many practitioners had to reconstruct their goals during the interviews, we believe that our taxonomy may prove beneficial to both teaching staff and developers of courses and support measures as a heuristic tool, helping them reflecting on their goals and teaching practice. It may also highlight ethical questions, e.g. by pointing out that some PMLS were designed to specifically support some students but not others. This taxonomy could also improve the communication about goals between students, teachers and institutions. It provides a common language and a frame of reference. In research, this framework is ultimately intended for the evaluation of innovative measures and so far proved useful in doing so in the ongoing WiGeMath project. For policy-

makers, a taxonomy may help in the evaluation of their decisions. In our study, we found that many practitioners had thought about various aspects of their work, but did not have a (shared) language to communicate these thoughts.

*The vector concept is an important concept students are confronted with in their first year at university. To be able to build on students' previous knowledge it is important to find out what they have learned about vectors from school. This study aims at exploring university freshmen's personal concept definitions of a vector. We therefore analyzed common German school textbooks to find out how vectors are introduced and what conception of a vector students might have developed at school. In addition, we administered a short pretest in which students were asked what a vector is and to explain vector addition and its properties. We ascertained that freshmen stated a lot of individual concept definitions. The majority of students stated geometric ones, which were mostly not fully adequate, i.e. improperly formalized to be embedded into the theory of abstract vector spaces. Furthermore, various misconceptions were identified.*

*Keywords: vector, concept definition, transition, textbook analysis.*

## Introduction

Many students face problems connected with the transition from school mathematics to university mathematics. To reduce students' difficulties during this transition, the Ministry of Innovation, Science and Research initiated the Studifinder project. Part of this project are the studiVEMINT learning materials. We have developed these learning materials (which are an e-learning based bridging course for mathematics) at the University of Paderborn since 2014 (Colberg, Mai, Wilms, & Biehler, 2017). The development was completed in summer 2016, although quality assurance still takes place. Students can use the course for several purposes: to fill gaps in their mathematical school knowledge, or to get used to elaborated forms of school content. In any case a focus lies on accurate language and notions and a mathematical discourse based on the definitions introduced, as it is expected at university.

An important concept students are confronted with at school and university (at a more abstract level) is the concept of vectors. In early 2016 we started the development of a chapter on vectors for the studiVEMINT learning materials by looking into school textbooks to explore how the concept could be introduced. While looking into many of these textbooks we observed the following:

1. The formal definition – that is either geometric as an infinite set of arrows with the same direction and length or symbolic as a triple of real numbers – is often not referred to again in the chapters following the introduction of the vector concept.
2. During the mathematical discourse related to vectors, several models (in the sense of Dörfler (2000)) of the concept are used without arguing about isomorphism.
3. The symbols labeled as vectors and used are not always conceptually coherent with the axiomatic definition of a vector space.

These observations led us to question which of the many representations of a vector that were labelled as vectors at school the students actually consider to be a vector. This question was examined by analyzing the common German school textbooks dealing with the vector concept and by administering a short test to university freshmen at the beginning of their university studies. The results are presented in this paper.

## Theoretical background

Although every formalized mathematical concept has a precise definition, students need to give it a meaning by operating with the concept (maybe just mentally) in order to understand it. Tall and Vinner (1981) use the term *concept image* to describe all associations students may have acquired by operating with it. These include examples, counterexamples, visualizations as well as properties of the concept. In order to specify the concept with words it has a *concept definition*. This can either be the formal definition accepted by the mathematical community, or student's reconstruction of a definition of the concept from their *concept image* (more precisely from the parts of the concept image that were activated during this reconstruction process, which Tall and Vinner (1981) call *evoked concept image*). In the latter case Tall and Vinner (1981) call it *personal concept definition*.

The formal definitions of the vector concept the students might have learned at school are the following ones, which were discovered when analyzing German school textbooks:

1. A vector is an infinite set of arrows with equal direction and length (Bigalke & Köhler, 2012; Bossek & Heinrich, 2007; Brandt & Reinelt, 2009; Weber & Zillmer, 2014).
2. A vector is a triple of real numbers or a matrix with one row (Alpers et al., 2003; Artmann & Törner, 1984; Griesel, Andreas, & Suhr, 2012; Griesel & Postel, 1990).

However, students' personal concept definitions, which they reconstruct from their concept images, may differ depending on individual experiences with the concept.

In the following we present for each of the two formal definitions of the vector concept, how they are introduced in German school textbooks and what *possible personal concept definitions* university freshmen might have, assuming these introductions formed their concept image at school from which they reconstructed their personal concept definitions. Then we discuss how the formal definitions are referred to further in the books when operating with vectors and how this might again influence the students' concept definitions reconstructed from their evoked concept image.

## Analysis of books using the geometric definition of a vector

The geometric definition as an infinite set of arrows with same length and direction is often motivated by translations (Bigalke & Köhler, 2012; Weber & Zillmer, 2014), and sometimes even defined by these (Brandt & Reinelt, 2009). The translations are then represented by arrows with the same length and direction. Afterwards, students are told that all of these arrows describe the same translation and can therefore be identified as the same object (e.g., see (Weber & Zillmer, 2014)). This path would lead to the adequate concept definition of a *vector as an infinite set of arrows with equal length and direction (D1)*. However, this identification step is rather difficult as is denoted in the literature, and may result in the incomplete conception that a *vector is considered as a single arrow (D2)* (Malle, 2005). The motivation of the formal geometric definition as a set of arrows with equal length and direction may also lead students to think that a vector is a translation. While a definition of a vector

as a translation mapping operation on the whole plane is consistent with its formal concept, literature shows that translations are often understood as the motion of an object (Yanik, 2011). So the students might think of a *vector as a translation of an object or translation of a point (D3)*. Yanik (2011) also found out that the connection between a vector and a translation is often not understood, and that many teacher students thought that a vector only gives the direction of a translation. This might lead to the following misconception: *vector as direction indicator (D4)*.

Besides using translations, some books also motivate arrows in space as a quantity characterized by length and direction in physical contexts like speed or force (Bossek & Heinrich, 2007; Weber & Zillmer, 2014). The recognition that two of these arrows can be considered as the same, since only the magnitude and direction matter (e.g., for the resulting movement of an object) leads to the adequate concept definition of *a free vector, which is a quantity characterized by length and direction and represented by a free movable arrow (D5)* (Watson, Spyrou, & Tall, 2003). But since forces are normally considered as dependent also on the point of origin (Watson et al., 2003), this approach can again lead students to the consideration that *a vector is a single arrow (D2)*.

The geometric definition requires not only a lot of effort in its introduction, it is also difficult to handle afterwards. In literature, this is denoted as a lack of operability of the definition (Bills & Tall, 1998). For example the geometric definition is difficult to handle when defining vector operations because for all operations the independence from the chosen representative of the vector has to be justified. In some books, this problem is discussed (Weber & Zillmer, 2014), others ignore it, and vectors are simply identified with arrows when defining vector operations geometrically (Bossek & Heinrich, 2007). This can again lead to the conception of *a vector as a single arrow (D2)*. Another option to deal with these difficulties is highlighted in Bigalke and Köhler (2012): the addition of vectors is defined via the addition of the components in the symbolic representation as an  $n$ -tuple (directly after its introduction) and from then on the geometric addition only serves as a visualization. This does not result in a misconception but becomes problematic when trying to embed the geometric vectors with operations defined between triples into the formal theory of vector spaces because in the formal theory the operations have to be defined on the set, whose elements will be the vectors if the axioms are satisfied. After the introduction of the vector operations and their properties, the definition as a set of arrows (or as a translation) is not referred to again (Bigalke & Köhler, 2012; Brandt & Reinelt, 2009; Weber & Zillmer, 2014). Instead, in the following chapters on analytical geometry, single arrows and their corresponding number triples are used to describe geometric objects. This can lead to a loose connection between the formal definition and students' concept image from which they might deduce their own personal concept definition (Vinner, 2002). The resulting personal concept definitions in this case would be: *vector as a single arrow (D1) or vector as a number triple (D6)*.

In summary, if the vector concept was introduced geometrically as an infinite sets of arrows with equal length and direction, the following concept definitions can be expected: *vector as an infinite set of arrows with the same length and direction (D1)*, *vector as a single arrow (D2)*, *vector as a translation of an object or translation of a point (D3)*, *vector as direction indicator (D4)*, *vector as a quantity characterized by length and direction (D5)*, or *vector as a triple of numbers (D6)*. The personal concept definitions *D1* and *D6* correspond directly to possible formal definitions of the vector concept, *D5* is also an adequate conception, in which the equivalence of arrows with equal length and direction is realized by independence from the space, *D2* and *D3* are incomplete concept

definitions (*D2* does not take into account that vectors are equivalence classes, *D3* does not take into account that a translation is a mapping on the whole plane) and *D4* is a misconception.

### **Analysis of books using the symbolic definition of a vector as $n$ -tuples**

The symbolic definition is often motivated geometrically by translations or arrows (Alpers et al., 2003; Griesel et al., 2012) or as coordinates of the points in the space (Griesel & Postel, 1990). Sometimes the symbolic definition is introduced earlier in connection with the theory of systems of linear equations (Artmann & Törner, 1984). The symbolic definition of a vector has the advantage of allowing a flexible interpretation as a point or an arrow. This can avoid the discussion about the equivalence of arrows (e.g., see Alpers et al. (2003)). However, besides the already mentioned incomplete conception of a vector as a single arrow, this flexibility can lead to another inadequate conception: *vector as a point (D7)*. The identification of vectors and points becomes problematic in higher mathematics, e.g., in the theory of affine spaces, in which they are considered different objects (Henn & Filler, 2015).

The way the vector concept is introduced in Artmann and Törner (1984) can also lead to another adequate concept definition. Artmann and Törner (1984) restrict their visualizations of vectors on points and arrows starting at the origin. If students identify the number triples with these arrows starting at the origin, they might consider *a vector as an arrow starting at the origin (D8)*. These arrows starting at the origin can serve as elements of a vector space (with suitable operations defined between them). Unlike the geometric definition of a vector as a set of arrows, the symbolic definition is operable when defining vector operations and justifying their properties like the commutative law. However, some books do not mention these properties explicitly (Alpers et al., 2003; Artmann & Törner, 1984; Griesel et al., 2012). One reason, which is also noted in literature, might be their self-evidence (Harel, 2000). However, the symbolic definition can also be difficult to handle in the case of the definition of geometric concepts related to vectors such as the norm of a vector. Purely algebraic definitions of these concepts seem unnatural without further explanation (e.g., see Alpers et al. (2003)). Geometric definitions of these concepts on the other hand (e.g., see Griesel et al. (2012)), have the danger that the vector defined as a triple is again identified with just a single arrow, which is an at least incomplete vector conception.

After the introduction of vector operations, the concept of a vector is mainly used in geometrical settings (describing lines and planes in the space). This might cause students to not identify vectors with the originally defined 'triple' but with its geometrical representations such as *points (D4)* or *single arrows (D2)* (students might reconstruct their personal concept definitions of vectors from these representations and not from the formal symbolic definitions).

In summary, the symbolic approach can lead to two further personal concept definitions besides the intended definition of *a vector as a triple (D6)*, which have not been mentioned yet: *vector as a point (D7)* or *vector as an arrow starting at the origin (D8)*. The identification of symbolic vectors with arrows starting at the origin is not problematic because the latter ones can truly serve as objects, which the vector operations can be defined upon. The identification of vectors with points, however, can cause conflicts later in the theory of affine spaces, where these two objects have to be distinguished.

## Methodology of the empirical study

### Research question

On entering university, what personal concept definition of the vector concept do students have?

### Data Collection

In September 2016 a short test was administered to 103 university freshmen in a mathematics bridging course at the University of Paderborn. These students were either freshmen majoring in mathematics or in mathematics for teachers at grammar schools. The pretest consisted of three open questions:

1. What is a vector?
2. Explain how you add two vectors  $\vec{a}$  and  $\vec{b}$ .
3. Explain, why for all vectors  $\vec{a}$  and  $\vec{b}$  the following is valid:  $\vec{a} + \vec{b} = \vec{b} + \vec{a}$ .

The first question was asked to identify what the students' personal concept definition of a vector in the sense of Tall and Vinner (1981) is. We did not ask for a definition because we did not want the students to try to recall the formal definition they had learned at school, but rather to specify the concept in their own words. We also did not use the term "definition" because we suspected that many students might not be familiar with the term and therefore might get confused.

The other two questions were asked to further analyze if the students used the defined objects to explain vector operations and their properties. This is important for a proper embedding of the old vector concept into the abstract notion of a vector space, which is a set with operations defined on its elements. However, this problem will be investigated later.

### Data Analysis

The answers to the first question "What is a vector?" were categorized by using possible personal concept definitions deduced from the analysis of the textbooks (see theoretical background, categories  $D1, \dots, D8$ ). Furthermore, four additional categories have been added. The first one, a *vector as an element of a vector space* was added before the analysis because, although this generalization is not taught at school, it may happen that some students had heard about it (e.g., in mathematical clubs at school). The other categories depict inadequate personal concept definitions that often showed up during the analysis: a *vector as a line segment*, a *vector as a line* and a category containing other inadequate concept definitions not yet mentioned.

The whole typology of 12 categories is shown in Table 1. The first five categories can be considered adequate, which means that objects described in the definition can serve as concrete examples of vectors in a vector space (if suitable operations are defined on them) or if vectors are already considered as elements of vector spaces. Categories 6 and 7 contain incomplete concept definitions, categories 8 to 12 contain inadequate concept image definitions, which can be considered as misconceptions.

Category	Prototypical Examples
1. Set of equivalent arrows	"An infinite set of arrows in the space, which are equal in their length and their direction."
2. Quantity with direction and magnitude	"A vector gives information about the length and the direction of an element in an at least two-dimensional space."
3. $N$ -tuple	"A matrix with $n$ rows and just one column."
4. Arrow starting at the origin	"A vector describes a journey to a point of $\mathbb{R}^3$ ."
5. Element of a vector space	"An element of a vector space."
6. Translation of a point or an object	"A vector is a translation of a point in the coordinate system to another point."
7. Arrow or line segment with direction	1. "Visually: an arrow." 2. "A vector is a line segment with direction."
8. Direction	"A vector points from a point into a direction."
9. Connection between points or line segment	1. "A connection between two points in the 3-dimensional space." 2. "A line segment in the 3-dimensional space"
10. Point	"A vector describes a point in the coordinate system."
11. Line	"A vector describes a line in $\mathbb{R}^3$ ."
12. Other wrong definition	"A multidimensional object, which is located in a multidimensional space."

**Figure 1: Answer categories to the question "What is a vector?"**

Two of the authors separately coded the data from the questionnaire. The interrater-reliability coefficient, Cohen's Kappa, was  $\kappa=0.803$ , which is good. Afterwards, they discussed the answers they had coded differently and agreed on a categorization.

## Results of the study

The students' personal concept definitions of the vector concept that were identified from the students' answers to the question "What is a vector?" are shown in Figure 2.

**Figure 2: Students' answers to the question "What is a vector?" (N=103)**

The bars of adequate personal concept definitions (which correspond roughly to possible formal concept definitions of models of the vector concept) are marked green, not fully adequate concept (i.e. they cannot be properly formalized or embedded into the abstract theory of vector space) are marked yellow, and other wrong definitions are marked red.

definitions are marked yellow, inadequate concept definitions are marked red. As can be seen in figure 2, the students had a variety of individual concept definitions of the vector concept when entering university. Most of them had a geometrical basis. However, in most cases these geometric concept definitions were either incomplete (the yellow bars, in which either the nature of a vector being an equivalence class was not mentioned or in which a vector was considered as a translation of points or objects and not as translations of the whole space) or inadequate (the red bars). Nevertheless, even the inadequate conceptions of a vector like “a direction”, “a connection between two points or a line segment” or “a point” have some properties of the adequate conceptions of vectors (e.g. if a vector is considered as a line segment, it has the property “finite length”, which is a basic property of the arrows, which represent a vector geometrically).

## Conclusion and outlook on possible further research

Our study shows that the students have a variety of concept definitions of what a vector is when entering university. Thus we should keep in mind that freshmen do not come to university with a shared idea on what a vector is. The majority of students stated geometric definitions which were mostly inadequate definitions in the sense that they cannot be properly formalized or embedded into the common definition of a vector in mathematics. This indicates that it is difficult for students to fully grasp the concept of a vector. However, many students seemed to be familiar with the symbolic definition of a vector as an  $n$ -tuple and that it can be interpreted in manifold representations. This property of the  $n$ -tuple approach seems very appealing. Dealing consistently with equivalence classes including the independence from the chosen representative can be circumvented with this approach. Hence, we chose this approach for the studiVEMINT course. We utilized the connection between the symbolic and geometric representations as often as possible. However, we avoided using the geometric representations while introducing the mathematical discourse on vectors that we wanted to be consistent with the provided definition (Sfard, 2000), similar to what is required from the students in their upcoming lectures about linear algebra.

For further research we will look into the students' answers to questions 2 and 3 more thoroughly with a more elaborated theoretical framework. We also intend to do a follow-up study to investigate the influence that the linear algebra course achieved on students at the end of the currently ongoing winter term 2016/17. Including a semiotic point of view and an analysis of textbooks from school as well as the introduction of vectors within the linear algebra course will improve the theoretical framework and provide further insights.

# What can calculus students like about and learn from a challenging problem they did not understand?

Ofer Marmur<sup>1</sup> and Boris Koichu<sup>2</sup>

Technion - Israel Institute of Technology, Faculty of Education in Science and Technology, Israel;

<sup>1</sup>[omarmur@tx.technion.ac.il](mailto:omarmur@tx.technion.ac.il), <sup>2</sup>[bkoichu@tx.technion.ac.il](mailto:bkoichu@tx.technion.ac.il)

*This paper reports on part of a study regarding student learning-experiences and affective pathways in undergraduate calculus tutorials. The following question is pursued in this paper: How do the students' key affective states relate to the type of mathematical discourse conducted in class? We present and discuss two lessons where two similar problems were considered. The lessons were filmed and followed by stimulated recall interviews with nine students. Though the students in both lessons did not understand the solution to the challenging problem, they evaluated the lessons and subsequent learning experiences very differently. We suggest the difference was related to the type of discourse employed by the instructor. The lesson that evoked a negative reaction utilized only an object-level discourse. The lesson that evoked a positive reaction additionally utilized a meta-level discourse. We will call this heuristic-didactic discourse. Implications are drawn.*

*Keywords: Undergraduate calculus, emotional states, key affective events, discourse.*

## Introduction

Emotions have long been recognized to take an integral part in mathematical problem-solving activities, especially when coping with non-routine problems. However, relatively little is known on the role emotion plays in undergraduate student learning, and even more so in context of frontal tutorials. This paper is part of a wider research investigating student emotion and learning-experiences fostered by problem-solving explanations in calculus tutorials. In this paper we present and discuss 2 cases. The first case, which is at the focus of this paper, consists of students regarding a lesson containing a highly challenging problem rather positively, whilst not fully understanding the solution. Our interest in this case lies in the generally positive attitude towards this part of the lesson, accompanied by students admitting that key parts of the proof were incomprehensible, and showing disbelief in their ability to solve such problems on their own. This lesson will henceforth be referred to as Lesson-P (positive student attitude). Lesson-P especially stood out when juxtaposed with a lesson containing a similar challenging problem also not understood by students, yet their lack of understanding was accompanied by negative emotions of anger and frustration. This lesson will be briefly presented in the paper as a contrastive background and referred to as Lesson-N (negative student attitude). Thus, we were faced with the following question: how can it be that the students of Lesson-P described their learning experience in a rather positive manner, though not fully understanding the solution?

## Theoretical background

### Frontal teaching style of undergraduate mathematics

Undergraduate mathematics courses are typically comprised of lectures and tutorials. This paper focuses on large-group tutorials, which are lessons that present problems accompanying the theoretical material (presented in the lectures), and are taught in a traditional-frontal style (Marmur

& Koichu, 2016). The common practice of the frontal teaching style (henceforth referred to as FTS) in undergraduate mathematics education possesses pros and cons. On the one hand, there is evidence that FTS can be effective in modeling mathematical reasoning for students by “conceptual scaffolding through demonstration and worked examples” (Pritchard, 2010, p. 611). This modeling can be motivational to students, particularly when exposing the struggle that precedes the reaching of a solution (Pritchard, 2010). On the other hand, it has been argued that FTS at university level consists of a one-directional communication based on transmitting information (Biggs & Tang, 2011) and treating the students as “non-emotional audience” who are granted no room for individual difficulties (Alsina, 2002, pp. 5-6). It is not our intention to either support or oppose these claims. Rather, we recognize that FTS is widespread and will most likely not disappear in the near future. Therefore, it is vital to gain a better understanding of how students learn in this environment in order to be able to improve the system from “within”, theoretically and practically, by identifying learning opportunities for students within the FTS paradigm. Lectures and tutorials comprise however only a certain percentage of the total time spent on an undergraduate mathematics course by students, and they are generally expected to spend many additional hours studying independently. Consequently, when we discuss the need to recognize and identify learning opportunities presented in the classroom, we mean not only those aspects related to the learning process in class, but also the aspects that support the learning that continues outside the classroom.

### **Emotions, learning, and discourse in the undergraduate classroom**

In this paper we utilize Goldin’s theory of local affect. Goldin (2000) defines *emotional states* as “the rapidly changing (and possibly very subtle) states of feeling that occur during problem solving” (p. 210). *Affective pathways* are regarded as a sequence of emotional states, and are linked by Goldin to mathematical cognition and heuristic processes students utilize at different stages of mathematical problem solving. Specifically, we choose to focus on what Goldin (2014) refers to as *key affective events* during mathematics learning, i.e., events “where strong emotion or change in emotion is expressed or inferred” (p. 404). Weber (2008) claims that emotional states may have a substantial impact on a student’s failure or success in a high-level calculus course. In his paper, Weber demonstrates how a single and strong positive experience of success may alter a student’s attitude and type of engagement with the material for the continuation of the course. Marmur and Koichu (2016) illustrate that also in a single lesson the creation of strong emotional experiences for students may significantly influence their level of focus, attention, and involvement in class.

Student emotions are examined in this paper in relation to the discourse led by the instructor in class. Theoretically, Evans, Morgan, and Tsatsaroni (2006) link emotions with discourse by regarding emotions as a “socially organised phenomena which are constituted in discourse” (p. 209). According to Sfard (2008), learning is perceived as a change in the mathematical discourse, while distinguishing between a discourse on mathematical objects, called *object-level discourse*, and a “discourse about this discourse” (p. 300), referred to as *meta-level discourse*. In relation to the FTS, the focus on the instructor’s discourse finds additional support in Sfard’s (2014) claim that this teaching style allows an expert to teach students how to “talk mathematics” and thus promote student learning through their introduction to a new mathematical discourse (p. 201).

## Research question

The study reported on in this paper is part of a broader research on the link between student emotions and learning during calculus tutorials. This broader research focuses on characterizing classroom events students respond to during calculus tutorials, students' affective pathways and learning experiences during tutorials, and classroom learning-opportunities as reflected by the students' own point of view. This paper addresses these issues by concentrating on the following question: How do students' key affective states relate to the type of mathematical discourse conducted in class?

## Method

### Context and participants

The two lessons reported on in this paper were of two separate tutorial groups that were part of the same second-semester calculus course. The course was highly demanding and challenging, and was attended by students from the computer science faculty. Both lessons were attended by approximately 50 students. The instructors (henceforth referred to as Instructor-P and Instructor-N) were both experienced instructors with a good reputation at the university.

### The problems

Lesson-P took place during the second half of the semester and was regarding the topic of the two-variable Riemann integral. For this lesson the students were asked to prove that the function below is Riemann integrable in two variables on  $[0, 1] \times [0, 1]$  (and the value of the integral is 0).

$$f(x, y) = \begin{cases} \frac{1}{q}, & x \in \mathbb{Q} \text{ and } y = \frac{p}{q} \in \mathbb{Q}, \frac{p}{q} \text{ in lowest terms, } q > 0 \\ 0, & x \notin \mathbb{Q} \text{ or } y \notin \mathbb{Q} \end{cases}$$

Lesson-N took place during the first half of the semester and was regarding the one-variable Riemann integral. The problem of interest was to prove that the “popcorn function” below (also known as “Riemann’s function”) is Riemann integrable on  $[0, 1]$  (and the value of the integral is 0).

$$f(x) = \begin{cases} \frac{1}{q}, & x = \frac{p}{q} \in \mathbb{Q}, \frac{p}{q} \text{ in lowest terms, } q > 0 \\ 0, & x \notin \mathbb{Q} \end{cases}$$

Both instructors referred to the definition of a Riemann-integrable function. The problem in Lesson-P was planned as a follow-up two-variable version of the “popcorn function”.

### Data collection and analysis

Both lessons were filmed by the first author of this paper who also took notes during the lessons. Subsequently, individual stimulated-recall interviews were conducted with nine volunteering students: five on Lesson-P and four on Lesson-N, each student participated in only one of the two lessons. The interviews were conducted over a nine-day period after the lessons. Stimulated recall was the chosen methodology as it presents a non-intrusive method to help students “relive” the lesson and reflect upon their thought processes during its course (Calderhead, 1981). During the interviews, the students were presented with an approximately 20-minute video excerpt of the filmed lesson in which the problem of interest was taught. They were explained that the video served as a tool to help them “relive” the lesson, and were instructed to stop the playback whenever they had a particular recollection of what they thought or felt at that moment. During this part of the interview the interviewer occasionally asked clarifying questions, mainly in the form of “can you explain *why* you

thought/felt this way at that specific moment?” After watching the filmed episode, the students were asked follow-up questions regarding the problem, lesson, and course, the main ones being: a) Was the problem memorable for you, and if so, in what way? b) What were you pleased and displeased with during the lesson? and c) What is your general attitude towards the course? The interviews were audio-recorded and ranged in length from 40 to 65 minutes, depending on the level of detail shared by the student.

For the data analysis we utilized a “general inductive approach” (Thomas, 2006) that allowed us to coordinate the raw data into a brief summary that addresses and explains the “underlying structure of experiences or processes” (p. 238) most apparent in the data. The goal of the analysis was to identify: 1) students’ key affective states as indicators of potential-learning or obstacle-for-learning episodes; and 2) types of mathematical discourse in the classroom. Specifically, we focused on: 1) episodes where all students stopped the video to reflect on the lesson; and 2) repeated statements or themes (whether within a specific interview or between interviews). Subsequently, we continued with a recursive process of going back and forth between the video observations and the student interviews in order to refine our conclusions. Although students were asked in each interview to express their emotional states *during the lesson itself*, it should be recognized that the accounts shared by the students might have been of their emotions *during the interview*. However, we considered this issue as a point of strength for the research, rather than a limitation. Such a selective recollection of emotions may shed light on the process, addressed by Goldin (2014), of how in-the-moment emotional states transform into longer-term attitudes and beliefs, and on how this process shapes the mathematical learning. Accordingly, while adopting Goldin’s (2014) terminology of “key affective events”, and in line with Marmur and Koichu (2016), we regarded: a) the most *memorable* emotional states of students as key emotional states that shape their overall learning experience; and b) student expressions of *strong* emotions as indicators of potential-learning or obstacle-for-learning episodes in class.

## Findings

Due to the scope limitations of this paper, in the Findings section we will focus on: a) the instructional episodes most prominently addressed in the student interviews; and b) student thoughts and emotions regarding these episodes. Additionally, the Findings section will predominantly focus on Lesson-P as the main explored phenomenon, utilizing Lesson-N as a contrastive background to illustrate and emphasize certain aspects of the findings.

### Lesson-P

After having presented the problem to the students, Instructor-P said: “Let us first try to understand what’s going on here. [...] I want us to make some observations.” The instructor reminded the students of the one-variable Riemann (popcorn) function, after which the following 10 minutes were focused on what was titled on the board as “Observation” and “Observation no. 2”. The first “Observation” entailed that for a fixed  $x$  we get  $\int_0^1 f(x, y) dy = 0$  and therefore the following iterated integral equals zero:  $\int_0^1 \left( \int_0^1 f(x, y) dy \right) dx = 0$ . After having written the title “Observation no. 2”, Instructor-P asked the students: “What happens if I fix  $y$ ?” The students participated in the discussion regarding a fixed  $y \notin \mathbb{Q}$  and a fixed  $y \in \mathbb{Q}$ , the latter giving the Dirichlet function  $D(x) = \begin{cases} \frac{1}{q}, & x \in \mathbb{Q} \\ 0, & x \notin \mathbb{Q} \end{cases}$ . This led to the

conclusion that the integral  $\int_0^1 f(x, y) dx$  does not exist and therefore it is impossible to calculate the (opposite-direction) iterated integral  $\int_0^1 \left( \int_0^1 f(x, y) dx \right) dy$ .

These observations led the class to two conclusions regarding the function: 1) Its *double* integral exists, yet the *iterated* integral (in one of the directions) does not; 2) It demonstrates the necessity of the *continuity* assumption in Fubini's theorem which allows us to calculate the double integral  $\iint_D f(x, y) dx dy$ ,  $D = [0, 1] \times [0, 1]$ , as the iterated integral  $\int_0^1 \left( \int_0^1 f(x, y) dx \right) dy$ . These conclusions were in fact surprising for the students, as conveyed in their interviews. It was only then that the instructor admitted that everything discussed so far “does not yet answer our problem”. At that point he wrote: ‘So how do we solve?’, and said: “In such a case we need to follow the definition.”

We interpreted the students' general attitudes towards that part of the lesson dealing with this problem, as rather positive in the following manner. At different levels of explicitness, all students claimed that the lesson and teaching were good, while mainly pointing at the problem presented above. For example, even before knowing what the interview was about exactly, Student A said: “You came to a very special lesson [...] The instructor chose a non-standard problem [the discussed one] to convey his messages. I really loved it”. Student B said: “You came to a good lesson, really!”, and referred to the discussed problem as “*the* problem” of the lesson (emphasis in intonation). Student C said: “The lesson was interesting. The lesson was clear. The first function [the discussed problem] was different and new.” Students A, C, and D called the problem beautiful. Students D and E claimed the problem was good since it prepared them for similar problems that may appear in the exam. However, all students admitted the problem was difficult and challenging, and the unexpected impression we got was that the students did not fully understand the solution, nor expressed confidence in their abilities to solve similar problems independently. For example: Student A admitted that a key line in the (actual) solution seemed to him like gibberish; Student C found the same line to be full of incomprehensible transitions which she referred to as “jumps”; Student B referred to the same line with: “What??? He said it, so it is probably true”, and later in the interview admitted: “If this problem was in the exam, I wouldn't have succeeded solving it”; and Student E hoped such a problem would not appear in the exam and hoped the lecturer did not have such a “dark heart”. However, these statements were not accompanied by any explicit expressions conveying negative emotions. Additionally, such statements barely appeared in other parts of the interviews, and did not even appear at all when the students were explicitly asked what they were displeased with during the lesson.

It is towards the opening “observations” part of the lesson that the students mainly expressed positive opinions on what had happened. Additionally, all students claimed that even though the “observations” part was not directly utilized in the actual solution, it was nonetheless an *indispensable* part in support of their learning. They supplied us with a variety of reasons: it exposed the thinking process of how to reach a solution; it allowed time to think about the problem; it included a counter-example for claims they thought were true; it imitated what they would actually do if they were to start solving the problem on their own (i.e., try to calculate the iterated integral); it helped them understand the problem through step-by-step analysis; it gave room for “mathematical play” where the goal was not merely to solve a problem; and it demonstrated that even if an attempt for a solution did not succeed, they should just try again in a different way. Some students clearly linked their

positive attitude with the following didactic aspect of the mathematical discourse led by the instructor in class. Student A shared that he really loved the approach taken by Instructor-P during the “observations” part. The student described that the instructor put himself in the position of a student, approaching the problem through their eyes, and instead of immediately solving the problem because he was already familiar with the solution, he started “playing” with it with the aim of seeing where this will lead them. A supportive angle is given by Student D who said that during the lesson Instructor-P really tried to give the impression that he did not already know the answer, but rather was trying to solve the problem with them. She said that only once she was convinced he was not “fooling” them, she started thinking with him. The instructor, however, was indeed familiar with the solution, and Student D admitted that only when watching the lesson again during the interview, she realized how planned and structured the lesson was.

### Lesson-N

After having written what needs to be proven according to the definition of a Riemann integrable function, Instructor-N told the students: “At the beginning you may experience some lack of understanding. Once we reach the end [of the solution] you’ll understand where I took the numbers from that initially might have looked a bit weird.” Then he wrote the following: Choose  $n_0$  such that  $\frac{1}{n_0} < \frac{\epsilon}{2}$ . This is a key moment where all 4 interviewed students stopped the video and expressed similar thoughts and strong dissatisfactions. The main criticism the students conveyed is expressed in the following interview excerpt: “It really bothers me that he reads the solution by the order of the proof and not by the order of how you think about the proof. [...] At the end it all works out. But it doesn’t help me with how to solve a problem.” The student then continues while expressing her anger: “It really pissed me off. He pulls the answer out of a hat, and I don’t know how he got to it.”

These negative opinions towards the lesson, while pinpointing the underlying reason to the key moment presented above, continued and repeated throughout all interviews. The students claimed that also at the end of the lesson they did not understand the solution, and that the promise made by the instructor at the beginning was left unfulfilled.

### Discussion

While the case of Lesson-N demonstrates that students can possess negative emotions towards a solution they did not understand, the case of Lesson-P, containing a similar problem, demonstrates that a lack of understanding can still be accompanied by positive student emotions. Both lessons contained episodes focused on the *solving* of a challenging problem, which we suggest to regard as an object-level type of discourse. However, the positive emotions in Lesson-P were mainly directed towards that part of the lesson focused on *how* to approach a challenging problem, which we regard as a meta-level type of discourse. While other explanations for the students’ positive attitude towards Lesson-P are certainly possible, our interpretation is based on what we found to be most prominently conveyed by students during the interviews. Furthermore, we suggest that not only did students appreciate this meta-level discourse, as expressed in their interviews, but that this discourse may have also had a neutralizing effect on the potential negative emotions related to not understanding the solution.

The meta-level discourse in Lesson-P revealed a heuristic approach on how to tackle a challenging problem. On the one hand, the discourse was planned and monitored from an expert’s point of view,

which may be viewed as a teacher's learning goal (Simon, 1995) that did not coincide with the declared main goal of solving the problem. In the case of Lesson-P, the "observations" part did not constitute a directionless exploration, but rather led to the conclusions mentioned in the findings. On the other hand, as also regarded by the students themselves, the discourse was led by the instructor through a student's point of view, considering students' cognitive and affective needs, their ways of thinking, their assumed misconceptions, and the steps they would most likely take. We call such a discourse, presenting heuristics monitored from an expert's point of view yet derived from a student's point of view, a *heuristic-didactic discourse*. In the case of Lesson-P, the heuristic aspect of the discourse may be viewed in line with what Featherstone (2000) refers to as "mathematical play", which puts emphasis on the act of exploring rather than solving, and may support the creation of a zone of proximal development, giving guidance to the learning student. The didactic aspect of the discourse may be viewed in line with what Jaworski (2002) refers to as "harmony" between "mathematical challenge" and "sensitivity to students" (both their cognitive and affective needs) in order to help students make mathematical progress. This is one example of a heuristic-didactic type of discourse, and we call for further research on characterizing different types of heuristic-didactic discourses in the undergraduate classroom.

In practice, the presented study suggests that university students wish for a more heuristic-didactic discourse to be held in the undergraduate mathematics classroom. In simple terms this means that it is necessary for students to get "tools" on how to approach a challenging problem on their own. In the presented lessons, not only were students satisfied when a heuristic-didactic discourse took place, students also showed strong emotional responses of anger and frustration when this need was not fulfilled. Furthermore, even though Lesson-P could have been improved by the students also understanding the solution better, it clearly demonstrated that the learning induced by the heuristic-didactic discourse was perceived by the students as the most valuable kind of learning, even at the expense of not fully understanding a solution. Sfard (2008) regards meta-level learning as a change in meta-rules of the discourse, while claiming that this change is not likely to be initiated by students on their own. Accordingly, meta-level discourse in class may serve as an initial point of aid for students to continue a meta-level learning-process at home. All this implies that lecturers and instructors should consider paying more didactic attention in revealing to students *how* they came up with their solutions and proofs. This learning-opportunity may be implemented in the common undergraduate frontal teaching style and could supply valuable tools for the learning process that the students are required to continue independently.

*We report on an analysis of ‘decision points’ that occurred during first year undergraduate calculus lectures. We analysed 135 accounts written by three lecturers concerning their own teaching; these accounts were written during a professional development project on employing the Discipline of Noticing (Mason, 2002). We classified the decision points in these accounts into eight categories. Furthermore, the triggers of these moments were identified and classified into seven categories; of these, the majority (58.2%) arose as a result of the lecturer monitoring either her own practice or the students’ engagement.*

*Keywords: Teacher noticing, decision points, mathematics lecture, university mathematics.*

## **Introduction**

Today I was happy with my ‘performance’ from a teacher-centred perspective as the lecture evolved: I felt I was coherent, explained and connected ideas well, used multiple representations of concepts and built on students’ prior knowledge. However, I realised more than halfway through the class that my lecture was just that – very teacher-centred! I tried to rectify this but was not happy that my attempts were successful. (Lecturer C)

Lecturer C speaks about a tension inherent in large-group mathematics lectures between teacher-centered and student-centered methodologies, and this is probably familiar to anyone who has taught such a course. It also highlights the dilemma that faces a lecturer when it occurs to her mid-way through a lecture that she might deviate from her original plan. The change of plan can feel like a risky strategy, especially when working with very large groups of students; however research on mathematics teaching at school level indicates that rich learning opportunities can arise from decisions to change direction (Rowland and Zaskis, 2013). It is important then, that lecturers are aware of opportunities that present themselves, for the simple reason that the quote in the title, borrowed from Schoenfeld (2011, p. 228), suggests. It is also important that lecturers develop the skills to take advantage of these opportunities as they arise. In this paper, we explore the opportunities to make decisions that might arise in a mathematics lecture; we have named instances when a non-trivial choice between alternative courses of action could be taken ‘decision points’.

The Discipline of Noticing developed by Mason (2002) consists of “a collection of practices which together can enhance sensitivity to notice opportunities to act freshly in the future” (p. 59). Mason notes that practitioners, of necessity, form habits in order to deal with issues that arise in their everyday practice. The practices described by Mason provide educators with techniques to assist them in developing the dual abilities to notice key events in the classroom, and secondly to have possible actions come to mind in-the-moment in order to respond to these in non-habitual ways.

Mason (2002, pp. 33-34) distinguishes between levels of noticing, from ordinary-noticing, through to marking, and finally recording. “Ordinary-noticing” is where a person’s memory of something can be jogged if another person remarks upon it; “marking” is where someone has taken sufficient notice of something to “re-mark” upon it at a later stage; and, finally, “recording” is where one records or makes a note of something one has noticed, usually in writing. To do the latter, Mason (2002, p. 46) advocates the practice of writing “brief-but-vivid accounts”. These are brief notes which give an “account-of” an incident, rather than an “account for” as Mason explains:

To *account-for* something is to offer interpretation, explanation, value-judgement, justification, or criticism. To give an *account-of* is to describe or define something in terms that others who were present (or who might have been present) can recognize. (p. 41)

The data for this paper comes from a set of brief-but-vivid accounts written by the three authors on incidents that occurred during teaching over a two-year period when they took part in a project aimed at using the Discipline of Noticing to study their own teaching (see Breen, McCluskey, Meehan, O’Donovan & O’Shea (2014) for more details).

In this paper we will present an analysis of the accounts which relate to large-group teaching of first year modules; in particular we will endeavour to answer the questions: What types of decision points can occur during a mathematics lecture? What triggers these decision points?

## Literature review

Teacher noticing has been receiving attention in the research literature recently, see for example the research studies included in the book edited by Sherin, Jacobs & Philipp (2011). In presenting an overview of these studies, the editors observe that while the conceptualisation of teacher noticing may vary, it is generally considered as consisting of one or both of two main processes. The first process, “attending to particular events in an instructional setting” (p. 5), relates to where the teacher does (and does not) place her attention in the classroom setting. The second process they describe as “making sense of events in an instructional setting” (p. 5) and note that some researchers conceptualise this process only as “interpreting” (p. 9) what is noticed, while others view it as “both interpreting and deciding how to respond” (p. 9).

Instances when a choice presents itself during teaching are labeled “contingent moments” by Rowland, Huckstep, and Thwaites (2005) in their work on the Knowledge Quartet. At these moments teachers have to think on their feet and possibly deviate from the planned lesson. Rowland, Thwaites and Jared (2015) identified three types of triggers of contingent moments in their study of mathematics teaching: responding to student ideas; teacher insight; and, responding to the availability of tools and resources. Teachers may deal with the first trigger in one of three ways: ignore; acknowledge but put aside; acknowledge and incorporate (Rowland and Zaskis, 2013).

Schoenfeld (2010) has developed a theory to explain what influences the decisions an individual makes when carrying out a particular task. He has applied his theory in particular to decision-making in mathematics classrooms. He proposes that decisions a teacher makes while teaching are a function of her resources, orientations and goals. Although “resources” is a broad term, Schoenfeld classifies the knowledge that a teacher possesses as being a key component of the resources she brings to the classroom. He uses “orientations” to encompass one’s “*dispositions, beliefs, values, tastes, and*

*preferences*” (p. 29). And while the term “goal” is self-evident, Schoenfeld notes that an individual may pursue a particular goal “simply in the service of other goals” (p. 20).

Most of the research studies discussed above in relation to noticing, contingent moments, or decision-making in the classroom have been conducted at the school level. An exception is the work of Barton, Oates, Paterson, and Thomas (2015) and colleagues in New Zealand who use Schoenfeld’s (2010) theory to discuss taped video excerpts from participating mathematicians’ and mathematics educators’ lectures as a means of engaging in professional development on teaching practice. However in terms of noticing and the occurrence of decision points in lectures, there is little research. Indeed to many it might seem like traditional lectures provide few opportunities for contingency. However McAlpine, Weston, Beauchamp, Wiseman and Beauchamp (1999) report on a study of monitoring of student cues by university lecturers. The lecturers in this study were found to attend to four types of cues: student written, student verbal, student non-verbal, student state. McAlpine et al. (1999, p. 117) posit that the lecturers had a *corridor of tolerance* for these cues and a decision to change practice was only taken when the cue lay outside of this corridor. In contrast to the work of both Schoenfeld (2010) and McAlpine et al. (1999), we focus here on the opportunities for decision-making that arise in lectures rather than the process of decision-making itself.

## Methodology

The authors are lecturers of mathematics at three different universities in Ireland. Each has a doctorate in mathematics or applied mathematics and has a minimum of fifteen years’ experience of teaching mathematics at the tertiary level. Between them they have taught mathematics classes from first year undergraduate through to postgraduate level, and have experience of teaching students in class sizes ranging from single figures up to a few hundred students. In 2010/11, along with two other colleagues, they embarked on a project aimed at reflecting on their teaching using the ideas and philosophy described by Mason (2002). As part of this process, over the course of two years, they engaged in writing brief-but-vivid accounts of incidents or moments that occurred in relation to their teaching. See Breen et al. (2014) for further details.

The accounts of all five members of the group were collected and a general inductive approach (Thomas, 2006) was used to identify themes in a sample of the accounts. We noticed that many accounts described instances where the lecturer was faced with a decision about what to do next, or, instances where an opportunity to make a decision that might change the course of the lecture or discussion was implicit. We labeled these moments *decision points* (DPs). In order to focus specifically on these moments, all accounts that did not specifically deal with lecturing were removed. The first and second authors (AOS and MM) independently analysed all the accounts to both identify and code the DPs. After some discussion they agreed on the identification of DPs and the codes assigned. In addition, AOS identified the triggers. Then all five members worked through all the accounts to confirm their agreement or express disagreement with the DPs and triggers identified and the codes assigned. By the end of this process, the group had reached a consensus. AOS then grouped the codes into categories, and the third author (SB) examined these for consistency. In some of the accounts, the *action taken* by the lecturer as a result of a DP was recorded, however we will not discuss the identification or classification of these here.

In this paper we present findings on the DPs and triggers from accounts written by each of the three authors while lecturing a first year mathematics class. In total there were 135 accounts with 141 DPs identified, as some accounts contained more than one DP. These DPS were classified into 8 categories. In order to provide a context for the accounts, we note that Lecturer A taught Calculus to a group of approximately 200 students consisting of both mathematics and finance students in the first semester of both 2010/11 and 2011/12. Lecturer B taught mathematics to a group of over 200 first-year business students in the first semester of both 2011/12 and 2012/13, while Lecturer C taught Calculus to a first year class of approximately 50 mathematics students for the duration of the academic years 2010/11 and 2011/12. The format for each course consisted of either 2-3 lectures per week given by the lecturer, to which all students were required to attend.

While all three lecturers engaged in what might be considered *lecturing* - that is, the lecturer speaks to the whole class, and perhaps writes on a projector or board while the class is expected to remain silent - they also engaged in initiatives aimed at increasing student participation. These fall into two categories – *whole class question or discussion* and *class activity*. The former relates to where the lecturer asks the whole class a question or attempts to conduct a whole-class discussion, while by class activity we mean an activity that students are expected to engage in during class, usually in small groups. As a final part of the analysis MM classified each account containing a DP as occurring in either Setting 1 (S1) – lecturing; Setting 2 (S2) – whole-class question or discussion; and, Setting 3 (S3) – class activity. We now present the findings.

		Lecturer A			Lecturer B			Lecturer C			Total
	Decision Points	S1	S2	S3	S1	S2	S3	S1	S2	S3	
DP1	How to engage students?	5	0	3	1	0	0	4	2	0	15
DP2	How to respond to students' questions, answers, or comments?	8	0	1	0	4	0	3	0	3	19
DP3	How to ask questions to gather information?	4	0	2	1	0	0	1	1	1	10
DP4	How to deal with disruption?	1	0	0	18	1	1	2	1	0	24
DP5	How to conduct class activity or discussion?	0	0	3	0	2	0	2	2	7	16
DP6	How to deal with students' mathematical difficulties?	4	0	2	0	17	0	1	7	5	36
DP7	What to do next in the lecture?	5	0	0	1	2	0	4	3	2	17
DP8	Other	1	0	0	2	1	0	0	0	0	4
	<b>Total</b>	28	0	11	23	27	1	17	16	18	141

**Table 1: Decision Points by Lecturer and Setting**

## Findings

In Table 1 we present the categories of DP with frequency by lecturer and setting. Lecturer A mainly wrote accounts about S1 and S3, Lecturer B about S1 and S2, while Lecturer C wrote about all three.

This is perhaps not surprising as she had a much smaller class. Over a quarter of all DPs identified belongs to the category “How to deal with students’ mathematical difficulties?” (DP6,  $n=36$ , 25.5%). It is noteworthy that 31 of these occurred in Settings 2 and 3. The next largest category of DPs is “How to deal with disruption?” (DP4,  $n=24$ , 17.0%) with three-quarters of these attributed to Lecturer B in the lecture setting. The third largest category is “How to respond to students’ questions, answers or comments?” (DP2,  $n=19$ , 13.4%) and while these DPs may be expected to occur in Settings 2 and 3, it is interesting to note that just under half are attributable to Lecturer A in the lecture setting. The category “What to do next in the lecture?” (DP7,  $n=17$ , 12.0%) contains DPs relating to opportunities for decisions that present themselves when moving from a whole-class question/discussion or class activity, back to the lecture setting. Four of the DPs did not seem to fit in any of the categories identified and were grouped as “other”.

Each DP was found to have an associated trigger and in Table 2 we present the categories of triggers with frequency by lecturer and setting.

		Lecturer A			Lecturer B			Lecturer C			Total
	Triggers	S1	S2	S3	S1	S2	S3	S1	S2	S3	
<b>T1</b>	Lecturer monitors aims/goals	3	0	1	1	0	0	2	1	3	11
<b>T2</b>	Lecturer monitors practice	6	0	1	2	1	0	3	1	0	14
<b>T3</b>	Lecturer monitors student nonverbal	9	0	0	0	5	1	8	4	0	27
<b>T4</b>	Lecturer monitors absence of student verbal	0	0	6	0	0	0	0	0	4	10
<b>T5</b>	Lecturer monitors disruptive behavior	1	0	0	18	0	0	0	1	0	20
<b>T6</b>	Student question or comment or answer	8	0	3	2	19	0	6	9	9	56
<b>T7</b>	Other	1	0	0	2	0	0	0	0	0	3
	<b>Total</b>	28	0	11	25	25	1	19	16	16	141

**Table 2: Triggers by Lecturer and Setting**

The first five triggers listed in Table 2 (T1-T5) are as a consequence of the lecturer monitoring her aims/goals for the class, her practice, what the students were (not) doing, which students were not answering questions or contributing, and student behaviour. These account for 58.2% of triggers identified. In terms of the triggers identified when the lecturer monitored students (T3-T5) there are some similarities between the cues identified in McAlpine et al. (1999) and those described in the accounts relating to these triggers. The category labeled “Student question or comment or answer” (TP6,  $n=56$ , 39.7%) contains student-initiated triggers and is the largest of the trigger categories. The “Other” category relates to triggers that are neither lecturer- nor student-initiated and relate to issues such as a cold room or poor attendance due to bad weather. These findings are similar to those of Rowland et al. (2015) who in their study classified triggers of contingent moments as emanating from the teacher, the students, or resources and tools, with the latter category accounting for far fewer triggers than the first two. Exploring links between DPs and triggers, not surprisingly almost all DPs

categorized as DP2 (18/19) and most of those as DP6 (29/36) arose from T6 triggers. Over half of DP3 and most of DP4 (20/24) resulted from T1 and T5 triggers respectively.

We now present some examples of accounts featuring DPs and associated triggers that occurred in the lecture setting. We note that the account by Lecturer C at the start of the paper is an example of a lecturer attempting to make her lecture more student-centred in order to engage students (DP1) as a consequence of monitoring her practice (T2). In the following account by Lecturer A, the trigger for the decision point about how to engage students (DP1) is the lecturer monitoring what the students are (not) doing (T3) while she is lecturing.

I continued the introduction to limits today. I was doing a lot of talking and I realized that people weren't taking anything down. I tried writing more explanations on the pictures I was drawing, so hopefully it will make more sense when they look at it again. (Lecturer A)

Similarly the account by Lecturer C describes how noticing students' expressions (T3) during a lecture, prompts her to explain what mathematicians do in an attempt to engage the students (DP1):

On noticing students exchanging glances when I asked them why they would attempt to solve a particular problem in a particular way, I was prompted to reiterate what "doing mathematics" (at this level) entails. (Lecturer C)

The next account illustrates how a student asking a question (T6) during a lecture results in a decision point for the lecturer about whether to review material already covered (DP2).

I found the limit of  $\sin(2x)/\sin(3x)$  as  $x \rightarrow 0$  when a mature student, who asks lots of questions, asked why you couldn't just cancel the sin's and the x's to get  $2/3$ . We proceeded to discuss the meaning of the term  $\sin(2x)$  and the difference between multiplication and composition. I had spoken about this before but felt talking about it here was useful. (Lecturer A)

When a lecturer monitors student behaviour (T5) during a lecture, decision points about how to deal with disruptions (DP4) may arise as illustrated in the following account by Lecturer B:

Shortly into the lecture I ask a group of four students to stop talking. Minutes later I tell two other students to stop talking. Some minutes later, I ask the first group to stop talking again. I look at the class – most of them are staring straight at me and not moving. I realize I am nagging and stopping the lecture for the sake of a few "talkers". As I continue to write and talk, I hear whispering coming from various parts of the theatre and my explanation falters. I decide I can't get any more annoyed. I put up a question and ask the class to work on it. (Lecturer B, T5, DP4)

Unlike the accounts so far which occurred in the lecture setting, the following account takes place during a class activity. During the activity the lecturer experiences a decision point concerning how best to respond to student questions (T6 and DP2). But on completion of the activity another decision point arises about what to do next in the lecture (DP7).

I put up an exercise for the students to work on. I remind them that the first part is revision – they have to find the profit function. As I walk around the theatre a student asks: "What are the fixed costs?" I remind him that this example is different to the one I did earlier in class. Another asks: "Do I multiply this function by  $q$  to get total revenue?" "No, you are given total revenue, you don't have to find it", I reply. "What is  $q$ ?" another asks. I feel deflated – this is revision. I planned to

finish the exercise today, but instead, show them how to get the profit function and complete the exercise in the next lecture. (Lecturer B)

## Discussion and conclusions

We wish to discuss three points in this section. The first concerns decision points that arise while lecturing. One might assume that in the traditional sense of a lecture, a lecturer delivers from a pre-prepared script and unless a student asks a question, the lecturer will not deviate from the script. However there is some evidence from the three lecturers' accounts on their practice that indicates that even while lecturing in the traditional sense, they monitor their aims for the class, their own practice, and how the student cohort are acting, and that this monitoring leads to the occurrence of many of the decision points. About one third of the triggers for decision points in our study were student initiated, (T6 in Table 2) in contrast to the findings of McAlpine et al. (1999), but in comparing one must be cognizant that our methodology differs from theirs. While we acknowledge that the fact that the three lecturers undertook a professional development project on using the Discipline of Noticing (Mason, 2002) to improve their practice may mean that they are not typical, it would be interesting to explore further what mathematics lecturers focus on while in a lecture as well as gathering more data to illuminate the relationship between triggers and decision points.

Secondly we observe from our findings that decision points relating to how to address students' mathematical difficulties usually emerged in the context of a whole class question or discussion or a class activity. This is perhaps not surprising but does highlight the importance of including such activities during a lecture in order to assess students' mathematical understanding. However it is also worth pointing out that over half of all the decision points identified in this study were as a consequence of such an activity, which may suggest an increased cognitive load for the lecturer who engages in such activities.

Our final point relates to the methodology used in this study. Our analysis of the settings seems to indicate the lecturers' individual preferences for pedagogical techniques and activities however we cannot use our data to draw conclusions about the proportion of class-time they each spent in the three settings, or make general claims about the relationship between the settings and the occurrence of decision points. This is because the lecturers in this study had complete autonomy over what incidents they chose to write about. They wrote about what mattered to them and many of the accounts relate to incidents where the lecturer felt unsure about what to do, or uncomfortable about a decision she had made. In any lecture, there may have been a multitude of more interesting moments worthy of noting, but either they did not notice them, or chose not to write about them. In this way there is a parallel with the findings of Barton et al. (2015). In choosing excerpts from a video-taped lecture for group discussion, the authors note that: "Counterintuitively, lecturers chose parts in which they felt less comfortable" and in group discussions "frequently chose to focus the group's attention on interludes in the lecture when unexpected decisions were made" (p. 152).

We return to the quote from Schoenfeld (2011): "Noticing is consequential – what you see and don't see shapes what you do and don't do" (p. 228). We suggest that the use of the Discipline of Noticing (Mason 2002) can help lecturers to identify opportunities for making (possibly different) decisions in their lectures. Individually the process also highlighted for each of us different aspects of our practice that we wanted to work on – for Lecturer A it was how to make her lectures more student-centered,

for Lecturer B the issue was how to deal with disruptive behavior, for Lecturer C, how to address mathematical difficulties effectively and sensitively. We also recommend that lecturers, as a professional development exercise, write a selection of brief-but-vivid accounts and discuss them in a group setting using Schoenfeld's theory (2011) to frame the discussion.

# To be or not to be an inflection point

Regina Ovodenko<sup>1</sup> and Pessia Tsamir<sup>2</sup>

<sup>1</sup>Center for Educational Technology, Tel-Aviv, Israel; [reginao@cet.ac.il](mailto:reginao@cet.ac.il)

<sup>2</sup>Tel-Aviv University, Tel-Aviv, Israel; [pessia@post.tau.ac.il](mailto:pessia@post.tau.ac.il)

*This paper describes students' grasp of inflection points. The participants were asked to define inflection points, to judge the validity of related statements, and to find inflection points by investigating (1) an algebraic representation of a function, and (2) the graph of the derivative. We found that participants provided their own "filtering conditions" to determine or deny the existence of an inflection point. In order to analyze participants' conceptions of inflection points, we used the lenses of Fischbein's theoretical framework.*

**Keywords:** Inflection point, formal knowledge, algorithmic knowledge, intuitive knowledge.

## Introduction

Functions receive considerable attention in secondary school, commonly in algebra and calculus lessons. Inflection point is one of the function-related notions addressed in high school and in further mathematics studies. In preliminary studies, we found some indications of common erroneous conceptions of the notion (e.g. Ovodenko & Tsamir, 2005; Tsamir & Ovodenko, 2004; 2013). These findings encouraged us to expand our research regarding the grasp of the notion of inflection point, and regarding possible sources of related common errors, while addressing a larger and diverse population who was given richer types of tasks (elaborated upon in the methodology section). In this paper, we present part of the findings from the extended study (Ovodenko, 2016). The research tools were designed and the findings analyzed with reference to a number of theoretical frameworks, including Fischbein's theory of algorithmic, formal, and intuitive components of mathematical knowledge (Fischbein, 1987, 1993a) and his theory of figural concepts (Fischbein, 1993b). Specifically, our research questions are: In the students' opinion, (1) When is a point an inflection point? (2) When is a point a non-inflection point?

## What does research tell us about students' conceptions of inflection points?

Literature gives some indications of students' difficulties when using the notion of inflection point. Some researchers (e.g. Carlson, 1998) have reported that students tend to use fragments of phrases taken from earlier-learned theorems, such as "if the second derivative equals zero [then] it is an inflection point" when solving problems in the context of dynamic real-world situations.

Other researchers have reported that early experiences with the tangent to a circle contribute to the creation of the intuitive grasp of the tangent as a line that touches the graph only at one point and does not cross it (e.g. Vinner, 1982). This intuition was evoked when students were asked to identify and draw a tangent line to a curve's points that included non-differentiable and differentiable inflection points (e.g. Biza & Zachariades, 2010).

In a previous study, we examined students' conceptions of inflection points, in which we came across a novel tendency to regard a "peak point" as an inflection point (e.g. Tsamir & Ovodenko, 2004). We found tendencies to regard  $f'(x) = 0$  as a necessity for the existence of an inflection point (Ovodenko & Tsamir, 2005), as well as tendencies to view  $f'(x) \neq 0$  as a necessary condition and

$f''(x) = 0$  as a sufficient condition for an inflection point (Tsamir & Ovodenko, 2013). Consequently, we designed a large study to examine students' conceptions of the inflection point when solving a rich variety of problems. Here we report on part of the findings (Ovodenko, 2016).

## Methodology

The research population included 223 participants from different educational levels of mathematics: high school students studying mathematics at the intermediate level, high school students studying mathematics at the advanced level, university students and university graduates (the latter majoring in mathematics-rich subjects, such as mathematics, computer science, and electronic engineering). All participants had studied the notion of inflection point during their calculus lessons.

According to the Israeli mathematics curriculum for secondary schools, an inflection point is defined as a point on a curve at which the curve changes from being concave up to concave down or vice versa, usually relating to functions that are at least twice differentiable in a small neighborhood of the point. It is important to note that the first encounter with inflection points occurs before the term is defined. It happens when students start investigating functions: they solve  $f'(x) = 0$  to find possible  $x$ -s of extreme points and accidentally encounter cases where  $f'(x) = 0$ , but there is no extreme point because the function is monotonic in the interval that includes this point. In such cases –  $f'(x) = 0$  but the point is non-extreme – students are first guided to label these points as inflection points for purposes of communication and to distinguish them from extreme points. Afterwards, useful theorems are introduced, e.g., a necessary condition for  $x_0$  to be an inflection point is  $f''(x_0) = 0$ ; a sufficient condition may be: (1)  $f''(x_0^+)$ , and  $f''(x_0^-)$  have opposite signs in the neighborhood of  $x_0$ ; or, (2)  $f'''(x_0)$  exists and  $f'''(x_0) \neq 0$ .

In order to widen the scope of the gathered data, two types of tasks were designed: Produce-a-Solution (production) tasks (i.e., solve mathematical problems), and Evaluate-a-Solution (identification) tasks (i.e., examine the correctness of given solutions). Tasks in each of the two types were presented in verbal, graphic, and algebraic representations (see Figure 1).

Evaluate -a- Solution	<b>Verbal representations</b> • Evaluate judgement and proof	<b>Verbal representations</b> • Define • Prove	Produce - a- Solution
	<b>Graphic representations</b> • Evaluate marked points on the graph	<b>Graphic representations</b> • Draw example • Mark inflection points • Connection $f - f'$	
	<b>Algebraic representations</b> • Evaluate the result and solution	<b>Algebraic representations</b> • Find inflection point	

**Figure 1: Structure of research questionnaire**

This systematic structure of tasks provided insight to the participants' ideas and reasoning. It was developed and empirically validated (during preliminary pilot studies) as a tool that allows students to explain related formal, algorithmic and intuitive components of their mathematical knowledge (Fischbein, 1987, 1993a). The contribution of these structured tools may go beyond the broad exploration of students' conception of inflection points; such structured tools could be useful to

reveal students' conceptions of additional mathematical notions. That is, the research tools offered in this study may serve as a model when designing research tools aimed at investigating students' conceptions of other mathematical notions.

In the following, we present four tasks (Produce-a-Solution) from the questionnaire.

Task 1: Define: What is an inflection point?

Task 2: True or false? Prove:

Statement 1:  $f: \mathbb{R} \rightarrow \mathbb{R}$  is a differentiable function.

If  $f'(x_0) = 0$ , then  $P(x_0, f(x_0))$  is an inflection point.

Statement 2:  $f: \mathbb{R} \rightarrow \mathbb{R}$  is a continuous, (at least twice) differentiable function.

If  $f''(x_0) = 0$ , then  $P(x_0, f(x_0))$  is an inflection point.

Statement 3:  $f: \mathbb{R} \rightarrow \mathbb{R}$  is a continuous, (at least twice) differentiable function.

If  $f'(x_0) = 0$  and  $f''(x_0) = 0$ , then  $P(x_0, f(x_0))$  is an inflection point.

Statement 4:  $f: \mathbb{R} \rightarrow \mathbb{R}$  is a continuous, (at least twice) differentiable function.

If  $f''(x_0) = 0$  and the function is monotonically increasing (decreasing) in the neighborhood of  $x_0$ , then  $P(x_0, f(x_0))$  is an inflection point.

Task 3: Find (if possible) the inflection points of the functions:

$$(1) f(x) = x^4 + 2x^3 - 1; (2) f(x) = x^4 + 32x; (3) f(x) = |x^3 - 1|;$$

$$(4) f(x) = \begin{cases} x^3, & x \leq 0 \\ -x^3, & x > 0 \end{cases} \quad (5) f(x) = \begin{cases} x^2, & x \leq 0 \\ -x^2, & x > 0 \end{cases}$$

Task 4: Find (if possible) the inflection points of  $f(x)$ ,  $g(x)$ ,  $t(x)$ , based on the graphs of  $f'(x)$ ,  $g'(x)$ ,  $t'(x)$  – see Figure 2.

Figure 2: Graphs in Task 4

Task 1 and Task 2 are in a verbal representation, addressing participants' formal knowledge, Task 3: in an algebraic representation, addressing what we expected to be algorithmic knowledge; and Task 4 in a graphic representation, addressing participants' figural conceptions. Intuitive knowledge may be expressed in all four tasks.

Before giving our high school participants the tasks, we asked their teachers whether these tasks would be familiar to them. We learnt that Task 3 was expected to be most familiar – students usually investigated algebraic expressions of functions. They seldom analyzed graphs of the derivative, as required in Task 4; and were rarely asked to determine and prove the validity of a statement, as required in Task 2. Students' modest experience with such tasks and the impossibility of applying routine algorithms in the related solutions led us to assume that students' knowledge might be challenged.

Based on the analysis of their solutions, 20 participants were invited to individual, semi-structured, follow-up interviews, where they were asked by the researchers to elaborate on their written solutions. Interviewees were chosen according to their solutions in the questionnaires, focusing on interesting, correct, and incorrect ideas, while aiming to understand their reasoning. Interviewees were asked, among other things, to explain their solutions and to analyze solutions proposed by other participants. The interviews took 30-45 minutes and were audiotaped and transcribed.

## Results

In this section, we answer the research questions: In the students' opinion (1) When is a point an inflection point? (2) When is a point a non-inflection point? We discuss each of the ideas as presented in relevant tasks. More specifically, we present each of the conceptions found as expressed in the four tasks, in descending frequency of the phenomenon.

### When is the point an inflection point?

Our data indicates six sets of conditions that in the participants' opinions guarantee the presence of an inflection point.

**Passage point from convex to concave or vice versa  $\Rightarrow$  Inflection point** – This conception was mainly expressed (55%) in Task 1 (Define): “Inflection point is a point where the graph shifts from concave to convex (or vice versa)”. However, no reference was made to characteristics of the function (domain, continuity or differentiability).

**$f''(x_0) = 0$  and a passage from convex to concave  $\Rightarrow$  Inflection point** – This conception prevented participants from finding the non-derivative inflection point of the functions, based on the graphs of derivatives in Task 4 (24%). In addition, it was also expressed in solutions to the algebraic representation of function  $f(x) = |x^3 - 1|$  (16%) in Task 3.

**$f''(x_0) = 0 \Rightarrow$  Inflection point** – This conception was evident in the participants' solutions to three tasks. In Task 3,  $f''(x) = 0$  considerations were erroneously used as sufficient for inflection points of polynomial functions and even of piecewise functions. For example, participants correctly found A(0, -1) and B(-1, -2) as inflection points of  $f(x) = x^4 + 2x^3 - 1$  by examining only  $f''(x) = 0$  (30%).

Similarly, the point (0, 0) was erroneously claimed to be an inflection point of  $f(x) = \begin{cases} x^3, & x \leq 0 \\ -x^3, & x > 0 \end{cases}$

by examining only  $f''(x) = 0$  (15%). About 30% incorrectly claimed that Statement 2 is correct (Task 2). Some of them added: “That is the definition: P is an inflection point if and only if  $f''(x_P) = 0$ ”. Others provided algorithmic considerations, mentioning solutions to investigate-the-function and stopping after solving  $f''(x_0) = 0$ , e.g.: “We find inflection points when looking for extreme points. If  $f''(x_0) = 0$ , then the point is not minima or maxima, and that is why it is an inflection point”. In their reactions to Statement 3 (Task 2) participants (10%) incorrectly answered that the statement is valid and explained that “ $f''(x_0) = 0$  is a sufficient condition for the existence of an inflection point”.

**$f'(x_0) = 0$  and  $f''(x_0) = 0 \Rightarrow$  Inflection point** – This conception was mainly expressed in Task 2; about half of the participants incorrectly claimed that Statement 3 was valid. Most of them provided the methods that they used to solve investigate-the-function tasks. They wrote: “[We] always find inflection points when looking for extreme points, thus starting this search with  $f'(x) = 0$ ”, then: “An inflection point is a point where  $f''(x) = 0$ ”. In addition, in Task 4 (Investigate the graphs of derivative), about 20% incorrectly found an inflection point only at  $x = 6$ , exhibiting an erroneous assumption: “We see that  $t'(6) = 0$ , that is, the slope of the tangent of  $y = t'(x)$  at  $x = 6$  is zero, so,  $t''(6) = 0$ , therefore at  $x = 6$  there is an inflection point.”

**$f''(x_0) = 0$  and monotonicity in the neighborhood of  $x_0 \Rightarrow$  Inflection point** – Participants (42%) incorrectly claimed that Statement 4 was valid (Task 2). They explained: “Those are sufficient

conditions for an inflection point”, or gave a supporting example, like  $f(x) = x^3 + 5$ . In their interviews, several of the latter explained their solution in terms of: “If the second derivative is zero and the function continues to increase when increasing and to decrease when decreasing, there is a change of convexity-concavity”. The combination of these two conditions is likely to determine an inflection point. However, this answer can be refuted by a counter example, like  $f(x) = x^4 + 32x$  (this function appeared in Task 3, but it was not used to refute this statement),  $f''(0) = 0$  and the function is increasing monotonically in the neighborhood of  $x = 0$  but  $(0, 0)$  is not an inflection point. Evidence about this set of insufficient conditions that seem to be “allegedly certain” for ensuring an inflection point, to the best of our knowledge, was found for the first time in this research.

**$f'(x_0) = 0$  and monotonicity in the neighborhood of  $x_0 \Rightarrow$  Inflection point** – Participants (16%) wrote, for instance: “A point where  $f'(x) = 0$  and the graph keeps increasing (or decreasing) before the point and after it is an inflection point” (Task 1). In reaction to Statement 1 (Task 2), participants correctly answered that the statement is false, but their explanation was: “ $f'(x_0) = 0$  is necessary but not a sufficient condition for an inflection point. If in addition to  $f'(x_0) = 0$  the function increases (or decreases) before and after the point, only then is the point an inflection point” (10%). It should be noted that a combination of these conditions define a particular type of notion – a horizontal inflection point. This grasp of inflection point probably ignores non-horizontal inflection points (Task 3), like the inflection point of the function  $f(x) = x^4 + 2x^3 - 1$  (10%).

### When is the point a non-inflection point?

We found three conditions that deny the existence of an inflection point:

**No differentiability  $\Rightarrow$  No inflection point** – In reactions to Task 3, investigate the function  $f(x) = |x^3 - 1|$ , most participants (63%) found an inflection point only at  $x = 0$ , providing algorithmic considerations of solutions to investigate-the-function, such as: “ $f'(0) = 0$ ,  $f''(0) = 0$ , before  $x = 0$ ,  $f''(x)$  is positive, so  $f(x)$  is convex and after  $x = 0$ ,  $f''(x)$  is negative, so  $f(x)$  is concave, thus  $x = 0$  is an inflection point”. Some of them added a correct graph to their investigation and, with relation to  $x = 1$ , wrote that “although at this point the function changes from concave to convex, it is a non-inflection point, because the function is not differentiable at  $x = 1$ ”. In their interviews, several participants explained: “The function is non differentiable at  $x = 1$  and therefore there is no inflection point”, or: “No differentiability, no inflection point.” Following this, a quarter of the participants defined “inflection point” (Task 1) as requiring differentiability. For example: “A point where  $f''(x) = 0$  and the function turns from concave to convex or vice versa”, or: “The slope of the tangent of the function at this point is zero, and the function is either increasing on both sides of the point, or decreasing on both sides of the point.”

**No second derivative  $\Rightarrow$  No inflection point** – This conception, that is consistent with the condition  $f''(x_0) = 0$ , is used as a filter to reactions to Task 3, Investigate the function  $f(x) = \begin{cases} x^2, & x \leq 0 \\ -x^2, & x > 0 \end{cases}$ , included explanations (23%) such as: “When there is no second derivative – there is no inflection point. All inflection points must satisfy the condition  $f''(x_0) = 0$ . Otherwise there is no infection point”. It was also found in reactions to Task 4 (15%), Investigate the graphs of  $f'(x)$ , that only the point  $x = 6$  that satisfies the condition  $f''(x_0) = 0$  was identified as an inflection point. The other point ( $x = 10$ ), where the second derivative is not defined, was ignored.

$f''(x_0) = 0$  and  $f'''(x_0) = 0 \Rightarrow$  **No inflection point** – expressed in the investigation of the function  $f(x) = x^4 + 32x$  (7%). Note that this function really has no inflection points. Yet, this correct judgment was based on a wrong consideration. A counter-example is  $f(x) = x^5$  has an inflection point, yet both  $f''(0) = 0$  and  $f'''(0) = 0$ .

Commonly studies report of students' conception of mathematical notions by reporting on criteria that lead to regard the notion as defined. Here we show a new angle of criteria that regards the notion as undefined.

## Discussion

We discuss the findings by using Fischbein's (1993a, 1993b) theoretical framework for analyzing students' errors and for examining possible related sources.

### What are possible sources of students' mathematical errors?

Fischbein studied broad aspects of students' mathematical reasoning, claiming that an analysis of students' performance has to take into account three basic aspects: algorithmic, formal and intuitive (Fischbein, 1987, 1993a). The algorithmic aspect includes knowledge of (a) "how" to solve a problem, and (b) "why" a certain sequence of steps is correct. The formal aspect includes knowledge of axioms, definitions, theorems, proofs and knowledge of how the mathematical realm works. The intuitive aspect of mathematical knowledge is an immediate and self-evident, though not necessary correct, knowledge, accepted with certainty. Fischbein's three components of mathematical knowledge and their interrelations play a vital role in students' mathematical performances. However, "sometimes, the intuitive background manipulates and hinders the formal interpretation or the use of algorithmic procedures", causing inconsistencies in students' solutions (Fischbein, 1993a, p. 14). Fischbein further addressed the impact of drawings (e.g., in geometry) on learners' mathematical reasoning by explaining that the figural structure may dominate one's reasoning instead of being controlled by the corresponding formal constraints (Fischbein, 1993b).

### What are the possible sources for students' errors with the concept of inflection points?

We found tendencies to determine or deny the existence of an inflection point under certain conditions. It is important to note that during the study we did not ask directly: Under which conditions, does or does not one get an inflection point? Participants provided "filtering conditions" by their own initiative. So, if one of the following sets is true: (1) convex-concave; (2)  $f''(x_0) = 0$  and convex-concave; (3)  $f''(x_0) = 0$ ; (4)  $f'(x_0) = 0$  and  $f''(x_0) = 0$ ; (5)  $f''(x_0) = 0$  and monotonicity in the neighborhood of  $x_0$ ; (6)  $f'(x_0) = 0$  and monotonicity in the neighborhood of  $x_0$ ; on the other hand, if there is (7) No differentiability; (8) No second derivative; (9)  $f''(x_0) = 0$  and  $f'''(x_0) = 0$  – then there is no inflection point. During the interviews, students reinforced these views.

An initial evaluation of the reasons underlying erroneous conceptions suggested two main causes: algorithmic experience with investigations of functions, and the impact of the drawing. Students tended to explain that: "This is how I find an inflection point when I investigate a function", or, [in relation to Task 4] "According to the graphs, each function has one inflection point at  $x = 7$  where the graphs shift from concave down to concave up". Thus, it seems that the answers may intuitively evolve from the participants' mathematical, algorithmic experiences (Fischbein, 1993a) and from their figural concept of inflection point (Fischbein, 1993b).

Four of the six sets of conditions that participants presented for “being an inflection point” do not necessarily lead to inflection points (sets 1, 3-5); the other two sets determine inflection points only for a limited family of functions (sets 2, 6). For example, in set 1, the participants provided intuitive definitions, without reference to the type of the functions (e.g., continuous or differentiable). In set 4, participants exhibited slope-zero figural concepts (Fischbein, 1993b) in their reactions to Task 4, when they incorrectly found an inflection point “where slope of the tangent is zero...”, or, “where the first derivative and second derivative cross the  $x$ -axis”. In set 5, the necessary condition  $f''(x) = 0$  was presented as a critical step in the algorithmic offering (Fischbein, 1993a), but in combination with the condition of monotonicity, that at first sight seems “sufficient” for an inflection point, surprisingly this does not necessarily lead to an inflection point (as presented in the results section). In set 6, the unnecessary condition  $f'(x) = 0$  was possibly used as a result of the “primacy effect”. That is, it might be the case because these are usually the first inflection points addressed in calculus lessons (Fischbein, 1987); but it was presented with the condition of monotonicity, and thus defined a particular type of notion – a horizontal inflection point.

The three sets of “denying conditions” can shed some additional light on students’ conception of inflection point from two perspectives: (1) types of functions that are usually investigated, and, (2) logical constraints of their knowledge. Requesting the necessity of differentiability (set 7) can be related to functions that are usually investigated or presented graphically in textbooks – most of these are differentiable at the inflection point. Thus, an intuitive image of a “smooth inflection point” was created. Here, as in many other cases, students recognize the concept “by experience and usage in appropriate contexts” (Tall & Vinner, 1981, p. 151; their emphasis). The necessity of twice differentiability (set 8) might be rooted in intuitive ideas that interfere with students’ formal knowledge (Fischbein, 1987; 1993a). That is, from the theorem, “If  $f(x)$  is twice differentiable in some neighborhood of  $x_0$ , and if  $x_0$  is an inflection point, then  $f''(x_0) = 0$ ” students erroneously conclude that “if no second derivative then there is no inflection point”. Here, this answer can be refuted by a counter example, like  $f(x) = x^{5/3}$ . In set 9, the inadequate declaration: ‘ $f''(x_0) = 0$  and  $f'''(x_0) = 0 \Rightarrow$  No inflection point’, might be rooted in intuitive ideas that interfere with students’ algorithmic knowledge (Fischbein, 1987). That is, from the theorem “ $f''(x_0) = 0$  and  $f'''(x_0) \neq 0 \Rightarrow$  Inflection point” students erroneously create the rule “if ... then..., if not ... then not...”.

This study considerably enriches the existing body of knowledge regarding high school students’, university students’, and university graduates’ conceptions of inflection points. Only a small number of studies have dealt with students’ conceptions of inflection points directly (e.g. Rivel, 2004; Tsamir & Ovodenko, 2004) and indirectly (e.g. Biza & Zachariades, 2010; Vinner, 1982). Reported studies usually addressed a limited population and dealt only with specific conceptions. The current research offers a broad collection of related correct and incorrect conceptions found among participants with suitable mathematical backgrounds (as specified in the methodology section), with reference to the type and the representation of the given tasks.

# Math teaching as jazz improvisation: Exploring the ‘highly principled but not determinate’ instructional moves of an expert instructor

Alon Pinto

University of California, Berkeley, USA; [allalon23@gmail.com](mailto:allalon23@gmail.com)

*When engaging students in genuine mathematical problem solving, how can instructors maintain a productive learning environment? In this paper, I examine a series of improvised instructional moves of Alan Schoenfeld, a renowned teacher of mathematical problem solving, and investigate his dilemmas, considerations, and in-the-moment decisions. I use the TRUmath framework to unpack the conflicts that underlie Schoenfeld’s dilemmas, and to propose a tacit teaching heuristic that help explains his hard-to-justify moves. I conclude that Schoenfeld’s in-the-moment decision making is tacitly oriented towards maintaining certain kinds of balances between his pedagogical principles. On the basis of this analysis, I recommend exploring further the use of TRUmath as a framework for analyzing in-the-moment decision making in the context of conflicting pedagogical principles.*

*Keywords: University math teaching, teaching dilemmas, decision making, problem solving.*

## Introduction

I think this kind of teaching is highly principled by not determinate. What I was thinking of is jazz improvisation. It’s anything but random; there are moves that the musician will say would or would not be right; but, there may not be a sound justification for any particular in-the-moment move other than ‘it just felt right’.

In this quote, Prof. Alan Schoenfeld reflects on a series of in-the-moment teaching decisions he made during a problem solving session. Schoenfeld is an expert teacher of mathematical problem solving (MPS hereafter); he has been studying and teaching MPS for more than three decades now. After so many years, Schoenfeld’s instruction seems anything but improvised. For this study, he has reflected on numerous teaching moves that he made during his MPS course, and he was typically able to provide a sound and detailed rationale for his decisions. However, there were certain decisions that Schoenfeld found hard to fully justify, as a key ingredient in their making was a tacit sense of where the class is and how different decisions could work out. In the quote above, Schoenfeld argues that this kind of hard-to-justify decisions makes the instruction of MPS a lot like jazz improvisation, in the sense that both activities are ‘highly principled but not determinate’. In this paper we investigate Schoenfeld’s jazz-like teaching moves through a case study of three hard-to-justify decisions in one MPS session. In this session, Schoenfeld faced a typical dilemma in MPS-oriented lessons: how should a teacher react when a student comes up with a beautiful and original idea that opens the door to a mathematical exploration that seems worthwhile for some of the students, and a step too far for other students? The aim of this paper is to unpack Schoenfeld’s conflicting pedagogical considerations in this case, and to provide insights into his decision making.

The lesson examined in this paper was part of Schoenfeld’s MPS course. Schoenfeld’s teaching in this course has been studied in several papers. For example, Arcavi, Kessel, Meira and Smith (1998) studied Schoenfeld’s teaching in relation to the establishment of classroom norms and MPS heuristics. Schoenfeld’s in-the-moment decision making in this course, which is the focus of this paper, has not been studied so far. This MPS course was given to education graduate students and

prospective teachers and comprised of paper reading, a small scale research project, and engagement in authentic MPS. In terms of goals and pedagogy, the lesson described in this paper is similar to lessons that Schoenfeld has taught in earlier years to undergraduate mathematics students. Therefore, the dilemmas and instructional moves discussed below are not specific to teacher-education courses, and should be viewed in the context of MPS-oriented instruction at university.

There are various approaches for explaining why teachers make the decisions they make as they teach. One approach, which has been gaining much attention in recent years, is to explain teaching decisions in terms of knowledge, goals, and orientations (Schoenfeld, 2010). This approach has been used at the university level in empirical studies (e.g. Pinto, 2013) and also in professional development programs, as an organizing framework for instructors' self-reflections on their teaching (e.g. Schoenfeld, Thomas, & Barton, 2016). However, a notable limitation to the explanatory power of this approach is that instructors' self-reflections are oriented towards what instructors notice in their teaching and have words for. Therefore, there is a need for an organizing framework that would draw attention to various important facets of the work of teaching. One candidate framework is the Teaching for Robust Understanding of Mathematics framework (TRUmath) (Schoenfeld, 2015). In this paper we analyze Schoenfeld's reflections on his teaching from a TRUmath perspective, and examine the use of TRUmath as an organizing structure for instructors' reflections on their dilemmas and decisions that attends to all the major contributors for productive learning environments.

## Setting and methods

This paper examines a lesson taught by Alan Schoenfeld in a "Mathematical Thinking and Problem Solving" course at the Graduate School of Education at UC Berkeley. The lesson took place during the 11<sup>th</sup> week of the semester. The class comprised of 21 students – graduate students in the school of education and students from teacher preparation programs. The class met once a week for a 3-hour lesson and every lesson included an MPS part where students worked alone or in small groups on a list of problems and then reconvened to share ideas and solutions. The author videotaped the lessons and took notes. After each lesson, Schoenfeld wrote down some reflections on his dilemmas, his instructional moves and decisions, and their impact on the lesson. In addition, the author conducted three 1-hour interviews with Schoenfeld at different stages of the semester that focused on where the class is with respect the learning trajectories for the course.

The analysis in this study is based in part on the TRUmath framework, which seeks to characterize the main contributors for productive learning environments. This framework was derived through a comprehensive literature review by distilling the factors that shape learning in classrooms into a small number of "equivalence classes". These classes are represented through five dimensions: (1) the richness of the mathematics, (2) cognitive demand and opportunities for "productive struggle", (3) equitable access to content for all students, (4) students' opportunities to develop agency, ownership, and positive mathematical identities; and (5) formative assessment. According to the TRUmath framework, these five dimensions are both necessary and sufficient for studying learning environments in the sense that instruction needs to do well along these dimensions in order to produce mathematically proficient students. Figure 1 provides a brief account of each dimension.

The Mathematics	Cognitive Demand	Access to Mathematical Content	Agency, Authority, and Identity	Formative Assessment
<i>The extent to which the mathematics discussed is focused and coherent, and to which connections between procedures, concepts and contexts (where appropriate) are addressed and explained. Students should have opportunities to learn important mathematical content and practices, and to develop productive mathematical habits of mind.</i>	<i>The extent to which classroom interactions create and maintain an environment of productive intellectual challenge conducive to students' mathematical development. There is a happy medium between spoon-feeding mathematics in bite-sized pieces and having the challenges so large that students are lost at sea.</i>	<i>The extent to which classroom activity structures invite and support the active engagement of all of the students in the classroom with the core mathematics being addressed by the class. No matter how rich the mathematics being discussed, a classroom in which a small number of students get most of the "air time" is not equitable.</i>	<i>The extent to which students have opportunities to conjecture, explain, make mathematical arguments, and build on one another's ideas, in ways that contribute to their development of agency (the capacity and willingness to engage mathematically) and authority (recognition for being mathematically solid), resulting in positive identities as doers of mathematics.</i>	<i>The extent to which the teacher solicits student thinking and subsequent instruction responds to those ideas, by building on productive beginnings or addressing emerging misunderstandings. Powerful instruction "meets students where they are" and gives them opportunities to move forward.</i>

**Figure 1 – The five dimensions of the TRUmath framework (Schoenfeld, 2015)**

In this paper, we explore TRUmath's explanatory power on Schoenfeld's own instruction, and use the five dimensions as an organizing structure for the discussion of his dilemmas and considerations. Schoenfeld is one of the leading developers of the TRUmath framework, and therefore it is particularly suitable for exploring his decision making. We examine a sequence of three hard-to-justify decisions, first from an outside observer perspective based on the videos of the lessons; then from Schoenfeld's inner perspective based on his post-lesson written reflections and the interviews; and finally, from a TRUmath perspective, where the dimensions are used to organize and compare Schoenfeld's various considerations, to unpack the pedagogical conflicts that underlie his dilemmas, and to investigate what kinds of balances he achieved in his in-the-moment decisions.

### The Square-ness task

The discussion analyzed in the paper revolves around the Square-ness task, given in the figure below, which was designed by Judah Schwartz in cooperation with members of the Balanced Assessment Group at the Harvard Graduate School of Education. In the lesson, Schoenfeld framed this task as "*an introduction to the game mathematicians play*", and directed students to start with their intuition as to what it means for a rectangle to be more 'squamish', and then mathematize this intuition by "*coming up with a mathematical characterization that would enable anyone to perform some sort of operations on a rectangle [...] and obtain a number that would tell, in some sense or other, how close to being a square that rectangle is.*"

Below you will find a collection of rectangles.

(a) Define a mathematical measure that allows you to tell which rectangle is the "most square" and which rectangle is the "least square".

(b) Define a different measure that achieves the same result.

(c) Is one measure "mathematically superior" to the other?

Argue why, and be prepared to defend your choice to the class

## Analysis

It's not the note you play that's the wrong note – it's the note you play afterwards that makes it right or wrong. (Miles Davis)

Taking a cue from a renowned jazz improviser, I maintain that improvised teaching decisions should not be examined in isolation but rather as part of the flow of instructional moves that teachers make during a lesson. Accordingly, this investigation of Schoenfeld's improvised teaching moves examines three hard-to-justify decisions in the context of Schoenfeld's instruction throughout the MPS session. The analysis is presented as a narrated description of the whole session that comprises of three threads: an outside-observer description of Schoenfeld's moves; a synthesis of Schoenfeld's reflections on his moves, as explicated in the interviews; and a TRUmath perspective on three challenging teaching dilemmas and their hard-to-justify resolutions.

The discussion of the Square-ness task began with a short introduction by Schoenfeld, after which he invited students to present their candidates measures. One of the students, Sophie, approached the board and suggested that the square-ness of a rectangle with side-lengths  $a$  and  $b$  will be defined by: "The ratio  $a/b$  ought to be close to 1". Two students objected to this definition, arguing that it is not well defined and that it should specify that  $a$  is the shortest side length. Sophie disagreed at first, claiming that "it does not matter", but was eventually persuaded. She added "where  $a \leq b$ " to the written definition, and walked back to her seat. At this point, Schoenfeld intervened:

Ok, I love it when the class takes over and raises mathematical objections. The question is, if you're characterizing the square-ness of this figure and you're getting a number, shouldn't we get the same number if we happen and bring it down this way instead? (Draws a figure of a rectangle rotated by 90 degrees) It's the same rectangle, so whatever measure you have should bring you the same number. If you have say, a 1 by 3 rectangle, then you get 1 over 3 which is not the same distance from 1 as 3 over 1; so, it begins to be problematic unless you lay it down so that 'a' is the smaller one of the two [side lengths], and then take 'a' over 'b'.

After making this remark, Schoenfeld leaned quietly against the wall and waited for the students to react. In his reflections, Schoenfeld noted that up to this point the discussion took off just as he intended, as the students were engaged in defining, comparing and criticizing measures, and by doing so, expressing their implicit expectations from a measure. Schoenfeld noted that it is quite typical that the first candidate measure is based either on the ratio or on the difference between adjacent side lengths of the rectangle. The measure Sophie suggested has the nice property that it can be defined in a way that makes it invariant under rotations and scaling. The students' debate on whether Sophie's measure was well defined did not address explicitly the properties of the measure. The students seemed more occupied with figuring out the exact routine for computing the measure. Nevertheless, Schoenfeld explained in the interview that this debate provided him with an opportunity to acknowledge, respond to and build on students' ideas, while rephrasing these ideas in a way that fit his goals – to engage students in discussing the desired properties of measures.

Emmy was the first to comment on Sophie's example: "I think that I can probably find a quadrilateral that is not a square, but would have that, hmm... would be a square under that measure of square-ness, but it is not a rectangle, is that OK?"

Schoenfeld's immediate response was to the entire class: "Do you want to take a vote? Is that OK?" The class seemed divided with some students wondering whether considering quadrilaterals other than rectangles is allowed, while others expressing interest in seeing Emmy's example. Schoenfeld agreed with the students that the problem is stated just for rectangles, but as several students responded in disappointment, he paused to make a quick evaluation and to decide how to proceed.

In his reflections on this moment, Schoenfeld noted that Emmy's example came as a surprise, and too soon with respect to where he felt the class was. He explained that he was more expecting students to propose another candidate measure, which he could compare to Sophie's measure; or to point out that Sophie's measure is invariant under scaling, which would have provided another opportunity to discuss properties of measures. Schoenfeld reflected on his dilemma: on the one hand, the class seemed eager to see Emmy's example; Emmy's comment was well aligned with his own agenda of discussing the desired properties of measures, as it pointed out the fact that Sophie's example might not be generalizable to parallelograms. He also considered this comment as an authentic and beautiful example of 'doing mathematics' and he wanted to acknowledge this; and, coming from a student, this generalization felt natural and organic rather than an artificial teaching move, making it even more appealing. On the other hand, Schoenfeld noted that he was worried that Emmy's example might steer the discussion towards arbitrary quadrilaterals, and he was not sure that the class was ready for this level of abstraction. He wanted more students to participate in the discussion and considered putting Emmy's example on hold so other students could present their candidate measures for rectangles. He also noted that he had examined some of the student work on this problem and that there were a few important insights that he wanted to draw from that work.

In the classroom, Schoenfeld responded almost instantly:

Now, before I throw [Emmy] out of class (laughing), let's examine what [she] said. One of the properties one might like for, hmm... any definition is to ask the question: what class of objects this definition applies to? [...] So, this measure (points at the Sophie's definition on the board) works for rectangles, but being my psychic self, I think the figure Emmy had in mind was a family of rhombuses (draws two rhombuses on the board), all of which have a measure 1 according to the definition, if we think in terms of side lengths; but they don't look like a square!

Note that Schoenfeld's response opened the door for Emmy's example, but that he presented the example himself, as he understood it, rather than letting Emmy present it in her own words. Looking back at his response, Schoenfeld noted that it is hard to justify, claiming that on one hand, it is highly principled in the sense that it is consistent with his goals and orientations, as explicated in his reflections on his dilemma. On the other hand, this decision was not determined by principles, as it was based in part on a tacit sense of where the class was, and how well things could work out.

We now turn to analyze Schoenfeld's hard-to-justify decision from a TRUmath perspective. One option Schoenfeld had was to invite Emmy to present her example in her own words. This option is well aligned with the Formative Assessment and Agency dimensions. Moreover, Schoenfeld considered Emmy's idea to be "a beautiful example of doing mathematics", and since his goals were to discuss properties of measures, he considered this option to also be well aligned with the Mathematics dimension. However, Schoenfeld's reflections suggest that he found this option less appealing from the perspectives of the Access and Cognitive Demand dimensions. He explained that

it is essential that students understand and relate to the goals of the exploration. Emmy, who might still be struggling to formulate her idea, could end up leading a discussion that the rest of the students could not engage with productively. Another option Schoenfeld considered was flatly rejecting Emmy's example, or putting it on a back burner. This option would have given Schoenfeld more control over the lesson, which has merits in terms of the Mathematics, Cognitive Demand and Access dimensions. However, Schoenfeld considered this route potentially harmful in terms of Authority, Agency and Identity, and Formative Assessment. Schoenfeld's response represents an alternative to these two options. He acknowledged and built on Emmy's idea (Formative Assessment), lowering the risk of being perceived as rejecting her thinking (Authority, Agency and Identity). However, he did so by proposing two visual examples of rhombuses, making the discussion more concrete and accessible (Cognitive Demand and Access). Moreover, Schoenfeld provided a crisp outlining of the topic of the discussion: "what class of objects this definition applies to" (Access), orienting the discussion towards the properties of measures (Mathematics). To summarize, Schoenfeld considered the first two options to be potentially beneficial as well as potentially harmful; his reaction chose a middle ground that he still considered beneficial, and safe.

The lesson continued with Sophie, Emmy and a few other students discussing how to modify Sophie's measure to make it 'more square'. This discussion led to a new candidate measure for square-ness: the product of the ratio between adjacent side lengths and the ratio between adjacent angles. However, Emmy criticized this measure, claiming that while this measure has the nice property that squares are separated from other shapes, she can no longer see what kind of ordering this measure induces on parallelograms, and whether this ordering has anything to do with her initial intuition as to what square-ness should mean. Several students endorsed this criticism, and the class abandoned this measure. One student suggested that it might not be possible to find a measure that works for both rectangles and rhombuses, and the whole classroom discussion started to break up into several concurrent discussions. At this point, Schoenfeld intervened:

I'll point out that what we're doing right now is exactly the business mathematicians are engaged in. [...] We start with rectangles and see candidate measures for rectangles; then the question is, what about parallelograms? Trapezoids? Arbitrary quadrilaterals? Is it possible to find a measure that could characterize square-ness for all of those? We only got one definition of square-ness of rectangles so far, and I want to see a few more. It is possible that if we are just looking at rectangles any of the candidate measures will do, although some might be easier to calculate, some might correspond more to your intuition in terms of how square something is. And then, as we move on, only some of those definitions work for more objects. That's the game mathematicians play. So, we have two directions to go. We have this definition (wipes the board clean and writes ' $a/b$  closest to 1 where  $a \leq b$ '). We can ask, are there any other characterizations, or reasons to like them more or less; and we can ask do they generalize and how much, which can also get us to a discussion about just what properties of definitions in general do we want, and what properties do we want in this particular case. The floor is open.

Reflecting on this intervention, Schoenfeld noted that this was a point where he sensed the class was indeed not ready for the exploration they initiated, as he anticipated might happen; in his message to the students, he was trying to steer the discussion back to rectangles, while making sure he is still giving due credit to the exploration the students were engaged with, framing it as the 'game

mathematicians play'. Schoenfeld considered this decision as essentially based on a tacit evaluation of where the class is. In the interview, he used TRUmath terms to make this evaluation somewhat more explicit: He explained that he was reading from the students' facial expressions that some students were getting disconnected, signaling Access was becoming an issue; he also noted that the fact students starting to question whether the problem could be solved at all was for him a signal that the Cognitive Demand of the task might be too high. Schoenfeld concluded that in his intervention he was implicitly trying to attend to the Access and Cognitive Demand dimensions.

At this point, Emmy suggested: "I have an idea, but I don't know how to turn it into a measure [...] I have a measure that would split out squares, but I don't know how to make it order everything else. Should I share it? (Schoenfeld nods) OK, my theory is that if you have a given a perimeter for a quadrilateral, the square will have the maximum area. So, I want something that takes perimeters and determine whether or not, hmm... determines whether or not that's the maximum area for that circumstance and then order everything else according to how not maximum it is, or something."

Emmy's suggestion led to a rapid exchange between her and Sophie, while the rest of the students remained quiet. In the interview, Schoenfeld referred to this moment as another challenging dilemma that led to a hard-to-justify decision. While he considered Emmy's comment to be mathematically inspiring, it also impeded his attempts to lead the discussion back to rectangles. Schoenfeld explained that he guessed Emmy's idea is intuitively based on the isoperimetric theorem, and he estimated that forming a measure for arbitrary quadrilaterals on the basis of this intuition might prove too difficult for most students, potentially reducing their confidence and sense of efficacy even further. Thus, even though following up on Emmy's comment was very appealing from the Mathematics and Formative Assessment perspectives, this option seemed very risky from the perspectives of Access, Cognitive Demand and Identity. However, Schoenfeld found that while his principles directed him to object to exploring Emmy's idea, his sense of the class suggested otherwise: he sensed that the students were quiet but not passive, that they were actively listening to Emmy and Sophie. Consequently, Schoenfeld explained he decided to try and provide the class with just enough scaffolding to enable more students to engage productively in the new exploration:

Ok, let's take what we do know and see if we can turn this to a measure. Hmmm... you may have heard [...] of this thing known as the isoperimetric theorem ... the general theorem is that if you take any figure whatsoever for a fixed perimeter, the circle is the figure with the largest area. If you limit yourself to quadrilaterals, to rectangles, it turns out that for any given perimeter the square is the figure with the largest possible area. So, the question is whether we can turn that into a measure we can use, and then think about abstracting this into some of these other figures.

In TRUmath terms, Schoenfeld's decision can be expressed as an attempt to amend the level of Cognitive Demand so to increase Access. The intervention paid off. Four more students joined Sophie and Emmy and participated in the exploration. It took just a few minutes of discussion for Sophie to come up with a measure that works: "*The perimeter over four, squared, over the area of the shape*". The class enthusiastically picked up on this suggestion, and eventually endorsed it.

## Discussion

In this paper, we examined a sequence of three in-the-moment decisions. Schoenfeld's first decision was to open the door to Emmy's original idea, but present it in his own words; when the exploration

of Emmy's idea seemed too challenging for the class, Schoenfeld's second decision was to try and steer the discussion back to the original problem; and finally, a quick evaluation of where the class was led Schoenfeld to reverse his second decision and allow an even more challenging exploration. Schoenfeld considered his decision making to be highly principled in the sense that his decisions were well aligned with his explicit orientations and goals; however, in his reflections, he also observed that some of these decisions were hard to fully justify since they were strongly influenced by a tacit sense of where the class is and how things could work out. This sense of the class is a resource Schoenfeld developed over years of teaching the course; his reflections suggest that this resource has a crucial role in his decision making when faced with challenging dilemmas: it helps resolve pedagogical conflicts that rise from tensions between competing goals and orientations. The TRUmath framework proved to be useful for unpacking these tensions by providing an organizing structure for the different considerations and the conflicts they present. For example, in the context of Emmy's original idea, when examining three alternative options, we found that Schoenfeld considered two of the options to very well aligned with some of the dimensions, but also potentially harmful from the perspective of the other dimensions. The TRUmath analysis suggested that Schoenfeld chose a path that he considered more moderate across all five dimensions in terms of potential gains and risks. This analysis led Schoenfeld to suggest a teaching heuristic that may have tacitly guided him: keep the lesson productive from the perspective of each dimension, and avoid the temptation to excel in just one or two dimensions at the expense of the other dimensions.

This paper illustrates the theoretical potential of TRUmath as a framework for explaining decisions made in light of conflicting goals and orientations, and the practical potential of TRUmath as an organizing structure for teacher reflection that highlights the gains and risks entailed in different instructional moves. As Schoenfeld is both the subject of this study and one of the developers of TRUmath, further research is required to assess TRUmath's explanatory power for other instructors.

# Identifying discussion patterns of teaching assistants in mathematical tutorials in Germany

Juliane Püschl

University of Paderborn, Germany; [jpueschl@math.upb.de](mailto:jpueschl@math.upb.de)

*Mathematical tutorials play an important role in tertiary teaching of mathematics in Germany. However, we do not know a lot about what actually happens in these tutorials. This paper reports from a small study in the context of a PhD project which investigates the work of teaching assistants (TAs). The result of this study is a typology of discussion patterns of tasks in mathematical tutorials. In this study typological analysis, including a hierarchical cluster analysis, was used to identify different ways in how TAs work on mathematical tasks in classroom discussions. The findings suggest that there are five main patterns for the discussion of tasks, differing in focus, length and support of students' learning.*

*Keywords: Teaching assistants, tutorials, problem oriented instruction, classroom discussion.*

## Introduction

In Germany, teaching assistants (TAs) play a vital role in the learning of mathematics at universities. A mathematical course usually consists of three parts: the lecture, homework assignments and small group tutorials. The lecturer delivers the lecture and assigns three to five tasks for the homework assignments. After working on these assignments for one week, the students hand in their solutions to the tasks, TAs correct them and later discuss these tasks in small group tutorials. Usually, the lecturer and TAs meet every week for planning the tutorial session. TAs do not assist the lecturer in his teaching activities, but they are on their own in the tutorials and free to discuss the tasks as they like. TAs in Germany are undergraduate students who are just a few years ahead of the students they teach and they are usually employed for one semester. By leading the tutorials, TAs are close to the students' actual learning and may function as link between students and lecturer, e.g., they shall connect the contents of the lecture to the tasks, they ought to get feedback from the students and report this to the lecturer. TAs are expected to be accurate and to facilitate students' learning by also sharing their own experiences as successful students.

Although TAs play such an important role in the learning of the students, there is hardly any research on German TAs' practices. Internationally, research on TAs has increased in the last 20 years. However, as their role and practices differ in many ways from that of German TAs, it is uncertain in what respect the results of these studies can be transferred to the German context. Therefore, the aim of my PhD project is to understand how German TAs organize their tutorials in order, later, to be able to provide a basis on which we can develop quality criteria for German tutorials and use them to support TAs in weekly meetings and tutorial trainings.

## Theoretical background

In the last years, research on mathematical teaching practices has increased and there have been a few studies that compare characteristics and teaching styles of instructors in different levels. Weber (2004) showed that one lecturer might use different teaching styles, depending on his learning goals and the content he is teaching. Weber could identify three different ways of teaching proofs in a

traditional lecture format: logical-structural, procedural and semantic. This suggests that, at least advanced lecturers, change their teaching styles intentionally.

There have also been studies on comparing teaching styles of different instructors. One example is Pinto's (2013) study on two TAs that are even supposed to follow the same lesson plan. Using Schoenfeld's resources, orientation and goals theory (Schoenfeld, 2011), Pinto illustrates how both TAs prepare and hold their tutorials quite differently according to their research background and experience in teaching this particular topic. Also Mali (2015) could accord to the findings of Pinto. In their study on two tutors in small group tutorials, they found out that teaching seems to be closely linked to research practices of the tutors: the mathematician "uses the graph to make fundamentally mathematical ways of thinking transparent to students", whereas the mathematics educator uses the graph "as an alternative to explain the mathematics" (p. 2193).

Of course, looking at TAs from the German context, they do not have a research background that might influence their teaching. However, their experience from their own tutorials or from teaching tutorials in former semesters as well as their learning goals, beliefs about learning or the mathematical contents might influence the way they discuss tasks. Therefore, the main research question for this paper is: What different "discussion patterns" do TAs use when working on mathematical tasks in tutorials? This includes sub-questions like: Do TAs focus on the problems they identified when correcting the students' work? Do they always discuss the whole task or only parts of it? How much do they support the students in their learning process? For this paper I combine the answers to these questions by trying to find overall patterns for classroom discussions.

## Methods and design

The study is being conducted at a German university. Students of mathematics for pre-service teachers are expected to attend lectures and additional small group tutorials of 10 to 30 students. Both, lectures and tutorials are weekly sessions of 90 minutes, the students are supposed to work on tasks out of class which are assessed by the TAs and discussed in tutorials. The videos for this study were generated in tutorial sessions containing 78 task discussions in total (2-3 discussions per tutorial). 32 TAs have taken part in this study, all of them pre-service teachers. The data set includes task discussions in tutorial sessions from different semesters of the years 2010 to 2015 and the discussion covered a range of topics from analysis, arithmetic and geometry. This great variety of tutorials was chosen to get a representative sample of task discussions, thereby reducing other influences (style of lecturer, difficulty of mathematical content, etc.).

The students in the tutorials were all bachelor students studying teaching mathematics in secondary schools. Students were not directly videotaped unless they presented parts of the solution in front of the class. Their questions, comments and other contributions to the task discussions are audible in the videos.

In a previous part of the PhD study, these 78 task discussions were analyzed for different aspects: how TAs start and end the task discussions, what methods they use, how they try to support the students using visualizations, references to the lecture, etc. Using qualitative content analysis, different categories were generated to investigate each aspect in more detail (Püschl, 2016).

This part of the study focus on the task discussion as a whole. As we want to find out different types of discussions, an empirical typification method, namely the "typological analysis" by Kuckartz (as

described in Kluge, 1999), was used for analyzing the data. An important part of typification methods is to identify features which characterize the different discussion patterns. These features for the classification of task discussions are based on some categories from the previous part of the PhD project (see Püschl, 2016). The following four features were considered for the typological analysis: *use of didactical elements*, *completeness of discussion*, *focus on problems* and *focus on strategies*.

The *use of didactical elements* is a key feature for the discussion, because it indicates to what extend the TAs support the students in their learning process. In the previous analysis of the PhD study, ten different didactical elements were identified: “use of visualization”, “highlighting common mistakes”, “reference to lecture, other exercises, school”, “giving structural advice”, “clarification of expectations”, “solving in several ways”, “recapitulation of main results”, “clarification of student questions”, “generating cognitive conflicts”, “returning students’ questions” and “asking advanced questions”. Some were only used in a few discussions (like “returning students’ questions”) while others could be found frequently (e.g., “use of visualization”). Some didactical elements are rather pedagogical (e.g., “returning students’ questions”), others demand more mathematical skills (e.g., like “asking advanced questions”). For the purpose of this paper instances in which a TA used a didactical element were counted, ranging from a minimum of 0 to a maximum of 13 elements per task discussion. The feature *completeness of discussion* tells, whether the TAs discuss the whole task or only parts of it. Therefore, this is a binary feature, 0 standing for an incomplete discussion. The other two features give insight into the focus of discussion and relate to categories from prior analysis. The focus could be on the mathematical problems the students had when working on the task. The *focus on problems* feature consists of three categories from the previous part of the study: “giving feedback on the work of students”, “highlighting common mistakes” and “telling the students to review specific parts of the task”. The *focus on strategies* feature is quite different: here, the TAs do not discuss mathematical difficulties, but rather pass on strategies that students need to solve a specific type of tasks. It contains the following three categories: “pointing out the task difficulty”, “giving structural advice” and “summarizing of task”. For both features, the elements in each discussion are counted, ranging from 0 to 4.

Based on these four features, agglomerative hierarchical clustering was used to find patterns in the 78 task discussions. Agglomerative clustering starts with all 78 cases, each building one cluster. The algorithm then merges a selected pair of clusters into a single cluster, so that after 77 steps only one big cluster is being left (Hastie, Friedman, & Tibshirani, 2001, p. 472). To equal the relative influence of the four features in the cluster algorithm, they were scaled between 0 and 1. The Squared Euclidean distance was used as a metric to calculate the distance between each cluster. To decide which clusters are joint in each step, the Ward’s Method was chosen as linkage criterion. The Ward’s Method tries to minimize the total distance from centroids by joining two clusters. This method facilitates the construction of clusters with similar sizes and is frequently used because it has often provided better results than other linkage criteria (Bortz, 2005, p. 573). As the clusters become more heterogeneous in every step of the algorithm, it is often recommended to stop at a number of clusters before the greatest increase of distance (Bacher et al., 2010, p. 241). The statistical analysis was facilitated by the software SPSS (version 23).

The data has been analyzed regarding the four features mentioned above. In addition, other factors have been taken into account as they might influence the results (Kuckartz, 2012, p. 125). Therefore, the discussion patterns identified by the cluster algorithm were analyzed in regard to a variety of other

factors. Three factors are presented in this paper: time spent on the discussion, the TAs' individual approaches and their experience in leading tutorials.

## Results

The results from the cluster analysis suggest five clusters from the 78 discussions. Using four or less clusters would have resulted in a high increase in distance between the cases in the cluster. Three cases of the 78 discussions were eliminated, because they did not fit one of these clusters for several reasons<sup>1</sup>. One case, for example, which showed a great distance to all of the other clusters, was a task discussion in which the TA was really ambitious and wanted to discuss the whole exercise with a lot of student participation, focusing on problems as well as strategies. However, in this way she ran out of time and was not able to discuss even half of the exercise in more than 40 minutes. As there is no similar task discussion in the data and it would have influenced the cluster algorithm too much, this case was eliminated according to these qualitative and quantitative considerations.

Cluster		<i>completeness</i> (1 complete, 0 incomplete)	<i>number of didactical elements</i> (0-10 elements)	<i>focus on problems</i> – number of elements (0-4 elements)	<i>focus on strategies</i> – number of elements (0-4 elements)
<b>1</b>	median	1	4	0	1
	N	18	18	18	18
<b>2</b>	median	1	2	0	0
	N	22	22	22	22
<b>3</b>	median	1	6	1	0
	N	10	10	10	10
<b>4</b>	median	0	5	2	0
	N	6	6	6	6
<b>5</b>	median	0	2	0	0
	N	19	19	19	19
<b>overall</b>	mean value	1	3	0	0

**Table 1: median of four features distributed into five clusters (N=75)**

Table 1 shows that most of the discussions fall into clusters 1, 2 and 5. Only 16 of the 75 discussions have a focus on problems. Cluster 2 and 5 make up more than half of the discussions (55%), both not focusing on either problems or strategies. Cluster 1 is the only cluster with a focus on strategies.

Taking into account the five clusters from cluster analysis five different discussion patterns could be identified in the material:

<sup>1</sup> For further explanations on this process of analysis see Hastie, Friedman & Tibshirani (2001, p. 473).

### **Heuristic discussion (Cluster 1)**

The TA discusses the complete task by focusing on strategies the students have to acquire in order to solve tasks from this specific type. The heuristic discussion is the only pattern with this focus on strategies and used 24% of all task discussions.

### **Pragmatic discussion (Cluster 2)**

The TA discusses the complete task without focusing on strategies or problems and with minimal use of didactical elements to support the students in their learning processes. The pragmatic discussion is the most frequently used discussion pattern (29%).

### **Student-oriented discussion (Cluster 3)**

The TA discusses the complete solution of the task while focusing on the specific problems the students might have had. This pattern is called student-oriented, because the TA satisfies the students' request for a model solution, but also tries to help them to overcome their difficulties. The student-oriented discussion is only used in 13% of the task discussions.

### **Problem-oriented discussion (Cluster 4)**

This type of discussion can be characterized by a focus on problems. The TA highlights the difficulties in the solution process, using many didactical elements to support the students. This pattern is similar to the student-oriented discussion, only differing in the completeness of the discussion. Only 6 task discussions fall into this pattern.

### **Minimalistic discussion (Cluster 5)**

TAs using the minimalistic discussion just discuss parts of the solution without a specific focus. The TAs hardly use didactical elements to support the students. This pattern is quite similar to the pragmatic discussion except for the completeness of the discussion. About 25% of the task discussions fall into this cluster.

### **Duration of discussions**

The average discussion time of one task is about 19 minutes long, ranging from a minimum of 2 to a maximum of 53 minutes. The boxplots in Figure 1 show how long the discussions last in each discussion pattern.

Although the differences in average discussion time between the different patterns is not statistically significant (one-factor ANOVA at a 5% significance level) there are some interesting observations to be made: The pragmatic discussion and the minimalistic discussion are about 10 minutes shorter than the discussions in the other clusters. Especially for the pragmatic discussion, this result is quite surprising as the TAs are going through the complete solution. However, both discussion patterns do not have a specific focus. TAs who discuss problems or strategies probably need some time to concentrate on this focus and need more didactical elements to support the students. Time might be an important factor for TAs to choose a discussion pattern like the pragmatic or minimalistic patterns as they often run out of time in the tutorials.

**Figure 1: duration of discussion in minutes each discussion pattern (N=75)**

### Individual approaches of the TAs

Another factor which might influence the choice of discussion pattern might be the individual approaches of the TA. Depending on their beliefs on learning, some TAs might prefer learning from mistakes and usually choose discussions in the problem-oriented or the student-oriented pattern. Others rather want to hand on the model solutions and therefore choose the pragmatic discussion pattern. One interesting aspect to investigate might be whether TAs usually choose the same pattern or whether they switch between the patterns when discussing different tasks.

As most TAs in the data only discuss one or two tasks, the data for this analysis is quite small. The following table shows the distribution of discussions from two TAs who discuss seven different tasks:

TA	discussion pattern					overall
	heuristic	pragmatic	student-oriented	problem-oriented	minimalistic	
Andrew	1	5	0	0	1	7
David	2	2	2	0	1	7

**Table 2: distribution of clusters on example of two TAs**

Andrew tends to use complete discussions with no specific focus. Although he discusses seven different tasks, he never focuses on strategies. David's discussions fall in four different patterns. He does not seem to have a preference for any of the different types. This result suggests that some TAs have individual approaches while others might be rather flexible in their choice of discussion pattern.

Both, Andrew and David, are experienced TAs who have led tutorials for several semesters. However, not all of the TAs are as experienced as David and Andrew. Like expert and novice teachers differ in some aspects of their teaching, rather inexperienced TAs might also choose different ways of discussing tasks. Only 11 TAs of the 32 TAs in the data have led tutorials before the semester of this study and are therefore labeled as "experienced" while the other 21 TAs are called "inexperienced".

experience of TAs	discussion pattern					overall
	heuristic	pragmatic	student-oriented	problem-oriented	minimalistic	
<b>experienced</b>	11	10	3	1	10	35
<b>inexperienced</b>	7	12	7	5	9	40
<b>Overall</b>	<b>18</b>	<b>22</b>	<b>10</b>	<b>6</b>	<b>19</b>	<b>75</b>

**Table 3: distribution of discussion patterns depending on experience of TAs (N=75)**

Table 3 suggests that there are some differences between experienced and inexperienced TAs. The experienced TAs, which have lead tutorials in the previous semesters, seem to prefer the heuristic, pragmatic and minimalistic discussions. The inexperienced TAs have a greater focus on problems. They use the student-oriented and problem-oriented patterns more frequently than the experienced TAs. This result is quite surprising as you would rather expect experienced TAs to have a specific focus in the discussion. However, the number of cases is quite small, it would be very interesting to analyze this aspect for a bigger set of data.

### Final remarks

This paper presents five different patterns for the discussion of tasks in mathematical tutorials. The “heuristic discussion” focuses on strategy teaching which is very important for learning. This type consumes more teaching time than the other types and is rather used by experienced TAs. As Brophy explains, this kind of instruction is not “only demonstration of and opportunities to apply the skill itself but also explanations of the purpose of the skill (what it does for the learner) and the occasions on which it would be used” (2000, p. 25). Therefore, the students can hopefully gain more than just another solution from this kind of discussion.

In the “student-oriented discussion” and the “problem-oriented discussion” TAs focus on aspects the students struggle with and help them to overcome these difficulties. These types of discussion take some more minutes than the average discussion. Interestingly these patterns are seldom used by experienced TAs. One explanation might be that inexperienced TAs are more aware of the students’ problems as they still remember their own problems. It could also be the case that experienced TAs do not believe that these patterns help the students in their learning process. However, this result might only due to the data.

More than half of the discussions have no specific focus and few didactical elements to support students’ learning. The “pragmatic discussion” and the “minimalistic discussion” consume the least teaching time, so time pressure in the tutorials might be a reason for the frequent use of these two discussion patterns. However, the TAs might have other motivations for using discussion patterns without focus. Possibly, TAs might pursue learning goals that we are not aware of in this study. This shows that further research on this aspect is needed.

According to the findings of Weber (2004), some TAs seem quite flexible in using the different discussion patterns. This result gives rise to possibility that we can support TAs in using the appropriate pattern for a specific learning goal. Especially, the heuristic and the problem-oriented

patterns could be practiced in tutorial training. Apart from that discussion patterns could be a topic in the weekly meetings, helping the TAs to plan their tutorials more goal-oriented.

# French engineers' training and their mathematical needs in the workplace: Interlinking tools and reasoning

Pierre-Vincent Quéré

CREAD, Université de Bretagne Loire, Rennes, France; [pierre-vincent.quere@ac-rennes.fr](mailto:pierre-vincent.quere@ac-rennes.fr)

*This paper deals with the theme "mathematics in the workplace" in the context of engineering work in France. In the continuity of recent research, it draws results from a two-step enquiry (questionnaire and interviews) with 237 French engineers. Using the Anthropological Theory of the Didactic (ATD), I study questions concerning the praxeological mathematical needs encountered by these engineers in their daily work ("in the workplace") and about their mathematical training and its adaptation to these needs depending on the training institution. This article shows that math should not only be considered as a "tool", because engineers sometimes need to have an accurate understanding of what they use. Furthermore, it shows that the two first years (called Preparatory Cycle) have a great impact on the future of these engineers' mathematical abilities.*

*Keywords: Engineering schools, mathematics in the workplace, praxeologies, preparatory cycle.*

## Introduction - Context

The field of "Mathematics in or for the Workplace" has recently received an increasing interest especially at Tertiary Level (Biza, Giraldo, Hochmuth, Khakbaz, & Rasmussen, 2016). Worldwide researchers have contributed to think about and beyond dichotomies such as "school versus work" maths (Bakker, 2014). In the case of engineering apprentices, Ridgway (2002, p. 189) shows that "mathematical challenges of engineering differ from the mathematical taught in school. In particular, great precision is required, applied to a variety of mathematical techniques; a good deal of practical problem solving is necessary". Hochmuth, Biehler and Schreiber (2014) go further considering differences between mathematical practices in higher mathematic lectures and in advanced engineering lectures. They highlight the idea that for "solving a specific task, (engineering) students have to make specific decisions regarding the relevance of knowledge" (p. 697). Kent and Noss (2002, p. 1) have identified "a pattern of mathematics-in-use in which mathematics of school (are) transformed in something rather different, [...] part of a social practice", and Romo-Vázquez (2009, p. 37) adds that "their most advanced dimensions tend increasingly to be supported either by experts or by software" and that "the needs of non-specialists seem to move towards the ability to manipulate these mathematics as a tool for communication through specific languages" (p. 37). All these works evidence that the usual training received by future engineers is not always adequate and depends on the kind of training institution. They also evidence that their mathematical needs are complex.

In the following, I investigate similar issues in the context of engineering education in France. In this country, "engineering schools" are independent institutions, not inserted within universities. To become an "engineering apprentice" in an engineering school, students first have to follow two years of "Preparatory Cycle" after the baccalaureate. These two-year studies can take place in different kinds of institutions:

- CPGE (Preparatory classes, Classe Préparatoire aux Grandes Écoles): This is a demanding training that concerns 50% of French future engineers. It takes place in "Lycées" (upper secondary schools) and has historically been created to allow students to enter the most prestigious engineering schools. The curriculum is rather generalist, and the admission very selective.
- CPI (Integrated preparatory cycle, Cycle Préparatoire Intégré): for nearly 25% of future engineers, this training takes place directly in engineering schools. The curriculum is more adapted to the specialty of the school (Mechanics, Chemistry, and so on); the admission is also selective.
- University: the remaining 25% of French future engineers follow their Preparatory Cycle in classical Universities (no selection for admission).

In this paper, after a presentation of the theoretical framework and my research questions, I explain the methodology and the details of my enquiry. It comprises two elements: an online questionnaire submitted to working engineers, and semi-structured interviews with some of the respondents. I analyze the answers to selected questions of the questionnaire and then the interviews. Finally, I discuss these results and present some perspectives.

## Theoretical framework and research questions

Mathematics practices in the workplace are conducted by the needs of the workplace itself. The diversity of existing tasks added to the particular tools and resources used in each workplace tend to make a research generalization difficult. Moreover, it is recognized that "school mathematics are often obscured by the production goal, technology, artifacts and established routines of workplace activity" (LaCroix, 2014, p.158). Furthermore, speaking of "school mathematics" requires making a difference again between the institutions where the training has taken place. For these reasons I have chosen an institutional perspective, provided by the Anthropological Theory of the Didactic (ATD) (Chevallard, 2006).

I use in particular the concept of praxeology that is a system  $[T, \tau, \theta, \Theta]$  designed to model every human activity (i.e. a certain subject's activity in a certain institution). Among the four elements of this organization, we can first meet the type of tasks  $T$ . The observed type of tasks  $T$  is associated to a technique  $\tau$  to create the "practical-technical block" (so-called a *know-how*). The second block is called "technological-theoretical block" formed by a technology  $\theta$  (meaning a rational discourse that justifies the technique that is used) and a theory  $\Theta$ , whose role towards the technology is the same as the one of the technology towards the technique. I am interested in "mathematical praxeologies", which means here praxeologies where mathematics intervenes in one or several components of the praxeology. In Chevallard's theory, praxeologies can moreover be adapted from a very general to a very precise point of view, following "codetermination levels" that I do not detail here (Chevallard, 2006). Using this approach, the two research questions I study in this paper are the following:

- (1) Which mathematical praxeologies live in the "workplace" institution for French engineers?
- (2) In which institution did they learn the mathematics they use in the workplace?

## Methodology

The first step of my enquiry is an online anonymous questionnaire addressed to active engineers. I have sent it to institutional mailing lists (more than 20) of former French engineering students. To be as relevant as possible, I have tried to spread this questionnaire in schools with different domains of specialty such as data processing, electricity, electronics, agronomy, finance, chemistry, mechanics, materials, etc. In fact, I was not able to know in advance the number of engineers that would receive the invitation to participate, nor how many of them would answer.

The questions mostly deal with the training engineers have received in maths and the questionnaire is divided in four parts. Only the first three ones will be analyzed in this work:

- The first one concerns personal and professional elements.
- The aim of the second part is to precise what kind of praxeologies they have encountered during their training in mathematics in their engineering school.
- The third part concerns their effective use of mathematical praxeologies: Is maths a real need for their job? For what type of tasks do they need maths more frequently? For what professional objectives? Have they had in-service or self-training after their engineering school? What difference with the techniques of the initial training? What kind of tools: software, books, community, lectures notes, MOOC, etc.?

The second step of my enquiry consisted of semi-directive interviews with 6 engineers selected according to their responses to the questionnaire and representing different classes according to the following variables: age, gender, institution of preparatory cycle (I've invited some ex-CPI students but none of them have unfortunately answered) and domain of specialty (see Figure 1).

	John	Peter	George	Matthew	William	Alice
Age/Gender	25/male	27/male	35/male	29/male	35/male	30/female
Qualification	Computer	Computer	Materials	Chemistry	Electricity	Materials chemist
Domain of work/job	Signal (audio) processing	Data security	Consultant	Control process engineering	Entrepreneur in financial analysis	Motorcars development engineering
Preparatory Cycle	CPGE	University	CPGE	CPGE/University	CPGE	CPGE

**Figure 1: The six engineers interviewed**

I describe here briefly the four parts of the interviews: The first one concerns the opinion of the engineers about their own training (preparatory and engineering curricula) regarding their current specific mathematical needs: what seems to them well adapted or not and why? Based on the same idea, the second part asked them to give indications of content that should be or should have been taught in their training, how and why. The third part concerns their view about student's autonomy; I do not use it in this paper. The fourth part concerns their self-training for learning useful specific mathematical praxeologies: which devices or resources? What difference with their initial training?

## Analysis of the answers to the questionnaire

237 engineers from all over the country filled this questionnaire, some of whom are currently working abroad. In part 1, I observe that the predominant represented domains of activity are Chemistry, Physics Materials and Energetic, Computer, Electrical and Electronics, Production and Mechanics, Generalist, Agronomy and Economy. The repartition according to the principal variables is as follows (Figures 2):

Age	Min	Med	Max	Avge	Gender	Women	Men	Preparatory cycle	CPGE	CPI	Univ
Years	24	29	61	32	%	38	62	%	68	12	20

**Figure 2: Age, Gender and Preparatory Cycles repartition**

In part 2, question 10 (have you received a training in mathematics in your engineering school?), 183 engineers amongst the 237 (77%) answered yes. Among the other 23%, we note that 83% are chemistry engineers. This may indicate that the mathematical training depends on the precise orientation of the studies.

Question 12 (During your training in engineering school, the main mathematical contents taught were...) concerns the mathematical contents mostly taught in the engineering schools, for which I proposed a list of main mathematical themes. I chose those themes according to groups of chapters mostly found in maths literature for engineers: the results are in Figure 3.

Contents	Scientific computation	Analysis	Algebra	Probability	Statistics	Modelling	Logic	Set Theory	Graphs
%	40.4	47.5	44.8	68.9	84.7	27.9	23.5	17.5	16.9

**Figure 3: Mathematical contents taught in engineering schools**

In Figure 3, I notice the score of Statistics and Probability: it seems to be the most common mathematical theme taught in the engineering schools in France, followed by Analysis.

In part 3, question 19 (Would you say that you encounter (or have encountered) a real need of mathematics in your job as an engineer?), 53% declare that they do not have a real need of maths. In the next question (question 20), like in question 12, I proposed a list of main mathematical themes used in the workplace; the results are presented in Figure 4.

	Scientific computation	Analysis	Algebra	Probability	Statistics	Modelling	Logic	Set Theory	Graphs
%	69.4	44.1	25.2	37.8	55.9	49.6	54	9	18

**Figure 4: Main mathematical contents needed**

In figure 4, the Scientific computation domain reaches the highest level. Then comes Statistics but with a far lower result compared with Figure 3; we observe the same for the Probability, Algebra and Set Theory domains. On the contrary, according to those percentages, the domains of Scientific computation, Modelling and Logic seem to represent important needs although they are not taught widely. In the answers to question 21 (For what kind of professional tasks?), the engineers explain

the practical use of these contents. The tasks mentioned are simulation, modelling, data analysis, software or algorithms development, basic calculus for estimations, budgets, chemical dosing...

## **Analysis of the interviews**

In this section I try to observe, drawing on sections 1 and 4 of the interview, the mathematical praxeologies present at the workplace, according to the interviewees. I recall that I consider as a "mathematical praxeology" a practice, and a discourse commenting/explaining this practice, where mathematics intervene. I propose a classification of these praxeologies, and I also try to identify in which institution the mathematics involved were met.

### **Transversal types of tasks and mathematical technologies**

I classify in this category praxeologies of the workplace where the types of task is general, not necessarily linked with mathematics (as we see below, it can range from "problem solving" to "communicating"); and the engineers mention mathematical techniques, and even more importantly technologies in the corresponding praxeology.

Some engineers identify, in the workplace, "reasoning" or "problem solving" type of task directly linked or not with mathematics (e.g. making an estimation of costs). Those coming from CPGE declare that, for such tasks, techniques and technologies they learned during this preparatory cycle are useful. The techniques and technologies they cite are linked with proof, testing hypotheses or logic. Obviously these techniques and technologies have been met in CPGE for very different types of tasks, but these engineers have transferred them to the workplace. For instance, John says that proof, seen as a method in CPGE, is very important to him in his job because it makes him understand the utility of mathematical rigor. George explains that, as a project manager, he has to understand the mathematical thinking hidden behind a phenomenon more than the phenomenon itself. William says that the prominence of hypotheses verification in reasoning is what sometimes makes the difference between him and some of his colleagues, as well as being able to rigorously check the result of this reasoning at the end. Finally, Alice tells us the importance of logic in her everyday job. She gives the example of the contraposition: when she had been taught this kind of logical reasoning in CPGE, she thought it would be useless for her. Years later, when she had to work on "experience plans", she realized that it is very important to master it when trying to show that an implication is true or false.

According to the declarations of the interviewees all the mathematical contents corresponding to these daily needs are taught especially in CPGE more than any other institution.

Another kind of transversal mathematical praxeology is what John, Matthew and William refer to as "basics" – that we identify with the term 'basic skills' used by Ridgway (2002). The corresponding types of task in the workplace are situated in many domains like cryptography (Peter), resolution of recursive problems in computing (John), and actuarial science (William). Because of the variety of tasks, it is also difficult to identify comprehensively all the techniques (integrating, solving equations or differential equations, etc.) and technologies (functions of several variables, geometry, matrices) in use. One important type of task appearing in the interviews can be formulated as: "Meeting and understanding new concepts". For this type of task, having a good general knowledge

in Analysis and Algebra, including theoretical aspects, is mentioned as very helpful. This can be seen as an evidence of the theoretical bloc of praxeologies in action.

In a similar way, I identified in the interviews the type of task: "communicating about or with mathematics". George declares that, thanks to his training in CPGE, he feels at ease to communicate about maths subjects with the people he works with. In this case the type of task is directly related with mathematics, and the techniques for presenting mathematics have been learned in preparatory classes. Another type of task cited by George is "Exploring new domains" like, for instance, static physics. I observed the same type of task for Matthew and William in other domains like computation or finance. For this type of task their initial training in mathematics is not sufficient, and brings to "searching on the Internet"(forums, specialized websites). Sometimes they have a look into their old lecture notes or in books as mathematical references that they need anyway to be able to enter the field. For this way of learning, they say that they feel satisfied to find the right information by themselves.

### **Types of tasks in specific domains and mathematical techniques**

In the interviews the six engineers also describe types of tasks met at their workplace but belonging to scientific domains, like physics; the techniques in the corresponding praxeologies include mathematics. In these praxeologies I did not clearly identify technologies. This is the second type of mathematical praxeologies I observe in my analysis.

First, I would like to highlight the fact that basic mathematical skills are also mentioned as providing techniques for many specific types of tasks in various domains, like for example the task "modeling the ageing performance of a material" (Alice). Nevertheless, the principle of use of the techniques and technologies differs: the aim is to be able to use some results (like theorems or formulae) without trying to understand them mathematically. Most of those basic skills are taught in the Preparatory Cycle, but the techniques (and technologies) they provide for the workplace are taught in the engineering schools. In fact these types of tasks are well known by them since many years; the same holds for the associated techniques.

Amongst these basic skills, the case of Statistics and Probability seems specific because this domain is mostly not taught in the various Preparatory Cycles in France. Each engineering school provides its own specific training adapted to its needs. According to the interviewees, once confronted in the real world of the workplace, sometimes a statistics formula becomes useful (they mostly remember having learnt at the engineering school a lot of theory which does not intervene in their work).

### **Reasoning + Using = "Reasusing": a concept for a personal and new mathematical experience**

A last category of mathematical praxeology I found in the interviews combines mathematics in the techniques, in the technology and even in the theory. This seems to be linked to specific types of task, requiring the development of original techniques – almost a research work. John cites a type of task that can be formulated as: "outperforming competitors in the design of new software". He explains that he has to know which theorem he must use, but not exclusively: he also has to have a deep understanding of the proof of this theorem to be able to understand which parameters will allow him to obtain a result in a smarter way than other colleagues. To illustrate this, he gives the example of audio latency that is one of the most important qualities for the client of music production software. The type of task here could be "Reduce the latency". It corresponds to a short

period of delay between when the musician plays and when he can hear the sound through the sound system (e.g. headphones). When the competitors offer a 20 milliseconds latency, John has to put his efforts to find in the theorems or in their proofs (mostly based on Fourier Analysis) how to minimize it to 6 ms. This will make the commercial difference and it requires that he really understands what is happening "inside" the theorem. This corresponds to the technique "analyze a theorem proof". I consider this as a third type of mathematical praxeologies with a type of task requiring some innovation.

## Discussion - Conclusion

Drawing on the results exposed in this paper, I now come back to the two research questions presented above.

Regarding the mathematical praxeologies that live in the "workplace" institution for French engineers, the primary result in this study is that only 47% declare they have a real need of maths in their everyday job. Concerning the mathematical needs, I have encountered three different kinds of praxeologies: A first one with a general type of task, like "solving a problem" or "communicating"; techniques, and mostly technologies involving mathematical elements like reasoning and proving, and also some elementary mathematical skills. Rigor, logic and an amount of maths basics (sometimes considered as useless at first sight, because lacking of concrete sense to them) are necessary for the everyday work of these engineers, and also allow them to communicate more easily with other people in their working environment. The second kind of praxeology that lives in the workplace comprises specific tasks (simulating, modeling, data analyzing, calculating, etc.) associated with mathematical techniques: here again, the maths basics are considered as very important but they are seen as providing techniques. The last and rather interesting kind of praxeology is the mix of reasoning and using (I call it "reasusing"): for an engineer, it means to interlink a technology or even a theory to make them become an integrated part of a technique for a specific kind of mathematical type of task (such as a logical analysis of a situation, understanding a theoretical mathematical concept).

For the second research question about the institution where they learn the mathematics they use in the workplace, I notice that the praxeologies developed in all types of Preparatory Cycles are mostly concerned with teaching basic mathematical skills. To end this analysis, I must highlight that the engineers who declare needing the first kind of praxeologies (thinking, reasoning and problem solving) that were taught during their Preparatory Cycle are all coming from the CPGE institution.

Finally, my study certainly has some limitations. It cannot be considered as fully representative of the whole population of French engineers (in terms of age, gender, domains of work, and Preparatory Cycles). Moreover a large part of it is based on what the participants *say* about the mathematics they have learned and use, but it is not clear that they all have in mind the exact same interpretation of things. I will work on this issue in my future research.

But the results that I expose can lead us to think that even if an important part of the engineers do not really need mathematics daily, they do not consider them exclusively as providing techniques. Receiving a training of the type "maths as a toolbox" is not satisfactory for them because they sometimes need to understand the precise functioning of the tools. It is possible for them thanks to their own mathematical "culture" (or background) and also their will to investigate by themselves

some new concepts. I interpret this as the need for "complete" praxeologies (Bosch, Fonseca & Gascón, 2004): the engineers do not only need the *praxis* (basically taught in engineering schools), but also the *logos* (essentially depending on the Preparatory Cycle training). Moreover, several interviewees declared that they did not perceive the usefulness of the theoretical aspects when they were students. We interpret this as a need to motivate the praxeologies when taught.

# Approaches to learning of linear algebra among engineering students

Ragnhild Johanne Rensaa

UiT the Arctic University of Norway, Norway, [ragnhild.rensaa@uit.no](mailto:ragnhild.rensaa@uit.no)

*The present paper investigates engineering students' own descriptions of what they mean by learning of linear algebra and how they know that they have learned something. I seek to extract keywords from engineering students' descriptions of learning of this discipline by drawing on grounded theory techniques and classifying the answers in conceptual and procedural approaches. By this, both detailed and more meta perspectives on learning are obtained. Results indicate that when explaining their learning of linear algebra, conceptual more than procedural approaches are emphasized. However, in order to know that they have learned something, many engineering students need to know that they are able to solve relevant tasks in the discipline.*

*Keywords: Approaches to learning, linear algebra, engineering students.*

## Introduction

Students' learning of mathematics is a main interest within the community of researchers in didactics of mathematics. We seek to know how students learn, what they learn, but also how they perceive their own learning (Sfard, 2007). Learning may be defined according to which point of view one has in an investigation, but also by taking into consideration what is relevant for the particular individuals of a study. A classical definition is given by Hiebert and Lefevre (1986), distinguishing between conceptual and procedural knowledge that may yield conceptual and procedural learning. Conceptual knowledge is defined as "knowledge that is rich in relationships" (ibid.1986, p. 6), which means that it cannot exist in isolation. Procedural knowledge includes sequential relationships or step-by-step instructions. Engelbrecht, Bergsten and Kågesten have found conceptual and procedural notions valuable in their research of engineering students (2009), and because the target group of the present investigation is engineering students, these constructs will be utilized.

The present paper focuses on engineering students' interpretation of their own learning in a linear algebra course. Such reflections are beneficial because the students then have to reflect on how they see their mathematical knowledge and for what purposes they study the discipline. Thus, asking questions about learning is valuable and frequently done by researchers. An immediate example is the present data collection, in which questions asked to the students were picked from a research investigation of a related group of students in a mathematics and physics foundation program for students going into an engineering program (Marshall, Summers, & Woolnough, 1999). Based on data from a longitudinal study over an academic year, they derive conceptions of learning held by these students. In my study the setting is somewhat different as the students are experienced engineering students, their reflections about learning are confined to a particular domain in mathematics, and it identifies students' reflections at the end of the course. In this particular setting the following research questions are asked: Which approaches do engineering students include in their description of learning in linear algebra and how do they explain their knowing that they have learned something?

## Theoretical background

The study reported on here investigates engineering students' description of their learning approaches rather than the cognitive processes of learning itself. As will be argued for, such approaches are adequately split in two main categories: approaches connected to conceptual and to procedural knowledge. The definitions were originally given by Hiebert and Lefevre (1986) and are widely used. In this framework, conceptual knowledge is pieces of knowledge connected together or, as explained by Kilpatrick, Swafford, and Findell (2001), "an integrated and functional grasp of mathematical ideas" (p. 118). Procedural knowledge, on the other hand, includes familiarity with symbols but also representation systems in mathematics along with knowledge of rules and procedures that can be used in task solving strategies in mathematics (Hiebert & Lefevre, 1986, p. 6). However, conceptual and procedural knowledges are partners and the interplay between them is valued, emphasizing how one knowledge may lead to the other (Rittle-Johnson & Alibali, 1999). Indeed, they are increasingly regarded as interrelated and inseparable, but also object for extensions to superficial and deep qualities of the knowledges (Baroody, Feil, & Johnson, 2007). Such relationships are multifaceted, and researchers move towards more integrated views in which determining the dynamics between the two is the objective (Engelbrecht et al., 2009).

Students often perceive linear algebra as difficult. This stems from three sources of difficulties (Dorier & Sierpiska, 2001). It is about the pedagogical approach, as proofs are found difficult (Rogalski, 1990). It is also a matter of difficulty with grasping the theoretical concepts and mathematical language; the 'obstacle of formalism' (Dorier, 1997). Finally, linear algebra demands a 'cognitive flexibility' as one has to move between different languages, both theoretical and practical forms. Students tend to think in practical terms (Sierpiska, 2000), and lack of connection to theoretical structures may hinder their learning (Dorier & Sierpiska, 2001).

Engineering students recognize mathematics as a foundation of their education (Khat, 2010). Still, they consider the discipline as a routine practice of their profession (Steen, 2001) and expect to be exposed to real-world engineering problems in mathematics (Hjalmarsen, 2007). With such an approach, the formalism of linear algebra may be especially hard to get a grip of. Engelbrecht and colleagues (2009) found that engineering students uphold mathematics as procedurally founded. As part of their investigation, the authors created tailor-made working definitions to focus on engineering students, thus these are adopted in the present study:

"Procedural approach: Use and manipulate mathematical skills, such as calculations, rules, formulae, algorithms and symbols.

Conceptual approach: Show understanding by e.g. interpreting and applying concepts to mathematical situations, translating between verbal, visual (graphical) and formal mathematical expressions and linking relationships." (Engelbrecht et al., 2009, p. 932).

## Methodology

The present investigation is part of an ongoing study dealing with engineering students' views about the learning of linear algebra. The teaching format in the course which was taught in English was 'traditional', with large group lectures followed by task solving sessions where students worked in groups. The 'untraditional' part was that a well-functioning video recording system recorded all

lectures and published them in-time. The linear algebra course was scheduled in the students' fourth year of studies to become master engineers, postponed in accordance with Carlson's recommendations (1993). However, some basic tools in linear algebra had been introduced in a mathematics course in their first year of studies, since these are necessary for use in the professional disciplines. All together 59 students attended the course this year, and data was collected as I was the teacher and arranged for a questionnaire to be answered at the end of the course. The open questions picked from (Marshall et al., 1999) discussed in the present paper were: "What do you mean by *learning* in linear algebra? And how do you know that you have *learned* something?" Due to experiences from a previous investigation (Rensaa, 2014), the questionnaire was made mandatory but anonymous to increase truthfulness, and the response rate was very good; 93% (55 out of 59).

Data analysis was done in phases. Initially, grounded approaches were used (Strauss & Corbin, 1998) to obtain codes that embrace engineering students' approaches to learning. Next, these codes were related to the definition of conceptual and procedural approaches as described by Engelbrecht and colleagues (2009) since this definition is tailor-made for engineering students. It offers a meta-perspective on the analysis results from coding, and this provides answers to the research questions about engineering students' approaches to learning.

## Analysis and results

The development of codes was done in steps. Initially, I wrote down headwords in each student's description which was given in English. By comparing these, some seemed to describe similar things, e.g., 'utilize for own goals' and 'use in gps' [Global Positioning System], both which could be interpreted as 'learning as applying mathematics'. Because I was working back and forth between statements and codes with an aim of reducing the number of codes without deteriorating their meanings, each time two replies were interpreted within the same category had to be put down as a criterion for the category. For instance, for descriptions of obtained learning, 'know the whole picture' and 'associate theory to applications' were both interpreted as being able to relate the different aspects of linear algebra to each other, thus crystalizing a category called 'ARel' (able to relate). The importance of emphasizing relation in this category was helped forward by a statement that did not fall into this category: 'use different theorems to achieve solutions to practical problems'. The emphasis here is on obtaining solutions more than the relation, thus crystalizing a category called 'ASol' (being able to solve problems). Going back and forth between statements and codes resulted in a final reduction to 8 categories for what learning is and 6 categories for what is meant by learning of linear algebra.

Next, the original data set and my developed codes were sent to another researcher for validation purposes. This researcher used the codes to independently code the data. Then, we met for comparison of results and refinement of codes. A main refinement was deepening the meaning of *applications*. Students had referred to applications when trying to describe learning in linear algebra, but we agreed that students should express that applications were actively studied in a mathematical connection in order to be coded as 'Study Applications' (SAp). An example of a statement where the coding was adjusted by this interpretation is the following:

Student 30: For me, learning is knowing the practical use of theory and how to execute said theory. As a computer engineer student specializing in games development, linear

algebra is central in the programming I perform. I only know I have learned something if I can associate theory to a problem I encounter.

We agreed that this student is not stating that he is studying applications, but rather that he is actually taking advantage of knowing applications from other disciplines as part of his learning process. Thus, ‘Utilize Theory’ (UTh) is a closer category as the statement points to how theory may be utilized for practical purposes. The other refinement of codes that was needed was a specification of *relations*, originally named ‘Rel’. It was unclear which types of relations this was referring to. The category had derived from students’ answers as relating back to previous knowledge, thus the category needed to be adjusted to ‘RelB’ (relating to background).

Two additional codes were agreed on: the categories ‘NoAns’ (no answer) and ‘Other’. All blank responses could be categorized as ‘NoAns’, while ‘Other’ refers to answers that responded to something else than what was asked about. The ‘Other’ category developed from cases in which divergence in our separate coding appeared. We both encountered problems because none of the codes actually fit with some of the particular answers. An example is ‘It really gives the knowledge of different engineering mathematical problems’. One researcher had interpreted this statement as ‘Study Applications’ (SAp), the other as ‘Able to understand why/what is going on’ (AUn), but the student does not seem to be actually describing his learning. Thus, the final coding for this response was ‘Other’. This joint coding process showed that the codes were adequate and could be used to code all statements. However, we experienced that coding statements together often resulted in finding more information in a reply than what we had done individually.

Ending the process, the following codes crystallized for engineering students’ description of what they mean by learning in linear algebra: **SAp** (Study Applications), **GUn** (Gain Understanding), **UTh** (Utilise Theory), **ForM** (Grasp Formalism), **SimP** (Simplify), **SoL** (Solve problems), **RelB** (Relating to Background), and **ToO** (Use Tools). Analytical results for this question are given in Table 1, presenting both the number of students in each category and percentage (rounded off) of the total number of 55 students. The category ‘No Answer’ consisting of 17 replies is left out, while a number of explanations covered approaches in more than one category. Thus, the sum of percentages does not add up to 100.

	<b>SAp</b>	<b>GUn</b>	<b>UTh</b>	<b>ForM</b>	<b>SimP</b>	<b>SoL</b>	<b>RelB</b>	<b>ToO</b>
Number/%	8/15%	11/20%	10/18%	2/4%	2/4%	11/20%	2/4%	2/4%

**Table 1: Responses to what engineering students mean by learning in linear algebra**

Coding responses to engineering students’ description of how they know that they have learned something gave the following codes: **ASol** (Able to Solve), **AExp** (Able to Explain), **AUn** (Able to Understand Why/What is going on), **AAp** (Able to Apply), **ARel** (Able to Relate), and **ARem** (Able to Remember). Analytical results for this question are given in Table 2, including responses coded as **Other** (answering something else). The table presents both the number of students in each category and percentage, and again multiple codes were found in some answers.

	ASol	AExp	AUn	AAP	ARel	ARem	Other
Number/%	15/27%	3/5%	6/11%	9/16%	1/2%	2/4%	5/9%

**Table 2: Responses to when engineering students know that they have learned something**

When the codes and categories were set, I assigned the codes in conceptual and procedural parts. As the codes had developed based on engineering students' own descriptions, they were aligned with Engelbrecht and colleagues' working definition (2009) for conceptual and procedural approaches of engineers. This was done by linking the description of codes to statements given in the definition. Some codes were easier to categorize, like GUn. Gaining understanding was classified as a conceptual approach as this is necessary to be able to expose mathematical understanding. Other classifications were harder. An example is ASol. Problems may be complex, theoretical and demand deep argumentations, and solving these should classify as a conceptual approach. On the other hand, problems may as well be 'standard', connected to a set of skills that are more like a routine part of a learning process. Such dual interpretations of an activity highlight the complexity involved in interpreting conceptual and procedural knowledges in a praxeology. However, engineering students tend to 'proceduralize' problems, even those of a conceptual nature (Engelbrecht et al., 2009). Considering this, I deduced that ASoL ought to be categorized as a procedural approach, but highly interdependent upon conceptual approaches

By going back and forth between the definition and codes, a final classification of codes was obtained. For what is meant by learning in linear algebra, the following codes were classified as *conceptual*: SAp fits with 'applying to mathematical situations'; GUn is about 'showing understanding'; UTh may be interpreted as 'translating between verbal and formal mathematical expressions'; and RelB is about 'linking relationships'. The remaining categories were classified as *procedural*: ForM is about 'manipulating' linear algebra expressions; SimP is simplifying by 'calculations'; SoL refers to a way of 'using mathematical skills'; and ToO is to use tools like 'rules, formulas and algorithms'. About knowing that something is learned, the following codes were classified as *conceptual*: AExp is about 'interpreting concepts'; AUn is about 'showing understanding'; AAP is about 'applying concepts to mathematical situations' and ARel is ability to 'link relationships'. The remaining codes were classified as *procedural*: ASol is knowing how to 'use and manipulate mathematical skills'; and ARem may be a part of the manipulation of mathematical skills by recalling how to do this. Drawing on these interpretations, Table 1 and 2 may be organized in conceptual and procedural approaches. Gray coloring of conceptual cells and white coloring of procedural cells indicate the appropriate classification. In many cases, an interpretation of a student's reply comprised more than one of the codes given. An example is the following statement with three codes of a conceptual type and one of a procedural type, codes included in parenthesis:

Student 6: Generally, I mean that learning is to study something until you understand (GUn) the theory (UTh), and is able to use it in both theoretical and practical problems (SAp and SoL).

A statement could be coded in a mix, as illustrated by the last part of the above statement. Interpreted as being ‘*able* to use it,’ this may be about studying applications as a way of utilizing knowledge in problem solving – SAp, a conceptual approach. Interpreted as being ‘able to *use* it’ this would be more about the solving process itself – SoL; a procedural approach. Thus, a statement could be coded in both procedural and conceptual categories, again illustrating the close relationship.

## Discussion

The analysis results summed up in Table 1 and 2 give some indications of engineering students’ conceptions of learning. In many cases, an interpretation of a student’s reply comprised more than one of the codes and one phrase could be coded in a mix as illustrated by Student 6’s explanation. Engelbrecht and colleagues emphasize that the distinction between conceptual and procedural approaches are complex and not absolute (Engelbrecht et al., 2009). Thus, mixed coding may be expected. Brought together, however, the frequencies of codes give a meta perspective on which approaches (procedural or conceptual) are most appreciated by engineering students. In this perspective, Table 1 shows that engineering students emphasize conceptual approaches more than procedural ones when explaining what learning in linear algebra means to them.

Table 1 shows that ‘Gain Understanding’ (GUn) is important to students, having the highest response rate. However, understanding is often – like in the above example – connected to knowing how to *apply* this understanding. Only when being able to apply their knowledge the students think they have understood linear algebra. This result is in line with the fact that these students are engineering students, busy with relating to the use of mathematics (Hjalmarson, 2007). To some students, however, solving of problems becomes the main issue and the scale by which they measure their learning. Lower interest is given to understanding, as the main objective is to obtain a correct answer. An example is the following:

Student 34: in my opinion, linear equations are some kind of tool (ToO) to solve the problems (SoL) in real industrial areas such as factories and... (AAp).

Not all replies coded as describing learning in a procedural way focus on solving problems. Grasping formalism, which is an aspect of difficulty for students when learning linear algebra (Sierpinska, 2000), may also be interpreted as a procedural approach in terms of manipulating the linear algebra language. This is illustrated in the following student’s description:

Student 5: the meaning of learning linear algebra is actually learning a mathematical language (ForM), a language you can use to solve big questions with many variables (SoL).

Responses to the question about engineering students’ knowing that they have learned something, summed up in Table 2, are more equally distributed between procedural and conceptual approaches. This is mainly due to the category ‘Able to Solve’, which takes all together 27% of the responses. An example of a statement coded within this category is:

Student 35: The simplest way to know that I have learned something is that I can solve some problems (ASol), when I am faced with some practical problems using this method.

This student indirectly says that he seeks to apply the mathematics in practical situations but knowing that he has learned something is concentrated to the solution process itself.

Altogether, a rough answer to the stated research questions may be that the present engineering students emphasize conceptual more than procedural approaches when explaining learning of linear algebra, but in order to know that they have learned something a noteworthy amount need to know that they are able to solve relevant tasks in the discipline.

## Conclusion

A result of the present analysis is that the engineering students emphasize conceptual aspects like understanding and utilizing theory as most important in their learning of linear algebra. This may be an anticipated result when dealing with students in general, but engineering students' expectations towards mathematics are slightly different. They consider mathematics more as a routine practice (Steen, 2001) and procedurally founded (Engelbrecht et al., 2009). Thus, the result is noteworthy. However, to know that they have learned something, the same students seek confirmation in terms of being able to solve problems; a more expected procedural approach. An explanation to this result may be that the mathematics course is one in linear algebra. This course is more theoretical framed than the initial calculus courses, thus students are somewhat new to proofs and proving when coming to the course. Students find such approaches difficult (Dorier, 1997; Dorier & Sierpiska, 2001; Rogalski, 1990), and engineering students may therefore put particular attention on these aspects in learning of linear algebra. Their consecutive measure of knowing that they have learned something in terms of ability to solve problems then shows that the connection between theory and task design is particularly important. Tasks should offer opportunities to engage in conceptual arguments on the preferred premises of solving tasks. However, as assessment guides students' ways of studying, task design in exams is the most vital part. Thus, an investigation of engineering students' learning approaches related to design of exam tasks will be an important follow-up of the present project.

Even if students in the present study were asked to reply in writing – which naturally reduces the richness of the replies compared to responding orally – interesting responses were given. The following is an illustration of this, concluding the paper:

Student 9: To learn does not necessarily mean to remember something, but to understand it in depth (GUn) and be able to utilize that information for your own goals (UTh). When one has truly learned something, one can easily explain it to someone else (AExp).

## Acknowledgment

Great thanks to Professor Barbro Grevholm who readily validated the coding by using my developed categories in an outsider coding process.

# Access to conceptual understanding – Summer courses for linear algebra and analysis after the first semester

Kirsten Schmitz<sup>1</sup> and Ingolf Schäfer<sup>1</sup>

<sup>1</sup>University of Bremen, Germany;

[kschmitz@math.uni-bremen.de](mailto:kschmitz@math.uni-bremen.de), [ingolf.schaefer@uni-bremen.de](mailto:ingolf.schaefer@uni-bremen.de)

*The transition from school to university mathematics is known to present a major challenge to many students, resulting in poor performances and high dropout rates during the first semesters. In this paper we present the preliminary results on summer courses in Linear Algebra and Analysis after the first semester, which were designed based on the Abstraction in Context framework (Dreyfus & Kidron, 2014) and on the self-determination theory (Deci & Ryan, 2000). In particular, we investigate the potential of this course design to contribute to the motivation of the students and to their ability to engage in concept construction. These qualitative preliminary results will be used in further research to quantitatively assess the effect of these courses as well.*

*Keywords: Mathematical concepts, advanced mathematical thinking, tertiary level mathematics.*

## Introduction

A recurring problem in undergraduate mathematical education is students' difficulty in coping with the transition from school mathematics to the higher paced, more demanding and more formal mathematics at university level. This can be seen in the high dropout rates of math students in the first semesters and the poor exam results. In particular, some students require more time to learn than the time span determined by the lecture course, and find it hard to catch up with their peers for the next course. The previous approach of the mathematics faculty at the University of Bremen had been to install weekly extra tutorials for the courses in Linear Algebra and Analysis, parallel to the corresponding lecture courses. Even though these were conducted by senior student tutors, they yielded poor results. Few students attended, and there was no perceived positive effect on motivation or performance with regard to concept building. Limited time during the semester was stated as the main obstacle to continuous attendance.

In response to this, a new approach consisting of summer courses in Linear Algebra and Analysis was developed and implemented by the authors. These were voluntary courses that took place within two weeks between the first and second semester, after the students had not only had the weekly feedback from their homework groups, but also some individual feedback on their progress by the end-of-semester test. In addition to the goal of enabling the students who had failed (or scored low in) the first test to pass the retake, the courses were intended to foster the students' motivation and help them create appropriate concept images (Tall & Vinner, 1981) of the core concepts of each course. This is assumed to be of vital importance, in order for them to be able to profitably take part in the follow-up courses in the second semester. From the experience gathered in the first implementation of these courses, we intend to give a preliminary evaluation with respect to these two factors. This will be used to make some adaptations to the following implementations, which will then be evaluated more thoroughly.

In this paper, we will focus on the description and evaluation of the Linear Algebra additional course given by the first author. The analysis course was designed analogously by the second author and the results were similar.

**Figure 1: Structure of the Linear Algebra module**

In figure 1 the structure of the whole Linear Algebra module in Bremen is displayed. The lectures extend over 14 weeks with 4 hours of lecture, 2 hours of exercise in groups and 2 hours of plenary exercises each week. The test at the end of the first semester takes place about a week after the lectures end and does not contribute to the final grade. The students nevertheless have to achieve a certain number of points in order to complete the module. The pass rate is set at a low level compared to the final exam, so the students know what to expect on the final, but are not impeded by having to retake the test, unless their score is very low.

## Theoretical background

In their extensive study on teaching Linear Algebra in the first university semester, Dorier et al. (2002) identified and described a main obstacle for students to learn the subject, which they called the *obstacle of formalism*. This obstacle is found to be a conglomerate of formal reasoning, abstraction and extracting ideas from concepts, due to the vast abstractions, simplifications, and unifications in the subject's history.

We tried to give students additional support to master this difficulty by a course design based on the *Abstraction in Context* framework, AiC, (Dreyfus & Kidron, 2014). This framework merges the idea of the *vertical mathematization* process by Freudenthal with Davydov's *method of ascent to the concrete* (ibid., p.87), in order to explain how abstraction processes can occur. Abstraction is assumed to happen in a “three-stage process: the need for a new construct, the emergence of the new construct, and the consolidation of that construct”. The corresponding (observable) epistemic actions are *recognizing* (R) the relevance of certain known constructs in a given situation, *building with* (B) these constructs to achieve (local) solutions and *constructing* (C), i.e., integrating the previously known constructs into a new whole. This model is referred to as the RBC-model.

Since performance at challenging and creative tasks is dependent on intrinsic motivation, we make use of the *self-determination theory of motivation* (SDT), which postulates the existence of three basic psychological needs (Deci & Ryan, 2000). When these needs for autonomy, competence and sense of relatedness are fulfilled at a satisfactory level, intrinsic motivation is likely to occur. Low achieving students, in particular, may benefit from an environment that fosters positive experiences with regard to these needs in relation to mathematics (Um, Corter, & Tatsuoka, 2005; Rakoczy, 2006). Hence, both in the course design and during the course hours themselves, special attention was paid to these factors of SDT.

As in the methodology of design research according to Gravemeijer and Cobb (2006), we plan to develop the design of the additional courses in experiment-reflection-cycles. Gravemeijer and Cobb identify three main stages: (1) preparing for the concrete design experiment, (2) experimenting in the classroom (in this case the actual implementation of the course), and (3) analyzing the

experiment retrospectively. At this point of our research, we consider ourselves to have obtained enough information from the initial design and implementation, as to be able to proceed to the first genuine design cycle within this framework.

## Research questions

The main research questions we want to deal with are the following:

- 1.) How does the participation in the course change the perceived fulfillment of the basic psychological needs and, thus, intrinsic motivation?
- 2.) What is the effect on the epistemic actions with regard to the relevant concepts for the participants in the following course?

In addition, a minor question can be seen to be “Is there a beneficial short term effect on the retake test?”, as this is the main motivation for the students to take part and also an institutional concern. We are, however, more interested in the long term effects.

## Description of the course design and design principles with examples

The Linear Algebra course consisted of five days of activity spread out over two weeks (alternating with the corresponding Analysis course). Each day was divided into a morning and an afternoon session of three and two hours, respectively, with a lunch break in between. The sessions themselves were each devoted to a central topic of the Linear Algebra lecture, e.g., bases, linear maps or different interpretations of matrices, and were split into smaller working units of varying types and content, which were occasionally adjusted spontaneously according to the students’ needs.

The instructional design of the course was based on the observation that low achieving students often do not have the mathematical resources to occupy themselves for a long time span with a given (in general more complex and open) task, but need to be guided to acquire these resources. Thus, the course proceeded from very short and clearly defined tasks of varying nature (but with immediate feedback) to longer and more open and self-determined ones. For example, the first task of the whole course consisted of a lecturer-guided group discussion of very small exercises concerning relevant geometric objects (lines, planes), while the very last task was a guided session, in which students were asked to create individual exercises to given topics by themselves and then solve each other’s exercises, including negotiations on the wording of the task and different approaches and solutions. In this way, the possibility of increasing the levels of fulfillment of the basic psychological needs was provided.

With respect to the subject specific aims, on the one hand the focus was on developing the core ideas of Linear Algebra and important techniques (Gauss’ algorithm, proofs relating to algebraic structures, etc.). On the other hand, great emphasis was placed on the creation and discussion of a zoo of examples and counter-examples to the relevant notions, as this is known to be very effective in the initial understanding of new concepts (see Dahlberg & Housman, 1997).

We illustrate how the AiC framework was used in the task design by the example of the concept of “linear independence” of vectors, which was comprehensively dealt with in the afternoon session of the first day and then later referred to throughout the whole course.

To aid the construction of viable concept images of “linear independence”, the students were given geometric situations, where this concept is relevant, e.g. describing a plane in a three-dimensional space as the span of two vectors and characterizing the pairs of vectors where this description fails. Thus, the students had to recognize (R) that this particular knowledge of a linear relation between vectors is relevant to particular geometric problems (note that at this point the students were already aware of the existence of the definition of linear independence). Afterwards, the students were given tasks, where linear independence appeared in different situations and in relation to other concepts (such as basis, coordinate system, etc.) as to integrate the concept into their mathematical views and work out means to examine and apply the concept locally (B). Finally, by discussions among the students and with the whole class, the students were encouraged to express and evaluate different views on linear independence, which we hope has helped the students in building an (at least preliminary) concept image of “linear independence” (C).

Since the students had already encountered the definitions during the lecture and found themselves naturally confronted with extracting meaning from them, we did not incorporate a component of guided reinvention in the sense of Freudenthal into the course. Students were not encouraged to create models of the key concepts themselves as proposed in RME (Gravemeijer, 1999), but instead the “models-of” were already given (e.g. in the form of the definition of linear independence) and had to be realized as “models-for” in corresponding applications.

Field notes including students' actions and reactions during the course were collected by the first author.

## Implementation and observations using AiC and SDT

We will illustrate the implementation of the course and relate it to the relevant theory by the help of two examples. In the first sessions of the course, the students were given explicit exercises of varying type and difficulty involving some recognizing of, but mainly building with, concepts. As a first example, we will therefore report on one specific exercise at this stage of the course.

### Problem 5

- (a) Find a basis of  $\mathbb{R}^3$ , such that every entry of every vector is strictly negative.
- (b) Find four vectors in  $\mathbb{R}^3$ , such that every choice of three of them is a basis of  $\mathbb{R}^3$ .
- (c) Let  $V$  be an arbitrary  $\mathbb{R}$ -vector space and  $(v_1, v_2, v_3, v_4)$  a basis of  $V$ . Is

$$(v_1 + v_2, v_2 + v_3, v_3 + v_4, v_4 + v_1)$$

a basis of  $V$ ?

- (d) Assume that  $(v_1, v_2)$  is a basis of a  $K$ -vector space  $V$ . Is  $(v_1 + v_2, v_2)$  a basis of  $V$ ? (Attention, there is one special case here, where you have to watch out. Where?)
- (e) Assume we have an  $\mathbb{R}$ -vector space  $V$  with a basis  $B = (v_1, v_2)$ . Then  $B' = (2v_1 + v_2, v_1 - v_2)$  is also a basis of  $V$  (can you prove this?). Find a method that can calculate the coordinates of any  $w \in V$  with respect to  $B'$  from its the coordinates with respect to  $B$ . Test your method with examples!

**Figure 2: A problem from the course in linear algebra**

The exercise shown in figure 2 was given to students on the second day, after the concept of basis had been established and been related to the concepts of generating system and linear independence. It was part of a set of exercises, on which the students worked in small groups of two or three or individually according to their own choice. The students took to the exercises well, and most of

them found access to part (a) quickly (possibly after short exchanges with other groups or with the lecturer). Part (b) was claimed to be impossible by some students, but this was resolved mainly among the students themselves without much intervention of the lecturer. The remaining parts were difficult. Part (c) was attacked by an attempt to prove that the vectors are linearly independent, and linear independence was claimed persistently. For time reasons, part (d) and (e) were only dealt with by some students, who all implicitly assumed  $K$  to be the real numbers,  $V$  to be the real plane and whose arguments were of a geometric nature. It is noteworthy, that the students refrained from trying to manipulate the expressions according to some formal rules they had not understood, but rather tried to give meaning to the statements, albeit not always succeeding. Similar effects could be observed throughout the course.

With regard to the epistemic actions in AiC, in this exercise the students were mainly building with the concept of basis, while recognition of the relevance and the role of linear independence was required. The students' reaction (i.e. the persistent claim of linear independence) to part (c) indicates that the concept of linear independence had not yet been consolidated, although it had been extensively covered before. The geometric approach to the tasks, however, seems to show that the students already had acquired a basic concept image and tried to use this, as opposed to merely manipulating the concept definition. There was no particular observation concerning the motivation for this exercise.

The second example to illustrate the implementation is taken from the last day of the course, where the students were given the task of creating exercises themselves. Each student was given an index card, which was labeled with one of the concepts that had been dealt within the course. He or she was then asked to make up an exercise together with a solution involving the corresponding topic and write up the exercise on the index card. Students who had quickly completed this task were given additional index cards, until everyone had made up at least one exercise. The cards were then redistributed randomly, and the students were asked to solve the exercise given to them. Once finished, they were told to check their solution with the creator and if both agreed, they repeated the process with another exercise.

There were very different approaches to this task by the students. Some students chose to model their exercises on the ones they had been given during the course with only slight changes (different numbers, different number of variables/equations, etc.), while others tried to produce an original task by combining things they knew. Both approaches were encouraged by the lecturer. During the creation of the exercises, the most striking observation was that the students suddenly felt the need for certain insights, which had been difficult to stir beforehand. E.g., one student wanted to create a linear system of equations, where a row of zeros would appear at some point in the process of Gaussian elimination, and was confronted with the need for a practical criterion to achieve this. Even though this issue had been dealt with during the course, she seemed to recognize the relevance of linear independence of the rows only at this point, when it was explicitly needed by her. Additionally, the participants were aware of the need to communicate their mathematical problem well enough for someone else to make sense of it and there seemed to be a genuine effort to achieve this. In the following session of solving each other's exercises, a dynamic of interaction was observed, where the randomly allocated pairs of creator and solver got together to sit down and negotiate the wording of the exercises and the validity of different approaches (in particular,

students who had not closely worked together before). There was very little intervention from the lecturer.

Concerning the epistemic actions in AiC, there was much activity of recognizing and building with concepts. Moreover, the proposition that there has to be a need for a concept for an abstraction process to occur was confirmed in some cases, e.g., in the case of the student described above. We do not know, however, at this stage, whether this led to the construction and consolidation of the relevant concepts, which we consider to be a long term process and not measurable in this short time span. With respect to self-determination theory, after a short period of orientation a high level of motivation was observed during this task. The students seemed to feel a strong sense of autonomy, as they were given the freedom to create a problem of their choice with only the general topic prescribed. During the period of solving, many students displayed a boost in perceived competence, particularly when they were in the creator-role, and experienced their exercise and their comments on it to be of value for someone else. Furthermore, the students appeared to build new, largely positive, relationships with each other via the random and varying allocations of creator-solver pairs. This interaction seemed to be of natural importance to the students (the extensive meetings of these pairs were their spontaneous creation and had not been suggested by the lecturer). Hence, the conditions for intrinsic motivation according to SDT were largely fulfilled, which might help to explain the unusually high motivation. We believe, however, that this exercise would not have worked out well if the participants had not been prepared for it in advance by the preceding days of the course.

## Results

One of the institutional measures to evaluate the success of the course was the pass rate of the test and retake test, which was compared to the one of the previous year (as the style of the lecture and of the exams were largely the same, this comparison seems justified). In 2015, the pass rate for the regular test was about 65%, while the retake test was passed by 50% of the participants. In comparison, the regular test in 2016 was passed by 78% and the retake by 95%. Although there are of course various factors, which play a role in these results, an effect of the additional course seems likely.

In addition, the course was hoped to have a positive lasting effect both on the motivation as well as on the ability of the students to achieve concept construction by themselves with the means of the relevant epistemic actions. This has not been quantitatively assessed yet and will be the subject of further research. However, there are many indications that such an effect might indeed be observed.

During the sessions of the course, the students appeared to be (at least extrinsically) motivated and confident of benefiting from the course. Confidence and perceived competence seemed to increase, as the students advanced from the passivity of merely carrying out tasks imposed onto them by the instructor to more self-determined action. This seemed to be accompanied by a shift from mere extrinsic motivation (to pass the retake) to at least some intrinsic motivation, e.g. some students were observed to carry on discussing tasks during the break. The actual mathematical competence was seen to increase accordingly, as students gathered experience and perceived deeper mathematical insights, which they worked to develop. By the analysis of the two examples above, it

can be inferred that in the framework of AiC and of SDT there have indeed been positive effects on motivation and the ability to perform epistemic actions with regard to the relevant concepts.

These positive effects reached far into the next semester. Most participants felt that they had acquired a basic knowledge and techniques, which were necessary for the following courses, and were repeatedly observed by the authors to use methods they had picked up on in the additional course during the exercise classes of the following course. In almost all cases this was bolstered by the fact that the retake had been passed. Many students expressed their conviction of having profited to a great extent from the additional courses, both immediately after the course and about half way into the next semester.

## **Conclusion and perspectives**

Compared to the previous approaches of the faculty of mathematics and to other approaches described in the literature (e.g. remedial courses as discussed by Di Pietro (2014), which were shown to be largely ineffective) to help the students in the transition from school to university mathematics, the additional courses described here seemed to be more effective with regard to the research questions posed above. Various factors are assumed to be of importance for this.

As this was a voluntary course aimed at students having failed the end-of-term test, it was made clear beforehand that it should be seen as a chance to acquire skills not yet developed rather than an obligatory task (as in Di Pietro, 2014). The course was announced at the beginning of the semester, giving the students the opportunity to take it into account in their planning. In general, the allocated time was met with approval, both because it meant no conflict with the workload during the semester and because the end-of-semester test provided some feedback for the students whether attendance was advisable (due to other time restrictions regarding school and computer practica for the students, however, the course should not exceed two weeks). In addition, the common goal to prepare for the next semester and pass the retake seemed to ensure a sense of belonging to a peer group with a common aim. Hence, the general framework of the course proved to be more feasible than the previous ones, and will be kept for the time being.

The design of the course with sessions devoted to central topics, which were each split into smaller units of varying tasks, were also perceived to have a positive impact with regard to the above questions. In particular, the general progress from rigidly set tasks to more self-determined ones seemed to be appropriate in this setting. The exercises themselves were developed using the AiC framework, and their construction will be refined, based on the observation of how the different tasks affect the perceived concept building in the students. For example, in the exercise given in figure 2, part (c) has already been modified to ask for linear independence of the differences of the given vectors as opposed to their sums. This allows for the generalization of ideas from lower dimensions to higher ones, giving the students the possibility to use previously built knowledge more directly. Moreover, part (d) was simplified to ask only for real vector spaces, as the additional difficulty of an arbitrary field seemed to be ignored or actually hindered the building with in the previous course. This will be reflected on further, using the gathered experience, and systematically revised for the next implementations. After this first preparatory cycle, we hope to be able to contribute to the research regarding the mediation of students' problems in the first year of university by carefully designing and evaluating the next cycle of the described additional courses.

We are going to evaluate the two main questions in the next cycle as follows. To assess the effect with regard to SDT, we propose to use a pre-post-test according to the items presented in Rakoczy (2006) with the pre-test set at the end of the lectures of the first semester and the post-test in the middle of the second semester. We want to check for correlations of these results with the performance in the end-of-first-term test. With regard to concept building, we are going to evaluate some abilities concerning the relevant epistemic actions at the end of the additional course itself with a free form questionnaire, supplemented by two or three interviews with students to reach theoretical saturation and to clarify the data.

*In this case study, we examined a mathematician's thought processes as he taught a course on Algebraic Topology. The mathematician shared his teaching-related journals over an entire semester and discussed them in depth during weekly meetings with the research team comprised of a mathematics educator, a cognitive psychologist, and a postdoctoral fellow in mathematics. Concurrently, one of his students took detailed journals on most lectures. The team employed Tall's three worlds of embodied, symbolic, and formal mathematical thinking as various lenses to gain insight into the mind of the working mathematician as he taught a course on Algebraic Topology. Although the analysis of the data from the instructor's journals and the in-depth discussion of the journals during the team meetings revealed his thought processes, the 35 handouts that he prepared, aligned with students' needs, provided the most insight into his way of thinking.*

*Keywords: Embodied, symbolic, formal, Tall's three worlds, Algebraic Topology*

## Introduction

Communicating advanced mathematical ideas to university students is a challenging endeavor. It is a common and accepted practice for many mathematicians to write definitions, theorems and proofs on the board and make comments as they introduce mathematical ideas to students. Thurston (1994, p. 162) asked the question: "How do mathematicians advance human understanding of mathematics?" In interviewing 70 research mathematicians, Burton (1999, p. 31) found that "intuition, insight, or instinct" was seen by most mathematicians as a necessary component for developing student knowledge. Although we have some literature on examining mathematicians teaching practices (e.g. Fukawa-Connelly, 2012; Stewart, Schmidt, Cook & Pitale, 2015), research on what takes place in the minds of mathematicians and their students is still scarce (Speer, Smith, & Horvath, 2010). Dreyfus (1991) believed that, "one place to look for ideas on how to find ways to improve students' understandings is the mind of the working mathematician" (p. 29). In this study, we examined a mathematician and one of his students' daily thoughts on Algebraic Topology. The overarching goal of this research was to investigate the way mathematicians and students think about mathematics and the possible pedagogical challenges that they may face.

## Theoretical framework

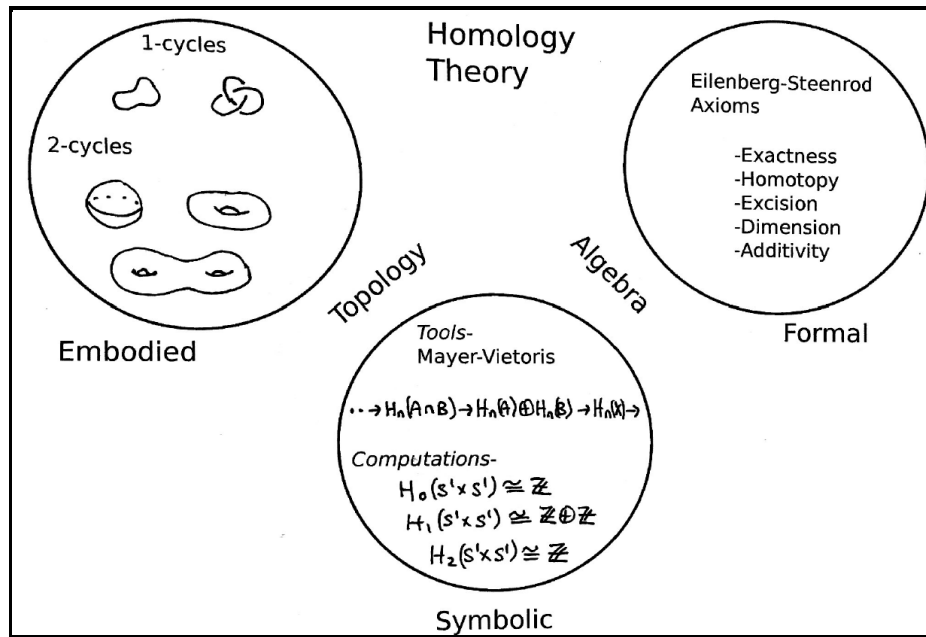

In this study, we employed Tall's (2013) three-world model of conceptual embodiment, operational symbolism, and axiomatic formalism in order to describe an expert geometer's ways of mathematical thinking. In Tall's view, the embodied world involves mental images, perceptions, and thought experiments; the symbolic world involves calculation and algebraic manipulations; the formal world involves mathematical definitions, theories and proofs. Tall (2008) asserts that, "all humans go through a long-term development that builds through embodiment and symbolism to formalism" (p.

23). Bridging between the embodied and symbolic worlds is of critical importance. Tall emphasizes that “a curriculum that focuses on symbolism and not on related embodiments may limit the vision of the learner who may learn to perform a procedure, even conceive of it as an overall process, but fail to be able to imagine or ‘encapsulate’ the process as an ‘object’ (p. 12).

Tall and Mejia-Ramos (2006, p. 3) declared that the word ‘world’ is carefully chosen and has a ‘special meaning’ in order to represent “not a single register or group of registers, but the development of distinct ways of thinking that grow more sophisticated as individuals develop new conceptions and compress them into more subtle thinkable concepts”. As Dreyfus (1991, p. 32) declares “One needs the possibility to switch from one representation to another one, whenever the other one is more efficient for the next step one wants to take... Teaching and learning this process of switching is not easy because the structure is a very complex one.” Duval (2006) claims that many students do not have the cognitive framework to perform the switch. The overarching goal of the first author’s research program is to investigate the ways in which mathematicians move between modes of thought and facilitate their students’ movements among these modes. Tall’s theoretical framework accounts for movement between the worlds of mathematical thinking and is a suitable scaffold for this research. Through our collaborations, we are beginning to understand how the minds of working mathematicians operate. Thus, we hope to evolve Tall’s theory and use it to analyze rich data from many mathematicians. We endeavored to investigate the following research questions: (a) How did the instructor and student move between the formal, symbolic, and embodied worlds? (b) How did the instructor use handouts in order to help students move between the worlds?

### **Viewing Homology Theory through three lenses**

The mathematician appreciated the developmental aspect of Tall’s framework in which one begins with a very embodied view of the world around them and then moves with increasing age and experience to a symbolic view as one matures. However, he took issue with the “formal” viewpoint as the ultimate destination of this progression, especially since formal from a math perspective (i.e., set theoretic axioms, definitions, and formal deductions from such a system) is not the way mathematicians think. One can program a computer to generate (i) statements and (ii) formal proofs of these statements within an axiomatic system. In what sense can we say that the computer is discovering a mathematical theory? Humans use a lot more when they discover/develop a mathematical theory. Among all the myriad of possible statements that could be true in this formal theory, mathematicians choose certain ones (usually as a result of intuition and metaphors possibly supported by symbolic computations to garner evidence for the particular statements) called conjectures, and they try to prove them. Instead, the mathematician made sense of Tall’s worlds by thinking of them as three lenses that allowed him to view a mathematical reality/world. Figure 1 illustrates his views of Homology Theory through these lenses. The embodied lens allows the mathematician to see cycles as geometric objects, and similarly for chains and various topological spaces. The symbolic lens allows the mathematician to use symbolic computation tools such as the Mayer-Vietoris sequence and produce symbolic computations (e.g., the homology of the 2-torus). The formal lens allows the mathematician to work with the Eilenberg-Steenrod axioms and results which can be derived formally from these axioms. The geometric side of topology spans the embodied and symbolic lenses. Algebra, primarily in the form of Homological Algebra, spans the symbolic and formal lenses.

**Figure 1: The three-lens view of Homology Theory**

We can think of similar lenses, for example, in medicine. One can look at a patient with one's eyes, take an x-ray or an MRI of the patient, view the patient through an infrared lens, listen to the patient's heart and lungs etc., talk to the patient about their symptoms, and draw blood and perform tests. These are different modes of gathering information to give a practitioner a more complete picture of the patient.

## Method

**The participants.** Our qualitative narrative study investigated the ways an expert mathematician navigated among Tall's worlds of mathematical thinking. The research team consisted of four members: a mathematics education researcher; a geometer, Noel Brady (the course instructor); a cognitive psychologist; and a mathematics postdoc familiar with both Algebra and Topology.

**The course.** The Algebraic Topology course was the first in a two-semester sequence of graduate courses. There were eight graduate students enrolled in the course. During class meetings, Noel often passed out handouts to help students follow along with the topic of the day. He believed some topics covered in the chosen textbook (Hatcher, 2001), needed to be handled in a more detailed fashion. "Hatcher is a bit fast and loose with all of this". Students actively solved problems together in groups, or individual students were called to the board to complete problems. Noel also helped to revive an extracurricular, student-led topology seminar.

**Data and procedures.** In this study, we analyzed a geometer's thought processes and actions while he taught Algebraic Topology over the entire Fall 2014 semester. One source of data was a series of teaching journals that contained Noel's reflections on his preparations for class, what happened during class, as well as some descriptions of the events that took place during office hours and a student-led topology seminar. The research team read his daily journal entries and discussed them during weekly research meetings. During these meetings, we asked Noel further clarification

questions, and he often drew additional pictures as he described the course content. These meetings were audio recorded and later transcribed and will be used as a source of data. Another source of data came from one of Noel's graduate students who also wrote daily journals. These student journals provided an additional perspective into the events that took place in class. In addition, further data came from 35 handouts that Noel provided.

**Coding scheme.** The data were analyzed thematically, meaning we mainly considered the key issues that emerged in this study. The main themes and their sub-categories were identified and coded (see Figure 2). In addition to assigning codes for the three worlds of mathematical thinking, we also created codes for movement between the worlds (e.g., embodied-symbolic). While coding Noel's journals, at times we assigned multiple codes for a particular instance. For example, an excerpt could be coded with both the "Teaching" and "Tall's Worlds and Movements" codes.

In the following section, we give a glimpse into the analysis of Noel's journals, as well as instances from the student's journals to illustrate how the student perceived movement among the worlds.

## Results and discussion

Figure 2 shows the percentage of total qualitative codes that were applied to excerpts from Noel's teaching journals.

Main Theme	Sub-Category	Percentage Use Main Theme	Percentage Use Sub-Category
Teaching		46%	
	Pedagogy		26%
	Examples		22%
	Handouts/notes		20%
	Proofs		11%
	In-Class Activities		10%
	Hatcher/textbook		7%
	Theorems		3%
	Homework		2%
Tall's Worlds and Movements		25%	
	Symbolic		25%
	Embodied (Intuition)		21%
	Topology - Algebra		20%
	Embodied-Formal		18%
	Formal		10%
	Embodied-Symbolic		7%
	Symbolic-Formal		0%
Reflections		20%	
	On students: understanding/preparedness		47%
	On self: Careful/precise		31%
	Pacing		22%
Students		9%	
	Igor (one of the students)		26%
	Students ask questions outside of class		26%
	Student seminar		26%
	Students ask questions in class		22%

Note: Percentage Use Main Theme adds to 100%  
Percentage Use Sub-Category adds to 100% for each sub-category

**Figure 2: Qualitative coding scheme**

The main theme of Tall's three worlds of mathematics comprised 25% of the total codes. Teaching was the main theme that was coded the most (46%) in Noel's journals. Reflections included 20% of codes, and codes pertaining to students involved 9% of the total codes. Analysis of the data revealed ample evidence that Noel repeatedly navigated between the three worlds of mathematical thinking. Below, we provide examples from our analysis of his teaching journals and a student's journals to illustrate movement between worlds.

### **Moving between embodied (intuition) and formal worlds**

According to Noel, this may have been the type of movement that the students found the most challenging: “There were a lot of questions about how to pass from an intuition to a formal proof (many of these examples used techniques/results from quotient spaces).”

The analysis of the student’s journals showed his concerns regarding the proofs. This excerpt was taken from one of his journals at the beginning of the semester:

Dr. Brady's way of proving results that come from concepts we're already supposed to have come across before his class is nice, I think. He gives a detailed outline verbally, which is helped along visually by his pictures and hand gestures. For the most part I'll watch without writing almost anything, but I definitely get a lot out of reviewing concepts in this way. I'm a little worried, however, that when we get to brand new material Dr. Brady's way of proving results might remain in the same verbal/hand-waving/picture-drawing style and that this won't be enough for me to follow the proof right there and then. He tends to speak and write very quickly, which is fine when we're reviewing. But since I can either copy furiously what he writes on the board or listen to him, but not both, this could become a problem.

Noel refused to give students proofs that were pre-packaged. More specifically, he wanted to provide students with intuitions/pictures that would help them understand the conceptual nature of the proof and ultimately lead them to it. In one of the research meetings Noel said:

I mean I can give verbatim proofs of things or give them more detailed proofs where Hatcher leaves stuff out, but that will just waste time and I'll reproduce a book and nobody will get anything out of it. So I've given them intuitions, enough of an intuition that they can tag that together with a formal proof.

Later in the course the student wrote: “I've seen van Kampen's theorem before, but Dr. Brady's from-the-ground-up approach was very nice in that it showed us through comprehensive diagrams just where exactly the theorem comes from.”

### **Movement between embodied and symbolic worlds**

Noel discussed moving from embodied demonstrations (e.g., rope trick) to having students complete symbolic examples (e.g., right-angled Artin group (RAAG) complexes and the torus knot spine):

More of the same. I connected back to several examples from the first week and from the intro to  $\pi_1$ . The pair of circle links in  $S^3$  example (a.k.a. the rope trick) and the RAAGs. This seemed to go ok. Mentioned again that RAAGs are deceptively simple looking groups, but that their subgroup structure is surprisingly rich. In particular, Bestvina-Brady (1997) and Agol-Wise (2012) contain very surprising results about subgroups of RAAGs. Told them that the story is still ongoing. Left off with an example of a torus knot spine (Hatcher).

### **The handouts**

Analysis of the 35 handouts that Noel created illuminated the motives behind some of his thought processes and movement between worlds. These handouts gave the team a more authentic glimpse into the mind of the mathematician than the teaching journals that Noel regarded as self-critical (self-aware). Figure 3 shows the first two pages of a handout Noel created on barycentric subdivision. The

start of the handout contains the formal definitions of “barycenter” and of “barycentric subdivision.” These definitions build on a previous definition (and square bracket notation) of an  $n$ -simplex. The definition of “barycentric subdivision” is recursive (i.e., defined in terms of lower dimensional versions of itself). The rest of the two pages is devoted to building students’ intuitions for these definitions. At the bottom of the first page, two embodied examples are provided which demonstrate how to unwrap the recursive definition to determine the barycentric subdivision of a 1-simplex (a line segment) and of a 2-simplex (a triangle). This is followed by an exercise which asks the student to add another layer of recursion and describe the barycentric subdivision of a 3-simplex (a triangular-based pyramid). This is a very embodied example. At this stage, Noel hoped that the student should be gaining confidence working with the recursive definition and should be developing an intuition that the symbolism will work in higher dimensions where one’s embodied intuition fails. The second exercise asks the student to iterate the barycentric subdivision process for a 2-simplex. Again, this is very embodied and can be drawn easily in the plane. Noel pointed out that developing an intuition about iterated barycentric subdivisions is important since they will form the heart of the proof of the “locality result” and the proof of the “excision theorem” for singular homology later on in the course. The two Roman-numeral-labeled observations at the end of page 2 build on the student’s embodied intuition of the behavior of iterated barycentric subdivisions in dimension 2 (obtained from doing exercise 2). They motivate the statement of the theorem that will be given and proven on subsequent pages of the handout. They also alert the student to the fact that some care will have to be given to the proofs on the subsequent pages. This is particularly so, since these proofs will hold in arbitrary dimensions.

Noel pointed out that, from a textbook perspective, one can skip straight from the definitions of barycenter and barycentric subdivision to the statement and proofs of the theorems about the behavior of the diameters of simplices under iterated barycentric subdivisions. Nothing in the logical progression and framework would be lost. However, students’ intuitions would be lacking (save for the rare student or two who can do some mental exercise equivalent of the examples, exercises and observations of these two pages.). This handout is one of a sequence of three handouts. These handouts get increasingly symbolic and abstract. Eventually, the results contained in the last handout are just what are needed in the formal proof of the “locality theorem” (and the “excision theorem”) of singular homology. At this stage, the proofs are very symbolic and far removed from geometry. It is good that students have developed an embodied intuition about iterated barycentric subdivisions, so that they have concrete models in their mind for how excision works on the geometric level of chains.

Barycentric Subdivisions — Geometry

① Def: [Barycenter] The barycenter of  $[v_0 \dots v_n]$  is defined to be the point  $b = \sum_{i=0}^n \frac{1}{n+1} v_i$  in  $[v_0 \dots v_n]$ .

Def: [Barycentric Subdivisions] This is a recursive definition.

The barycentric subdivision of a 0-simplex  $[v_0]$  is just  $[v_0]$ .

The barycentric subdivision of an  $n$ -simplex  $[v_0 \dots v_n]$  is the expression of  $[v_0 \dots v_n]$  as a union of  $n$ -simplices of the form  $[b, w_0, \dots, w_{n-1}]$

where

- (1)  $b$  is the barycenter of  $[v_0 \dots v_n]$ , and
- (2)  $[w_0 \dots w_{n-1}]$  is an  $(n-1)$ -simplex in the barycentric subdivision of some  $(n-1)$ -face  $[v_0 \dots \hat{v}_i \dots v_n]$  of  $[v_0 \dots v_n]$ .

Pictures

$n=1$

$n=2$

② Exercises

① Draw a picture of the barycentric subdivision of a 3-simplex,  $[v_0, v_1, v_2, v_3]$ :

② Take the barycentric subdivision of a 2-simplex  $[v_0, v_1, v_2]$ . Now take the barycentric subdivision of any 2-simplex in that result. This is called the 2nd barycentric subdivision of the 2-simplex. Draw a picture of this.

After doing exercise ② you may notice a few things:

- (i) the shapes of the new simplices in the iterated barycentric subdivisions keep changing (eg. some angles  $\rightarrow 0$ )
- (ii) the diameters of the new simplices are strictly smaller than the original ...

We want to control this — argue that diameters of new simplices are smaller than diameters of original by a definite factor. This is not immediately obvious because of phenomenon (i) above. We'll argue carefully  $\rightarrow$

Figure 3: An excerpt from Noel's handout

## Concluding remarks

This study revealed that Noel viewed Algebraic Topology through all three mathematical lenses (embodied, symbolic, formal), and his handouts provided his students with opportunities to view the course material through these different lenses as well. In one of the research meetings, Noel mentioned:

When I think of the mathematical world of algebra I have examples in my mind, many of which are very embodied, and many of which are symbolic, I also know the axiomatic definitions of concepts in this world like "group," "ring," "field" etc. So, when I think of the world of algebra all three lenses (embodied, symbolic, formal) kick into gear. Likewise, for the mathematical world of topology.

Our research team, comprised of a mathematician, a mathematics educator, and a cognitive psychologist, are working together to apply and evolve Tall's theoretical framework by analyzing the teaching journals of mathematicians and their students. We have come to realize that the embodied, symbolic, and formal worlds blend together as applied to Algebraic Topology; it is often not clear where one world starts and another world ends. In addition to thinking about problems from the ESF perspectives, mathematicians often translate a problem from one area of mathematics (e.g. Topology) to another (e.g. Algebra). This translation is achieved using mathematical constructs called *functors*.

Noel used the analogy of a translator to describe the mathematical notion of a functor. When a statement of a problem is translated from one language to another, some of the details may get lost in

the translation. Perhaps this loss of information has an unexpected benefit; the simpler formulation of the problem in the new language might allow for new insights or intuitions to be gained, and perhaps even for a solution to the original problem.

Noel talked about functors in his journals, and described how they are used to solve problems in topology by first translating then into algebra problems:

We introduced some other situations where Algebraic Topology functors might help solve topology problems, and mentioned that the homology functors would be introduced and studied in the course.

We are using analogies and metaphors to communicate with one another as we attempt to understand the pedagogical decisions of the working mathematician. As Thurston (1994, p. 168) asserted: “we mathematicians need to put far greater effort into communicating mathematical ideas. To accomplish this, we need to pay much more attention to communicating not just our definitions, theorems, and proofs, but also our ways of thinking...we need to appreciate the value of different ways of thinking about the same mathematical structure”.

# Discursive shifts from school to university mathematics and lecturer assessment practices: Commognitive conflict regarding variables

Athina Thoma and Elena Nardi

University of East Anglia, United Kingdom; [a.thoma@uea.ac.uk](mailto:a.thoma@uea.ac.uk)

*We report part of an ongoing study that aims to characterise lecturers' assessment discourse, especially on closed-book examinations. We focus particularly on lecturers' discourses that concern the transition from school to university mathematics, and we do so through highlighting one commognitive conflict regarding the use of variables in a task from an examination paper for a Year 1 module on Sets, Numbers and Probability taught in a UK mathematics department. We show evidence that the lecturer's assessment practices aim to facilitate students' avoidance of errors that are occurring because of said conflict. Here, we focus on students' scripts which illustrate that, nonetheless, students make errors and do not draw on the discourse of integers when deciding the domain of the variables used in the task. We conclude with a brief discussion of students' experience of commognitive conflict in the transition from school to university mathematics.*

*Keywords: Undergraduate examinations, assessment routines, commognitive conflict, variables.*

## Introduction

Studies in mathematics education have focused on students' transition from secondary school to university (e.g. Gueudet, 2008). Part of how students experience said transition is evidenced in their engagement with examinations during their first-year undergraduate modules. The nature of tasks in examinations has been studied using different theoretical frameworks (e.g. Tallman, Carlson, Bressoud & Pearson, 2016). Researchers have also examined lecturers' perspectives on examination tasks (Bergqvist, 2012; Tallman et al., 2016). In our study, we take a discursive approach in analysing examination tasks and lecturers' perspectives focusing on aspects of the transition from secondary school to university mathematics. This theoretical approach allows a characterisation of the mathematical discourse the students engage in when solving the tasks, and provides insight into lecturers' assessment practices and their expectations from students' responses.

In this paper, we analyse a task from a first-year module on Sets, Numbers and Probability offered in a UK mathematics department. We build on previously reported work from this study (Thoma & Nardi, 2016) in order to delve into lecturers' assessment practices facilitating students' transition to university mathematics in more detail. Specifically, we take the case of variables and the way these appear in a Number Theory task of the module's examination paper. In choosing this particular case, we take cue from previous works (e.g. Epp, 2011) which note that variables have diverse uses in mathematics, some of which often create difficulties for students' transition to algebra and other advanced topics. Of particular relevance in this paper is the discussion by Biehler and Kempen (2013) about the difficulties with variables that students face.

In the part of our study reported here, we focus on a commognitive conflict concerning the number domains in the secondary school and university mathematics discourses. First-year mathematics undergraduate students' errors regarding variables, when engaging in a Number Theory task, provide evidence of this unresolved commognitive conflict. In what follows, we present briefly the theoretical framework of the study, the examination task and the study's participants. We then analyse the task

and the interview data with the lecturer who posed the task. The interview data illustrate the lecturer's ways of assisting the students to avoid the errors. Finally, we highlight the errors evidenced in the student scripts despite this assistance, we present the case that these errors stem from aforementioned commognitive conflict and conclude with a discussion of findings and how these are embedded into the larger study.

### **Commognitive conflicts and assessment routines facilitating discursive shifts**

Sfard's (2008) theory of commognition is a discursive approach that is being increasingly used in mathematics education (Tabach & Nachlieli, 2016), as well as specifically in university mathematics education (Nardi, Ryve, Stadler & Viirman, 2014). Mathematics in this approach is a discourse that can be described in terms of the following four characteristics: *word use* (e.g. divisor), *visual mediators* (e.g. algebraic symbols), *endorsed narratives* (e.g. definitions) and *routines* (e.g. proving). The routines are distinguished in *deeds* ("an action resulting in a physical change in objects"; Sfard, 2008, p. 236), *rituals* ("creating and sustaining a bond with other people", p. 241) and *explorations* ("producing endorsed narratives", p. 259) with the explorations further categorised in *recall*, *substantiation* and *construction*. Of particular relevance to our analysis here is the construct of *commognitive conflict* "the phenomenon that occurs when seemingly conflicting narratives are originating from different discourses – from discourses that differ in their use of words, in the rules of substantiation, and so forth." (p. 257). For example, a commognitive conflict may occur between the different relationships that the number domains have in school and university mathematics discourses. In school, number domains are introduced progressively. They are used for some time; and then subsumed in the next number domain. Positive integers are introduced first. Then, as the students learn about division, rational numbers follow. After a while, the discourse about unsigned rational numbers (which includes integers and rational numbers) together with negative numbers constitute the discourse on rational numbers (p. 121). The discourse of real numbers is introduced in later stages of the secondary school. In the university discourse, the number domains play a different role. They are presented as crucial abstract structures, the ring of integers and the fields of rationals, reals and complex numbers. In particular modules, the focus of study are those abstract structures and that is the case for Number Theory, where the domain of the variables is restricted in the discourse of integers.

In our study, we examine students' participation in the university mathematics discourse taking also into account the lecturers' perspectives, particularly their rationale for the choices of the examination tasks and the wording of the tasks. Our previous analysis of examination tasks and lecturers' assessment practices (Thoma & Nardi, 2016) highlighted the following assessment *routines*: giving directions to the students regarding the steps their response to a task may take; structuring the tasks and subtasks in ways that allowed students to secure and optimise marks as they progressed from one part of a task to another; and, providing guidance regarding expected justifications in the students' responses. Overall, these routines aim at assisting students' shifting from school to university mathematics discourse. Here, we aim to extend our previous analyses, also taking into account lecturers' assessment routines, which aim to avoid expected errors. We will make the case that unresolved commognitive conflicts are responsible for those errors. We are, therefore, starting to look in tandem at aspects of students' experience (here: commognitive conflicts relating to variables in a Number Theory examination task) and lecturers' perspectives on – and intended practice relating to

– this experience. In the following, we outline the larger study our paper originates in; and, introduce the examination task and a brief commognitive analysis of it. We then offer an analysis of the lecturer's perspectives on the task, highlighting those assessment routines that aim to help students avoid errors relating to variables. Finally, we present the student examination scripts, which illustrate these errors and examine whether, and how, the unresolved commognitive conflict in the different relationships with number domains at school and university, may be seen as responsible for these errors.

## The examination task and the participants of our study (lecturer and students)

The data of our study consists of examination tasks from different modules, lecturers' interviews on those tasks and students' scripts corresponding to these examination tasks. The focus of this paper is on one task from the module

- (i) Prove by induction that for all natural numbers  $n$ ,
- $$2^1 + 2^2 + 2^3 + \dots + 2^n = 2^{n+1} - 2.$$
- (ii) (a) Suppose  $a, b, d, m, n$  are integers. Give the definition of what is meant by saying that  $d$  is a divisor of  $a$ . Using this, prove that if  $d$  is a divisor of  $a$  and  $d$  is a divisor of  $b$ , then  $d$  is a divisor of  $ma + nb$ .  
 (b) Use the Euclidean algorithm to find the greatest common divisor  $d$  of 123 and 45. Hence (or otherwise) find integers  $m, n$  with  $123m + 45n = d$ .  
 (c) Do there exist integers  $s, t$  such that  $123s + 45t = 7$ ? Explain your answer carefully.

Figure 1: Compulsory task on Sets, Numbers and Proofs

Sets, Numbers and Probability. This is a first-year module and has two parts: Sets, Numbers and

(ii)(a)  $d$  is a divisor of  $a$  means that there is  $k \in \mathbb{Z}$  with  $a = kd$ . [2 marks]  
 If  $d$  is a divisor of  $a$  and of  $b$  then there exist  $k, l \in \mathbb{Z}$  with  $a = kd$  and  $b = ld$ . Then for all  $m, n \in \mathbb{Z}$  we have

$$ma + nb = m(kd) + n(ld) = (mk + nl)d.$$

As  $(mk + nl) \in \mathbb{Z}$ , it follows that  $d$  divides  $ma + nb$ . [2 marks]  
 (ii)(b) Following the method in lectures, let  $a = 123$  and  $b = 45$ . Carrying out the Euclidean algorithm we obtain:

$a = 123$	$45 = b$
$2b = 90$	$33 = a - 2b$
$a - 2b = 33$	$12 = 3b - a$
$6b - 2a = 24$	$9 = 3a - 8b$
$3a - 8b = 9$	$3 = 11b - 4a$
$9$	
$0$	

We conclude that  $\gcd(123, 45) = 3$  and that

$$3 = 11b - 4a = 11 \cdot 45 + \{-4\} \cdot 123 = 123m + 45n$$

where  $m = -4$  and  $n = 11$ . [8 marks]  
 (ii)(c) No. Since 3 divides both 123 and 45 it follows from (ii)(a) that 3 divides  $123s + 45t$  for all  $s, t \in \mathbb{Z}$ , but 3 does not divide 7. [2 marks]

Figure 2: Model solution of part (ii) of the compulsory task

Proofs taught in the autumn semester and Probability taught in the spring semester. The final examination includes six tasks: the first two are compulsory and the other four optional. One of the compulsory and two from the optional tasks are on Numbers, Sets and Proofs and the others on the Probability part of the module. At the final examination, the students have to solve both the compulsory tasks and three from the optional tasks. The total grade of the examination is 100 marks and the pass grade is 40 marks. This paper focuses on the compulsory task from the Sets, Numbers and Proofs part of the module (Figure 1). More specifically, in this part of the module, the topics covered are: Set Theory (notation, operations, cardinality and countability), Functions (introduction to functions, injection, surjection), Proofs (direct proof, proof by induction, proof by contradiction, proof by counterexample), Number theory (greatest common divisor, prime numbers, modular arithmetic) and Equivalence relations. The topic examined in this task is proof by induction and Number theory. Our analysis will focus on students' responses to the Number theory part of the task, task (ii). The model solution for part (ii) created by the lecturer for departmental use is in Figure 2. We note that this solution is not made available to the students.

Fifty-four students took part in the final examination and the marks of their responses in this task ranged from 4 to 20, with the mean being 16.85 marks. The scripts of 22 students were selected by the first author to represent a variety of marks (Figure 3). The errors based on what we see as an unresolved commognitive conflict regarding variables were observed in 6 students' scripts. Here we report: first, analysis of the task and from the lecturer interview data; then, a sample from the analysis of the six students' scripts.

### Task analysis and the lecturer interview

In part (i) of the task (Figure 1), the students are asked to engage in a substantiation routine (proof by induction). The wording of the task directs the students to this type of proof. In part (ii), the

students are directed to engage first in a recall routine, giving the definition of a divisor, and then in a substantiation routine of a relationship describing the connection between the linear combination of  $a$  and  $b$  and the divisor  $d$  of  $a$  and  $b$  (iia). The students are then directed toward using the Euclidean Algorithm in (iib) and, in the last part (iic), they are expected to engage in a proof by contradiction (not explicitly mentioned in the wording of the task) in

**Figure 3: Marks from all the students' scripts**

order to prove that the linear combination given is not divisible by 7 – see (Thoma & Nardi, 2016) for more detailed analysis of the task. For the purpose of this paper, we focus on the lecturer and student data corresponding to the second part of the task, (ii).

During the interview, the lecturer said:

Lecturer: (...) my memory of school mathematics is that there was a lot of doing things but not necessarily a lot of formally defining things (...) And of course they came to university thinking that they knew what that [the definition of the divisor] meant but in this situation it really matters that they are restricting themselves to the-to the ring of integers (...) and all the symbols represent integers so what it means to divide is very different than if they were working with fractional numbers or something where they could write  $a$  over  $b$  and things like this.

Our commognitive analysis highlights the differences in the lecturer comments between the school discourse and the university discourse and, more specifically, with regard to the routine of defining and the importance of understanding that “all the symbols represent integers”.

He highlights the differences between what the students are used to and what they are expected to do at university level. Our analysis sees this as the differences between the two discourses: on the one hand on the focus of the routines; on the other hand, on the constraints of the different discourses that exist within the mathematical discourse at university level. More specifically, the students, working with this definition have to restrict their work on integers – and not on rational or real numbers. The lecturer, then, speaks about the nature of the symbols involved. We recognize this comment by the

lecturer as foreseeing students' errors in the case that they treat the divisor as a rational instead of an integer, drawing on the discourse of rational numbers instead of the discourse of integers. Integer numbers are rational numbers, and making the distinction between the two – and then opting for working within the discourse of integers – is not something that these students have been routinely working with in school. This shows that the lecturer expects students to use division in the way that they were taught in school, instead of considering the abstract structure that this task is asking them to restrict their activity in. In the excerpt that follows, the lecturer explains his assessment routines which aim to assist students with avoiding errors that are happening because of what we see as a commognitive conflict: subtask (ii) is gradually structured as first asking the definition, then, substantiating a narrative that draws on this definition, engaging with the Euclidean algorithm and, finally, combining all the above to engage in a proof by contradiction. He comments on the purpose of this gradual structure as follows:

Lecturer: (...) what's being tested here is their ability to write down something formally and correct. And I would worry that if I didn't prompt them to write down formally the definition of what it means for one integer to divide another in the exam, in the pressure of the exam and so on, then their answers could start looking very 'creative' at the second part and they might start writing down fractions.

Therefore, he aims that the gradual structure aids students towards achieving the expected solution. This can be thought of as a way of helping students avoid experiencing errors stemming from what we labelled as commognitive conflict, where  $a$  and  $b$ , would be treated by students as rational numbers, instead of integers: this gradual structure serves as a reminder that they should restrict themselves in the discourse of integers. Additionally, the analysis shows that the lecturer stresses the routine of justification and the rigor of the university discourse compared to the school discourse, a further staple of the transition that these students are at the moment experiencing (Gueudet, 2008).

Lecturer: (...) the only challenging part would be the last part, the part that requires some thought and they need to sort of understand or remember that somehow it relates to what happened up here [shows parts (iia) and (iib)] (...) to remind them that I want them to explain why they are answering what they are saying.

In the excerpt above, the lecturer comments on the challenge of the (iic) part of the task and the purpose of the prompt "Explain your answer carefully". In this part of the task, the students have to engage in a substantiation routine that is based on the endorsed narratives that they have created for parts (iia) and (iib). The lecturer suspects that the students may omit justifying their response regarding the substantiation of the given relationship and aims that this prompt will help them do so.

From the above, we see that the lecturer has identified students' difficulties with the nature of the variables being used in this task. Our commognitive analysis sees this as evidence that the lecturer appears alerted to this difficulty as a difference between the school and the university discourse. The students, during their school years, gradually moved from the discourse of the natural numbers, to the one of the integers, then to the rational numbers and finally to the reals. Now, in this task, they are asked to endorse the discourse of the integers, which is subsumed in the discourse of rational numbers, within which they have been performing division of numbers in school. We now turn to students' responses, which evidence that, despite aforementioned aid provided by the lecturer, errors

illustrating this commognitive conflict were not avoided. Of the twenty-two student scripts analysed, six contained said evidence ([01], [03], [06], [11], [16], [17]).

### The students' scripts

Student [03] first communicates the relationship between the divisor  $d$  and  $a$  using written verbal

iia) If  $d$  is a divisor of  $a$  it means that  $d$  is able to be a factor and divide  $a$  without leaving a remainder.

$\frac{d}{a}$  and  $\frac{d}{b}$       If  $\frac{d}{a} = m$  and  $\frac{d}{b} = n$   
 then  $d = ma$        $d = bn$       0

$ma + bn = 2d$  which has  $d$  as a divisor

b)  $45 \overline{) 123} \quad 2 \quad 3$   
 $\underline{90} \quad 33 \quad 123 \quad 5$   
 $\underline{30} \quad 24 \quad 123 \quad 41$   
 $\underline{3} \quad 123$       gcd = 3      3

$123m + 45n = 3$   
 $41m + 15n = 1$

$m = \frac{1}{41} \quad n = 0; m = \frac{1}{41} \quad n = \frac{1}{15}; m = \frac{1}{82} \quad n = \frac{1}{30}; m = \frac{2}{123} \quad n = \frac{1}{45}$

$m = \frac{1}{123} \quad n = \frac{2}{45}$       0

c) Yes there is (eg  $s = \frac{1}{41} + \frac{1}{15}$ ) as there are other primes and integers combined when added which are divisors of 123 and 45 which can make other numbers      2

Figure 4: Student [03]'s script to (ii)

visual mediators. In the second part of (iia) the student writes, using symbolic mediation, that  $d$  is a divisor of  $a$  and  $d$  is a divisor of  $b$ . However, in the symbolic realisation of the divisor, the student deploys fractions, with  $d$  being the numerator and  $a$  and  $b$  being the denominators. This way of writing that  $d$  divides  $a$  can be seen as a translation of the written verbal mediator into a symbolic mediator without taking into account that the fraction line means that the denominator divides the numerator. In the case of the task, this division would result in a non-integer number. This way of writing signals that the student may see  $m$  and  $n$  (written on the right hand of the script) as numbers and not as integers. Then, the student writes the relationship between the symbolic mediators  $m$ ,  $d$  and  $a$  and concludes that  $d$  is equal to the product of  $m$  and  $a$ . The student used all the symbols given in the wording of the

task to produce a narrative that involves fractions. Fractions could be part of the discourse of rationals, and this task asks the students to restrict their activity within the discourse of integers. We see the appearance of fractions and the absence of the constraints regarding the variables as evidence of the commognitive conflict regarding the relationships between the number domains in school and university mathematics discourses. Unclear meaning making regarding the object of a divisor is evidenced as the student starts by explaining that  $d$  is a factor of  $a$ , then engages in the discourse of rationals concluding that  $d = ma$  but then saying that the product  $2d$  has  $d$  as a divisor. Having concluded that the greatest common divisor is 3 (Figure 4) using long division - and not the Euclidean algorithm - the student writes  $123m + 45n = 3$ . Then s/he divides all the terms of the equality by 3 and takes different cases where the new equality is true.

In doing so though, [03] does not take into account the nature of the variable symbolic mediators and the variables become rational numbers. Also, there are multiple values in the rational numbers that satisfy this equality as can be seen in the response (Figure 4). Finally, in the last part of the task, the student responds affirmatively that there are "integers"  $s$  and  $t$ . However, the  $s$  and  $t$  s/he gives are

rational numbers chosen to result in 7. This signals a ritualised use of the word “integers”: the student uses the word integer, seemingly repeating the wording of the task but in fact providing numbers that are not necessarily integers.

Figure 5: Student [16]’s to (iic)

Two more students [16] and [17] give similar responses. Student [16] (Figure 5) does not give a definition of the divisor, attempts the substantiation of the relationship describing the connection between the linear combination of  $a$  and  $b$  and their divisor  $d$ , finds

the greatest common divisor and uses only integers similarly in the identification of the integers  $m$  and  $n$  which give the linear combination of the greatest common divisor. However, when responding to (iic), [16] finds two non-integer rational numbers for  $s$  and  $t$  and confirms that the expression results in 7. Similarly, in the scripts from the students ([01], [06], [11]) there are instances where errors occur as the number domain of the variables is not clarified and the students work in a different number domain than the integers, which is what the task calls for.

### Symbolic visual mediation and the transition to university mathematics

Looking at the model solution produced by the lecturer (Figure 2) and the wording of the task (Figure 1), we can see that there are four different instances where the students have to define the symbolic mediators they use: first, in the definition of the divisor where an integer is introduced to illustrate the relationship between  $a$  and  $d$ ; then, in the narrative which connects  $a$ ,  $b$  and their divisor  $d$ ; next, in the substantiation of the relationship between the linear combination of  $a$  and  $b$  and their divisor  $d$ ; and, finally, in order to prove by contradiction that a linear combination of  $a$  and  $b$  is not divisible by 7. In the last instance, the symbolic mediators on both sides of the equality have to be integers and, as 7 is not divisible by 3, the contradiction occurs. The wording of the task, where the lecturer stresses that all the variables in this part of the task are integers, and the structure of the task aim to signal to the students that they have to be working within the domain of integers. Our analysis suggests that lecturers design the tasks being aware of the students’ potential errors regarding the variables belonging to different number domains and thus adds to Bergqvist’s (2012) results on what lecturers take into account when designing assessment tasks. The data from the students’ scripts shows however, that, in six out of the twenty-two analysed responses, students’ errors signal an unresolved commognitive conflict that relates to making a distinction about the nature of the variables. Engaging with this distinction is not a routine that students are typically engaged with, at least in the UK secondary classrooms where the students participating in this study have been educated in: number domains are introduced progressively and students are simply expected to always work within the latest introduced number domain. However, in the university, the numerical context of a task may differ from task to task and the students are expected to be able to swiftly identify the domain that is appropriate for each task and work within it. We approach this issue therefore as a non-negligible aspect of the students’ transition from school to university mathematics. Our results resonate with those in Biehler and Kempen’s (2013) study. They found that, frequently, their participants would use symbols without providing information regarding the domain of the variable; in our case, not attending to such information results also in leaving parts of the task practically not answered – especially in the cases where the explicit request for “integers  $s$  and  $t$ ” in (iic) receives non-integer responses.

*We report analyses from a collaborative, developmental research project between two Norwegian centres of excellence in higher education ([MatRIC](#) and [bioCEED](#)) in which biology-related mathematical modelling (MM) activities are introduced to biology students as a means to motivate their appreciation for, and competence in, mathematics. This phase of the project involved four sessions with 11 first-semester students. We report data and analyses from two activities: Yeast Growth and Digoxin. Our commognitive analyses trace the evolution of the students' mathematical discourse in two episodes, revealing a scaffolding story about the gradual transition from ritualized to exploratory engagement with MM, and pointing to the crucial role played by the teacher in this process. We conclude with discussing some implications of our analysis for the design and use of MM activities for students of Biology, and other non-mathematics specialists.*

*Keywords: Theory of commognition; mathematical modelling in biology; mathematical discourse; routines; rituals and explorations.*

## Teaching mathematics to biology students through mathematical modelling

Research into the mathematical needs of non-mathematics specialists is by no means new (e.g. Kent and Noss, 2003). Participants in many university-level studies are often non-mathematics specialists (e.g. engineers or pre-service teachers), but their specialism often remains a mere part of the study's backdrop (Biza, Giraldo, Hochmuth, Khakbaz & Rasmussen, 2016). The relatively small but growing number of studies in this area (e.g., Gould, Murray & Sanfratello, 2012) have touched on issues such as: the double discontinuity between school, university and workplace mathematics; the challenges of teaching mathematical modelling at school and university levels; issues of confidence in and appreciation for mathematics; and, embeddedness of mathematics into other disciplines.

Within biology, mathematics is becoming increasingly important, placing new demands on the education of future biologists. In the US, for example, the recognition of these demands has led to two national projects focusing on developing undergraduate biology education (Brewer & Smith, 2011; Steen, 2005). A potential problem with placing greater emphasis on mathematics in biology education is that “biology education is burdened by habits from a past where biology was seen as a safe harbour for math-averse science students” (Steen, 2005, p. 14). The project that we draw on in this paper aims to improve student appreciation for mathematics through helping them experience the relevance of mathematics to their field of study. It does so through exploring the suggestion made by several authors (e.g. Brewer & Smith, 2011; Steen, 2005) for greater integration of mathematics and biology in the curriculum. MM, as Brewer and Smith (2011) point out, is a basic skill within the ‘core competencies and disciplinary practices’ (p. 17) of biology – and a vehicle for improving student appreciation for the role that mathematics can play in scientific research.

Studies which have investigated the use of MM in university biology education (e.g. Chiel, McManus & Shaw, 2010) indicate that engagement with MM activities can contribute to more positive attitudes towards, and self-perceived competence in, both biology and mathematics. Concerning an integrated approach to mathematics and biology, Madlung, Bremer, Himelblau and Tullis (2011) investigated whether such an approach might have adverse effects, such as breadth at the expense of depth, or mathematics anxiety problems. Two versions of a bioscience module, one of which contained a computational statistical element, were developed and offered to an introductory and an advanced biology class. Results showed no detrimental effects of an integrated approach but indicated that advanced level students were more able to benefit from it.

To examine the evolution of biology students' appreciation for, and competence in, mathematics as they engage with MM activities we espouse a discursive perspective – particularly that of the theory of commognition (Sfard, 2008; Nardi, Ryve, Stadler & Viirman, 2014, p. 183-5) – according to which learning is change in one's participation in well-defined forms of activity (discourse). In what follows, we introduce those components of the commognitive perspective pertinent to the data analysis we present in this paper; we then present a sample of our data and analysis (two episodes from students' engagement with two MM activities, *Yeast Growth* and *Digoxin*).

### **The commognitive construct of *routines*: *Explorations*, *deeds* and *rituals***

According to the commognitive perspective, 'it is by reproducing familiar communicational moves in appropriate new situations that we become skillful discursants, and develop a sense of meaningfulness of our actions' (Sfard, 2008, p. 195). A *routine* is a set of meta-rules that describe a repetitive discursive action. Sfard defines three types of mathematical routines: *explorations*, *deeds* and *rituals*, with *deeds* and *rituals* presented as predecessors of *explorations*. A routine is called an *exploration* 'if its implementation contributes to a mathematical theory' (p. 224) (e.g. equation solving, defining and proving). *Explorations* involve the *construction*, *substantiation* or *recall* of narratives about mathematical objects. *Routines* that involve practical action (action resulting in change in objects, either primary or discursive, p. 241) are called *deeds*. *Deeds* are therefore different from *explorations*, which aim to effect change on narratives. Often, however, there are *routines* that "begin their life as neither *deeds* nor *explorations* but as *rituals*, that is, as sequences of discursive actions whose primary goal [...] is neither the production of an endorsed narrative nor a change in objects, but creating and sustaining a bond with other people' (p. 241).

Sfard claims that *rituals* are a 'natural, mostly inevitable, stage in this development process' (p. 245) and that the road to *exploration* often leads through *ritual*. The data and analysis sample we present in this paper examines this claim with a particular focus on the following research question: "What characterizes the use of *routines* by Y1 Biology students as they engage in MM activities?"

### **Aims, methods, data and participants of the study**

The research design of our study comprises cycles of developmental activity (planning, implementation, reflection, feedback) which are theoretically informed, contribute to the emergence of theory and take place in a partnership between teachers (in this case, a university mathematician) and didacticians (Goodchild, Fuglestad & Jaworski, 2013). This ongoing project is a collaboration between two Norwegian centres of excellence in higher education – the Centre for Research, Innovation and Coordination of Mathematics Teaching ([MatRIC](#)) and the Centre for Excellence in

Biology Education ([bioCEED](#)). The aim of the project is to improve biology students' motivation for, interest in, and perceived relevance of mathematics in biological studies through the use of MM. The teaching took place at a well-regarded Norwegian university where biology students take one compulsory mathematics course, taught in the first semester, designed not specifically for the biology undergraduate programme but for students from about twenty different natural science programmes. Typically, in this university, there is little collaboration between the mathematics and biology departments, and few opportunities for focusing on issues specific to biology in the mathematics course. The data for this paper originate in four three-hour sessions with twelve volunteer students, nine female and three male. Activity during the sessions was video and audio recorded, both from whole-class and small-group work. Also, all written material produced by the students was collected. The teaching was conducted in English, but all student group work and most student contributions to group discussions were in Norwegian. The first session began with an introduction to the basic ideas of MM and to the modelling cycle. Students were then asked to work in smaller groups on modelling problems of varying complexity, but requiring only pre-calculus mathematics. The structure of the three remaining sessions was similar, but the initial exposition instead introduced specific types of models relevant to the problems given in that session. The data we draw on in this paper are taken from sessions two and three, and concern one group of four female students as they work on two different, but related, tasks, *Yeast Growth* and *Digoxin*. In the analysis, we examined the discourse of the students looking for recurring patterns that could be described as routines, for instance graph construction. Furthermore, we looked for signs indicating the type of routine use. For instance, we aimed to discern the motives (if any) students provide for their activity. Since the changes in discourse that we aim at charting in this paper take place gradually and over extended periods of time, they are difficult to exemplify through data excerpts within this short paper. Hence, in presenting the data analysis we have opted for offering instead a condensed, selectively detailed narrative account of key incidents illustrating these changes.

### **Mathematical modelling for biology students: *Yeast Growth* and *Digoxin* tasks**

A large part of the first session was spent on a very open task where the students were asked to estimate the density of a rabbit population based on the number of roadkill rabbits along a stretch of highway. Reflecting on the session, the lecturer felt that the students had not been able to work productively enough on this task, and he decided to make the second session more structured. The first 45 minutes of that session were spent first on a follow-up of a homework task given at the end of the previous session, followed by a brief lecture on “steady-state box models” and, related to this, a very short task on pollution in a lake. Then the focus shifted to modelling change, introducing a task concerning the growth of a yeast culture in a petri dish (*Yeast Growth*). Contrary to the first session, however, the task was broken into subtasks that the students worked on for 10-15 minutes each, with whole-class summaries in between.

For the **first *Yeast Growth* subtask**, the students were given a first part of a table of data, taken from an old research paper (Pearl, 1927), with three columns (time, amount of biomass, change in biomass) describing the growth of a yeast culture. The students were asked to: analyze the numerical data in the table; plot the data and analyze the graph; suggest a simple model based on a difference equation of the form  $\Delta p_n = k_1 p_n$ , where  $p_n$  is the size of the yeast biomass after  $n$  hours,

$\Delta p_n \stackrel{\text{def}}{=} p_{n+1} - p_n$  is the change of biomass between two measurements, and  $k_1$  is a positive constant; and, explain what their expectations would be regarding the predictive power of the model they constructed. The initial plan for the **second subtask** was to give students the second part of the table and ask them to: analyze this new data (noting the change in population per hour becomes smaller as the resources become more limited); plot the population against time, explore the shape of the graph and state what they would expect in the long run; and, calculate the expected value for “carrying capacity” in this case (noting that, based on the graph, the population appears to be approaching a limiting value, known in biology as “carrying capacity”). However, in the actual session (due to limitations of time) the students were instead given a non-linear model based on incorporating the carrying capacity: “We may estimate carrying capacity to be 665 (this value is not precise and your value may differ a bit). As the number  $665 - p_n$  gets smaller and smaller as  $p_n$  approaches 665, we may adjust our simple linear model replacing it with a nonlinear model  $\Delta p_n = k_2 p_n (665 - p_n)$  or alike, if you have chosen 664 or 666. Test a new model by plotting  $\Delta p_n$  against  $p_n (665 - p_n)$  to check whether a reasonable proportionality is observed. Then, estimate the proportionality constant  $k_2$ . What is your value?” For the **third and final subtask**, the students were asked to use the new model, with  $k_2 = 0.00082$ , to compute values and compare them with the actual data (“Compute twelve values of  $p_n$  using the formula and starting with the initial value  $p_0 = 9.6$ .”).

**Digoxin** was the first task of session 3 and also concerned the modelling of change, in this case the decay in the body of *Digoxin*, a drug used in the treatment of heart disease: (a) For an initial dosage of 0.5mg in the bloodstream, the table shows the amount of digoxin  $a_n$  remaining in the bloodstream of a particular patient after  $n$  days, together with the change  $\Delta a_n$  each day. Plot  $\Delta a_n$  versus  $a_n$  and explore the graph. Suggest a simple model based on a difference equation of the form  $\Delta a_n = k_3 a_n$ , where  $k_3$  is a positive constant. What is your choice of  $k_3$ ? (b) Now our objective is to consider the decay of digoxin in the blood stream to prescribe a dosage that keeps the concentration between acceptable levels so that it is both safe and effective. Design a simple linear model describing the following scenario: we prescribe a daily drug dosage of 0.1mg and know that half the digoxin remains in the system in the end of each dosage period. (c) Consider three different options where the initial one-time dose of medicine received by the patient is  $a_0 = 0.1\text{mg}$ ,  $0.2\text{mg}$  or  $0.3\text{mg}$ . What are your conclusions? What would you recommend if you were this patient’s GP?”

In *Yeast Growth*, the students were expected to find an approximately linear relation between the change and the amount of biomass, estimate the proportionality constant, and conclude that this rate of growth cannot continue indefinitely. With the additional data then provided, they were then expected to conclude that the growth decreases and the amount of biomass stabilizes at the carrying capacity of the petri dish, in this case 665. The students were then given a suggested non-linear model and were expected to check the validity of the model by finding the proportionality constant. Finally, they were expected to use the model to generate values that could be compared with the actual data. To do this, they needed to solve the equation  $\Delta p_n = p_{n+1} - p_n = k_2 p_n (665 - p_n)$  for  $p_{n+1}$ .

In *Digoxin*, in part (a) the students were expected to find a linear relationship between the change and the amount of digoxin remaining, and estimate the proportionality constant from the graph. In

part (b) they were expected to construct a model of the form  $a_{n+1} = 0.5a_n + 0.1$ , and then, in part (c), use this model with the different initial conditions to realize that, in all cases, an equilibrium of 0.2mg will eventually be reached, leading to a recommended initial dose of 0.2mg.

In what follows we highlight two critical incidents, one from *Yeast Growth* and one from *Digoxin*.

### ***Yeast Growth: Ritualized engagement with mathematical modelling***

The group ignores the first question in the subtask, about analyzing the data in the table. Instead, their initial efforts concern the practical details around graph construction and data plotting: choosing the right scale for the axes, and the like. They do all work in parallel, constructing one graph each, on millimetre grid paper, but they still work collaboratively, discussing their work at every turn. The routines they are using seem familiar to them, but there is no evidence of any reflection concerning the purpose of the activity they are engaging in. The task requests of them to plot the data, and since this is something they know how to do, they do it. We see this as suggestive of ritualized routine use. After about ten minutes, however, they seem confused about how to interpret the data in the table: what does  $\Delta p_n$  actually mean? They start discussing how to fit a straight line to the data, but the relative inefficiency of their working method – putting a lot of effort into the design of the graph and all drawing their own copy – means that, in the end, they do not have the time to do this, let alone find the proportionality constant. In the first whole-class follow-up, the students quickly agree that the problem concerns exponential growth, but none of the groups have succeeded in finding the constant  $k_1$ . It turns out that that they have constructed the wrong graph: plotting change against time, not against amount. We see this as evidence of ritualized routine use. Had the students engaged with the first question in the subtask, and reflected about the interpretation of the data, this mistake might have been avoided. Instead, the students resorted to a well-established routine for data plotting, using time as the independent variable. After this mistake has been clarified, the students are given additional data, and start discussing the validity of the model: is unlimited growth reasonable? The need for a revised model is established.

The work on the second subtask still mostly revolves around plotting the data, but now the group only constructs one plot. There is, however, some remaining confusion regarding the nature of the data: does  $\Delta p_n$  represent change or the actual amount? One of the students interprets the decrease in  $\Delta p_n$  as evidence of a population crash (a catastrophic decline in population), but the other group members point out that the decrease is in change, not actual amount: “But this is just the change, this is not the number of living cells.” Thus, when engaged in biological discourse, they are able to reason in a meaningful manner about the interpretation of the mathematical symbols. However, the formulation of the task creates additional confusion. It explicitly mentions a nonlinear model, but at the same time asks for proportionality. Finding proportionality between the more complexly presented quantities in this task seems unfamiliar to the students – and, since this is something not normally done in school, it probably is. Following the recent whole-class discussion, but contrary to what is written in the formulation of the subtask, the students do what they were expected to do in the first subtask, plotting the change  $\Delta p_n$  against  $p_n$  instead of against  $p_n(665 - p_n)$ . They thus struggle with fitting a straight line to the data, since their plot does not describe a linear relationship. In the whole-class follow-up, it turns out that, yet again, none of the groups have been able to compute the constant  $k_2$ , and, in the end, the lecturer provides the students with an estimated value

and asks them to use the model they now have to compute a number of values of  $p_n$  and to check the predictive value of the model. This turns out to be very confusing for our group, who are at a loss as to how to proceed: “I don’t have a clue. I feel so stupid.” The work they have been doing in both sessions so far has been geared towards constructing models, not validating them, leaving them unprepared for this way of using models. Furthermore, the routines they have been using have all concerned graph construction and plotting, and now they are supposed to compute values. After some initial confusion, they start doing computational work, but their nervous laughter and exclamations of surprise suggest that they have little faith in that what they are doing makes sense. Indeed, the different numbers they are juggling around suggest that they are making various computational errors. Also, they spend quite some time plotting the values that they obtain. We see this as indication that their routine use is still highly ritualized: they do certain things because they feel that it is expected of them, without having any clear rationale for why they are doing so.

Looking at the way the students engage with the *Yeast Growth* task, we conclude that what was intended by the lecturer as scaffolding – dividing the task into clearly delineated, smaller subtasks – in fact amounted to restricting student agency. We propose that this restricted agency is connected to ritualized routine use. The formulations of the subtasks state explicitly what the students are supposed to do, and even suggest what specific routines to invoke (plot the data; estimate the constant). This decreases the need for reflection about what routines to use and why, thus inviting ritualized routine use. This interpretation is further supported by how they struggle when asked to perform a different set of routines, using a given model for substantiation purposes, rather than constructing a model from given data. This indicates to us that they are not yet using the construction routines in an exploratory manner.

### ***Digoxin*: Towards exploratory routine use**

Although there seems to be a connection between the highly scaffolded format of the *Yeast Growth* task and students’ ritualized routine use, we do not intend this to be seen merely as a cautionary tale. Indeed, looking at the students’ work on the *Digoxin* task in session 3 four weeks later, there is evidence of progress towards making the discourse of growth model construction their own. The *Digoxin* task was presented as a whole, without the same amount of scaffolding as the *Yeast Growth* task. As in the second session, the group focuses their effort on constructing the graph, but has some problems interpreting the task because of unfamiliar terminology (e.g. difference equation). Contrary to *Yeast Growth*, in *Digoxin* time is not included as a column in the table of data, thus minimizing the risk of students resorting to the “plotting against time” routine. Still, one of the students suggests using  $n$  as the independent variable, in an attempt to fall back on the familiar routine. After some discussion, they decide not to resort to the earlier default option of using time as the independent variable, and, using the graph and the table, they manage to find the proportionality accurately. This might be interpreted as an indication of what Sfard (2008, p.251) calls “thoughtful imitation”. Having failed at constructing the requested plot in subtask 2 of *Yeast Growth*, and then being shown by the instructor what should have been done, they are now able to engage more fruitfully with this similar, but less complex, task. There is some additional confusion due to the formulation of the task (even though we are dealing with decay, the task still prescribes that  $k_3$  should be positive). Here we see signs that the group have still not made the discourse fully their own, but rather are emulating the discourse of the teacher. Rather than trusting their own

reasoning, they handle the problem in a manner familiar to many students – they adapt the answer to fit the teacher’s expectations: “Let’s just drop the minus sign.” As for parts (b) and (c) of the task, they (as well as the other two groups) run out of time before managing to make much headway. Still, it appears as if the ritualized routine use when working on the *Yeast Growth* task has supported the students’ pathway towards handling the *Digoxin* task in a more exploratory manner.

### **The path to exploration passes through ritual: Conclusions and ways forward**

In this paper, we examine a case (Y1 Biology students’ engagement with MM) of how new routines evolve, and particularly how discursants experience a step from ritualized to exploratory routines. The analysis points to the crucial role played by the teacher in facilitating this process. For instance, through the tasks presented to students, he influences their routine use, not only in the obvious way of suggesting *what* routines to use, but also *in what way* to engage with these routines. We have seen how a highly scaffolded task, which explicitly states what routines to invoke, might in fact invite ritualized routine use, whereas a less strongly scaffolded task might necessitate reflection about what routines to invoke and why, thus inviting a more exploratory engagement. At the same time, our analysis suggests that perhaps the ritualized routine use suggested by more scaffolded tasks might be a necessary step on the route towards exploratory routine use.

Per Sfard (2008), rituals are a ‘natural, mostly inevitable, stage in this development process’ (p. 245) and, recognizing this as so, recognizes fully the ‘inherently social nature of human thinking and learning’ (p. 245). Our claim here resonates with Sfard’s: the road to exploration must sometimes pass through ritual. There is an inherent circularity in this evolutionary process: a learner ‘could not possibly appreciate the value of the new routine until she was aware of its advantages; such appreciation, however, could only emerge from its use’ (p. 246). Furthermore, ‘the deed-enhancing mathematical explorations would sometimes involve new abstract objects, objects that can only emerge through implementation of this very routine’ (p. 247) and this holds for the evolution of an individual’s mathematical discourse as well as that of the field of mathematics as a whole. Discursive researchers – Sfard herself as well as Bakhtin – posit that thoughtful imitation can be a transitory phase in transforming ritual into exploration (where imitation is meant as a non-trivial process that involves evaluation, assimilation, reworking and re-accentuation). Indeed, in the students’ work on the *Digoxin* task, we have shown signs of such “thoughtful imitation”.

Deritualization results in consolidated discourse, namely a ‘well-developed network of interlacing, partially overlapping routines’ (p. 254). In this trajectory of growth there are at least two ‘basic conditions for effective mediation’: the principle of the continuity of discourse (‘introducing a new discourse by transforming an existing one’, p. 254); and, the principle of commognitive conflict (‘the situation in which different discursants are acting according to different metarules’ (p. 256) – a potential source of discourse change, and thus of learning). In this paper, we sample evidence mostly of the former principle. Our scrutiny of the entire dataset is now gearing towards the identification of evidence of the latter. Further, we anticipate that rolling out more MM activities to a new cohort of Y1 Biology students will lend corroborative power to the conjectures we explore here. It may also provide an opportunity for a more extended testing out of using the commognitive framework towards analyses that inform pedagogical practice.

*In this report we analyze one student's meta-representational competence as he engages in solving a quantum mechanics problem involving the linear algebra concepts of basis, eigenvectors, and eigenvalues. We provide detail on student A25, who serves as a paradigmatic example of a student's power and flexibility in thinking in and using different notation systems. This case study, which lays the groundwork for future analysis, provides evidence that meta-representational competence (MRC) is beneficial to a student's ability to make sense of and use concepts from linear algebra while solving quantum mechanics problems.*

*Keywords: Linear algebra, meta-representational competence, physics.*

## Introduction

The National Research Council's (2012) report, which charges the United States to improve its undergraduate Science, Technology, Engineering, and Mathematics (STEM) education, specifically recommends "interdisciplinary studies of cross-cutting concepts and cognitive processes" (p. 3) in undergraduate STEM courses. It further states that "gaps remain in the understanding of student learning in upper division courses" (p. 199), and that interdisciplinary studies "could help to increase the coherence of students' learning experience across disciplines ... and could facilitate an understanding of how to promote the transfer of knowledge from one setting to another" (p. 202). Our work contributes towards this need by investigating student understanding of linear algebra in quantum mechanics. Two research questions that guide us in this paper are: what are the various ways in which students reason about and symbolize concepts related to eigentheory in quantum physics, and in what ways might meta-representational competence impact how they make sense of linear algebra concepts in quantum mechanics?

In this paper, we focus on one student's reflection on symbolizing choices he makes while solving a quantum mechanics problem that involves linear algebra. In particular, we analyze his reasons for how and why he chooses a specific symbol system – either Dirac notation or matrix notation – for solving an expectation value problem. We align our analysis with the frameworks of meta-representational competence (diSessa, Hammer, Sherin, & Kolpakowski, 1991) and of structural features of algebraic quantum notations (Gire & Price, 2015). This case study, which lays the groundwork for future analysis, explores in what ways MRC might aid a student's ability to make sense of and use concepts from linear algebra while solving quantum mechanics problems.

## Background and theoretical framework

In this section, we give an overview of research conducted on student understanding of symbols and representations in mathematics and physics, as well as our theoretical orientation. We conclude with a brief introduction to eigentheory in Quantum Mechanics and Dirac notation.

## Student understanding of symbols and representations

The recognition of the importance of students' understanding of symbols used in mathematics and physics has grown over the past few decades. Arcavi (1994, 2005) coined this as “symbol sense,” which includes aspects such as being “friendly” with symbols, engineering symbolic expressions, choosing which aspects of a mathematical situation to symbolize, using symbolic manipulations flexibly, and sensing the different roles symbols can play in various contexts. Other research along this vein include: an explication of how different perspectives, such as cognitivist, situationist, and social-psychological, provide vastly different ways to understand how students make sense of and use inscriptions and symbols (Kaput, 1998); a study of how students mathematize their language from a Vygotskian perspective (Van Oers, 2002); and an exploration of how notational systems can serve as a mediational tool which triggers and sustains mathematical activity (Meira, 2002).

Research into students' competence with symbols and representations is not limited to primary and secondary school studies. For example, Hillel (2000) described three modes of description (abstract, algebraic, and geometric) of the basic objects and operations in linear algebra and pointed out that “the ability to understand how vectors and transformation in one mode are differently represented, either within the same mode, or across modes is essential in coping with linear algebra” (p. 199). Thomas and Stewart (2011) found that students struggle to coordinate the two mathematical processes captured in  $A\mathbf{x} = \lambda\mathbf{x}$ , where  $A$  is an  $n \times n$  matrix,  $\mathbf{x}$  is a vector in  $\mathbb{R}^n$ , and  $\lambda$  is a scalar, to make sense of equality as “yielding the same result.” This interpretation of the “equals” symbol is often novel and nontrivial for students (Harel, 2000). Harel also posits that the interpretation of “solution” in this setting, the set of all vectors  $\mathbf{x}$  that make the equation true, entails a new level of complexity than does solving equations such as  $c\mathbf{x} = d$ , with each taking values from the reals. Thomas and Stewart (2011) conjecture that this complexity may prevent students from progressing symbolically from  $A\mathbf{x} = \lambda\mathbf{x}$  to  $(A - \lambda I)\mathbf{x} = \mathbf{0}$ , which is particularly useful when solving for the eigenvalues and eigenvectors of a matrix  $A$ .

Research into students' understanding of quantum mechanics also investigates student use of symbols, such as how students make sense of and use a novel notation, called Dirac notation (explained in the subsequent section). Most closely related with this current study, Gire and Price (2015) looked at structural features of three different notation systems used in quantum mechanics (Dirac, matrix, and wave function) and how students' reasoning interacts with these features. The features identified by the authors are: (a) individuation, or “the degree to which important features are represented as separate and elemental” (p. 5); (b) externalization, or “the degree to which elements and features are externalized with markings included in the representation” (p. 7); (c) compactness; and (d) symbolic support for computation. Using problem-solving interviews with students as insight into these features, Gire and Price found that students readily used Dirac notation, and that the structural features vary across the different notations and among contexts.

Relatedly, diSessa et al. (1991) importantly discovered that students have a great deal of knowledge about what good representations are and are able to critique and refine them, which the authors defined as Meta-Representational Competence (MRC). diSessa and Sherin (2000) explained that MRC includes inventing and designing new representations, judging and comparing the quality of representations, understanding the general and specific functions of representations, and quickly learning to use and understand new representations. Furthermore, diSessa (2002, 2004) offered a

variety of critical resources students possess as part of their MRC for judging the strength of representations, such as compactness, parsimony, and conventionality. Two particular resources encompassed by MRC that we focus on in our data are “critique and compare the adequacy of representations and judge their suitability for various tasks,” and “understand the purposes of representations generally and in particular contexts and understand how representations do the work they do for us (diSessa, 2004, p. 94).

In this study, we align ourselves with the theory that representations are a sense-making tool, in that “the construction of representations on paper during problem solving mediates and organizes one's understanding of mathematical concepts” (Meira, 2002, p. 101). We couple this with a framing of MRC, specific to two particular notational systems, to investigate a student's reflection on his own notational preferences in quantum mechanics and what that may reveal about his understanding of change of basis and eigentheory in that context.

### **Brief introduction to eigentheory and Dirac notation in quantum mechanics**

In quantum mechanics, certain physical systems are modeled and made sense of using eigentheory. To a physical system we associate a Hilbert space (such as  $\mathbb{C}^2$ ), to every possible state of the physical system we associate a vector in the Hilbert space, and to every possible observable (i.e., measurable physical quantity) we associate a Hermitian operator (usually given in its matrix form). The only possible result of a measurement is an eigenvalue of the operator, and after the measurement the system will be found in the corresponding eigenstate.

Dirac notation, also known as bra-ket or just ket notation, is a commonly used notational system in quantum mechanics. A vector representing a possible state is symbolized with a ket, such as  $|\psi\rangle$ . Mathematically, kets behave like column vectors, such as  $|\psi\rangle \doteq \begin{bmatrix} a_1 \\ a_2 \end{bmatrix}$ ,  $a_1, a_2 \in \mathbb{C}$ , and are usually normalized. The complex conjugate transpose of a ket is called a *bra*, which behaves mathematically like a row vector, such as  $\langle\psi| \doteq [a_1^* \ a_2^*]$ . In addition, the eigenvalue equations for observables are central to many calculations. For example, the eigenvalue equations for  $S_x$  (the operator measuring the  $x$ -component of intrinsic angular momentum) of a spin- $1/2$  particle are  $S_x|\pm\rangle_x = \pm\frac{\hbar}{2}|\pm\rangle_x$ , where  $|+\rangle_x$  and  $|-\rangle_x$  form an orthonormal eigenbasis of  $S_x$ , and  $\pm\frac{\hbar}{2}$  are the two possible measurement results of the observable. When symbolized in terms of this eigenbasis, the matrix representation of  $S_x$  is  $\begin{bmatrix} \hbar/2 & 0 \\ 0 & -\hbar/2 \end{bmatrix}$ . One can also measure spin along other directions, such as  $z$ ; similarly, the eigenvalue equations are  $S_z|\pm\rangle = \pm\frac{\hbar}{2}|\pm\rangle$  (it is common for no subscript to be used for the  $z$ -direction). Thus, “within its own basis,” the matrix representation of  $S_z$  would be identical to the aforementioned diagonal one for  $S_x$ . It is often beneficial to change between bases; for example,  $|+\rangle_x = \frac{1}{\sqrt{2}}|+\rangle + \frac{1}{\sqrt{2}}|-\rangle$  and  $|-\rangle_x = \frac{1}{\sqrt{2}}|+\rangle - \frac{1}{\sqrt{2}}|-\rangle$ , so  $S_x$  in the “ $z$ -basis” is  $\begin{bmatrix} 0 & \hbar/2 \\ \hbar/2 & 0 \end{bmatrix}$ . Finally, inner products are involved in computing the expectation value of observable  $A$  for state  $\psi$ ,  $\langle\psi|A|\psi\rangle$ . These calculations require the bra and ket expansion to be in the same eigenbasis as the matrix representation of  $A$ . As such, expectation value problems present a rich setting for investigating students' symbolizing of eigentheory and change of basis in a physics context.

## Methods

Participants for this study were third year undergraduate physics majors at a large, public, research-intensive university in the Pacific Northwestern United States. They were drawn on a volunteer basis from a class of 35 students in a Spin and Quantum Measurements course; this course met for 7 class-hours per week for three weeks and involved many student-centered activities and discussions. The data for this report come from individual, semi-structured interviews (Bernard, 1988) conducted with 8 students at the end of the course. The goals of the interview questions were to learn how students reasoned about linear algebra concepts (e.g., normalization, basis, and especially eigentheory), how they reasoned with these concepts as they discussed quantum mechanics concepts and solved quantum mechanics problems, and how they symbolized their work.

To begin our analysis, we viewed the video and observed how students navigated the interview problems, while we kept in mind the overarching research questions regarding students' reasoning about and symbolizing eigentheory in quantum physics. We noticed some students were particularly fluent in how they talked about and worked with both matrix and Dirac notations. This compelled us to investigate the literature about student use of symbols and notations, the most relevant of which were discussed above. Our analysis draws most heavily on the work of diSessa and colleagues regarding MRC, and that of Gire and Price (2015) regarding structural features of algebraic quantum notations. In particular, we coded for instances of students mentioning structural features of the mathematics or students making explicit meta-commentary on the representations they chose to use. This allowed us to integrate our analysis of students' MRC with Gire and Price's types of structural features in a way novel to the physics and mathematics education fields.

In this report, we focus on one student: A25, a double major in physics and nuclear engineering who had completed two 10-week courses in linear algebra. The reason we chose to focus on participant A25 was his demonstrated ability to articulate his thinking. During the interview, he exhibited flexibility in reasoning about the concepts we were probing, and through his explanation a great deal of MRC seemed visible and analyzable.

## Results

In the beginning of the interview, student A25 volunteered that he sometimes explicitly chooses between doing calculations in matrix notation or in Dirac notation:

- I: So how do you feel like, using eigenvectors and eigenvalues, in spins has been similar to and different from how you've experienced those in other classes?
- A25: Uh, well, it's very similar because you're doing a lot of the same math ...the difference especially in physics, you're looking at kets. In, in at first I was kind of jarring, like to- to try to do the math in kets. But now, it's kinda- it's kinda easier, there's problems, there certain problems...where there's two ways to do them, they're kind of parallel, you can do it and you can expand the- the state in- in like as a- and expand them as kets in a different basis, or you can write that state as a- as a, as a vector, in that basis, and you can either do the matrix math for the like expectation values for example, you can do the matrix math or you can do the ket math, and sometimes it's, I'm finding that I, rather expand something in the ket.

From the transcript we see that A25 was aware multiple legitimate ways exist to solve the problem, seemingly understanding the various mathematical nuances and implications of his notational choices. His brief explanation highlights sentiments that are consistent with Arcavi's characteristics of symbol sense, such as being "friendly" with symbols and using them flexibly. Also, A25's self-reflection on his symbol usage adds a metacognitive aspect to the symbol sense characterization.

Because A25 volunteered expectation value problems as a situation in which he could use either notation, the interviewer had him work on such a problem right away, even though it was prepared to be at the end of the interview: "Consider the state  $|\psi\rangle = -\frac{4}{5}|+\rangle_x + i\frac{3}{5}|-\rangle_x$  in a spin-1/2 system. Calculate the expectation value for the measurement of  $S_x$ ." A25 immediately worked on the problem using Dirac notation, saying, "basically to find the expectation value... it's like denoted that way [writes  $\langle A \rangle$ ] but really what you're doing is you're taking the, the bra of the state, and then you're putting the operator [writes  $= \langle \psi | A | \psi \rangle$ ] in the middle of the inner product." He continued to explain his work as he proceeded, with statements such as "you know that  $S_x$  is just going to um, like apply it's eigenvalues to these, so, so like the eigenvalue corresponding to plus  $x$  is going to be  $+\hbar/2$  and the, the eigenvalue corresponding to  $-x$  is going to be  $-\hbar/2$ , so you end up with this equation that looks like this [points to the second half of line 2 in Figure 1a]. Note that his work in Figure 1a, which led him to the correct answer of  $7\hbar/50$ , involved the state's expansion and use of eigenvector equations for  $S_x$  in ket notation. He did not need to physically write the expansion of  $|\psi\rangle$  in the  $x$  basis kets, nor did he write out the eigenvector equations; however, his verbal description of his process relied on his understanding of both basis and the eigenvector relationships at play. Furthermore, this notation was novel to the students during this course; as such, A25 was clearly quick to use and understand this representation (a quality of MRC, diSessa & Sherin, 2000).

After discussing his work and solution, the interviewer asked: "Before you were telling about bra-ket versus matrix notation, you brought up an expectation value as an example of like, either or both, so can you, now that you had this problem, kinda revisit that?" A25 immediately solved the problem completely within matrix notation. He began by saying "if we're strictly in the plus and minus  $x$  basis" and wrote the column vector  $\begin{bmatrix} -\frac{4}{5} \\ i\frac{3}{5} \end{bmatrix}$  associated with the given ket  $|\psi\rangle$ . He then said, "and then the bra would be, um, minus 4 over 5 and then minus  $i$  3 over 5," writing out the row vector  $\begin{bmatrix} -\frac{4}{5} & -i\frac{3}{5} \end{bmatrix}$  as he spoke (see Line 1 in Figure 1b). He then said, "and so what you do is take this [copies the column vector]...and then you have the operator in the middle [writes an empty 2x2 matrix], and then you have the bra here [copies the row vector], and the operator in this case is  $S_x$  and we're in the  $x$  basis so it's just  $\hbar/2$  and  $-\hbar/2$ , 0, 0" [fills in the 2x2 matrix values] (see line 2 in Figure 1b). Impressively, he was able to fluidly move from his original ket notation to matrix notation, flawlessly making translations from the bras, kets, and operators in ket notation to row vectors, column vectors, and matrices in the matrix notation, further evidence of his strong MRC. Next, he explained his process for computing the matrix times the column vector before he did the computation, noting that "you're gonna get a vector." Again in line 3 he explained "then I do it again, so, um, this time you're gonna get a number out," meaning he anticipated that a row vector times a column vector would be a number. This shows two aspects of A25's strong understanding: first, a fluency in the calculations and computations within matrix notation similar to his ease in working in ket notation, including the ability to anticipate results before actually carrying out a computation (as in anticipating the result of

a matrix times a vector); and second, an ability to compare the two notations as well as an understanding that the two notations represent two ways to conceptualize the quantum physical calculation of expectation value. We see this as flexibly using symbolic manipulations (Arcavi, 1995) and an anticipation of results.

$\langle A \rangle = \langle \psi   A   \psi \rangle_{S_x}$ $= \left( \langle +   -\frac{4}{5} + \langle -   -\frac{3i}{5} \right) \left( -\frac{\hbar 4}{10}   + \right) + \left( -\frac{\hbar 3i}{10}   + \right)$ $\frac{\hbar 16}{50} - \frac{9\hbar}{50} = \left  \frac{7\hbar}{50} \right $ <p style="text-align: center;">(a)</p>	$\begin{pmatrix} -\frac{4}{5} \\ \frac{3i}{5} \end{pmatrix} \begin{pmatrix} -\frac{4}{5} & -\frac{3i}{5} \end{pmatrix}$ $\begin{pmatrix} \frac{\hbar}{2} & 0 \\ 0 & -\frac{\hbar}{2} \end{pmatrix} \begin{pmatrix} -\frac{4}{5} \\ \frac{3i}{5} \end{pmatrix}$ $\begin{pmatrix} -\frac{4}{5} & -\frac{3i}{5} \end{pmatrix} \begin{pmatrix} -\frac{\hbar 4}{10} \\ -\frac{\hbar 3i}{10} \end{pmatrix} = \frac{16\hbar}{50} - \frac{9\hbar}{50} = \left  \frac{7\hbar}{50} \right $ <p style="text-align: center;">(b)</p>
--	--

**Figure 1: A25's expectation value problem, in ket notation (a) and matrix notation (b)**

The interviewer then asked A25 to reflect on any preference between the two notations:

- A25: Uh...To be honest, I don't really, I don't really know why I prefer this [Figure 1a], I think it's just because, um, I like this notation. This specific notation [Figure 1a line 1] like this to me is like a cleaner way of writing that [Figure 1b line 2] because that- I mean this and that [touches Figure 1a line 1 and Figure 1b line 2 simultaneously] I feel like are your starting points, so you, you start here with this nice, like, looking thing [traces one finger under  $\langle \psi | A | \psi \rangle$ ], or you start here with this big array of numbers [puts two open hands around Figure 1b line 2], and I prefer this [Figure 1a line 1], even though you have to expand this into basically the same amount of information [Figure 1a line 2]. And also, the nice thing about, about this [Figure 1a line 1], is it—actually this is really why it's better—is because you can, you can say ok  $S_x$  works- acts directly on these kets, you can just get rid of the matrix altogether...

We see his use of “nice looking thing” and “big array of numbers” in comparison to one another are an example of compactness. He also compares Figure 1a line 1 and Figure 1b line 3 regarding the “amount” of information they convey, which involves reflection on the physical and mathematical content expressed in the compared notations. Finally, acting directly on the expansion in terms of the eigenstates of the operator allow him to forego the matrix calculation entirely, which speaks to A25's view of compactness, parsimony, and symbolic support for ket notation for this problem.

When asked about his notation preferences if the basis expansion of a given state vector and the operator “didn't match,” A25 recalled a problem from his last homework that was “actually easier...to do the matrix multiplication,” stating “you don't want to have to change these kets into different bases all over the place 'cause they're already all written in the same basis and you know what the operator is in that basis so you might as well just, do the matrix multiplication.” Here we see how strong A25's understanding is of the important linear algebra concepts of bases and change of bases, and how they relate to the matrix multiplication within expectation value quantum mechanics problems.

Furthermore, we see another aspect of his MRC, namely his understanding that different notations have different strengths and weaknesses, and his ability to leverage these strengths and weaknesses depending upon the particular quantum mechanics situation. This speaks to his awareness of symbolic support as well as using symbols flexibly. Finally, when asked if the concepts of basis or eigenvectors/eigenvalues come up more in one notation than the other, A25 stated, “certainly...every time you write down a ket you're, you're very conscious of what basis you're in. In this one [points to Figure 1b] it's just kinda implied...all this [is] in the same basis, so you're just, you're just writing out numbers, an arrays of numbers, but here [in Figure 1a] you're thinking ok, this is the  $S_x$  operator, this is the  $x$  plus ket, this is the  $x$  minus bra...so I think that you're definitely more aware of what basis you're in when you're using this, because you have to be.” This explanation is consistent with externalization (Gire & Price, 2015), in that the ket notation allows features of the problem, namely basis, to be externalized in a way that matrix notation did not provide for A25. This again attests to his understanding that notations have different strengths and weaknesses, an element of MRC that seems particularly important within quantum mechanics.

## Conclusion

In this report we analyzed one student's MRC and his understanding of change of basis and eigentheory as he solved an expectation value problem in quantum mechanics. This case study lays the groundwork for future analysis by being a paradigmatic example of a student's power and flexibility for thinking in and using different notation systems. In addition, it provides evidence that MRC seemed to positively impact this student's ability to make sense of and use concepts from linear algebra while solving quantum mechanics problems. In addition to analyzing the other students from our data set, future research includes investigating how classroom interactions may have influenced students regarding their notational choices, what aspects of MRC seem most important to success in using linear algebra when solving quantum mechanics problems, and what that implies regarding students' understanding of the mathematics and physics content involved.

# **The impact of the teacher's choices on students' learning: The case of Riemann integral in the first year of preparatory classes**

Inen Akrouti and Sassi Haddad

Virtual University of Tunis, ISEFC, Tunisia; [akroutiinen@yahoo.fr](mailto:akroutiinen@yahoo.fr)

University of Carthage, Tunisia; [haddad.sassi@icloud.com](mailto:haddad.sassi@icloud.com)

*Keywords: Riemann integral, action and formulation, and students' work.*

The teacher's practice plays a major role in the learning process and influences students' behavior. Moreover, teacher's choices affect students' self-perception and guide their work. Ghedamsi (2008) also established that mathematical activities of students depended on mathematical organization and teachers' designs. Robert and Rogalski (2002) also found that the mathematical activity of students such as calculus was affected by the way an exercise was organized. The work presented in this paper continues along the same lines and analyses the impact of the teacher's practice on students' learning of the Riemann integral concept in the first year of university.

## **Theoretical considerations and method**

Studying the impact of the teacher's choices on students' learning in the case of the Riemann integral in the first year of preparatory studies led me to considering a tool developed by Ghedamsi (2015) for analysing the teaching and learning process in a regular lesson at the first year of university. This tool includes two dimensions: teacher management and students' work. In this paper, the students' work consists of two levels. The first is based on action and formulation by which students formulate questions concerning specific knowledge; spontaneously express knowledge by changing semiotic setting, making examples, or linking several notions; and formulate a view on knowledge. The second level is based on validation when students indicate technical methods; perform their own validations; and discuss patterns proposed by peers or by the teacher.

Students participating in this study were in first-year preparatory classes at IPEIT (Preparatory institute for engineering school) in Tunisia. They had all obtained a mathematical baccalaureate. The method used in this research consists of three phases. In the first phase, we prepared a preliminary test for 25 students to be taken before studying the concept of Riemann integral, aimed at analysing and understanding their background. This test proposed tasks found at the end of the secondary school. Then, we observed some regular lessons (18 students were present in these lessons). In preparatory classes, the courses are organized into lectures and tutorials that each lasts two hours. Tutorials represent an opportunity to apply the definitions and theorems taught previously during lectures. We developed a detailed analysis of the two tutorials on the Riemann integral. Observation of these lessons allowed us to see the interaction between the teacher and the students. Finally, we prepared a second test after the teaching of this concept; 15 students participated in this test. The questions; which were presented in the second test primarily involved problems concerning Riemann integral concepts.

## Results

Based on an analysis done using the tool of Ghedamsi (2015) cited above, we can conclude that the Riemann integral is used in the calculation of limits of some sequences that refer to Riemann sum. The teacher had the intention to invite debates and give students the opportunity to express themselves about the knowledge at play but the contract he established limited the students' opportunity for interactions, thus hindering the students in developing their analytical skills and improving their critical thinking.

The intervention of the teacher seemed to point out the importance of the integral as a tool for calculations.

The classroom observation allows us to see more clearly the impact of the teacher's choices on the quality of students' learning. We can make the following observations:

- Only the teacher offers the solutions and the different techniques required. The mathematical activity of the students is reduced to simple applications of the procedures proposed by the teacher. Thus, the practical implementations of knowledge are limited to the technical level.
- The organization and structure of the tutorial sequences conducted by the teacher do not encourage student's autonomous work. The types of tasks proposed do not invite reflective thought that mobilizes the supposed acquired knowledge, but rather invite algorithmic work. Students' work is limited to a few memory techniques to solve most often stereotyped questions.
- The majority of tasks can be treated in the algebraic register. There is no recourse to other registries such as graphic register.

## Conclusion

The analysis of the data collected suggest that is possible to develop teaching sequences for the Riemann Integral concept which take into consideration students' autonomous work and encourage them to create their own self-perception. Hence, a Didactic Engineering can be elaborated in order to surmount the problems identified in this analysis and to propose another alternative improving the teaching-learning process of the Riemann Integral concept.

## Transition and fragmentation

### Transition problems from school to university in mathematics

Tall (2008) presented a theoretical model which he called the three worlds of mathematics to describe the transition problem from school to university in mathematics. He postulates the difference within the existence of a so-called axiomatic-formal world at university and a separated conceptual-embodied respectively proceptual-symbolic world at school. This model helps to account for some difficulties of many students' transition to university in mathematics, resulting in missing common threads and not knowing connections. Consequently, one of the ideas of our visualization project is the attempt of following “known” conceptual-embodied and proceptual-symbolic truths – where possible through development in time – into the axiomatic-formal world in order to see their genetic connection, the desired and meaningful so-called “golden thread”.

**Figure 1: The three worlds of mathematics (Tall, 2008)**

### Interactive mathematical maps

The concept of “mathematical maps” was introduced by Brandl (2008) as a didactical tool in the form of a virtual tree or net, which shows interrelation between topics (horizontal dimension) as well as the development of a subject matter – starting from an initial problem – in time (vertical dimension). A structural model can be seen in Figure 2. This concept offers several opportunities to foster joined-up thinking and will allow the student to follow the development of an initial problem in time. For example, the visualization in three dimensions allows for an ideal transparency of the interdependencies or the connection of single nodes which additionally offer contents from other platforms by link (Brandl, 2008, pp. 106–109). Another concept, especially for the horizontal orientation, is made by Acevedo (2014) with the “OpenMathMap” which organizes different subjects of

**Figure 2: Structural visualisation of the development of an initial problem in time**

mathematics by size according to the amount of published papers and by closeness representing the relationship of two subjects (pp. 6–7).

## Design-based research methodology

The new teaching format for students in mathematics and mathematics teacher education at the University of Passau will be developed via design-based research methodology. Interactive mathematical maps will be used as a didactical tool to show the interrelationship between different mathematical topics as well as between mathematics at school and at university level, connected by the development of the subject matter in time.

The current status of our work-in-progress is ongoing conceptualization of the teaching format and development of the code for the interactive mathematical maps. Figure 3 shows a screenshot of a first attempt (via JavaScript) to produce content knots which are connected to related content knots by lines in an automatically evolving 3D-visualisation. In order to link the interactive mathematical maps with contents, ILIAS will be used as an e-learning tool (which is the common tool for online courses at the University of Passau). Reasons for the use of e-learning formats are given by constructivism, improvement of quality of teaching, motivation of students and preparation for lifelong learning (Kreidl, 2011, p. 15).

**Figure 3: Screenshot of the work-in-progress ICT-tool**

The final product will be implemented in mathematics teacher education for (higher) secondary schools (i.e. Gymnasium) to serve for a de-fragmentation process of mathematical contents learned at school and at university. We intend to improve teaching by using e-learning – particularly blended learning – in connection with these interactive mathematical maps. Furthermore, there will be special courses connecting courses in mathematics (first: geometry) and didactic of mathematics (first: didactics of geometry) using the presented ICT-tool in mathematics teacher education.

# In what ways do lecturers receive and use feedback from large first year mathematics classes?

Anthony Cronin and Maria Meehan

University College Dublin, Ireland, School of Mathematics and Statistics;

[anthony.cronin@ucd.ie](mailto:anthony.cronin@ucd.ie); [maria.meehan@ucd.ie](mailto:maria.meehan@ucd.ie)

*Keywords: Feedback, large class instruction, mathematics support.*

We report on a study aimed at examining the ways in which lecturers of large mathematics classes receive and use feedback from their students, with a particular focus on how they use feedback received via the Maths Support Centre (MSC). Three separate interviews with each of thirteen lecturing staff over the course of one semester were conducted. We discuss the ways in which these lecturers receive and use ten modes of feedback from their students and examine where the feedback received by the MSC sits in the general context of this feedback. We conclude that MSC feedback is one of the most valuable to lecturers and state the reasons given for such a claim.

## Research questions

- How do lecturers receive and use feedback from large first year mathematics classes?
- In what ways, if any, do lecturers find the feedback provided by the MSC on students' visits, useful? How do they use it?
- Where does MSC feedback sit placed in the general context of formative feedback?

## Methodology

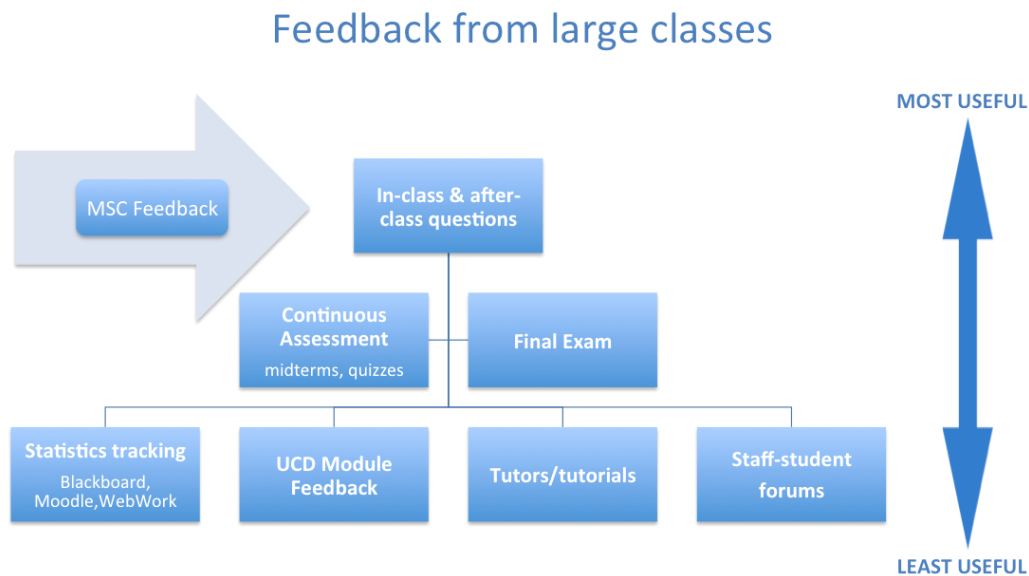

Thirteen lecturers from a research-intensive university in Ireland volunteered to participate in this study. Lecturing experience varied from two to seventeen years and two lecturers were teaching their particular module for the first time. The modules' sizes ranged from 66 to 550 students in subjects including Calculus, Statistics, Linear Algebra, Computer Science and Applied Mathematics. Twelve of the 13 classes we examined were mathematics/statistics modules taught to non-mathematicians, in particular the cohorts consisted of agriculture, computer science, engineering, business, science and applied mathematics students.

Thirty-seven semi-structured interviews consisting of three interviews with each lecturer were conducted in semester one of 2014/15 (interview one was not conducted with one lecturer as there was no MSC feedback to discuss at that time and the final interview for one module was conducted with both co-lecturers of that module simultaneously). This feedback, on the content of each students' visit, is generated by the attending MSC tutor and electronically uploaded (anonymously) in real time via the MSC software system where it can be viewed at any time by the lecturer (Cronin & Meehan, 2015). Interview 1 was an exploratory interview conducted in week 4 of the teaching term where lecturers were asked to review the MSC feedback collected from their module to see if they could identify the topic and mathematical difficulty being reported. The mathematical content of this feedback is discussed in the PhD of Nuala Curley and more information is available in Curley & Meehan (2016). Interview 2 was conducted in week 8 where lecturers were asked to comment on the various ways in which they receive feedback from their students and to comment on the usefulness of each. The third interview, conducted three weeks after teaching had finished, invited lecturers to

summarise their experiences with the MSC feedback mechanism throughout the term and discuss the value associated with each of the feedback forms they received from students throughout the module. Interviews were analysed using thematic analysis (Braun & Clarke, 2006).

## Findings

Lecturers reported nine ways in which they receive feedback from large classes. These are: in-class questions, after-class questions, continuous assessment (e.g. quizzes), midterms and final exams, module tutors, online activity (Blackboard, Moodle, WebWork etc), the institution's Module Feedback system, staff-student fora and MSC feedback (Figure 1). Lecturers identify MSC feedback as one of the most valuable forms of feedback from a large mathematics class. In particular it is *specific, detailed* and lecturers reported that it aligns closest to in-class questions as it is *content based, formative* and in *real time*. It is *mathematically accurate* being the MSC tutor's interpretation of the student's difficulty. Lecturers stated that it is *reassuring* and *confirms what is been asked* at (and after) lectures. Many instructors stated that reviewing MSC feedback has had impact on their practice including; revising lecture content, writing midterms and revision classes, omitting material and delaying (or bringing forward) continuous assessment components.

**Figure 1: Usefulness of feedback forms to lecturers**

## **Measuring gains in knowledge within algebra instruction at community colleges: Assessing the efficacy of the Algebra Pre-Calculus Readiness (APCR) test**

*Keywords: Mathematics, postsecondary instruction, algebra, classroom-based research.*

The measurement of student learning for a federally funded project, EHR #831882, (Watkins, Duranczyk, Mesa, Ström, & Kohli, 2016) will be used to investigate the connection between instructional practices and student learning in algebra courses at six community colleges in three states of the United States. The poster focused on measurement issues faced in identifying students' learning gains in the pilot data.

Although we like to think that teaching causes learning, the truth is that such connection has not been established empirically (Hiebert & Grouws, 2006). As a first attempt to establish this connection, we investigate the extent to which there is a correlation between what occurs in the classroom and what students learn in a one semester course. Whereas there is some research documenting how individual and institutional characteristics (e.g., prior achievement, family support, financial aid, learning support and tutoring centers, and ratios of full- to part-time instructors) factor into failure rates and other performance measures (Bradburn, 2002; Feldman, 1993), there is little information about the fundamental work of teachers in the classroom, and the interaction that occur between instructors, students, and the mathematical content. The Quality of Mathematics Instruction (QMI), a video analysis tool used in P-12 settings (Learning Mathematics for Teaching Project, 2011), was adopted to measure faculty and student interaction at the community college. Research in K-12 and four-year colleges documents that the association between quality of instruction and student outcomes can be moderated by instructors' knowledge and attitudes towards innovative teaching practices, knowledge of algebra for teaching, and their beliefs about mathematics, its curriculum, and students' learning. The association is also moderated by students' attitudes, beliefs, and confidence about mathematics, their patterns of adaptive learning orientations, and the perceptions they have about their instructors' behaviors in the classroom and by the personal characteristics of instructors and students. The Algebra and Precalculus Concepts Readiness (APCR) test (Madison, Carlson, Oehrtman, & Tallman, 2015) was used to measure student learning.

The first phase, presented here, is the pilot testing of the APCR instrument to measure learning gains. The algebra instruction captured for analysis focused on three key algebra topics: linear, rational, and exponential equations. The APCR tests these topics and was administered in the second week of the semester before the topics were introduced and then two weeks before the end of the semester after the three focal topics had been taught.

The analysis based on the APCR data from 6 community college faculty and 161 students in beginning, intermediate and college level algebra courses lead to questions about the suitability of

the instrument for our work. Examining the descriptive statistics, item analysis, and reliability measures from classical test theory (Thorndike & Thorndike-Christ, 2010) revealed problematic point-biserial correlation and poor item discrimination. Ten item on the test fell well below acceptable levels (point-biserial correlations below 0.20).

Reliability measure gives information about the extent to which the scores produced by such measurement procedures are consistent and reproducible. The APCR had a Cronbach's alpha of 0.676 for the pretest data and 0.784 for the posttest data. The test-retest coefficient reliability coefficient (Crocker & Algina, 1986) for the APCR data was equal to 0.597, another low indicator.

Conversations were held with the authors of the APCR and the instrument is undergoing major revisions to be re-tested in April 2017. Working collaboratively with the APCR team on the newly revised version hopefully will generate an instrument that performs at a higher standard for greater reliability and discrimination. The poster presentation provided an excellent venue to review the testing results and confer with colleagues in possible next steps which were taken in March, 2017.

*Keywords: design for action, convergence of sequences, complex numbers.*

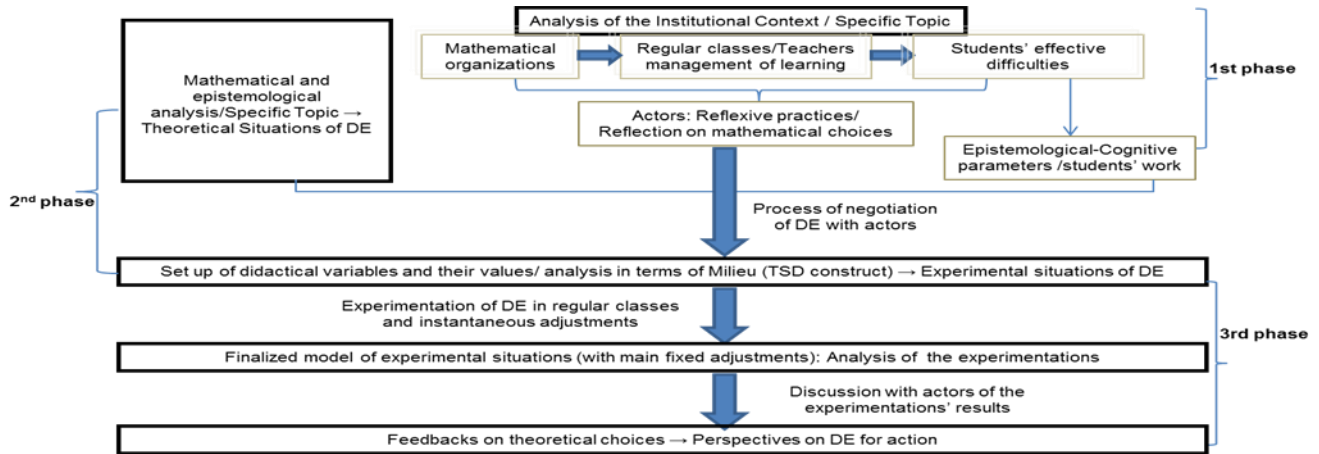

### **The dilemma of the didactical design**

This poster reports on a large study dealing with the issue related to the implementation of didactical designs in the institutional context. This presentation is an attempt to specify some methodological principles for planning didactical design that could be used as a resource by the institution. We build on the Theory of Didactic Situations (TDS) construct of didactical engineering (DE) (González-Martín, Bloch, Durand-Guerrier, & Maschietto, 2014) to first address the issue concerning the use of DE both as a fundamental research tool and as a tool ready to be used for action (Artigue, 2016). We then briefly introduce preliminary results of two studies which empirically investigate this issue in the case of the teaching and learning of convergence of sequences and complex numbers. DE is a research methodology usually associated to TDS, that “*consists of designing, regulating and making controlled observations of experimental situations where certain mathematical knowledge appears as the optimal way to address a mathematical problem.*” (González-Martín et al., 2014, p.120). Three global steps shape the design of DEs as a research tool: 1) Epistemological and cognitive analyses which deal with the mathematical specificities of the targeted knowledge and their impact on the cognitive process of learning; the results are supposed to define the didactical variables – namely the parameters that influence students’ work, which should be taken into account to design the projected situations; 2) The phase related to the *a priori analysis* leads to the identification of the values of the didactical variables that are used to build the experimental situations; these situations are thus analyzed in terms of milieu – “*namely the set of material objects, knowledge available, and interactions with others*” (p. 119) including the interactions with the teacher; 3) The results of the *a posteriori analysis* (by comparing with the *a priori analysis*) permit to assess the relevance of the experimental situations and the validity of the theoretical model. The aim of the final analyses is to give feedback on the theoretical frame and its efficiency; the research does not actually consider the conditions for the implementation of the DE in the institutional context. In the last decades, research dealing with didactical design has increased its focus on the issue concerning the “*application role when didactical design is seen as a way for organizing the relationships between research and practice or, in other words, for developing educational actions inspired by research and incorporating its results.*” (Artigue, 2008, p. 9). Yet, this issue is still pending and the didactical actions are not defined neither theorized. In the following section, we describe the methodological tool that we have elaborated to plan efficient DEs for action.

### **The methodological tool for empirical investigation: the cases of the convergence of sequences and complex numbers**

The fundamental principle of the two DEs we have constructed is based on two essential ideas: 1) the necessity to negotiate and to plan such DEs with the actors of the educational system (teachers,

trainers, policy makers, etc.); 2) the experimentation should provide some flexibility to the teacher in order to make adjustments depending on the class context. We rely on the research version of the design methodology (DE) and go forward to provide three empirical phases used as a method to plan and to experiment DE for action (Figure 1).

**Figure 1: A methodological tool - DE for action**

Its use with more than one mathematical topic gives more legitimacy to our methodological tool. In spite of their mathematical differences, these two studies revealed the cornerstone role of the institutional mathematical organization in the teaching and learning processes and how to manage it for more efficiency, for instance: 1) regarding the convergence of sequences: improve the neglected role of approximation and numbers; 2) regarding complex numbers: rehabilitate the operational level of these numbers by emphasizing the role of their several representations. For both cases, the results of the implementation of the first step corroborate the necessity of such adjustments.

<sup>2</sup>CASTeL and School of Mathematical Sciences, Dublin City University, Ireland.

*We have investigated the difficulties encountered by undergraduate physics students when studying differential equations, and how these are best addressed. We developed a survey to identify these difficulties that was administered to a pilot cohort of students. The results were used to develop an instructional intervention, informed by APOS Theory, that seeks to address the difficulties uncovered by the survey. The intervention comprised fourteen one-hour tutorials. The tutorials were trialled for the next iteration of the module in question and the survey was given to the students who had completed the module. Applying a design based research approach, the results from these surveys were used to improve the intervention which is being evaluated using a combination of pre- and post-testing and interviews with students in the coming academic year. The interviews will be analyzed using the APOS framework, which acts as the overall conceptual framework for this research*

*Keywords: Mathematics education, physics education, APOS theory.*

## Research questions

1. What is the precise nature of the difficulties encountered by physics students in using (identifying the need for/setting up/solving) differential equations?
2. How may these be addressed?

These questions lead to the following specific aims for the project which are: (1) identify the areas students struggle with and excel in during their study of differential equations; (2) develop a set of tutorials based on the data from the survey; and (3) evaluate and improve the tutorials that were developed.

## Conceptual framework

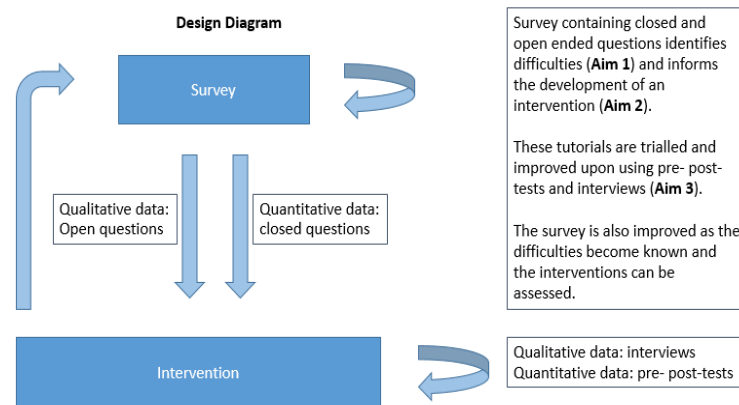

In 1984, Dubinsky began developing a theory of how mathematical concepts may be learned. This eventually became known as APOS Theory and is a constantly evolving model developed and refined through application in research and instructional design. As described by Arnon et al.

APOS Theory focuses on models of what might be going on in the mind of an individual when he or she is trying to learn a mathematical concept and uses these models to design instructional materials and/or evaluate student successes and failures in dealing with mathematical problem situations. (2014, p.1)

As explained by Dubinsky (1991), APOS Theory describes the mental structures and mechanisms an individual constructs and applies when trying to understand a problem in mathematics. This project primarily uses APOS Theory as an analytical, evaluative tool. The language of APOS Theory is used to describe the level of understanding displayed by students during their interviews.

## Methodology

Achieving the aims outlined in the opening sections will require the combination of both qualitative and quantitative data. The design diagram below shows how the project is structured.

**Figure 1: Design diagram**

The first aim, identifying difficulties, gave rise to both quantitative and qualitative data, gathered using a survey. The Diagnostic Survey was divided into four separate sections assessing different aspects of the students' learning in differential equations: prior mathematical learning; conceptual issues in the study of differential equations; transfer issues; and modelling. To evaluate the tutorials a series of pre- and post-tests and interviews are being used to assess the effectiveness of the intervention. These results feed into the evaluation and improvement of the tutorials.

## Results

The results obtained from the Diagnostic Survey show that of the four sections contained in the survey, students struggle most with conceptual understanding, indicating (in terms of APOS Theory) shortcomings in their ability to encapsulate Actions and Processes as Objects. Comparing to the results of the students who completed the tutorials, we saw a dramatic increase in their conceptual understanding, in addition to improvements in the three other sections of the survey. The pre- and post-test data were also used to amend the tutorials for the second research cycle.

# A practical study of a design of university mathematics courses for humanities and social sciences students

Mitsuru Kawazoe<sup>1</sup> and Masahiko Okamoto<sup>2</sup>

<sup>1</sup>Osaka Prefecture University, Japan; [kawazoe@las.osakafu-u.ac.jp](mailto:kawazoe@las.osakafu-u.ac.jp)

<sup>2</sup>Osaka Prefecture University, Japan; [okamoto@hs.osakafu-u.ac.jp](mailto:okamoto@hs.osakafu-u.ac.jp)

*Keywords: Mathematical literacy, decontextualization, structuralization.*

## Problems in university mathematics education: in the Japanese context

It is becoming more important for all students regardless of educational level to acquire the ability to use mathematics in a variety of contexts, especially in real world situations (Niss & Jablonka, 2014). From this viewpoint, mathematics education for non-mathematics students at university is becoming an important issue; however, it is still under-investigated (Artigue, 2016). In Japan, it is an emergent issue that we have no successful mathematics curriculum designed especially for humanities and social sciences students. Many of those students have math anxiety and difficulty in doing and learning mathematics, and do not understand how mathematics is used in the real world. Hence mathematics education for those students is a challenging issue.

## Design principles of mathematics courses for humanities and social sciences students

Continuing empirical studies from our previous research (Kawazoe et al., 2013), we have developed the following design principles of mathematics courses for humanities and social sciences students: (1) Design lessons according to mathematical modelling processes; (2) Choose topics and contexts by considering which mathematical knowledge students will encounter in real life and in which situations they will encounter it; (3) Present problems in different contexts associated to the same mathematical knowledge; (4) Connect different areas of mathematical knowledge by using different *mathematizations* of the same problem or mutually related contexts; (5) Explain mathematical concepts and operations in both mathematical language and everyday language; (6) Engage students in group activities rather than individual activities; (7) Design worksheets based on hypothetical cognitive processes of students' understanding and use them as tools for formative assessment.

The above principles originate in the four perspectives of learning environments developed in learning science (Bransford, 2000, Chapter 6). The first four principles (1)-(4) also originate in discussions on mathematical literacy (cf. Sfard, 2014) and mathematical modelling (cf. Kaiser, 2014). Especially, (3)-(4) are aimed at making students' knowledge *decontextualized* and *structuralized* respectively, because it is often claimed that teaching mathematics in real world contexts makes students' knowledge restricted to the learning contexts (cf. Sfard, 2014). In a previous study (Kawazoe et al., 2013), we showed that mathematics courses designed according to the above principles are successful in reducing students' math anxiety and motivating them to learn math. However, their effectiveness for decontextualization and structuralization was not examined. To examine this effectiveness is the research objective of the present study.

## Evaluation of decontextualization and structuralization

To evaluate the effectiveness of our design principles for decontextualization and structuralization, we analyzed the performance of examinations and the free descriptions in the self-report questionnaires conducted at the end of each semester in *Basic Math I* and *Basic Math II*, which are successive one-semester mathematics courses for humanities and social sciences students designed according to the above principles. The data were collected in the academic year 2012, when 300 and 244 students took the courses respectively, with students divided into four classes.

The examinations mainly consisted of problems in real world contexts, but the contexts were different from the learning contexts. The mean scores of the exams of Basic Math I & II were 85.9 and 75.4 out of 100, respectively. The results of the exams indicated that students were able to use mathematics in contexts different from those they had studied before, suggesting that they acquired abilities to use mathematics in real world situations.

In the qualitative analysis of the self-report questionnaire, we found evidence of structuralization of mathematical knowledge only in a small number of descriptions. Here we show an example:

Student: In this course, it seemed that mathematical formulae, which were just isolated pieces of knowledge, had been changing into meaningful ones. I felt that the knowledge base of mathematics that I had became harder and stronger; in that respect, it was a meaningful time.

In sum, the design principles can be considered to be effective for decontextualization, however, the structuralization is still a challenge. More study is needed for structuralization.

*Keywords:* Approximation, decimals, convergence, irrationals, praxeology.

## Introduction and research problem

Progressing from the study of rational numbers to irrational and real numbers can prove challenging for students. The way irrationals and reals are introduced in secondary school textbooks does not seem to promote the development of ideas that allow students to adequately grasp convergence or density in their tertiary studies (González-Martín, Giraldo, & Souto, 2013). Difficulties with irrational numbers also have been reported in university students (Kidron, 2016). However, we believe that certain activities, such as studying the approximation of irrational numbers by sequences of rationals, could help students grasp, informally, the ideas behind the formal  $\varepsilon - N$  definition of convergence at university. We have not found works in the literature that address the connections between the teaching of these two notions. For this reason, we seek to investigate how they are presented in textbooks and study the connections that are made (or the lack thereof). Our research is guided by the following questions: 1) how do pre-university textbooks organise and present the notions of limit and of approximation of a real number by a sequence of rationals?; and 2) how do textbook tasks help students develop connections between the two notions?

## Theoretical framework

Our research uses tools from Chevallard's (1999) anthropological theory of the didactic (ATD). ATD acknowledges that every human activity generates a *praxeology* or *praxeological organisation* identified by the quadruplet  $[T/\tau/\theta/\Theta]$ , where  $T$  is a type of task,  $\tau$  is a technique used to complete this task,  $\theta$  is a discourse (technology) that justifies and explains the technique, and  $\Theta$  is a theory that includes and justifies the given discourse. The couple  $[T/\tau]$  is the practical block (or *praxis*) and  $[\theta/\Theta]$  is the theoretical block (or *logos*). We focus on the *institutional relationship* with the notions of real number (and activities of approximation) and limit, as reflected by the textbooks.

## Methodology

Our study uses the tools provided by ATD to analyse the textbooks and recommendations of the Tunisian Ministry of Education's official programme. Teachers in Tunisia use a different textbook for each school level; all are published by the Ministry. We chose two textbooks for our analysis: the first is used in the ninth level of the basic cycle (14-15 year-old students) and the second is used in the third level of secondary school (17-18 year-old students), which is the penultimate year before university. In examining the first textbook, we analysed the content related to real numbers, paying special attention to tasks concerning the approximation of an irrational by a sequence of decimals. We focused on whether such tasks implicitly use a theoretical block based on the notion of limit. For

the second textbook, we looked at two chapters, “Sequences of Real Numbers” and “Limits of Sequences of Real Numbers”, to determine whether those chapters develop *praxeologies* that use (implicitly or explicitly) any of the elements present in the first textbook.

## Main results and discussion

We identified three types of tasks in the first textbook (geometrical, algebraic and numerical). These are:  $T_{pr}$  (prove that a given figure is a square and calculate its area),  $T_{cl}$  (calculate the square of rational numbers using a calculator) and  $T_{bn}$  (determine lower and upper bounds of a square root). All these tasks seek to introduce routine techniques, such as the algorithm for bounding  $\sqrt{2}$  between two decimals. The institutional relationship with this notion is characterised by an institutional void with regard to the theoretical block, which includes two technologies:  $\theta_{pr}$  (the diagonals of a square are perpendicular and isometric, and they intersect at the same midpoint) and  $\theta_{cl}$  ( $0 < a < b < c \Rightarrow \sqrt{a} < \sqrt{b} < \sqrt{c}$ ), both of which are derived from Euclidian Geometry and elementary algebra.

This institutional void may have an impact later on in the third level of secondary school, during the introduction of limits and convergence. Concerning the second textbook, it proposes three types of tasks (calculus, geometrical and numerical) focusing on bounding square roots and  $\pi$ . With respect to calculus, the textbook presents an activity related to the Fixed Point theorem and, essentially, the application of the algorithm of Newton’s method. This task, “determine upper and lower bounds for  $\sqrt{37}$ ,” proposes a technique that breaks the exercise down into three sub-tasks:  $T_{res}$  (solving of an equation),  $T_{rep}$  (representation of a sequence), and  $T_{bnd}$  (bounding of  $\sqrt{37}$ ). The technology is implicit in this activity because the students have not yet studied the Fixed Point theorem. The two geometrical activities concern the approximation of  $\pi$  using Archimedes’ polygonal approach. Finally, the numerical activity asks students to determine the rank  $n$  of a recurrent sequence  $(x_n)$  that verifies  $|\sqrt{a} - x_n| \leq 10^{-p}$ . Our results indicate that all tasks presented in the two textbooks are routine. Both textbooks insist on the approximation of square roots and  $\pi$ . This could affect students’ learning of real numbers when the latter are formally introduced in university. We also found that both textbooks contain praxeological organisations that insist on the practical block and that implicitly present the theoretical block. Furthermore, the activities are presented using algorithms, without discussing the useful application of the knowledge gained.

# Unconventional didactical choices for the benefit of course instruction: A glimpse into a lecturer's decision-making

Igor' Kontorovich

The University of Auckland, New Zealand; [i.kontorovich@auckland.ac.nz](mailto:i.kontorovich@auckland.ac.nz)

*Keywords: Decision making, root concept, university lecturers.*

The Mathematics community often does not agree on definitions of concepts and on the meanings of their symbols. For example, in the topic of complex numbers some Israeli textbooks propose that  $\sqrt{a + bi}$  represents a single value, while others maintain that two values are indicated (in the field of real numbers there seems to be a consensus around  $\sqrt{a^2} = |a|$ ). When introducing such a debatable concept to students, teachers usually choose a particular approach among mathematically acceptable alternatives, and stick with it. In this poster, I am focusing on the question “what does a university lecturer take into account when making such a choice?”.

I embark on the question with Schoenfeld's (2011) theory of decision making. According to this theory, in-the-moment decisions that teachers make in classroom situations can be modelled with three explanatory constructs: *resources* (consisting of teacher's knowledge inventory, social and material resources), *goals* that are set to be achieved (either consciously or unconsciously) and *orientations* (including beliefs, values and preferences). Schoenfeld suggests that the model can be further used for structuring developmental trajectories and promoting teacher expertise.

For an experienced university lecturer, the choices among mathematical alternatives are hardly “in-the-moment”, in the sense of spontaneity. Instead, I argue that these choices are systematically reproduced by some decision-making mechanisms that a lecturer brings to bear in a variety of teaching situations. Indeed, after the choice has been shared with the students (i.e. in one ‘moment’ during a course), for the benefit of course coherence, a lecturer is expected to maintain the choice through consequential inferences. Accordingly, making sense of these choices might illuminate some aspects of one's epistemological perspectives on *mathematics didactique*. I showcase this idea with the case of Elza and direct interested readers to Kontorovich (2016), where additional illustrations were analyzed with a different theoretical lens.

Elza is a highly-reputed lecturer in a technological university in Israel, who holds a master's degree in mathematics and a PhD in mathematics education. Elza has more than thirty years of teaching experience, and she specializes in teaching linear algebra. These facts suggest that her knowledge inventory is rich and solid. Elza's specialization determines a significant component of her instructional setting; typically, students in Elza's university learn a single course in linear algebra, which is a pre-requisite for many other courses. In this way, didactical choices that Elza makes shape students' knowledge development in her course and in the courses taught by her colleagues.

An interview with Elza revealed a variety of interesting didactical choices that she makes, some of which are barely conventional. To name a few, it turned out that in the field of real and complex numbers, she defines  $\sqrt[n]{a}$  to be multi-valued - all solutions to the equation  $x^n = a$ . Elza explained that this is her way to connect roots of numbers, roots of equations and roots of polynomials, all of which are discussed in her course. When a singular positive root is required, she uses the symbol ‘ $+\sqrt{\phantom{x}}$ ’. For example, when computing a module, Elza writes  $|a + bi| = +\sqrt{a^2 + b^2}$ . With regard to

an apparent conflict between her multi-valued approach to real roots and a single-valued approach which is used in the calculus courses, she indicated that, “[I]n calculus they have functions and [here] we are dealing with values in linear algebra. Every branch of mathematics works with its own premises”. It also turned out that Elza avoids using complex numbers, the Cartesian form of which contains roots (e.g.,  $\sqrt{3} + i$ ) because “they look like a single thing but are actually two numbers”. Lastly, Elza explained that she has just a few hours to cover the foundations of complex numbers, and then she does not go into “nuanced details”. She would have expanded the scope of the course if it was intended for pre-service teachers only.

Several observations can be made based on Elza’s choices. On the one hand, a multi-valued approach to the root concept and radical symbol entails consistency between several topics in her linear algebra course. For instance, real roots of a number are preserved and possibly extended with non-real numbers in the field of complex numbers. Then, for Elza’s students a transition from the field of reals to complex numbers is mostly a matter of concept extension rather than redefinition. On the other hand, Elza’s choices create ‘monsters’ (cf. Lakatos, 1976), such as inconsistency with mathematics studied in other courses, ambiguity and unconventional symbols. When monsters are necessary for linear-algebra purposes, Elza conducts “monster-adjustment” to familiar categories (e.g., ‘ $+\sqrt{\phantom{x}}$ ’), otherwise, the “monster-barring” method is used to expel the problematics from the course scope (e.g.,  $\sqrt{9} + i$ ).

In terms of Schoenfeld (2011), Elza’s didactical choices can be explained with a complicated intertwining of resources, goals and orientations. A limited resource of time promotes setting pragmatic goals, the scope of which does not go beyond a particular course. In some cases, the choices lead to unconventional consequences and artificial limitations of the course content. In other cases, the choices seem to benefit the course instruction through tightening the connections between the topics. Evidently, the choices align with Elza’s orientations about the nature of mathematics (e.g., different branches can have incompatible approaches to the same concept) and students’ academic needs (e.g., roots should be taught differently to pre-service teachers). In this way, the choices seem to reflect an ‘equilibrium’ that Elza achieved in her didactical decision-making.

Are Elza’s choices really beneficial for her students? Are students aware of non-chosen alternatives? How unique is Elza’s decision-making? I invite the community of university mathematics education to join me in pursuing these interesting questions through further research.

*Keywords: Taylor approximation, dialectic tool-object, syntax, semantics.*

## Introduction and research problem

Our motivation for engaging in this research project relies on recurrent students' difficulties in the appropriation of the concept of Taylor approximation. Despite the richness of this concept as a tool in many fields of application (e.g calculation of limits, local study of a function and the study of physical phenomena), for what we know, there is little research on this topic in mathematics education. Beyond the lack of comprehension of the notion of convergence for Taylor series (Martin, 2013), we hypothesize that the articulation between syntax and semantics is not clear for students, creating a fuzzy area that prevents them from being able to apply Taylor approximation as a tool in applied mathematics. In this paper, we summarize the main results of our epistemological investigation and the first element of a didactic study of teaching material on this topic, in order to identify paths for improving its teaching and learning.

## Theoretical framework

Throughout our epistemological and didactic investigations, we refer to the dialectics between semantics (graphic interpretation, dynamic interpretation and numerical approximation) and syntax (the different formulations of the Taylor approximation), including their articulation with the *tool-object dialectic* (Douady, 1991) and the *registers of semiotic representations* (Duval, 2006). (this approach is developed and used in Kouki, to appear).

## Epistemological investigation

We outline the evolution of the mathematical object known as “Taylor approximation” through a historical and epistemological investigation. Our study emphasizes the co-existence of different types of techniques mainly with geometric, algebraic and dynamic origins that contributed to the emergence and development of this object (Kouki, Belhaj Amor, & Hachaïchi, 2016).

Our research identifies key moments in the development of infinitesimal calculus and local approximations which led to the calculus as it is taught nowadays. In particular, the works of Roberval, Euler, Fermat, Leibniz, Newton, until Taylor and Weierstrass are significant in the development of Taylor approximations.

## Didactic investigation

Based on our epistemological investigation, we have conducted a didactic study of the Tunisian curriculum, textbooks and course handouts on Taylor approximation. The Tunisian curriculum, three handwritten courses and four handbooks were analyzed. Through this study, we confront the various dimensions of this concept revealed by the epistemological investigation with those that are present in teaching materials.

This study supports the hypothesis that there are gaps in the teaching of Taylor approximation. In particular, some of them are due to insufficiencies of graphical representations and numerical approximation, corresponding to a deficit of semantic work, the emphasis being put on the syntax.

## Conclusion

The epistemological and didactical investigations summarized in this paper are part of a larger project aiming at developing propositions for enhancing the teaching and learning of Taylor approximation. This enhancement can help to foster an appropriation of the concept allowing to use it in the various applications undergraduate students could meet in further studies, in particular in applied mathematics.

# The flipped learning model in teaching abstract algebra

Tore Alexander Forbregd and Magdalini Lada

Norwegian University of Science and Technology, Norway; [magdalini.lada@ntnu.no](mailto:magdalini.lada@ntnu.no)

*Keywords: College mathematics, algebra, flipped learning.*

## Introduction

Flipped learning is a relatively new model of instruction currently growing both in popularity and success. In a flipped classroom the elements of typical lecture and homework are reversed. Students are introduced to new material at home, mostly through videos prepared by the teacher, while the classroom time is reserved for solving problems, group work, discussions and other activities that help students control, deepen and extend their understanding and knowledge.

The board of the Flipped Learning Network has defined Flipped Learning as

... a pedagogical approach in which direct instruction moves from the group learning space to the individual learning space, and the resulting group space is transformed into a dynamic, interactive learning environment where the educator guides students as they apply concepts and engage creatively in the subject matter (FLN, 2014)

The number of college and university instructors who practice Flipped Learning has increased over the past two years and has expanded in all subject areas. Research in Flipped Learning has shown positive impact both on students' achievement and engagement (Overmeyer, 2015).

## Methodology

During our study we collected data from the students, the lecturer and the class. We conducted a semi-structured interview with the lecturer in the middle of the semester at the university campus and had several informal discussions through Skype and emails at the end and after the end of the semester. The students were given evaluation forms to fill out both in the middle and in the end of the semester, the latter being enriched with open questions where the students were asked to describe their experience with the flipped course. In addition, we visited the class and observed how in-class time was spent and how the students interacted with each other and with the teacher.

The researchers in this study have direct experience with the course material and the way it was previously taught, as they attended it as students. The second author has also taught the course.

## The structure of the course

The lecturer-informant recorded videos, using a mobile phone, while writing down on a blank A4 paper what he would otherwise write on the blackboard in a traditional lecture. The videos were then made available to the students through the course's webpage. The problem sheets, which are, except from small changes, the same sheets that were used in previous years, were also put out on the web. The students were instructed to watch the videos at home and work with the problems when they met in class.

Ten to twelve students on average were normally attending the class, which is an expected number for this course. In a relaxed and informal environment, students formed groups freely and worked with the problems, while the lecturer was walking around answering questions and guiding them

through the problems. The groups were let to progress through the problem sheets at their own tempo and already in the middle of the semester different groups were working with different parts of the curriculum. Thirteen students took the exam at the end of the semester.

## Findings

Even on this primitive form the Flipped Learning Model turned out to be beneficial to the learning outcome of the students. The students spent more time working on computational problems, concretizing difficult abstract concepts such as for example the radical of rings and modules, projective and injective modules, exact sequences, resolutions and dimensions, clarifying in this way the connection between theory and concrete problems on special classes of algebras.

Some more advantages pointed out by the lecturer include, among others:

- Differentiated guidance according to the level of each student
- Students forced to work more actively with the course, during the whole semester
- Better balance between learning the theory and working on problem solving

What the students found more beneficial was, among others,

- Watching the videos at their pace. Pause it, think, watch it again.
- Thorough explanations from the lecturer
- Working the problems in groups, learning from each other.

There was a slight improvement on the average of the grades, compare to the previous years the lecturer-informant had taught the course, though the class is too small to make any safe conclusions.

# Mathematics and medicine: The socioepistemological roots of *variation*

Angélica Moreno-Durazo<sup>1</sup> and Ricardo Cantoral<sup>2</sup>

<sup>1</sup>Center for Research and Advanced Studies of the National Polytechnic Institute (Cinvestav-IPN), Mexico; [gamoreno@cinvestav.mx](mailto:gamoreno@cinvestav.mx)

<sup>2</sup>Cinvestav-IPN, Mexico; [rcantor@cinvestav.mx](mailto:rcantor@cinvestav.mx)

*Keywords: Variation, prediction, shortened variation, medicine.*

## Introduction

Variational Thinking and Language (PyLV) is a line of investigation developed at Cinvestav, whose objective is the study of forms in which individuals deal with change mediated by their culture for predictive purposes. It is a form of methodology for the elaboration of teaching proposals based on the investigation. PyLV is founded in the Socioepistemological Theory of Educational Mathematics (Cantoral, 2013), where mathematical knowledge is recognized as part of human wisdom, that is to say, of the articulation of knowledge of diverse nature (scientific, technical and popular knowledge); this requires a *decentration of the mathematical object*, which leads to the analysis of the practices that accompany the construction of the object; we call this process the social construction of mathematical knowledge.

This way, we assume change and variation as a substantial part of the scientific and technical work areas and the daily experiences of individuals and social groups in non-school situations. In these areas, the prediction is socially constructed by the development of normed practices that we call social practices (Cantoral et al., 2006; Tuyub & Cantoral, 2012). Derived from the projects developed, strategies and fundamental variational arguments were characterized for prediction. Therefore, a series of teaching sequences was developed for the improvement of education both in and outside school; moreover, the results of PyLV have had an impact in the educational reforms in Mexico. The prediction of the phenomena that have been investigated under PyLV involve mathematical models whose resolution needs the convergence of the Taylor series in a given domain (deterministic nature) as the future state, the value of  $f(x+h)$ , depends only on the starting values of  $h$ ,  $f(x)$ ,  $f'(x)$ , etc. through the expression:  $f(x+h) = f(x) + \frac{f'(x)h}{1!} + \frac{f''(x)h^2}{2!} + \dots$

Now, based on this research, the goal of our project is to characterize the nature of the predictions made by mathematizing phenomena not governed by the analytical study of a formal mathematical expression, as described above. We have taken interest in the analysis of the ways in which change and variation are used in the estimates made by doctors in their professional practice. In this scenario, the dynamics of the system are not deterministic but rather chaotic, since the conclusion of the trajectories that patients follow after a certain treatment may be divergent - sensitive to initial conditions. The development of these objectives requires an in-depth study of the dynamics followed in cardiac functioning, through the analysis of original works and medical specialized books (Castellano, Et al., 2004; Harvey, 1994), the analysis of the medical practices, and its articulation in previous investigations in the PyLV.

## First findings

We found that medical practice requires more than assuming that something changes, it is necessary to recognize how fast the change is in order to diagnose patients. Our first finding was that, in the case of the interpretation of electrocardiograms, the recognition of how, how much and why the heart rhythm behavior changes, is done by the practices of comparison and seriation; reported as variational strategies in the study of optimization problems and calculation of the derivative of a function (Caballero, 2012). Hence, we claim that the basic practices of the study of change and variation are shared by medical professionals and students or teachers in Calculus courses. In addition, we identified the use of different orders of variation in the location of different types of blockages in electrical conduction in the heart. For example, in the figure, we can see that type II Mobitz I block requires the identification that the time invested in the PR segment has a progressive extension and a progressive decrease in that increase (Lobelo et al., 2001, p. 2126); that is, it is necessary to analyze the change in the change in the PR segment between beats.

## Final thoughts

The next phase in the research corresponds to an ethnographic study where the theoretical construction on the study of variation is contrasted with the practices developed by medical professionals. It is important to mention that the future intention of our research is the impact on the educational system, particularly in higher education. Concerning this, the characterization of basic forms of reasoning is fundamental for theoretical proposals of sociocultural nature, especially for the socioepistemology that bases the redesign of the school mathematical discourse on the assumption that knowledge is constructed based on practices.

# Developing conceptual knowledge by using ICT on mathematics lessons

Mária Slavičková

Comenius University in Bratislava, Faculty of Mathematics, Physics and Informatics,  
Bratislava, Slovakia; [slavickova@fmph.uniba.sk](mailto:slavickova@fmph.uniba.sk)

*Keywords: course evaluation, diagnostic teaching, active learning, Bloom taxonomy*

## Theoretical background and research question

According to our previous study (Slavičková, 2013) we state the following research questions: “*How to design a course of calculus to help students obtain higher level of understanding of the topic? How to implement an ICT into this process? Will be using of and ICT helpful?*” To find the answers we used mathematical and didactical software in the lectures for presentation of mathematical terms, definitions, properties etc. We also created an e-learning course in the Learning Management System Moodle (LMS). We used this LMS as a primary communication channel between the teacher and the students, we published there all the materials from the lectures, as well as some extra tasks for the students (solving of these tasks was not obligatory).

Activities implemented into the educational process were based mostly on constructivism. Our goal was prepare such activities which help students obtain cognitive dimension “Apply” according to the RBT (Revised Bloom Taxonomy) according to Anderson & Krathwohl (2001) and Web-link Bloom taxonomy (2015). Most of the activities were supported by ICT and we used mostly the works of Jonassen (2000) and Kadijevic (2006).

The important notes concerning the learning/teaching process according to RBT:

- Before you can understand a concept, you must remember it.
- To apply a concept you must first understand it.
- In order to evaluate a process, you must have analyzed it.
- To create an accurate conclusion, you must have completed a thorough evaluation.

## Intervention

We used Derive, Graphic Calculus, MS Excel and GeoGebra software in the lessons to demonstrate mathematical properties of functions, sequences, limits of a sequence, a function etc. We prepared small environments for observing, modeling and exploring.

## Organization of the teaching - learning process

**Lectures:** lectures were lead by us; we used the computer and data projector to project mathematics formulas, theorems, some parts of the proofs and the most important – to demonstrate the relationships between the theory and the praxis.

**Seminars:** The main work was on the students. We use data projector and computer to project the tasks, questions, some interesting schemas etc. Students can use computers to solve them or to help themselves to get deeper view into the problem. The materials from the activities were uploaded to the LMS Moodle, so students can use them at home preparation.

The Table 1 shows the focus on the lessons and test – on the lessons we focused every field marked with “x”. On the test were only task highlighted by red.

	Remember	Understand	Apply	Analyze	Evaluate	Create
<b>Factual</b>	x	x	x	x		
<b>Conceptual</b>	x	x	x	x	x	
<b>Procedural</b>	x	x	x	x	x	
<b>Metacognitive</b>						

**Table 1: Cognitive and the knowledge dimension according to RBT**

## Results

The implementation ICT and using different type of software we obtained the good results. The most important results from the observations in our group are:

- students take an active part of the teaching/learning process,
- students wanted to discuss the interesting mathematical topics on the lessons,
- students started modelling of the situation without a teacher's command,
- students interest in the topics was higher than in the other group (taught by our colleagues – it could be also by the personality of the teacher, but previous years showed us, that in our and colleagues group were similar result),
- some students started studying more outside the classroom so they can follow the topics without the troubles (we avoided the troubles which still resist in colleague group, like if we change the task a little, students do not know what to do)

## Discussion

The preliminary results shows that there is potential in using ICT on calculus lessons to obtain deeper knowledge and better understanding of the topic. Using different kind of software shows students different approaches to the different issues. The next step in our research will be to enlarge the sample and to prepare more technology oriented materials for the research.

# Heuristic strategies in mathematics teacher education

Peter Stender

University of Hamburg, Germany; [Peter.Stender@uni-hamburg.de](mailto:Peter.Stender@uni-hamburg.de)

*Keywords: Heuristic strategies, teacher education, tutorial in mathematics.*

Here a tutorial is described that focuses on mathematical methods that implicitly appear in the mathematics shown in a Linear Algebra lecture, and makes these methods explicit for the students. Interviews with students at the end of their first semester show some effects.

## Theoretical framework

Mathematics, as all sciences, comprises content (e.g. definitions, theorems, finished proofs, ...), but also mathematical methods.

Pólya (1945) underlined the importance of the mathematical methods in the subtitle of “How to solve it -A new aspect of mathematical methods”. We use a broad approach of heuristic strategies as a central part of the mathematical methods shown in the following list:

- *Organise your material / understand the problem:* change the representation of the situation if useful, try out systematically, (Pólya, 1945) use simulations with or without computers, discretize situations,
- *Use the working memory effectively:* combine complex items to supersigns, which represent the concept of ‘chunks’ (Miller, 1956), use symmetry, break down your problem into sub-problems,
- *Think big:* do not think inside dispensable borders, generalise the situation (Pólya, 1945),
- *Use what you know:* use analogies from other problems, trace back new problems to familiar ones, combine partial solutions to get a global solution, use algorithms where possible (Pólya, 1945),
- *Functional aspects:* analyse special cases or borderline cases (Pólya, 1945), in order to optimise you have to vary the input quantity,
- *Organise the work:* work backwards and forwards, keep your approach – change your approach – both at the right moment (Pólya, 1945).

Other mathematical methods are e.g. “proof strategies” which make extensive use of formal language such as mathematical induction, proof by contradiction, proof by exhaustion, the invariance principle or others. Another kind of methods are the use of mathematical language e.g. in depth reading mathematical texts or writing down mathematical proofs correctly.

## Tutorial example

In the tutorial we made mathematical methods implicitly used in the lecture explicit. We also used these methods giving additional explanations and reflected this use afterwards in the tutorial. The concept of quotient spaces in linear Algebra was established on rings. One example given in the lecture was  $\mathbb{Z}/m\mathbb{Z}$ . In the tutorial we reduced this example to the case  $\mathbb{Z}/4\mathbb{Z}$  and gave additional representations of this concept, some of them shown in figure 1.

**Figure 1:  $\mathbb{Z}/4\mathbb{Z}$  in several representations.**

Here the four residue classes are shown in several representations, together with the way of calculating on that structure. The similarity of the calculation on a common clock was stressed as a possible link to school mathematics and further explanations were given. Calculating on the equivalence class that are supersigns from the heuristic point of view was difficult for the students and the similarity to calculating with fractions that are equivalence classes and supersigns as well was discussed. Furthermore, moving between representations was stressed as a method to deepen the understanding of the content or to find a way to solve a problem.

## Students' feedback

At the end of the first semester we interviewed five students who participated in the tutorial over the whole semester. The interviews were transcribed and analyzed using quantum content analysis.

All students remembered well the connection to school mathematics based on mathematical methods that appear in university and school as well. The students also emphasized that visualized explanations with less formal language were very helpful. These explanations using “a change of representation” were remembered well.

The input related to the heuristic strategies was remembered by the students. The concept of “heuristic strategy” was remembered and the students could describe examples given in the tutorial, connecting the examples to the appropriate heuristic strategy.

## Conclusions and looking ahead

Supporting students by stressing mathematical methods, and particularly by stressing heuristic strategies, seems to have a positive impact, but is not realized easily. For this we will continue with this tutorial in the third and fourth semester bringing in heuristic strategies wherever possible.

# Supporting university freshmen – an intervention to increase strategic knowledge

Thomas Stenzel

University of Duisburg-Essen, Germany; [thomas.stenzel@uni-due.de](mailto:thomas.stenzel@uni-due.de)

*Keywords: Secondary-tertiary transition, problem solving, metacognition.*

## Rationale

At school, we actually only had exercises where we could calculate with numbers and formulas. Now, it was really abstract what we had to do. [...] We didn't really know: Where should we begin? How does this work? (Aylin, mathematics student, 1<sup>st</sup> semester)

The quote above shows that some strategic knowledge is needed for problem solving at university level. Additionally, a necessary condition to deal with those problems is to be familiar with the related content of the lecture. The literature provides a lot of successful strategies both for problem solving (Pólya, 1945) and learning (Ramsden, 2003), but it is also known for a long time that it is insufficient for improving students' skills to provide them with a list of those strategies (Schoenfeld, 1985). Therefore, I am cyclically developing an intervention program to help students act strategically.

## Research interest

This study aims to test how an intervention may influence the students' problem solving and learning processes and how the induced changes affect their success in university mathematics.

## Design of the intervention

The intervention is embedded into the classic problem sessions of a first-semester lecture of B.Sc. students and future secondary school teachers (weekly sessions, 14×90 minutes). So far, there have been two pilot studies accompanying the Calculus 1 lecture. The classic purpose of the problem session, to discuss homework already submitted by the students, has not been altered. However the main objective of the intervention is to foster students' self-regulation by engaging them in metacognitive processes. Therefore the students' actions are systematically reflected. This is done in three steps:

- 1) From a constructivist point of view it is of great importance that students develop their own strategies rather than using a checklist. Therefore students work on a few problems every week at home and write down used strategies.
- 2) To support the individual development of strategies, different approaches are collectively reflected. In particular, those students who were unable to find a solution themselves get the opportunity to explicate their strategies and can benefit from the experience of their more successful fellow students. A lot of different ideas, especially those that might not lead to a solution, are reviewed and evaluated. Lastly, at least one solution chosen by the students is completely expanded upon. That way, students who were not able to solve the problem by themselves can have a deep insight into that process.
- 3) During a reflection phase at the end of each class, the utilized strategies are discussed once again and those that could be helpful for more than one particular problem are written down on a "strategy board". Usually those strategies resemble those postulated by Pólya (1945) and Schoenfeld (1985).

For instance, when dealing with sequences or series, one firstly needs to clarify affiliated concepts like convergence and divergence. Then different strategies might be helpful, for example to generate different representations (a sketch, tables, etc.) or look at special cases. Considering related problems might also be a helpful strategy.

## Evaluation

The program evolves cyclically based on student interviews, observation of solving processes, evaluation sheets and systematically documented experiences. At the end of the first pilot phase, the students were asked how often they use certain strategies (4-level likert scale). It showed that those displayed on the strategy board had significantly higher values than others. Especially self-reflection and clarification of concepts are frequently used. Nevertheless a qualitative analysis of videographed solving processes showed that the students still had a lot of difficulties to clarify concepts on their own. Therefore, in the following phases, we tried to increase their activity level concerning this task. We also integrated one unknown problem per week so we could experience a whole problem solving process together.

In the second pilot phase, the design needed to be altered since the composition of students was very different. In summer most of the students have already failed at least one exam in Calculus 1.-In addition to possible lower mathematical skills, their academic self-concept might be affected. We observed a much lower activity level than in winter, so we had to add introductory tasks to encourage the students to actively take part in the sessions. This could also apply to single weaker students that in winter would be unnoticed.

## Perspective

As the order of courses was changed in the academic structure, the main study, starting April 2016 will take place in the context of Linear Algebra. The necessary adaption of the concept will be an interesting task. For the first time, we will also be able to treat a statistically relevant number of students, so in addition to ongoing qualitative research, quantitative evaluation will be possible.

# Teaching mathematics to non-mathematicians: The case of media technology undergraduate students

Evangelia Triantafyllou and Olga Timcenko

Aalborg University, Department of Architecture Design and Media Technology, Copenhagen, Denmark; [evt@create.aau.dk](mailto:evt@create.aau.dk), [ot@create.aau.dk](mailto:ot@create.aau.dk)

*Over the past years, a number of engineering programs have arisen that transcend the division between technical, scientific and art-related disciplines. Media Technology at Aalborg University, Denmark is such an engineering program. In relation to mathematics education, this new development has changed the way mathematics is applied and taught in these disciplines. This paper discusses a doctoral dissertation that investigated and assessed interventions to increase student motivation and engagement in mathematics among Media Technology students. The results of this dissertation have been used to assess and improve practice in Media Technology and they may inspire interventions in other trans-disciplinary engineering programs.*

**Keywords:** Mathematics education, non-mathematicians, media technology.

## Introduction

This poster presents the main contributions of a doctoral dissertation, which aimed at investigating mathematics teaching and learning for Media Technology students (Triantafyllou, 2016). Media Technology at Aalborg University is a program that focuses on research and development, which combines technology and arts and looks at the technology behind areas such as advanced computer graphics, games, electronic music, animations, interactive art and entertainment, to name a few. This dissertation investigated and assessed interventions to increase student motivation and engagement in mathematics among Media Technology students. These interventions focused on two directions: a) teaching methods and b) ICT-based learning environments. As far as teaching methods are concerned, this project has applied the flipped instruction model (or the flipped classroom). Regarding ICT-based learning environments, a game engine (Unity) has been introduced as a domain for mathematical learning. Since many studies have indicated that the attitude towards mathematics influence the achievement of learning goals, Media Technology students' attitudes towards mathematics were also investigated.

This dissertation employed several mixed method studies. Observations and a survey study were employed for gathering information on student attitudes towards mathematics, student approaches on mathematical problem solving and student competences (Triantafyllou, Misfeldt, & Timcenko, 2016). In regard to research on ICT-based learning environments, a use case study was conducted exploring development of student mathematical knowledge and effect on student motivation, when mathematics is being taught by programming in a game engine (Triantafyllou, Misfeldt, & Timcenko, in press). As far as the flipped classroom approach is concerned, two use case studies and a statistics course redesign and assessment took place (Triantafyllou & Timcenko, 2014; Triantafyllou & Timcenko, 2015; Triantafyllou, Timcenko, & Busk Kofoed, 2015).

This dissertation has provided insights in student attitudes towards mathematics in Media Technology. It was found that these students often lack mathematics confidence and they consider

mathematics a difficult subject that they do not like but value. The adoption of the flipped classroom instructional model revealed that students perceive learning with online resources on their own pace as contributing to their understanding and they reported that they could adjust the learning process to their own needs. This dissertation has also proposed the use of a model of reflection for designing activities that promote experience-based learning in flipped classrooms. As far as ICT-based learning environments are concerned, the study on the use of a game engine for mathematics learning provided insights on how students apply knowledge from a mathematical model to implement a physical model. This study shed light on students' misconceptions and difficulties but also on their opportunities to challenge their understanding. This dissertation contributed to the discussion of the theoretical foundation of the flipped classroom and discussed aspects of ICT-based mathematics learning for Media Technology. These results can be furthermore used to assess and improve practice in Media Technology and other trans-disciplinary engineering programs.

# Getting into university: From foundation to first year engineering

Stephanie Treffert-Thomas

Loughborough University, UK; [s.thomas@lboro.ac.uk](mailto:s.thomas@lboro.ac.uk)

*Keywords: Engineering mathematics, foundation degree, transition, motivation, activity theory.*

I present a longitudinal study with engineering students taking a (science) foundation course (FC). The aim of the research is to explore the reasons why students decided to take the FC going beyond the rather obvious reason, “because they did not have the necessary qualification for direct entry”. Secondly, I explore students’ mathematical progression into first year engineering. Many UK universities have addressed students’ lack of mathematical preparedness (e.g. Hawkes & Savage, 2000) by establishing drop-in centres or one-to-one support with specialist tutors; some offer a one-year FC as an alternative route into higher education, primarily aimed at students wanting to study a STEM subject. While the FC is often seen as aimed at students who ‘missed’ (perhaps narrowly) their target grades at A-level, it became clear to me that students came from varied backgrounds and qualifications, work experience, and included students with health problems that impacted on their progression. Thus I became interested in the motivational factors that led students to take a FC and the mathematical progression that students make. The FC at my institution consists of a number of modules, of which mathematics and physics are compulsory for engineering students, the largest group in the cohort. Topics studied include indices, logarithms, differentiation, integration, matrices and complex numbers. I pose two research questions: (1) Why did students take the FC? (2) What is students’ mathematical experience when moving into first year engineering study?

## Methodological considerations

So far two cohorts of students have been interviewed at the end of their FC; one cohort has been re-invited for interview at the end of the first year of their engineering course. Ten to eleven students were interviewed each year. I, therefore, pursue a case study methodology within an interpretive paradigm. The study is longitudinal in design with further interviews planned over the next years. Data analysis is qualitative with a focus on the reasons that students gave for taking the FC. I take an activity theory perspective since identifying reasons means identifying the motive of activity, hence closely linked to characterising activity (Leontiev, 1981). Action-goals can be used to discuss students’ mathematical goals, and actions taken in pursuit of these, a focus in future analyses. Research was with students I had taught. Interview questions were communicated in advance and followed a fixed order. All interviews were recorded and subsequently transcribed and analysed.

## Research findings and conclusions

I report on two separate findings. First, in interviews in 2015, students were asked why they had chosen a FC. Students replied in a variety of ways, giving one or more reasons. As part of analyses, these were categorised using an open coding procedure and summarised in Figure 1. Most students cited career advancement and gaining entry to their engineering course when A-level grades had not been good enough. Some did so strategically, i.e. there was no need to re-apply through UCAS, the UK body overseeing university applications, since passing the FC guaranteed entry. Also represented were six students who took the view that it gave them an advantage over other students when entering the first year of engineering. Thus students’ motives were nuanced, going beyond

Reasons given	Freq
Change of career or advance current career	6
A-level grades were not good enough	6
Wrong subject taken at A-level/change of mind	3
Interest/passion for the subject	5
Foundation year gives an advantage in year 1	6
Foundation year as orientation course	1

**Figure 1: Reasons for choosing the FC**

“because they did not have the necessary qualification for direct entry”. Most (not all) students reported having difficulties with the mathematics content of the FC, and some students said they were overwhelmed by them. Second, I report on three of seven students who were re-invited for interview and asked to compare current experience with how they recalled their experience during the FC. The second and third column (Figure 2) relate to students’ experience and achievement during the FC (as recalled by the student one year later); the last column to students' current experience. Clearly there are some differences in how students perceived their transition.

	Foundation Year	FC Maths grade	Year 1 Engineering degree
<b>Student A2-14</b>	Maths is not strong		Student feels settled
	GCSE is highest qualification	40 to 60%	Student achieved 40 to 50% (Maths)
	Student is <u>not</u> confident		Degree programme is <u>not</u> heavily reliant on mathematics
<b>Student A2-12</b>	Maths is not strong		Student is struggling
	BTEC is highest qualification	60 to 70%	Student has re-sit exams in mathematics
	Student is <u>not</u> confident		Degree programme is heavily reliant on mathematics
<b>Student A2-15</b>	Maths is strong		Student does not feel settled
	IB is highest qualification	80 to 90%	Student achieved 40 to 50% (Maths)
	Student is confident		Degree programme is heavily reliant on mathematics

**Figure 2: Results from three interviews**

The FC is well established at my university and students are thought successful in progressing into their engineering courses. Students cited different motivational factors for taking a FC. While some were not surprising (e.g. change of career, A-level grades not good enough) others were, and related to students employing a more strategic decision (e.g. to gain an advantage later on in their studies). Considering students’ progression it is clear that this is far from linear. Both mathematically strong and not so strong students cited struggling with the mathematical demands placed on them, while a mathematically weaker student reported feeling settled and coping well. This raises some questions to explore further, e.g. to what extent can the FC provide a good mathematical basis for all students.

### **Introduction**

For the second successive CERME two groups addressed mathematics education research concerning technology. TWG15 focused on issues concerning teaching, teacher education and professional development, whereas TWG16 focused on students' learning with technologies and software and task design issues (see Drijvers, Faggiano, Gerianou & Weigand, Introduction to TWG16 in this volume).

TWG15 engaged in work that was stimulated by contributions in the form of 19 research papers and 6 posters that had responded to the call, which had highlighted the following themes:

- The specific knowledge, skills and attributes required for efficient/effective mathematics teaching with technologies and resources.
- The design and evaluation of initial teacher education and teacher professional development programmes that embed these knowledge, skills and attributes – to include programmes that involve teachers' working and learning in online communities.
- Theoretical and methodological approaches to describe the identification/evolution of teachers' practices (and of effective practices) in the design and use of technology and resources in mathematics education.
- Theory and practice related to the formative/summative assessment of mathematical knowledge in a technological environment.

The work of TWG15 drew upon research from 17 countries: Australia, Austria, Denmark, Faroe Islands, France, Israel, Italy, Lebanon, Germany, Greece, Norway, Palestine, Spain, Sweden, Turkey, United Kingdom and USA.

### **TWG15 themes**

The contributions to TWG15 were grouped according to the following themes: large-scale professional development through online courses; technology-mediated assessment of students' mathematical learning; establishing quality criteria for digital mathematics tasks; understanding teacher perspectives on technology use; in-service teachers' knowledge and practice; pre-service teachers' knowledge and practice; and the advancement of theories on technology use in mathematics education.

The TWG15 was organised as follows:

1. A research paper by Kimeswenger was selected to be the focus of a single TWG session as it highlighted a new issue for the TWG, which was the development of quality criteria to support the selection of (dynamic) digital resources for teaching mathematics.
2. Two symposia, to address the themes: on-line large-scale professional development courses; and digital assessment of students' mathematical learning. These included selected papers that were presented by the main author, followed by an invited reaction by one participant.
3. The remaining papers were grouped by theme and presented as individual short presentations by the main author, followed by individual reaction by another invited participant.

In all cases, the discussion was opened to the whole group (in small groups of 6-8 participants), which provided the opportunity for explicit links to be made with the topics of the poster submissions by both the TWG leads and participants, and to encourage all participants to share their own knowledge and experience during discursive work. Brief feedback from these small groups was collected at the end of each session.

### **Large-scale professional development: Online courses**

The papers by Hohenwarter et al., Taranto et al. and Panero et al. focused on the design and early evaluation of three large-scale professional development online courses that had been designed for participants from Austria-Romania-Turkey, Italy and French-speaking countries respectively. Central to all three courses was the objective to offer practicing teachers an opportunity to develop their uses of technology in mathematics classrooms. These courses were described as either 'open online' (OOC) or 'massive open online' (MOOC), where the word 'massive' implied that there were no geographical boundaries nor limits to teachers' registration and participation, although the language of the course was a limiting factor.

The three courses used theoretical frames in different ways. Hohenwarter et al. adopted Koehler and Mishra's Technological, Pedagogical and Content Knowledge model (TPACK, Koehler & Mishra, 2005) to inform their course design. Panero et al. and Taranto et al. sought to network the theories of meta-didactical transposition (Arzarello et al., 2014), documentational genesis (Gueudet & Trouche, 2009) and communities of practice (Wenger, 1998) to understand the collaborative work of teachers in the online context as seen through their productions.

The invited reaction given by Bretscher stimulated a discussion that raised the following issues: defining and understanding 'participation' within open online courses; specific design features of (M)OOCs for teachers of mathematics and the balance between technological and mathematical content; the appropriateness of (M)OOCs for the (large-scale) professional development of teachers; and how research methodologies might need be developed to assess the impact of (M)OOCs on teachers' classroom practices.

### **Assessing students' mathematical learning**

The papers by Sikko et al., Chenevotot-Quentin et al. and Olsher & Yerushalmy were centered on the use of technology in classes by teachers and students, for activities and assessment. Even if referring to different school levels, they focused on the technology as a means to support teachers' assessment activities. In the first case, Sikko et al. presented the use of motion sensors in the Norwegian primary

school classroom to support pupils' construction of meanings for functions and their graphs. This work was set in the context of a large European project (Formative Assessment in Science and Mathematics Education, FaSMEd) aimed at researching the use of technology for formative assessment. In the second case, Chenevotot-Quentin and colleagues showed the use of a technological tool for the assessment of lower secondary school students' learning of numbers and equations. Their technological tool is applied in a way that is consistent with an epistemological analysis of the topics and with the theoretical perspective of the Chevallard's Anthropological Theory of Didactics (ATD, Chevallard 1985). Olsher & Yerushalmy presented a platform where students respond to geometrical tasks using a dynamic geometry environment, which are then classified within the platform according to their geometrical dynamicity. From the teacher's perspective, the three papers presented in this session engaged the participating teachers with professional considerations in diverse and deep ways: as designers of tasks for assessment, as teachers while teaching; and as observers of students. The papers highlighted the importance of teachers' and researchers' collaborative work in the design and evaluation of such resources for the classroom.

The discussion at the end of the presentation, stimulated by the invited reaction given by Yerushalmy focused on: the potential impacts of online formative assessment on teaching; the nature of online mathematics tasks and their formative/summative assessment; possible theoretical frameworks to support design and evaluation; automatization of students' responses and subsequent feedback to students/teachers; high stakes testing; and issues of design.

### **Quality criteria for digital mathematics tasks**

The paper by Kimeswenger problematized the existence of online platforms that host many thousands of user-generated digital resources for teaching mathematics, which presents a particular challenge for (other) teachers as they seek to locate suitable resources that meet their individual requirements. The author described a project in its early stages that seeks to develop a research-informed set of criteria to support different methodologies for user-review. The research focused on the views of 'experts' with respect to the existence of quality criteria alongside their personal descriptions of the 'educational value' of digital mathematical resources, concluding eight quality dimensions. This has led to an exploration of the possible correlation between resources that are highly rated as other users have decided that they have a 'high-quality author' and those that are identified by users as containing 'high quality material'.

As anticipated, the TWG15 participants were most interested by, and animated to discuss, the issues raised by this paper, given that many had themselves been involved in the design of open educational resources or worked alongside teachers to try to support them to make thoughtful resource selections. This discussion concerned: the authors of quality criteria and the mathematical cultures/content/values on which such criteria might be based; the role of a consumer-led approach (i.e., 'likes' by teachers?) or a community-led approach; and, given the vast number of available resources, the usefulness of new algorithms that might automatically score 'quality', based on developed criteria

### **Technology integration: Understanding teacher perspectives**

The two papers by Abboud & Rogalski and Bretscher both addressed aspects of technology integration into 'ordinary' secondary mathematics classrooms in France and England respectively.

Whilst Abboud & Rogalski analyzed videos of lessons at distance using an ‘ergonomic’ theoretical approach (Robert & Rogalski, 2005) that highlighted tensions and disturbances in the observed practice, Bretscher used classroom observation and interviews to research aspects of a teacher’s mathematical knowledge for teaching with technology. These two papers instigated a critical discussion within the working group that was revisited several times during the conference as TWG15 sought to understand, and question the use of the word ‘ordinary’ to describe teachers (and their classrooms) within research studies. For some this referred to experienced teachers who are dependent on their own ability to (re)design lesson with technology (as in Abboud & Rogalski). For others, it referred to teachers who are required to adapt their teaching to their situation and institutional constraints in a world of changing digital tools. There was a general agreement that teachers who are involved in research studies/projects/communities concerning the use of technology in mathematics were rarely ‘ordinary’. One helpful description that was offered described the set of teachers who were not yet aware of their own instrumental genesis with new technologies (or that of their students), which seemed to resonate with many of the researchers in the TWG. The TWG15 participants concluded that ‘ordinary’ was an unhelpful descriptor and this highlighted the importance that researchers describe teachers’ contexts more fully (i.e. country, teacher background, school system, school curriculum, etc.) to enable deeper and more critical insight into each other’s research settings.

The paper by Kolovou & Kynigos differed from the two previous papers by focusing specifically on the learning processes of the designers of dynamic digital resources to foreground students’ and teachers’ mathematical creativity, which is fully described in their paper. By focusing on a ‘community of interest’ (which included teachers) that had been formed around the design of a particular creative book (c-book), the authors show how the participants’ learning was stimulated by the boundary objects (Fischer, 2005) in the design process.

### **A focus on pre-service teachers**

The papers in this theme offered different approaches to pre-service teachers’ training and the different interpretations of their required knowledge about technology.

Prodromou investigated the usefulness of a flipped classroom approach in tertiary education in Australia. The theoretical frame was that of the ‘four pillars’ that define a flipped classroom, which take account of the flexible environment; a shift in the learning culture; intentional content; and the role of educators (Flipped Learning Network, 2014). The analysis of an experiment with pre-service teachers was presented with a particular focus on the role of the lecturer in a flipped classroom. The study by Herrelko tracked the implementation of technology in a mathematics methods course for pre-service teachers in the USA. The method, based on the Apple Classroom of Tomorrow framework (ACOT, Dwyer, Ringstaff, Haymore & Sandholtz, 1994), sought to describe the necessary conditions for the development of pre-service teachers who are knowledgeable about instructional technology. Baya’a et al. focused on pre-service teachers’ TPACK (Koehler & Mishra, 2005) and provided analyses of the impact of teacher preparation courses that had been shown to develop teachers’ TPACK.

The main questions that these presentations highlighted, and were discussed by the TWG, are linked to understanding the pre-service teachers’ perspectives in the design and implementation of

mathematics with technology. Leading on from this, there is a need for deeper understanding of the required technological, mathematical, pedagogical, and epistemological knowledge that is essential for future teachers in order to prepare them to use digital tools effectively in their teaching.

### **A focus on in-service teachers**

This theme concerned in-service teachers, their professional engagement in the various activities related with teaching: planning lessons; using technologies; working in communities; orchestrating different devices in laboratory activities for students; balancing laboratory activities and more traditional teaching. The presenters of the papers showed various aspects of the ways that teachers work with technologies, both related to their teaching practices and to the design and management of educational materials.

Tamborg shared research on the use of a platform in Denmark, Meebook, for planning mathematics lessons in accordance with the teachers' pre-determined learning objectives, teaching approaches and curriculum. The framework used for the study is the 'instrumental approach' (Gueudet & Trouche, 2009), along with the 'documentational approach' (Gueudet et al., 2012) to describe the teachers' collective processes in their use of the platform to plan their lessons. Kayali's study centered on an investigation into the uses of mathematics education software by English secondary mathematics teachers, to understand why some software is used more or less than others, in which ways and for which reasons. Again, the instrumental and documentational approaches are the adopted frames alongside the 'teaching triad' (Jaworski, 1994), for the collection and analysis of data on teachers' considerations when implementing tasks in mathematics lessons. Zender and colleagues showed a motivating way to support students' learning with technologies outside of German classrooms using MathCityMap, a geo-located application for smartphones, which is used as an instrument for a range of situated mathematical tasks. The collaborative professional development of teachers in Lebanon on the use of GeoGebra in mathematics classes was the theme introduced and discussed by Kasti et al.. They based their research on the frame of Valsiner's three zones (Valsiner, 1997) and the TPACK theory (Koehler & Mishra, 2005), using questionnaires and interviews to investigate how GeoGebra is introduced in various mathematics activities.

### **Advancing theories on technology use in mathematics education**

The papers by Gustafsson and Grønþæk et al. both focused on advancing theories on technology use in mathematics education. Gustafsson investigated the potential of Ruthven's Structuring Features of Classroom Practice framework (2009) as a tool to analyze empirical data to conceptualize and probe teachers' rationales for technology integration in the mathematics classroom. Gustafsson's results showed that, whilst the framework captures most aspects of their rationales, it did not fully encompass teachers' justifications with respect to their students' attitudes and behaviors. Hence, he suggested the addition of a new (sixth) structuring feature that relates to teachers' craft knowledge of the use of technology to manage different types of student behaviors or attitudes.

Grønþæk et al. suggested the addition of the concepts of *out-* and *in-sourcing* to Chevallard's (1985) Anthropological Theory of the Didactics. These concepts, taken from the field of business economics, are used as metaphors within the dialectics of tool and content in the planning of teaching. Their addition offers a 'production model' to support teachers' reflection on crucial choices between instrumented and non-instrumented praxeologies. This highlights the need for teachers to be able to

identify core activities (with potential for in-sourcing) and non-core activities (candidates for out-sourcing) based on the learning goals and the possible praxeologies when planning their use of technology in mathematics lessons.

## TWG15 participants' reflections

During the final TWG session, the participants were invited to reflect upon, and record on paper, their own insights and learning during the conference. A textual analysis of the 31 responses highlighted the following aspects of knowledge exchange:

- **Broader appreciation of theoretical frames and their uses:** exposure to new theories; consideration of the limitations of theories; discussions of networking theories; and reflections on personal interpretations and applications of theories.
- **Deeper understanding of international contexts:** theoretical traditions; institutional constraints (i.e. curriculum and examinations); the rejection of the concept of an 'ordinary' teacher, which seems difficult to define or to establish a common meaning across countries.
- **Widening of knowledge on emerging themes:** opportunities afforded for large-scale teacher development through MOOCs and OOCs; the need for 'quality' criteria for digital resources to support their selection/uses by teachers; and the role of technology within formative and summative assessment that relates strongly to the mathematics curriculum, its values and traditions.

Some participants reflected upon the unintended consequences of the division of the technology group for the two different foci (teachers and students), highlighting that an opportunity was missed to explore 'How to develop a good framework to capture the interplay between mathematics content, technology (tools/resources), teachers *and* students/learners?'.

Finally, a few participants commented on the collegiality of TWG15, highlighting they had also been 'inspired' as they learned about the CERME spirit: 'humility - and how to express both orally and in writing with humility'.

## Conclusions

The broad range of papers and posters presented at CERME 10 highlighted the diversity of research interests in the participating countries. However, many common concerns prevail. The design and implementation of programmes and courses for future and practicing teachers was one such challenge. Debate over the exact content of such courses in order to address the knowledge and skills to integrate technology into future mathematics teaching practice was paramount, alongside the modes of delivery and the integration of teachers' classroom experimentations. This highlighted the different views and perceptions of the simplicity and complexity for teaching mathematics with digital tools and the dilemma between technology appearing to make a teacher's role easier (e/g/ by automatically marking students' productions), whilst at the same time introducing new teaching challenges (e.g. by introducing new representational forms and related interactions). The TWG discussed ways to face such challenges through the development of research-informed teachers' collaborative professional development models that integrated coaching, face-to-face and online communities, often conducted or sustained over a time period of years, rather than months, drawing on the outcomes of the recent ICMI Survey on this theme (Robutti et al., 2016).

A common challenge is the scaling of such professional development models, for which (M)OOCs might offer some solution, although substantial research is needed to evaluate the ‘best designs’ to respond to the many different cultural contexts and requirements. The networking of theories proposed by Panero et al. and Taranto et al. provided some potential theoretical and methodological tools to this effect.

The topic of the automated assessment of students’ digital work led the group to question deeply the nature of mathematical activity (and mathematics itself) that warranted such assessment. This raised a general concern over the ease with which closed mathematical questions can be posed and digitally assessed and the much greater technical challenge to design automated assessment that privileged mathematical processes such as reasoning, justification and proof. The poster by Recio and the two papers by Olsher & Yerushalmy and Chenevotot-Quentin et al. respectively contributed greatly to this debate.

TWG 15 critiqued advancement in theories concerning teachers’ uses of technology in mathematics education. In particular, the notions of ‘tensions and disturbances’ as a theoretical construct to support analyses of teachers’ practices (Abboud & Rogalski), alongside extensions to Ruthven’s ‘Structuring Features of Classroom Practices’ (Bretscher & Gustafsson, and the poster by Simsek & Bretscher).

Looking ahead to CERME11, TWG15 concluded the following questions, which might inform individual and collaborative research efforts over the next two years:

- Which theoretical frames and methodological approaches focus on aspects of the collaborative work of researchers and teachers within the context of the use of technology for teaching mathematics?
- What approaches might be fruitful to raise teachers’ awareness of the mathematical-pedagogical decisions concerning the design and use of technology for learning and its assessment?
- How do we create opportunities and approaches that support teachers to appreciate and plan for the process of students’ instrumental genesis?
- In the design of technology-focused professional learning for mathematics teachers (pre- and in-service), what is the balance between professional needs across generic technologies and mathematics-specific needs? and how can this be achieved?

# Real uses of ICT in classrooms: Tensions and disturbances in mathematics teachers' activity

Maha Abboud<sup>1</sup> and Janine Rogalski<sup>2</sup>

<sup>1</sup>LDAR, University of Cergy-Pontoise, France; [maha.blanchard@u-cergy.fr](mailto:maha.blanchard@u-cergy.fr)

<sup>2</sup>LDAR, University Paris Diderot; [rogalski.muret@gmail.com](mailto:rogalski.muret@gmail.com)

*This paper presents an extension of approaches of the teacher technology-based activity, articulating the Double Approach alongside with the Instrumental Approach within the overarching frame of Activity Theory. Tensions and disturbances are defined for analysing the dynamics of the teacher's activity when ICT tools are mediating both teacher's and students' activity. The approach is illustrated throughout a comparative study of two "ordinary" teachers using dynamic geometry. Various tensions related to the temporal, cognitive and pragmatic dimensions were observed, differently managed depending on personal, material and social determinants. Tensions are inherent to the dynamics of the situation. Together with disturbances, they are lenses contributing to a fine-grained analysis of teachers' activity.*

*Keywords: Teachers, technology, activity, tensions, disturbances, dynamic environment*

## Introduction

The activity of "ordinary" teachers integrating technology into teaching is constrained and depends on several determinants, namely personal, institutional and social. The work of researchers such as Ruthven (2009), Drijvers et al. (2010) and Abboud-Blanchard (2014) emphasize the need to study the practices of these teachers, often not technology experts and practicing in non-experimental conditions (i.e. ordinary practices). One of the aims of such studies is to better understand what happens in the classroom and thereby to address professional development issues (Clark-Wilson, 2014). The aim of the present paper is to contribute to this research line by introducing two new theoretical concepts, *tensions* and *disturbances*. These concepts were developed within a model of instrumented activities of teacher and students and were actually used as complementary resources within ICT teacher education programs.

We consider the teacher as managing an "open dynamic environment" (Rogalski, 2003), and we focus on both the relationship between the lesson preparation and its actual implementation (anticipation, adaptation); and also on the management of the inherent uncertainty within such an environment. Indeed, the use of technology adds a "pragmatic" dimension emphasizing the "open" character of the environment that constitutes the classroom activity. Monaghan (2004), stresses that this use leads to an increased complexity in teachers' practices and also that the uncertainties related to students' mathematical activities with technologies bring teachers to modify their objectives *during* the lesson in progress, leading them to focus on new "emergent goals". The concepts we introduce enable an

analysis of the impact of the dynamics of students' interactions with technology tools on the management of the planned (by the teacher) *cognitive route* (Robert & Rogalski, 2005), and the possible divergences from this during the lesson. In this paper, we provide an example of the comparative analysis of the activity of two "ordinary" teachers' uses of dynamic geometry with their (6<sup>th</sup> grade) students to describe the methodology and associated analytical tools and to highlight their usefulness. We selected this particular example from our research data as it is relatively easy to present in a short paper.

## Theoretical and methodological approaches

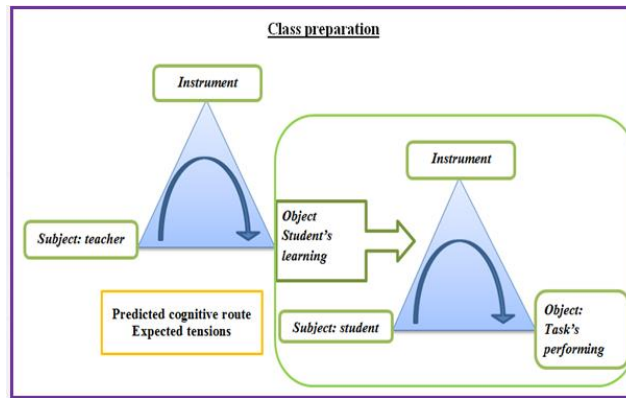

The ergonomics theoretical perspective considers teaching as a case of dynamic management of the teaching environment (Rogalski, 2003). This environment is "open" as it contains many uncertainties due to the fact that the students' activity cannot be completely predicted and the teacher is often in an improvisation mode. The teacher's conceptions of the mathematical domain to be taught, and of the relation students have to it, are subjective determinants of his professional activity. These conceptions condition the "didactical process" he wants his students to follow i.e. the planned *cognitive route*, alongside the management of the processes developed during the lesson (Robert & Rogalski, 2005). Although the didactic scenario is familiar, the students' diversity and the specific context of the class introduce a factor of uncertainty. This uncertainty is exacerbated when students are working with a technological tool as the teacher may encounter difficulties to control the tool's feedback due to students' manipulations and to identify their emerging interpretations. Teachers often have to deal with tensions due to the presence of the tool and its role in the student's activity, and also its interaction with the mathematical knowledge at stake.

Following Rabardel's Instrumental Approach (2002), technological tools can be viewed from both the teacher's and the students' perspectives. In both cases, the subject-object interactions are mediated by the tool. As Rabardel states:

Beyond direct subject-object interactions (dS-O), many other interactions must be considered: interactions between the subject and the instrument (S-I), interactions between the instrument and the object on which it allows one to act (I-O), and finally subject-object interactions mediated by an instrument (S-Om). Furthermore, this whole is thrown into an environment made up of all the conditions the subject must take into consideration in his/her finalized activity (Rabardel, 2002, p.42-43).

Nevertheless, the object of teacher's activity is the students' learning, whereas the object of the students' activity is the content of the task given by the teacher; their instruments based on the same tool are thus different. Figure 1, presents how these two instrumented activities are articulated within the dynamics of class preparation.

**Figure 1. Teacher's and students' instrumented activities within the preparation phase**

We now consider the classroom environment and present how the two instrumental situations are articulated within the dynamics of class management, indicating possible tensions and disturbances.

### Tensions and disturbances

In our approach, we depart from the way Kaptelin & Nardi (2012) introduced the terms "tension" and "disturbance" when presenting the concept of contradiction central in Engeström's framework of analysis for how activity systems develop (Engeström, 2008). These terms appear in their familiar use; emphasis being put on the analysis of contradictions in activity systems as main learning sources.

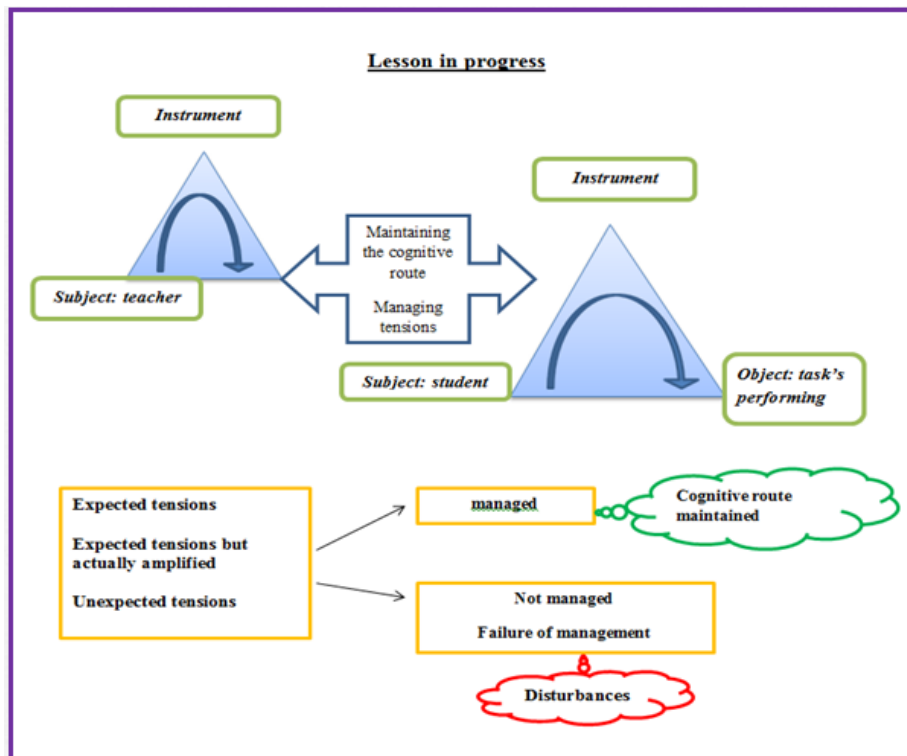

We do not define tensions as conflicts or contradictions. In the teacher's activity *tensions* are manifestations of "struggles" between maintaining the intended cognitive route and adapting to phenomena linked to the dynamics of the class situation. Some of these tensions might be predicted by the teacher and so he/she plans how to manage them. Others are unexpected and constrain the teacher to make decisions, in situ, that direct his/her actual activity.

*Disturbances* are consequences of non-managed or ill-managed tensions that lead to an exit out of the intended cognitive route. Disturbances happen when a new issue emerges and is managed while the current issue is not completely treated or when the statement of a new issue is not part of the initial cognitive route.

We consider here only tensions and disturbances related to the local level of a class session; while some tensions are or might be managed at a more global level (i.e. over several sessions). Figure 2 illustrates how tensions can be related to different poles of the system of teacher-and-student activities; they can be shaped differently along three dimensions (previously introduced by Abboud-Blanchard (2014)): temporal, cognitive, and pragmatic.

Tensions related to the cognitive dimension appear in the gap between the mathematical knowledge the teacher anticipated would be used during task performance and the knowledge that is actually involved when students identify and interpret feedback from the instrument. Tensions related to both the pragmatic and cognitive dimensions are produced by the illusion that mathematical objects and operations implemented in the software are sufficiently close to those in the paper-and-pencil context

(we refer to Balacheff (1994) analysis of the “transposition informatique”). Tensions related to a temporal dimension are frequent in ICT environments and are linked to the discrepancy between the predicted duration of students' activity and the actual time needed to perform the task. Teachers are generally aware of such tensions; they often manage them by taking control of the situation, either by directly giving the expected answer or by manipulating the software themselves. Finally, a tension non-specific to ICT environment may concern the didactical contract: Students cannot identify the type of answer the teacher is expecting. ICT environments may amplify this type of tensions when students are uncertain of the goal of the activity i.e. is it about a mathematical object to manipulate with the software or about the use of the software itself.

**Figure 2. Tensions and disturbances within the dynamics of class management**

### **Illustrating the theoretical approaches through a comparative case study**

We present how tensions and possible disturbances appear in the case of two teachers, Alan and Colin, using dynamic geometry software (Geoplan) with 6<sup>th</sup> grade students to introduce the notion of perpendicular-bisector. They are both “ordinary” teachers who use technological tools occasionally, and willingly, in ways that are in line with the institutional expectations, that is to introduce students to an experimental approach. The two teachers designed the same cognitive route based on the succession of two tasks: moving several points (eight) on Geoplan screen in order to place each of them at the same distance from two fixed points, M & N, (ICT task) and then similarly drawing 8 points with the same condition in a paper-and-pencil context (p&p task). Each teacher’s final goal was to: give the definition of the perpendicular-bisector as a set of points equidistant from two given points; and establish an efficient associated construction method using compasses. Alan’s school is

in a low-income socio-economic zone, while Colin is in a middle-class zone. Their working environments are different: Alan had access to a traditional classroom and a computer room that lacked either a video projection device or a black board, while Colin worked in a classroom equipped with laptops.

The sessions included in our analysis were video recorded by the teachers themselves. Our choice of data collection approach is to reduce as far as possible the impact of researchers on the teacher's and students' activity in the class. The analysis of the teachers' preparation documents and deferred interviews enable the identification of some personal and social determinants. We then compare the observed succession of episodes in the video alongside the planned cognitive route, to enable us to detect tensions and disturbances.

## Results

A somewhat surprising result is that both Alan and Colin managed the session without temporal tensions despite a number of “unfavourable” material and social determinants. In Alan's case, these could have resulted in strong tensions, e.g. the time needed to move from classroom to computer room and students' prior cognitive difficulties. In fact, Alan took into account the social determinants of his class and the material constraints by anticipating and avoiding tensions that could have produced disturbances through a threefold organisation: temporal, pragmatic and cognitive. Indeed, Alan closely supervised his students and organised their activity by structuring the cognitive route as a succession of well-defined sub-tasks. This mode of guidance has been identified previously as a common approach that teachers use to manage such experimental approach in order to avoid students' erratic behaviour (Abboud-Blanchard, 2014). The rhythm of sub-task completion is also strictly planned and guided. This is probably linked to Alan's personal determinants that led him to establish strong routines to discipline students in all moments. Indeed, not all teachers with this type of students are able to establish such routines and to be at ease when implementing them. Colin avoided temporal tensions in quite different ways. He started by presenting the task both with ICT and p&p. During the session, he used the IWB for sharing elements of the task outcomes with the whole class. He particularly drew students' attention to where they should look on the screen, and by doing so, avoided some pragmatic and cognitive tensions. Colin's open attitude may be related to a personal determinant of “compliance” inherent in his relationship with his students.

Regarding tensions related to the cognitive dimension, an important result is the shared illusion of transparency: Implicitly, Alan and Colin took for granted that after completing the ICT task, all students *would* have detected the existence of a straight line on which all equidistant points are situated. This was clearly not the case. This tension was not managed as indicated by the absence of any collective comment concerning the point of transition between the ICT task and the p&p one. For some students, this fact led to a divergence from the intended cognitive route: a “local” disturbance. These students persisted conscientiously throughout the whole session to draw equidistant points without appreciating the notion of a straight line as the set of such points. A tension related to the

didactical contract was also observed in both classrooms when, during the p&p task, some students tried to place the 8 points at the same positions they occupied on the screen. What may have triggered this students' interpretation of the task differs for the two teachers. Alan had introduced the p&p task, by saying "now we will do the same task but without the computer". However, for Colin, the computers were not shut down and thus students may have continued to refer to what they saw on the screen. During the session, both teachers succeeded in managing this tension by explaining the differences of the two situations.

Finally, a pragmatic tension that was not managed was an implementation issue that could be related to a shared belief among teachers that students are skilled with technology using a trial and improvement approach. At the beginning of the ICT task, for any given point (P) on the screen, the students *could* read the relative distances to the point M and N and, when moving this variable point, they *could* observe the numerical changes. However, dragging the point P to maintain the equality involved two degrees of freedom on the plane. Therefore, an efficient approach relied on both students' awareness of this constraint and their development of an adequate concept-based strategy to "maintain a constant dimension when moving along the other" or "anticipate the curve on which the point is moving" (as shown in Abboud-Blanchard, 2015). In Colin's class, some students continued to drag points without any strategy even when the teacher asked them to engage in the p&p task. As a consequence, they could not easily be aware of the efficiency of using compasses instead of rulers when switching to the p&p context. For Alan's students, we can infer that some of them succeeded to place only few points with limited opportunities to notice their alignment.

Overall, we have identified a set of tensions in the activity of two ordinary teachers use of dynamic geometry and have illustrated the dimensions they may affect. By predicting many tensions, these teachers avoided some of these tensions by anticipating and organising the students' activity relative to the temporal, cognitive and pragmatic dimensions. The teachers managed others *in situ* mainly via individual interactions with, and support for the students. Their approach to classroom management depends on personal, material and social determinants. Nevertheless, the analysis also shows that even though they succeeded to maintain the essence of their intended cognitive goal, some unrecognised or ill-managed tensions led some students to diverge from the planned cognitive route.

## Discussion and conclusion

In this paper, we have presented how and why we developed the notions of tensions and disturbances to analyse the dynamics of teachers' activity in ordinary contexts when they are using ICT in line with the institutional demands. We first schematised how ICT occupies two different positions as an instrumental tool for the teacher and for the students. The first schema is based on the postulate that there exists a crucial difference in the object of activity of the teacher (e.g. students' understanding/learning of the mathematical content involved in the task), and of the students, which is essentially to complete the task. Within the second schema, we added and defined several types of

tensions that may appear within the teacher's activity along three dimensions: temporal, cognitive, and pragmatic, and at the level of the didactical contract. The cases of Alan and Colin are examples of ordinary, experienced teachers investigated within a larger study, who use technology regularly. In addition, they are convinced that dynamic geometry enables students to make pertinent observations through the immediate feedback (this belief is widely shared by teachers). We identified a set of tensions: some of which were managed through anticipation; others in real-time (depending on different personal and social determinants); some were not detected or detected and not managed by the teachers. If teachers are able to identify and manage tensions, they can maintain the intended cognitive route for students or, when disturbances occur, modify this route to different effect. Several issues remain open for further research. First, the present study focused on the “local level” - an analysis of a specific classroom session. It will be necessary to extend our concepts and methodological tools to analyse tensions and disturbances at the more global level of a sequences of tasks on particular mathematical topics. Secondly, we analysed cases with “simple” ICT-based students’ tasks; other cognitive and pragmatic tensions could appear when the tasks involve objects and operations that are more deeply modified by the “transposition informatique”. Finally, at the deeper level considered in Artigue (2007), what different kinds of tensions would teachers encounter when students are engaged in mathematical activity involving mathematical objects (an epistemic orientation) compared with more specific computer-based tasks (a pragmatic orientation). Finally, we consider that the concepts of tensions and disturbances have enriched the range of theoretical tools to study teachers' instrumental activity, in particular for the identification and analysis of critical aspects of the dynamics of this activity. We conjecture that this could also inform approaches to teacher education.

# Out- and in-sourcing, an analysis model for the use of instrumented techniques

Henrik P. Bang<sup>1</sup>, Niels Grønbaek<sup>2</sup> and Claus R. Larsen<sup>3</sup>

<sup>1</sup>Christianshavns Gymnasium, Denmark; [hb@cg-gym.dk](mailto:hb@cg-gym.dk)

<sup>2</sup>Department of Mathematical Sciences, University of Copenhagen, Denmark;  
[gronbaek@math.ku.dk](mailto:gronbaek@math.ku.dk)

<sup>3</sup>Christianshavns Gymnasium, Denmark; [cl@cg-gym.dk](mailto:cl@cg-gym.dk)

*We outline a model for analyzing the use of ICT-tools, in particular CAS, in teaching designs employed by ‘generic’ teachers. Our model uses the business economics concepts “out-” and “in-sourcing” as metaphors within the dialectics of tool and content for the planning of teaching. Out-sourcing is done in order to enhance outcomes through external partners. The converse concept of in-sourcing refers to internal sourcing. We shall adhere to the framework of the anthropological theory of the didactic, viewing out- and in-sourcing primarily as decisions about the technology component of praxeologies. We use the model on a concrete example from Danish upper secondary mathematics to reveal what underlies teachers’ decisions (deliberate or spontaneous) to incorporate instrumented approaches.*

## Introduction

Has use of computers in schools resulted in better education? With the steadily growing take-up of technology throughout the world, this question is as important as ever. The role and importance of technology has undergone phases from initial excitement to, more recently, a mixture of cautious optimism, moderate skepticism, and the stance that the use of computers might forfeit the true values of educational discipline. A recent, rather extensive international report (OECD, 2015) indicates countries’ improvements in learning by a number of measures against their investment in ICT. The foreword summarizes the implications for educational policy:

Mere embracement of ICT in itself is at best harmless. Access to ICT does not automatically improve learning, “The results also show no appreciable improvements in student achievement in reading, mathematics or science in the countries that had invested heavily in ICT for education”.

In person teacher-learner contact is essential, “One interpretation of all this is that building deep, conceptual understanding and higher-order thinking requires intensive teacher-student interactions, and technology sometimes distracts from this valuable human engagement”.

There is a need for alignment of technology and learning: “Another interpretation is that we have not yet become good enough at the kind of pedagogies that make the most of technology; that adding 21st-century technologies to 20th-century teaching practices will just dilute the effectiveness of teaching”.

A deeply rooted trust in the progressive power of ICT (but with a somewhat unimaginative scope to traditional learning material), “Why should students be limited to a textbook that was printed two years ago, and maybe designed ten years ago, when they could have access to the world’s best and most up-to-date textbook?”.

A tall order on teachers to meet the expectations (by pedagogy rather than by subject discipline), “Perhaps most importantly, technology can support new pedagogies ... it is vital that teachers become active agents for change” (OECD 2012).

Other meta-studies (Higgins, Xiao, & Katsipatakis, 2012; MBUL, 2015) point to similar conclusions, “There is at most a weak positive correlation between bulk use of computers and learning outcome.”

In contrast, there are numerous reports on very fruitful and insight-giving use of computers (Böhm, Forbes, Herweyers, Hugelshofer, & Schomacker, 2004; Heid, 2003; Nabb, 2010). These are often the result of computer focused teaching designs that are part of didactic research or teaching development, carried out by dedicated teachers. Therefore, the question is not how much, but how, about what, and by whom.

### **The Danish landscape**

In the OECD report Denmark is ranked second in use of computers. From the mid 1990’s there has been rapidly growing CAS-use in Danish high schools, starting with graphing calculators and accelerated through the extensive use of PC’s from around 2005. The situation now is that most high schools use Maple, TI-Nspire, Geogebra, and/or a CAS-tool specially developed for Danish high schools (WordMat, a CAS engine integrated within Microsoft Word). Students bring their own PC to the classroom, and use of PC is required at examinations. Initially, the transformation was carried through by progressive and CAS-curious teachers, many of whom were inspired by reform pedagogic ideas that supported a shift from abstract mathematics towards applications and more intuitive conceptual understandings. There was (and is) also an element of believing in diffusion: If CAS helps advanced (university) students to solve advanced problems, we might as well use CAS to help less advanced students solve less advanced (but to them difficult) problems. The educational system eagerly supported the development. Mathematics has been a vehicle for use of PC in other subjects, and examinations using CAS could (possibly) help more students achieving higher levels in math. Since 2005, CAS has gone from being a tool for enthusiastic teachers to a tool for everyone, including teachers with less interest and less competency in CAS. There has been no essential change in the standard curriculum (only minor ones allowing time for, say,  $\chi^2$ -test) – and standards for CAS use have not been introduced. On the contrary, the curriculum endorses the use of CAS in mathematical modeling and concept building, but without any indication of how, and in connection with what topics, to carry this out. In this landscape, many teachers have developed templates that students are allowed to use in exams, and the preparation of students to use these has become an important activity during normal lessons. Students of teachers, who for one reason or another disfavor such, may find templates on the internet or borrow from friends. Most of such templates have little *epistemic value* and a rather narrow *pragmatic value* in the sense of (Artigue, 2002) towards solving (standard) problems. With CAS at the national tests these tendencies of trivialization are even more pronounced, as problems must be formulated to be equally solvable on different CAS platforms,

Denmark’s extended use of computers in education reflects of course a trend in society but is also as described above to a large degree the result of explicit educational policies. Hence, a teacher has to find his/her pathway through the affordances, constraints, possibilities etc. stipulated by official guidelines, curriculum and instruction plans. As indicated, successful use of computers does seemingly not scale up (MBUL, 2015). In order to understand the reasons for this better we propose

an analysis model to help understand teachers' decisions on use of computers in mathematics teaching.

## Theoretic framework

As our proposal aims at elucidating teaching in an institutional context we find the anthropological theory of the didactics (ATD, Chevallard, 1999) well suited. We start by briefly recalling the most important concepts of ATD that we shall use. Mathematics as an enterprise (educational as well as scientific) is seen as human activity composed of two blocks each with two parts, a *praxis block* comprising types of problems, *tasks*, with *techniques* to accomplish these and a *theory part* comprising *technology* and *theory*. Together such two blocks are termed a *praxeology* (praxis + logos). Tasks are the immediate goals of the activity, i.e. finding the slope of a graph of a function at a given point. A task can be accomplished by several techniques, i.e. plotting the graph on a computer, zooming in on the point in question until the graph appears linear and reading off the slope. The technology part concerns the discipline discourse of the technique and its relation to the tasks, i.e. the scope and limits of computer rendering of graphs (in relation to variation of functions). The theory part is a discourse on the technology part and its relation to the praxis block, i.e. on the concept of linear approximation that the sketched approach leads and on how it is related to a larger body of mathematical knowledge and practice, for instance that of the theory of differentiation.

We would like to stress a couple of points. A given task can be unfolded in many praxeologies. To choose, detail and organize such unfoldings is the essence of teaching design. Any praxeology has underlying praxeologies, i.e. praxeologies aimed at slope of a linear function, and is itself related to/part of other praxeologies. A praxeology always comprises all four parts. This is one key point of the analysis in (Barbé, Bosch, Espinoza, & Gascon, 2005).

Praxeologies take place within organizations of mathematical practice and knowledge. In ATD such organizations are formed by two components, a mathematical body consisting of a totality of objects, concepts, statements, interrelationships, procedures, etc., termed the *scholarly knowledge* and an *institution* of society within which this body is taught, manifesting possibilities and constraints for acquisition of learning. The passage from scholarly knowledge to its institutional version (which has more components than indicated) is in ATD conceptualized as *didactic transposition*.

In (Artigue, 2002, p. 271) it is noted that didactic transposition in its first version was described with respect to rather traditional scholarly mathematics. In order to underline a computerized setting Artigue has singled out the term *instrumented techniques*.

## The model

In ATD the teacher is considered as the director of the learners' didactical processes (Barbé et al., 2005), that is, responsible for the establishment of relations between learners and organizations of knowledge within institutions. We shall take this a step further, viewing it as production of learning outcomes through production activities, the praxeologies. For this production, the teacher has at his/her disposal a palette of resources, typically in terms of techniques (along with their theoretical block) to solve tasks. The 'employees' who use the techniques towards the production are the students.

This setup is very similar to a business economic model of the production of a corporation. In order to enhance the outcome a corporation director makes sourcing decisions on the allocation of resources. In modern terminology, one speaks of outsourcing, insourcing, backsourcing<sup>1</sup>, “outsourcing involves allocating or reallocating business activities (both service and/or manufacturing activities) from an internal source to an external source” (Schniederjans, Schniederjans, & Schniederjans, 2005, p.3). Insourcing can be viewed as an allocation or reallocation of resources internally within the same organization. Any business activity can be outsourced or insourced (dichotomy), but this decision is crucial to the success of the corporation. The basic idea of outsourcing is old, essentially, it is the dictum ‘buy or make’. However, in the last few decades, outsourcing has grown almost explosively. A main reason for this is the development of ICT. But outsourcing is risky. It is reported (Schniederjans et al., 2005, p. 12) that half of all outsourcing agreements fail due to lack of appropriate analysis, and the necessity of *strategic planning* has become evident. There seems to be general acceptance (Schniederjans et al., 2005, p. 9) that such starts with an analysis to identify the strengths of the corporation, in terms of *core activities* (‘core competencies’ in (Schniederjans et al., 2005). Loosely, a core activity is what the corporation does better than its competitors and possible outsourcing providers. Core activities must be insourced, non-core activities are candidates for outsourcing and a balanced decision to achieve the strategic goals must be made. Key advantages of outsourcing of inspiration for didactic equivalents are: focus on core activities, gain of outside technology, enhancement of capacity and lower cost, whereas some key disadvantages are loss of control, increased costs, negative impact on employees’ morale and difficulties in managing relationships with outsourcing provider.

In the didactic version, the *client* is a didactically transposed knowledge organization along with the teacher(s) to direct the didactic processes. The *outsourcing provider* is an external knowledge organization, typically within a CAS. In the business model, external/internal refers to ownership. For our purpose the fundamental feature of ownership is that it allows for control of processes, i.e. outsourcing implies loss of control. We shall take this as the defining property. Hence *outsourcing a mathematical activity means allocating it to a resource at the price of giving up control of processes*. A blunt example could be a teacher encouraging students to find solutions to homework on the internet; a more elucidating example is employment of instrumented techniques in the form of black-box applications of CAS. As pointed out, any activity can be outsourced or insourced, that is full praxeologies, be it punctual, local or regional, or just parts of praxeologies, typically the praxis block. To be more precise, the starting point of CAS outsourcing is typically a problematic task to be solved by the outsourcing provider’s technique thereby creating a transformed or new praxeology. We stress that a CAS such as Maple is not solely a provider. To the extent that a teacher exercises control over CAS processes, these are considered insourced. Outsourcing to CAS is a more restrictive concept than mere use of CAS. (Teacher control must be distinguished from student control as the latter is the result of the first, and perhaps of other competencies, acquired without the influence of the teacher.)

---

<sup>1</sup> Backsourcing means reallocating tasks from external sources to internal. This could be in order to regain control of the production process but could also be imposed by outside regulatives. In an educational context such could be new stipulations of use of CAS at national tests.

A simple example (an object of many controversies) illustrates the concepts. Arithmetical computations require a careful analysis of what are core activities that accordingly should be insourced. Depending on (long-term) learning goals, these could be the systematics of paper and pencil algorithms, skills of mental arithmetic with “nice numbers”, etc. On the other hand, multiplication of many-digit numbers is hardly a core activity and is therefore a candidate for outsourcing to calculators<sup>2</sup>. This does not mean that tasks, which can be solved by mental computation, should not be insourced by calculator techniques. The point is that the core activity of mental computing may give control also of some calculator computations. Note that a calculator praxeology is completely different from its non-instrumented equivalents, for instance its theory part may involve representation of numbers in a finite memory.

The very decision to use CAS (or other *instrumented techniques*) involves, regardless of its specific use, outsourcing. The teacher has no control of the coding that underlies the CAS, the syntax, the defaults, the library of routines, etc. Most CAS-tools are developed with teaching in mind, at least partly. Perhaps most importantly, the CAS design may have didactic intensions, which the teacher may surrender to if not disable. Maple’s ‘clickable math’ is a good example of this. The relationship between non-instrumented mathematics and computerized mathematics resembles that of a *strategic partnership* with mutual outsourcing. This relationship is dialectic in nature. The potential of CAS in mathematical praxeologies needs non-instrumented mathematics to be redeemed.

There is of course nothing new in the very idea of strategic planning. Mathematical activity has at all times involved use of ‘non-controlled’ components and didactic considerations have always had this as a condition. The modern aspect of CAS is the magnitude of impact, calling for a much clearer elaboration of such planning. The addition of the concepts of out- and insourcing to ATD offers a model for reflection on crucial choices between instrumented and non-instrumented praxeologies on basis on insight in the CAS-tool and in possible mathematical activities. On one hand, the model gives a framework for investigation of ordinary teachers’ undertakings and perhaps more importantly, of what is not undertaken. On the other, it provides a strategic planning scheme for the teacher cf. (Schniederjans et al., 2005, Figure 1.3), where II+III are the crux of the matter:

- I. Establishment of content and learning goals of the mathematical organization to be taught
- II. Detailed analysis of subject matter and activities of possible praxeologies.
- III. Identification
  - a. Core activities
  - b. Non-core activities
- IV. Sourcing decisions
  - a. Core activities are insourced
  - b. Non-core activities are candidates for outsourcing.

---

<sup>2</sup> A business equivalent of the historically initial excitement about the freeing potential of calculators and the afterthought concerning (permanent?) loss of core activities: The reservation system of the flight company TWA was superior to those of its competitors, i.e. a core activity, but was outsourced in the 90’s. TWA never regained its market share and went out of business in 2001.

How do teachers decide on what is a core activity? The dialectics of pragmatic and epistemic value (Artigue, 2002) seems inevitable, but is not directly reflected in the dichotomy of out- and insourcing. The computational power of several thousand digits, obviously to be outsourced, may have epistemic value in relation to approximation by decimal expansions. The pragmatic value of graphing of polynomials may be an asset of outsourcing in order to study whether polynomials have desired properties, which are considered epistemic of certain mathematical models. In other praxeologies graphing, by hand or by CAS, may be insourced.

## Methodology for prospective work with the model

We aim at a fully-fledged model to give a general description of ordinary teachers' implementation of CAS and through this, an insight in the scaling-up question mentioned previously. Our first step is to analyze a rather extensive material of reports on teaching designs with CAS, succeeded by reflections on further development, modification and refinement of our model. These reports are produced by project participants at Center for Computer based Mathematics Education (CMU<sup>3</sup>), University of Copenhagen, as the last step of a reflective practitioner process. The mission of CMU is to support use of CAS in Danish high schools respecting core mathematics qualities in order to reverse the trivialization tendencies described above. The only condition for participating is a moral subscription to this mission. Thus, teachers have been free to choose subject, CAS platform (within CMU's coaching expertise), design of teaching, etc. This first round of analysis data is collected in contemplation of dissemination, rather than evidencing answers to research questions, but in a systematic way that allows for a grounded theory approach.<sup>4</sup>

Having an elaborated model, we intend a large-scale investigation on Danish mathematics high school teachers' choices and rationale for outsourcing to CAS.

## A sketch of an analysis: a praxeology of finding derivatives

The so-called 3-steps method of finding the derivative,  $f'(x_0)$ , of a function is the canonical approach to differentiation in Danish high schools, explicitly mentioned in official guidelines. We recall: (1) With  $\Delta y = f(x_0 + \Delta x) - f(x_0)$  form the fraction  $\frac{\Delta y}{\Delta x}$ ; (2) reduce the fraction to make  $\lim_{\Delta x \rightarrow 0} \frac{\Delta y}{\Delta x}$  accessible (3) find the limit  $\lim_{\Delta x \rightarrow 0} \frac{\Delta y}{\Delta x}$  (if it exists). These are tasks in three praxeologies with rather separate theory blocks involving algebra, topology and geometry. In a CMU – project (Differentialregning, tretrinsreglen), the teacher, in the sequel L, wants to improve on students' understanding of the method by CAS-outsourcing “to give the students hand-on experience of secant and tangent slope and limits through experimentation with CAS sheets” (our transl.). An outsourcing strategy like this is rather common in Denmark. L has worked on the teaching problematics of the 3-steps method for many years ‘without really understanding why students find it so difficult’ (our

---

<sup>3</sup> The Danish Industry Foundation, Department of Mathematical Sciences at University of Copenhagen, The Danish Ministry of Education, and Maplesoft Inc. sponsor CMU.

<sup>4</sup> For further details about the CMU material, we refer to the CERME 10 poster of TWG 15 (Bang, Grønbaek, & Larsen, 2017)

translation from Danish taken from the project report). This time L starts with a thorough analysis of prerequisites ending in 12 points. L decides to use CAS in the case of  $f(x) = x^2$  on three points of the 12: '(5) computing slope of a straight line; (7) understanding what tangent and slope are; (12) understanding (the concept of) limit' (our transl.). A few observations: (A) L is by his very wish to understand reasons for learning difficulties led to in- and outsourcing considerations. (B) There is a tendency to regard pragmatic and epistemic values as separate features: (5) is pragmatic and (7) & (12) are (by L phrased as) aiming at epistemic value. (C) Some core activities are recognized as such and insourced, i.e. algebraic reduction of polynomial expressions such as  $\Delta y$  for  $y = ax^2 + bx + c$  - partly insourced to paper and pencil, partly to CAS. Other core activities are outsourced, i.e. use of sliders on the graph  $y = x + 2$  to find  $\lim_{x \rightarrow 0} x + 2$ , as last step in the 3-step method with  $x$  replacing  $\Delta x$ ; (D) non-core activities are not spelled out. What is it that sliders can do for secant-tangent considerations without sacrificing core activities? (E) Affective aspects are outsourced: 'CAS tools should ... activate students and challenge their desire to ... explore mathematical problems' (our transl.) From L's reflections, it appears that the outsourcing (D) is indirectly motivated by the textbook treatment of the subject. Textbooks rarely have core activity considerations, but rather bold instigations to CAS use. This risk of dilution of mathematical competency is pinpointed by the concept 'outsourcing core activities'.

### Further use and development

L is an example of a teacher with neither desire nor reputation to be a front-runner, but navigating resourcefully and dedicatedly under post-modern circumstances of mathematics teaching. Our observations (A), ... (E) apply to many teachers (CMU, 2015; CMU, 2016) so the sketch of an out-/in-source analysis of L's project is testimony that our approach may have potential for shedding light of the kind of decisions, with shortcomings and potentials, that ordinary teachers make. The business metaphor seems confluent with natural praxis of resource considerations, thus providing a framework for large-scale investigations much similar to studies of business economics forces that govern trade and production. One may fear a risk of introducing yet another business corporation model to education. Outsourcing is growing in business due to the incitement of fierce competition. While perhaps tempting, a flat educational interpretation of this is misleading. The rooting in a business model is motivated within a local or regional mathematical organization through its level of didactic co-determination. Even though mathematics may be seen as a productive force, learning outcome is not a commodity. It cannot be bettered simply through optimization tactics.

Our sketch has focused on director decisions, i.e. the teacher's planning. Further development must include employees, i.e. students, that is, the last step of the didactical transposition: matter taught  $\rightarrow$  matter learned.

*The ministry of education is launching a national project to implement the use of ICT in the Israeli education system. To prepare pre-service teachers with whom we work for this kind of implementation, we designed a model, which supports them to learn to use digital tools effectively while integrating a particular pedagogy for teaching a specific mathematics or science content. The goal of the present research is to study the development of these pre-service teachers' Technological, Pedagogical and Content Knowledge (TPACK), attitudes toward computers and their ICT proficiency. For this purpose, we used and adapted questionnaires from different sources. The research results show significant improvement in the TPACK level and ICT proficiency, but no significant effect of the preparation on most of the components of the teachers' attitudes toward computers, being positively high before and after the preparation.*

*Keywords: Pre-service teachers, TPACK, digital tools, professional development.*

## Introduction

Shulman (1986) suggested the PCK (pedagogical content knowledge) model to represent the interaction of two types of teachers' knowledge: content knowledge and pedagogical knowledge. He proposed that this interaction be considered in order to understand teachers' expertise in teaching a particular subject matter. Various researchers (for example Koehler and Mishra, 2009; Niess et al., 2009), built on Shulman's PCK to describe the interaction of teachers' understanding of educational technologies with their PCK that results in effective teaching with technology. Specifically, they talked about the technological pedagogical and content knowledge of teachers (TPACK), where this model describes the interactions between and among the three main components of teachers' knowledge: content, pedagogy, and technology. These interactions result in new types of teachers' knowledge, namely PCK, TCK (technological content knowledge), TPK (technological pedagogical knowledge), and TPACK. In this paper, we describe the development of pre-service teachers' TPACK as a result of preparing them in the use of digital tools over one academic year.

## Technological, Pedagogical and Content Knowledge

Though some researchers consider TPACK too blunt an instrument (e.g., Clark-Wilson & Hoyles, 2016; Thomas & Palmer, 2014), other researchers refer to it when studying mathematics teacher's professional development (e.g., Balgalmis, Shafer, & Cakiroglu, 2013; Bowers & Stephens, 2011). Generally speaking, TPACK is the knowledge of how to integrate technology in teaching the subject matter. This knowledge also includes the appropriation between a specific technological tool, the teaching of a specific topic and being aware of the difference between various technological tools in teaching a specific topic. Further, this knowledge means being aware of students' problems of the subject matter that could be overcome by using specific technological tools. It also includes the

awareness of students' difficulties of the subject matter that result from using specific technological tools and how to overcome these problems (Koehler & Mishra, 2009).

Robova, and Vondrova (2015) studied mathematics teachers' awareness of the specific technological skills needed for their teaching (making functions visible on the screen, changing visual appearance of graphs, interpreting numerical results, using dynamic features of a tool) and their ability to design teaching which takes the specific skills into account. Furthermore, Koh and Divaharan (2011) described an instructional model for developing pre-service teachers' TPACK. We follow the previous attempts to suggest a preparation model for developing pre-service teachers' TPACK in utilizing digital tools in their teaching.

### **Pre-service teachers' attitudes toward computers**

Fishbein (1967) defined attitude as a learned tendency to respond to an object in a consistently favorable or unfavorable way. Other researchers (Zan & Di Martino, 2007) defined attitude in terms of emotions: a positive or negative emotional reaction toward a specific situation. These definitions show the possible influence of attitudes on behavior in general and on pre-service teachers' behavior in particular. Attention to attitudes has risen when ICT started to emerge as a possible tool for the improvement of teaching and learning. In this context, researchers found that these attitudes have major influence on the success and meaningful use of the ICT in their teaching (Albirini, 2006).

In our research, attention was given to pre-service teachers' attitudes toward computers, together with the development of their TPACK and ICT proficiency, as a consequence of their preparation in the use of digital tools. We used the 'teacher's attitudes toward computers' questionnaire (TAC) as it probes teachers' attitudes toward ICT use in teaching and their intention to do so (Baya'a & Daher, 2013). We were also interested in the pre-service teachers' proficiency level in ICT as an indicator of their intention to use ICT in their teaching as the proficiency variable is reported to affect teachers' readiness to use ICT in their teaching (Granger, Morbey, Owston & Wideman, 2002).

### **The research questions**

The main research question is: How will the preparation of pre-service teachers in the use of digital tools, according to the model that we designed, affect their TPACK level, ICT proficiency and their attitudes toward computers?

### **Research context, participants and the preparation model**

This current research accompanies the preparation of pre-service teachers to study how to use effectively digital tools in the mathematics or science classroom. This knowledge is the core of the TPACK model. We administered questionnaires to measure the advancement of the TPACK levels and attitudes toward computers of the pre-service teachers who implemented the model, as well as their ICT proficiency. Approximately 55 students majoring in mathematics and science teaching in intermediate schools completed the questionnaires at the beginning and end of the preparation. These students were in their third year of training alongside two courses that provided a background in the use of ICT for teaching mathematics and science.

The preparation model aimed to improve the pre-service teachers' selection of a suitable digital tool for a specific pedagogy and subject. It also tried to improve the integration of digital tools to teach some specific content. This preparation model concentrated on two aspects. First, knowing the tool technically and being able to adapt it to teach some specific content. Second, developing the ability to select and integrate suitable digital tools for some specific content and pedagogical method. In more detail, each pre-service teacher worked independently to learn to use at least two digital tools and to prepare user guides (as PDF file or digital book) that included descriptions of the most significant functions of these digital tools. Furthermore, the pre-service teachers were required to record video clips of screen shots while performing operations in these digital tools as explanations for another user. The pre-service teachers were asked to select the digital tools from a catalog of general digital tools prepared by the ministry of education in Israel. This catalog includes various digital tools that could be adapted for use in various subjects and levels, such as: Flipsnack for creating online digital books, Linoit for creating collaborative bulletin board, Socrative for personal and class assessment and Mindomo for creating mind maps.

Moreover, each pre-service teacher was required to prepare pedagogical materials on how to use the digital tools that she was engaged with in teaching mathematics or science, and then present the materials in the training workshop to receive comments from her peers and the pedagogical supervisor. Following that, the pre-service teacher reflected on her developed materials, adjusted it and uploaded all the materials to an internet site that was constructed by the pre-service teachers and the pedagogical supervisors. This internet site constituted a data bank for digital tools. In addition, each pre-service teacher was requested to prepare at least two lessons for teaching mathematics or science and pick three digital tools from the catalog (including one that she was engaged with) to use them in her teaching. These lessons had to involve also collaborative investigations that encourage the use of higher order thinking skills. Finally, each pre-service teacher picked a subject from within a digital textbook for teaching mathematics or science, and added connections to pedagogical activities based on using digital tools from the data bank site.

During the first semester, the pre-service teachers had two options: to start from the digital tool and integrate it for teaching some specific content, or starting from the content and selecting a suitable digital tool to teach that content. In the second semester, each pre-service teacher was asked to experiment with the prepared materials and lessons in her training school with at least one of the chosen tools, and reflect on the experience. This reflection was on the actual implementation of the digital tool in the classroom environment, and it was posted in the data bank for digital tools for other pre-service teachers to consider as they selected digital tools for their own use.

## **Research instruments**

The research instruments included three questionnaires as follows: Questionnaire 1: Technological, Pedagogical, and Content Knowledge (TPACK) (revised) questionnaire, constructed on the basis of the TPACK instrument for pre-service teachers developed by Schmidt et al. (2009).

Questionnaire 2: Teachers' Attitudes toward Computers (TAC, v. 6.1) questionnaire: This questionnaire was tested by Christensen and Knezek (2009) who concluded that it is a well-validated and reliable instrument for teachers' self-appraisal of their attitudes toward computers.

Questionnaire 3: The Use of ICT in Colleges of Education (UICT): This questionnaire was developed by The MOFET Institute (A Center for the Research, Curriculum and Program Development in Teacher Education in Israel) to track the professional development of pre-service teachers' use of ICT. We used the ICT proficiency part of the questionnaire.

The validity of the questionnaires was considered by giving the Arabic translations to a group of pre-service teachers who were requested to examine if the questionnaires' statements were clear to the reader. As a result, some items of the questionnaires were rephrased to clarify their meaning.

The pre-service teachers' scores in the overall constructs and their categories, before the preparation and after it, were examined for internal reliability using Cronbach alpha. The results showed high Cronbach alpha (above 0.85 for all the categories and for the overall construct) indicating adequate internal reliability for the questionnaires and their categories. These results were expected due to the extensive use of these questionnaires in the literature.

## Data processing

Data was analysed using paired-samples t-test to determine if there were significant differences between scores of pre-service teachers in the various questionnaires before and after the preparation. Cohen's d (the ratio between the difference of the means and the average of the standard deviations) (Cohen, 1969) was used to compute effect sizes to assess the practical significance of results.

## Results

### Pre-service teachers' ICT proficiency

Table 1 shows the proficiency level of the pre-service teachers before and after the preparation (values between 1 to 5), as well as paired sample t-test between the two observations.

Outcome	Before Preparation		After Preparation		<i>t</i>	<i>d</i>
	M	SD	M	SD		
Score of ICT proficiency in UICT	3.80	0.56	4.20	0.59	4.17***	0.70

\*\*\*  $p < 0.001$

**Table 1: Means, standard deviations and t-test for pre-service teachers' ICT proficiency level (n=54)**

As displayed in Table 1, the results show that the pre-service teachers' ICT proficiency level differs significantly before and after the preparation. Large positive effect size of 0.70 was derived for the preparation on the pre-service teachers' ICT proficiency level. This advancement was mainly the result of the major improvement in their 'multimedia tools proficiency'.

### Pre-service teachers' TPACK level

The TPACK level comprised the total score of the TPACK questionnaire and six other scores for each partial type of knowledge for technology, pedagogy, content and intersections between them. Table 2 shows the TPACK components' scores of the pre-service teachers before and after the preparation (values between 1 to 5), as well as paired sample t-test between the two observations.

Outcome	Before Preparation		After Preparation		<i>t</i>	<i>d</i>
	M	SD	M	SD		
TPACK	3.93	0.53	4.50	0.46	8.19***	1.15
TK	3.90	0.63	4.44	0.59	6.31***	0.89
PK	4.04	0.52	4.57	0.46	6.35***	1.08
PCK	3.81	0.57	4.57	0.49	8.49***	1.43
TCK	3.78	0.76	4.45	0.52	7.02***	1.05
TPK	4.02	0.67	4.50	0.63	4.85***	0.74
TPCK	3.88	0.78	4.51	0.68	5.19***	0.86

\*\*\*  $p < 0.001$

**Table 2: Means, standard deviations and t-test for pre-service teachers' TPACK level (n=54)**

As displayed in Table 2, the pre-service teachers' scores in the components of TPACK differ significantly before the preparation and after it. Large positive effect sizes of 0.74 and more were derived for the preparation on the pre-service teachers' TPACK and its components.

#### **Pre-service teachers' attitudes toward computers**

Attitudes toward computers were assessed using 9 categories. Table 3 shows components' scores of the pre-service teachers' attitudes toward computers before and after the preparation (values between 1 to 5, except perception 1 to 7), as well as paired sample t-test between the two observations.

Outcome	Before Preparation		After Preparation		<i>t</i>	<i>d</i>
	M	SD	M	SD

**Table 3: Means, standard deviations and t-test for pre-service teachers' TAC level (n=54)**

As displayed in Table 3, the pre-service teachers' scores in the categories of attitudes toward computers differed significantly before the preparation and after it in the categories: interaction, concern, absorption and TAC general. In these constructs, a small effect size of 0.26 was derived for the preparation on the pre-service teachers' general TAC score, and moderate effect sizes of 0.41,

0.36 and 0.37 were derived for the preparation on the interaction, concern and absorption respectively.

## **Discussion and conclusions**

The research aimed to examine how the preparation course affected the pre-service teachers' ICT proficiency, TPACK level and their attitudes toward computers. The research results indicated several significant positive effects of the preparation model used in that preparation that related to the pre-service teachers' abilities and knowledge regarding the integration of digital tools in teaching.

### **Pre-service teachers' ICT proficiency**

The research results indicated significant improvement in the pre-service teachers' ICT proficiency as a consequence of the preparation, especially in multimedia tools proficiency. The mathematics and science pre-service teachers usually have high ICT proficiency, but the requirements in the preparation model led to significant improvement particularly in their multimedia proficiency. These results are due to a consideration of the technology knowledge related to the digital tools in the preparation process. This resulted in the pre-service teachers increased competence in their use of digital tools for personal and professional purposes, which caused them to feel confident to utilize new digital tools independently and individually (Prestridge, 2012), and thus improved significantly their ICT proficiency. This suggests that pre-service teachers need to be given the opportunities to work with technological tools in order to improve their ICT proficiency and their readiness to integrate ICT in their teaching (Muir-Herzig, 2004).

### **Pre-service teachers' TPACK level**

As a result of the preparation, the general TPACK level of the pre-service teachers, as well as its six partial types, were significantly improved. These results could be due to the attention of the pre-preparation model to the ability of the pre-service teachers to appropriate the digital tools pedagogically to teaching a specific content, and vice versa. It could be said that the pre-service teachers' diverse experiences in the workshop improved their knowledge in different types of knowledge related to their teaching mathematics or science. Thus, the preparation model provided the pre-service teachers with opportunities to maintain and shift their instructional approaches enriched with innovative educational technologies (Martin, 2015). This preparation model could be implemented worldwide when taking into consideration the particular background and conditions of the pre-service teachers involved.

### **Pre-service teachers' attitudes toward computers**

The results of this research show that following the preparation process, no significant improvement was detected in the pre-service teachers' attitudes toward computers for most of the TAC components, with exception of TAC general, interaction, concern and absorption. We should note that in both cases, before and after the preparation, the attitudes were very favorable toward computers.

As for the positive change in some attitudinal categories, such as absorption, the pre-service teachers had, during the workshop, the chance to be actually involved and improve their knowledge in computers and ICT. This might have improved their ability to solve problems related to the

computer use in the classroom; which encouraged them to insist to solve these problems, even the hard ones. This influence of teachers' experience in technology on their ability to solve technological problems is supported by DeLuca (1991) who claims that technological knowledge overcomes technological problems in the classroom. This could improve pre-service teachers' attitudes toward computers.

# Beyond a positive stance: Integrating technology is demanding on teachers' mathematical knowledge for teaching

Nicola Bretscher

UCL Institute of Education, London, UK; [n.bretscher@ucl.ac.uk](mailto:n.bretscher@ucl.ac.uk)

*Research on technology in mathematics education highlights the importance of teachers having a positive stance towards technology for successful integration into classroom practice. However, such research has paid relatively little attention to teachers' knowledge of specific mathematical concepts in relation to technology. This paper examines the innovative use of technology by a teacher, Robert, as a critical case study, to argue that the significance of mathematical knowledge for teaching using technology should not be overlooked nor underestimated.*

*Keywords: Computer uses in (secondary mathematics) education, knowledge base in teaching, TPACK, situated abstraction.*

## Introduction

Seeking to understand teachers' integration of technology, research on technology in mathematics education (e.g. Zbiek et al., 2007) has documented the important role teachers' beliefs and conceptions play in their integration of technology into classroom practice. For example, Zbiek et al (2007) identify the constructs of pedagogical fidelity and privileging as useful in understanding the extent and nature of technology integration in a teacher's classroom practice. Pedagogical fidelity is described as the degree to which teachers' beliefs about the way a digital technology allows students to act mathematically coincides with their beliefs about the nature of mathematical learning (Zbiek et al., 2007). Privileging is a notion developed by Kendal and Stacey (2001) to describe how teachers, consciously or unconsciously, frequently use or place a priority on certain things in their practice, for example, types of representation, skills or concepts and by-hand or by-technology methods (Zbiek et al., 2007). Both these constructs relate to teachers' conceptions of mathematics as a discipline (Thompson, 1992), their beliefs about the nature of teaching and learning mathematics and how these interact with their beliefs about technology.

Such studies have in common a focus on teachers' global conceptions of mathematics as a discipline and on teachers' beliefs about the nature of teaching and learning mathematics with technology. They do not tend to focus on teachers' knowledge of specific mathematical concepts in relation to technology. This is an important omission since the documented shifts in teachers' views suggest a move towards models of teaching aimed at developing conceptual understanding. Such models may require a great deal of knowledge for successful implementation and inconsistencies between teachers' professed beliefs and practices may be the result of lacking sufficient knowledge and skills necessary to implement them (Thompson, 1992).

Whilst highlighting the role of teachers' conceptions in technology integration is important, this paper argues that the significance of mathematical knowledge for teaching using technology should not be overlooked nor underestimated. For example, Bowers and Stephens (2011, p. 290) assert that the set of (teachable) knowledge and skills for teaching mathematics using technology may be empty, emphasising instead that teacher educators should seek to nurture a favourable conception of

“technology as a critical tool for identifying mathematical relationships”. Whilst it may be that teacher educators should seek to nurture favourable conceptions towards using ICT in their trainees, this paper argues the knowledge required to put such conceptions into practice should not be neglected.

## **Theoretical framework**

The central Technology, Pedagogy and Content Knowledge (TPACK) construct of Mishra and Koehler’s (2006) framework is useful in highlighting mathematical knowledge for teaching using technology, by emphasising technology as a knowledge domain alongside pedagogy and content knowledge (Bretscher, 2015). Whilst space does not allow for a full description of the framework, the central TPACK construct serves to highlight the situated nature of such knowledge. In particular, in this paper, mathematical knowledge for teaching using technology is viewed as a *situated abstraction* (Noss & Hoyles, 1996), that is, ‘abstract’ mathematical knowledge simultaneously situated in the context of teaching with technology.

Borrowing from Shulman (1986), mathematical knowledge for teaching using technology is assumed not only to be a matter of knowing how – being competent in teaching mathematics using technology - but also of knowing what and why. That is, although much of teachers’ knowledge may be tacit, craft knowledge (Ruthven, 2007), at least some of their know-how is underpinned by articulated knowledge that provides for “a rational, reasoned approach to decision-making” (Rowland et al., 2005, p.260) in relation to teaching mathematics using technology. In other words, mathematical knowledge for teaching using technology, as defined in this study, is when know-how or knowledge-in-action is underpinned by and coincides with the teacher’s articulated knowledge. This intersection between articulated knowledge and knowledge-in-action is important because it is this type of knowledge that initial or in-service teacher education programmes focus on developing.

## **Method: Robert as a critical case**

Four teachers were selected from a group of English mathematics teachers who took part in a survey of secondary school mathematics teachers’ use of ICT (n=183) and who further agreed to be contacted as case study teachers (Bretscher, 2011; 2014). The four case study teachers were chosen along two dimensions of variation likely to be associated with mathematical knowledge for teaching using technology, based on their responses to survey items. Firstly, the case study teachers were chosen to be two of the most student-centred and two of the most teacher-centred in their approach to mathematics teaching in general (not limited to ICT use) of those who volunteered. Secondly, two teachers were chosen to be from schools with a high level of support for ICT and two with a low level of ICT support. In addition, the four case study teachers had described themselves as being confident with ICT. As technology enthusiasts, the case study teachers were likely to display mathematical knowledge for teaching using technology; the variation in case selection aimed to highlight such knowledge – making it more ‘visible’.

Each case study teacher was observed teaching one lesson in a computer suite where pupils were given direct access to ICT. These observations provided opportunities to infer the case study teachers’ knowledge-in-action in a situation involving the work of teaching mathematics with technology. Post-observation interviews then provided an opportunity to infer the case study

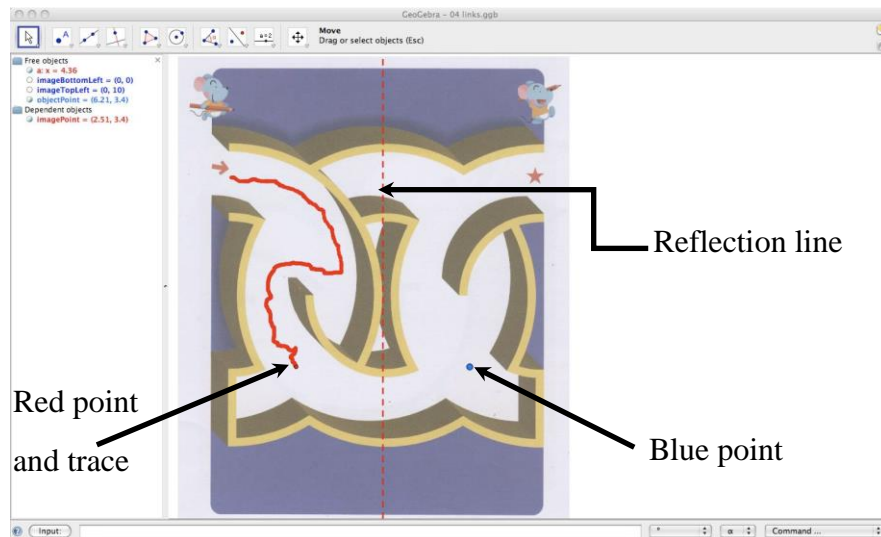

teachers' articulated knowledge and hence, triangulated against their knowledge-in-action observed in the lesson, provide evidence indicating mathematical knowledge for teaching using technology.

Robert was selected as a case study teacher because he was one of the most student-centred teachers in the survey sample. In addition, his school appeared to be generally supportive of ICT use compared to the other schools surveyed. He stood out, even amongst the case study teachers, as being a critical case of a teacher likely to display mathematical knowledge for teaching using technology for two main reasons. Firstly, Robert showed a favourable conception of technology, as described in the following section, in relation to mathematics teaching and in line with Bowers and Stephen's (2011) description of viewing "technology as a critical tool for identifying mathematical relationships". Secondly, Robert's lesson appeared to be exceptional: he used GeoGebra software to affect his pupils' learning in an innovative way that would not be easy to achieve without digital technology, in comparison to the other lessons observed where software was used to replicate and enhance paper-and-pencil activities. He had 4-6 years of teaching experience, held a management position within the mathematics department and had completed a Masters in Education degree. Robert was also the most technologically proficient of the four case study teachers: his undergraduate degree was a Bachelor of Engineering in Computing.

## Analysis and discussion

### Robert's favourable conception of technology use in mathematics teaching

For the first part of his lesson, Robert had created a series of maze activities, embedded in GeoGebra files, designed to take advantage of his 12-13 year old pupils' tacit understandings of reflection as a means of making them explicit and thus leading towards a more formal understanding of reflection. Using the mouse to direct the movement of a point, coloured in blue, the pupils had to guide the blue point's reflection, shown in red, successfully through a maze (see Figure 1).

**Figure 1: One of Robert's GeoGebra maze activities - by dragging the blue point, guide the reflected red point through the maze**

The reflection line was super-imposed on the maze diagram and the path of the red point was traced. Robert hoped that the activity would encourage pupils to predict how the reflected red point would move in relation to movement of the blue point as a means of increasing their chances of

completing the maze successfully. By predicting the movement of the red and blue points, he hoped his pupils intuitive understandings of reflection would be made more explicit.

In the post observation interview, Robert explained what inspired him to create the maze activities. He provided a critique of similar GeoGebra activities as lacking an impetus to focus attention on and articulate tacit understandings:

Robert: I had a look on the GeoGebra wiki and most things tended to be ‘Here’s a mirror line, here’s a shape, if you drag this, what’s happening?’ just kind of ... and say what you see. And I could imagine them sitting there with that and basically just dragging the mouse a bit and seeing it happen and ... and then where does it go from there?

He also described a pedagogic strategy of predict-then-test that he aimed to use in the lesson to make pupils’ understandings of mathematical relationships explicit:

Robert: just you know introduce that ‘pause’ of what do we think is going to happen and then let’s test that it’s going to happen

and how he intended to formalise these understandings during the lesson by introducing mathematical vocabulary:

Robert: So one of the things I wanted to talk about was that if you’re moving that point parallel to the mirror line, the point moves in the same direction, whereas as soon as you’re moving it in a direction that’s not parallel, the point doesn’t move in the same way.

Summarising at the end of the lesson, he did introduce mathematical vocabulary during class discussion, in a similar way to the intention described above, describing the movement of the red and blue points. Thus Robert’s design of the maze activities, his use of them in the lesson and his comments about the lesson in the post-observation interview demonstrate the strong emphasis he placed on the use of technology to explore the mathematical relations behind the mathematical phenomenon of reflection, consistent with Bowers and Stephens’ (2011) description of a favourable conception of technology.

### **Robert’s mathematical knowledge for teaching using technology**

Using the series of maze activities successfully to meet the aims of the lesson depended on transforming students’ strategies for completing the mazes into more formal understandings of reflection that could be used as strategies for constructing the image given an object and line of reflection. As indicated above in excerpts from the post-observation interview, Robert recognised his interventions with individual pupils and directing whole class discussion as being critical to effecting this transformation.

The maze activities potentially addressed two complementary strategies for using geometric properties to construct the image given the object and line of reflection: 1) using the local geometry of the object together with the properties of reflection, namely, preservation of length and of direction parallel to the line of reflection and reversal of direction in the axis perpendicular to the line of reflection, to construct the image; and 2) using the geometric property that the line of

reflection is the perpendicular bisector of line segments connecting corresponding points on the object and image.

The first strategy was addressed through the maze activities by the necessity of considering how to drag the blue point, i.e. in what direction and how far, to guide the reflected red point through the maze. In particular, the main challenge in completing the maze is derived from the reversal of direction caused by the reflection. Less obvious perhaps is that length is preserved: dragging the blue point causes the red point to move the same distance. The second strategy was addressed in later maze activities by the addition of the line segment connecting the blue and red points as a possible aid to maze completion.

Robert was not satisfied with his interventions during the lesson. In the post-observation interview, he pointed to technical difficulties, his desire to let the students enjoy the maze activities and his rush to move onto the second activity as contributing to the result that he did not spend as much time as intended on discussing the geometric implications of the pupils' maze-solving strategies. Timing was certainly a factor and technical difficulties meant that he was unable to direct a whole class discussion juxtaposing the identical mazes with and without the line segment joining the red and blue points. As a result, Robert was unable to address the second strategy outlined above involving recognition of the line of reflection as the perpendicular bisector of the line segment joining the red and blue points. However, he did have two opportunities during the lesson to elicit the geometric properties of reflection that underpin the first strategy through whole class discussion.

The first opportunity came when Robert brought the class back together after some time engaging with the maze activities. He displayed one of the early maze activities with a vertical line of reflection and asked pupils to give instructions to a pupil-volunteer to direct their movement of the blue point. Robert summarised their responses, drawing attention to the relative direction of movement of the red and blue points i.e. that when the blue point was dragged up or down the red point moved in the same way but that dragging the blue point left or right caused the red point to move in the opposite direction. Whilst drawing their attention to the direction of movement, Robert did not mention that dragging the blue point causes the red point to move the same distance, thus he did not draw his pupils' attention to the geometric property that length is preserved under reflection.

Robert then displayed a maze with a horizontal line of reflection and, employing his predict-then-test strategy, asked the pupils to predict whether the relative direction of movement would be the same or different. The pupils correctly predicted it would change: now, dragging the blue point left or right would result in the red point moving in the same way but dragging the blue point up or down would cause the red point to move in the opposite direction. Contrasting these diagrams made the point that the relative direction of movement of the red and blue points was connected to the orientation of the line of reflection. At this juncture, Robert could have introduced the mathematical terms parallel and perpendicular to specify the nature of the connection between the relative direction of movement and the orientation of the line of reflection, thus generalising to state the effect of reflection on direction. He could also have noted that in both maze diagrams, independent of the orientation of the line of reflection, dragging the blue point causes the red point to move the same distance, hence length is preserved under reflection.

Robert did not introduce the mathematical terms parallel and perpendicular at this point nor did he note the geometric property that length is preserved under reflection. Instead, apparently on impulse, he offered his pupils a new challenge: to find out whether turning the mouse back to front would help them to complete the mazes, presumably by double-reversing the direction of movement. This challenge risked distracting from the aims of the lesson, since turning the mouse back to front involves a rotation of 180 degrees and not a reflection. Later in the post-observation interview, Robert dismissed it as “just a silly question to get a few of them thinking”. However, in asking this question, he missed an opportunity to capitalise on his pupils’ correct predictions to generalise their maze-solving strategies towards a shared, formal understanding of the geometric properties of reflection. In particular, Robert’s challenge highlights the situated nature of mathematical knowledge for teaching using technology in terms of weighing up the pedagogical value of interpreting how the mouse movement relates (or not) to the geometric properties of reflection.

The second opportunity occurred at the end of the lesson. Due to the shutdown of the computer system, the students were unable to begin the second GeoGebra activity Robert had prepared. After spending some time wrestling with the technology, Robert gave up and gathered the pupils to summarise the lesson. In this moment of contingency, Robert was inspired to ask his pupils to imagine the join between two rectangular tables, where they met along their longest edge, was a mirror. One of the pupils sitting at the table was holding a ball: this became the de facto ‘blue point’. Robert discussed moving the ‘blue point’ close to the mirror, through the mirror (which he noted you can’t do in reality), and finally parallel to the mirror. He did not have another chance to discuss what happens when the ‘blue point’ moves perpendicular to the mirror nor to discuss the preservation of length under reflection because, at that point, the bell rang for the next lesson.

Although his second opportunity to elicit the geometric properties of reflection was cut short, in the post-observation interview, when asked what he wished to do had there been more time, Robert did not articulate that he meant to discuss what happened when the blue point moved perpendicular to the line of reflection and to note that distances remained the same under reflection. These missed opportunities, together with the post-observation interview, suggest that Robert had not planned precisely what and how he would use mathematical terminology in his interventions to support his pupils’ interpretation of controlling the red and blue points via the mouse, thereby transforming his pupils’ maze-solving strategies into more formal understandings of reflection to connect with the aims of the lesson. In addition, when asked what he would have done differently in preparing the lesson, he focused solely on planning to prevent the technical difficulties arising rather than suggesting he could have been more precise in his use of mathematical terminology. Although Robert did not have much time to deliberate over the lesson (as the author has) and it is understandable that the technical difficulties that were so disruptive were uppermost in his mind, this suggests his experience during the lesson did not prompt Robert to recognise the need to plan his interventions more precisely to connect his series of maze activities with the mathematical aims of the lesson. In particular, Robert appeared to lack a frame of reference to help him identify what his mathematical difficulties were in using technology to make his pupils’ tacit understandings explicit and, as a result, why his interventions appeared unsatisfactory. However, such a frame of reference can be seen as part of mathematical knowledge for teaching using technology, since in this study such knowledge is assumed not only to be a matter of knowing how – being competent in teaching mathematics using technology - but also of knowing what and why (Shulman, 1986, p.13).

## Conclusion

Despite his favourable conception of technology, using the maze activities in practice was not trivial and Robert did not entirely succeed in making explicit the mathematical relationships the pupils were exploring using the GeoGebra software. His difficulties, in supporting his pupils' mathematical interpretation of controlling the red and blue points via the mouse to elicit the properties of reflection, appear at once *mathematical* and yet simultaneously *situated* in the context of teaching using technology. In particular, the strength of Robert's maze activities lay in the real difficulty of controlling the direction of movement of the reflected red point via the mouse. This difficulty focused attention on how the direction of movement changes under reflection, which Robert drew to his pupils' attention through his interventions, albeit without making use of precise mathematical terminology. However, dragging the blue point using the mouse results in the red point moving the same distance unproblematically. Thus the maze activities did not draw attention to preservation of length in the same way, underlining the need for teacher intervention to highlight this property of reflection. The strain placed on his mathematical knowledge for teaching using technology was most evident perhaps when Robert included a challenge relating to rotation, finding out what happens when the mouse is turned back to front, which distracted from his stated lesson aims regarding reflection. This challenge again highlights the situated nature of mathematical knowledge for teaching using technology in terms of weighing up the pedagogical value of interpreting how the mouse movement relates to the geometric properties of reflection.

This suggests that a positive stance towards technology, in terms of global aspects of teacher knowledge (e.g. Bowers & Stephens, 2011; Zbiek et al., 2007), may not be sufficient to ensure a teacher's use of technology enhances mathematical instruction. The missed opportunities to transform pupils' maze-solving strategies into more formal statements of the geometric properties of reflection, using precise mathematical terminology to make connections between the maze activities and the aims of the lesson, suggest that mathematical knowledge for teaching using technology has a significant role to play in successful technology integration. Thus, whilst highlighting the role of teachers' conceptions in technology integration is important, this paper has argued that the significance of mathematical knowledge for teaching using technology should not be overlooked nor underestimated.

## Introduction

In their publication “Learning Outside the Classroom” the English and Welsh Department of Education and Skills strongly recommended that more lessons should take place outside of the classroom. They listed many benefits “nurture creativity, develop skills, improve attitude to learning, stimulate and improve motivation” just to name a few. (DfES, 2006)

The advantage is quite obvious, going outdoors means to encounter real life objects. For mathematics education, it is possible to create authentic tasks such as: What is the height of a certain building? how many stones have been used to build that wall over there? how much water is in that pond? and so on. Tasks such as these immediately require many process competences such as problem solving, reasoning and proof, communication, connections and representations. In the early 1980s Blane and Clark proposed the idea to connect those kind of tasks to form a *mathematics trail*. This requires a map on which to find the tasks, a description of the tasks (both together is called the *trail guide*) and then you can start to walk around and solve mathematical problems. (Blane & Clark, 1984)

In short, a mathematics trail is a set of mathematical outdoor tasks in walking distance. To solve the tasks you normally will need tools like a measuring tape and so on, which should be listed in the trail guide.

Although mobile devices and computers are widely used in every aspect of our daily lives (especially among pupils), they play a small role in education (Chen & Kinshuk, 2005). Going on a mathematics trail could be greatly enhanced by the use of mobile devices, since they allow learning to occur in an authentic context and extend to real environments. At the Goethe University of Frankfurt am Main we started the MathCityMap Project (MCM) which combines traditional mathematics trails with the opportunities of new technologies. In 2013 the first ideas were made concrete

(Ludwig, Jesberg, Weiss, 2013), but it took until 2016 to finally launch an accompanying web portal and mobile application. These have been released mainly for teachers to use in class, but are openly available to anyone who wishes to use it.

In spring 2016 we started to promote mathematics trails in combination with MCM by providing in-service teacher training and student courses at the university. Although the feedback on the training and courses was highly positive, the real usage of the MCM tools falls short of our expectations. In this article, we investigate reasons for this phenomenon we have encountered.

## **Theoretical background**

### **Challenges creating a mathematics trail**

Many mathematical tasks today are contextualized and appear to be realistic. But are they authentic? Following the definition Vos (2011) has given, an object is authentic, if it is clearly not created for educational purposes. Consequently, it is not easy to find authentic tasks. The objects in the tasks of MCM can be described as real-life objects, however, the authenticity of the tasks depends on the creators. We provide assistance by offering training alongside best-practice examples.

Usually the creation process of a mathematics trail consists of designing appropriate tasks and the trail guide or trail booklet (Cross, 1997). On the one hand, creating the tasks can be challenging for teachers as studies have shown (Jones & Pepin, 2016). On the other hand, manually putting the tasks together into a trail guide which should also contain a map overview and a title page, may be time consuming.

### **Difficulties integrating new technologies into mathematics classes**

Given the availability of new technology in schools, questions have always arisen such as, do teachers work with the new tools? how do they use them? and so on. Drijvers made a study in 2012 about the factors for successful use of new technology amongst teachers. One of the three important factors is the role of the teacher (Drijvers, 2012). In Germany, a majority of teachers report to have not enough time alongside their daily tasks at school (Schneider, 2015 p. 20). Consequently, the time a new tool needs to be set up is an important issue. The MathCityMap project tries to simplify the creation process of designing tasks and trails to make it less time consuming for teachers.

In addition, Kuntze, Siller and Vogl (2013) have shown that both pre-service and in-service teachers self-perception towards mathematical modelling is mainly negative. Especially the in-service teachers lack of knowledge about new technologies and modelling. They feel unprepared for modelling by their university education. Pre-service teachers on the other hand feel a lack of diagnostic pedagogic skills and feel unable to give good hints to the pupils. There is a difficulty to integrate modelling into classes, especially with new technologies.

### **GPS-based applications in mathematics education**

Two examples of applications in mathematics education, that already successfully use mobile GPS-data, are Wijers, Jonker & Drijvers (2010), who developed a game which allows students to walk along the shape of geometric objects outside the school, and Sollervall and de la Iglesia, who have developed a GPS-based mobile application for embodiment of geometry (Sollervall & de la Iglesia, 2015)

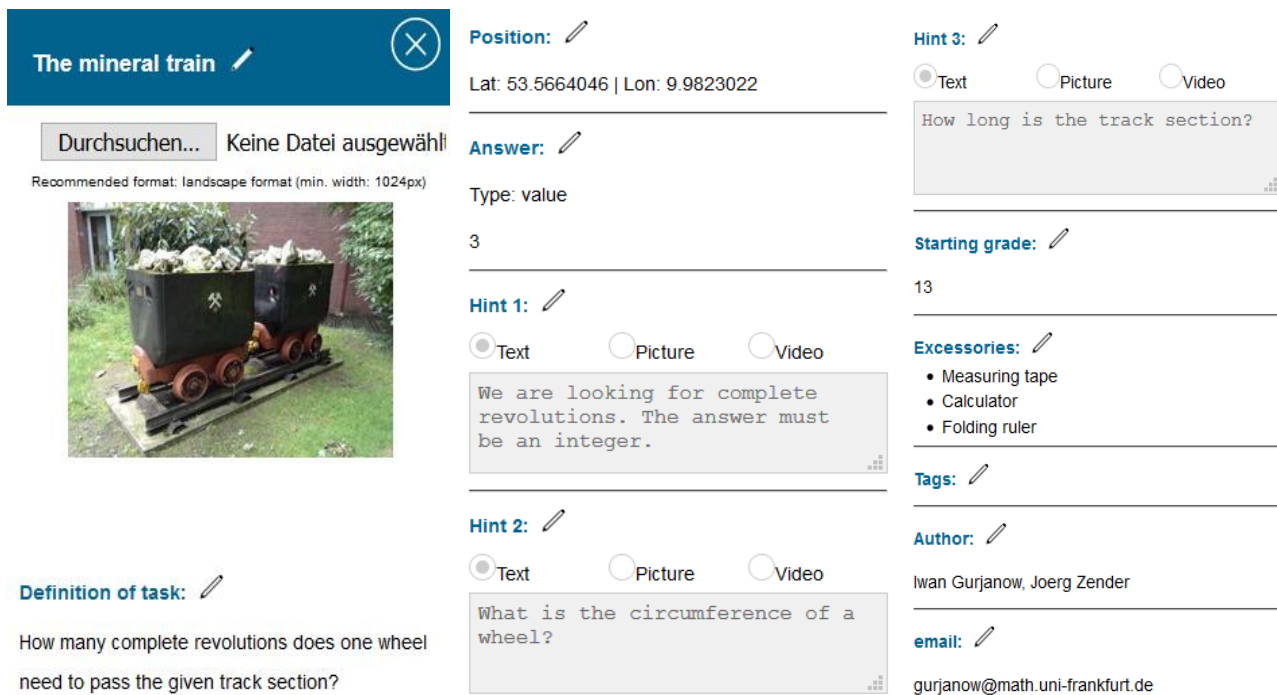

## The MathCityMap project

The intention of the MathCityMap (MCM) project is to automate many steps in the creation of the mathematics trail booklet/guide and to provide a collection of tasks and trails that can be freely used or just viewed to get inspiration for own tasks. Furthermore, it gives users (e.g. groups of pupils) the possibility to go on a mathematics trail more independently by using mobile devices' GPS functions to find the tasks location, by giving feedback on the users answer and by providing hints in the case that one got stuck at a particular task. The core of the MCM project can be divided into two parts, the MCM web portal and the MCM app.

### MCM web portal - [www.mathcitymap.eu](http://www.mathcitymap.eu)

The web portal is a mathematics trail management system. After a short registration, the user can view public trails and tasks or create his own tasks and trails by typing in the necessary data (e.g. position, the task itself, the answer, an image of the object etc.) into a form (see Figure 1). For every mathematics trail, the mathematics trail booklet can be downloaded as PDF or accessed via the MCM App (see Figure 2). It contains all task information, a map overview and a title page.

### MCM app for mobile devices

The MCM app allows the user to access mathematics trails created within the web portal. The trail data, such as images and map tiles, can be downloaded to the mobile device. After this procedure, it is possible to use a trail without an internet connection (see Figure 2). This design decision minimizes technical issues when using the app without mobile internet or in an area with low connectivity. Furthermore, the app offers an open street map overview for orientation purposes, feedback on the entered answers and a stepped hint system. The hint system enables pupils to solve the tasks independently and additionally has a positive impact on learning performance, learning experience and communication (Franke-Braun, Schmidt-Weigand, Stäudel, & Wodzinski, 2008).

**Figure 2: Screenshots of the MCM App**

To describe the pedagogic functionality of MCM, we use the model by Drijvers, Boon and Van Reeuwijk (2010). It divides digital technologies into three groups of didactical functionalities: (a) do mathematics, (b) practice skills, (c) develop concepts. MCM offers mathematical tasks at real life objects where the user mainly can practice his skills.

### Research question

Following the teacher training events, we had expected more teachers to become active by creating own mathematics trails with MCM. This leads us to the research question:

Why do (and don't) in-service teachers and student teachers use MathCityMap? By this question we follow Drijvers study of the usage of digital tools by teachers (Drijvers, 2012).

### Methodology

To promote MathCityMap as a digital tool (and therefore the usage of mathematics trails in school) we have implemented three teacher trainings with 143 participants and two university student courses with 30 students during spring/summer 2016. To evaluate the trainings and gather further information for future improvements of the MCM tool, an online questionnaire was created. Additionally, we have analyzed the usage statistics.

### Teacher training

The training is a half-day intensive training for in-service teachers. Since they have already studied mathematics and have a lot of teaching experience, we keep the theoretical parts on outdoor mathematics and task design rather short and prefer to go out on a prepared mathematics trail so they can experience this kind of activity. Later on, we also let them find tasks and focus more on the handling of the web portal and the app. After this course every teacher will have experienced doing mathematics outdoor with MCM, but also how to create new tasks in the web portal.

### Student courses

The student courses took place at Goethe-University in Frankfurt (11 students) and the University of Potsdam (19 students) in the summer semester of 2016. The following topics formed part of the seminar: Theoretical introduction to mathematics trails, introduction to the MCM App and going on

a mathematics trail with the app, aspects of outdoor task design, creating new tasks and setting them up in the MCM web portal, arranging a mathematics trail, testing the trail with a school class (grade nine), reworking the trail, testing the trail with another class (grade eight). Compared to the teacher trainings the students had to really engage themselves in mathematics trails with MCM.

### **Online survey**

About 200 people (143 participants of the teacher trainings plus registered users of the web portal), who have agreed to receive e-mails about MCM, were invited to take part in the survey. Twenty (eight students and twelve teachers) of them completed the questionnaire.

The online survey consists of 27 items, from which twenty are closed questions or statements and seven are open text fields. The questionnaire is divided into five sections:

1. General Information (Five closed questions)  
Sample item: How did you hear about MathCityMap?
2. Usage of the MCM web portal (Seven mainly closed questions)  
Sample item: Do you already have created a task in the web portal?
3. Statements about the MCM web portal (Seven 5-point Likert scale items: I do not agree – I agree)  
Sample item: The interaction between web portal and app is easy to understand.
4. Feedback on MCM (Four mainly open questions)  
Sample item: Which are the reasons for you to use MathCityMap?
5. General use of digital tools in mathematics classes (Four closed and open questions)  
Sample item: What are your requirements for using a digital tool in mathematics classes?

## **Results**

### **Questionnaire**

Four of twelve teachers stated that they had created their own tasks. Two of them had already used the mathematics trail with a class. All eight students had created tasks and went on a mathematics trail, because it was part of the seminar.

Due to the low number of participants we report the reasons why MathCityMap was used or is going to be used and the reasons why it was not used yet in a qualitative way by forming categories. The answers were collected by an open text field, so multiple reasons could be given. The following categories are sorted by the number of mentions.

**Figure 3: results of the survey about the reasons for using / not using MCM (13 / 8 persons in total, open text answers)**

If we take a look at the things teachers do require from a digital tool to be used by them, MCM is doing quite fine. MCM is easy to get and free to use. It is not time consuming to learn it and some of the teachers already have positive experiences (see Figure 4).

**Figure 4: results of the survey about the requirements to use a digital tool in class (17 persons in total, preset answers, several selections possible)**

### Usage statistics

Independent of the online survey, we also analyzed the statistics relating to the web portal and the app to describe the current state. In September 2016 74 users were registered in the web portal. Thirty of these were in-service teachers who participated in the trainings, about 20 were students who were part of the student courses. The other users were not part of the trainings or courses. In total 33 unique users (45%) created 140 tasks. About 25 mathematics trails were created by 22 unique users (30%). The app has been installed 210 times which means that there must be some people who use only the app, without being registered in the portal (e.g. pupils).

## Discussion

MathCityMap as a digital tool seems to be mainly used as the mathematics trail idea is considered positively (high motivation for students and connecting mathematics to the reality). Hereafter the integration of digital tools in mathematics classes is another reason to use MCM (see Figure 3).

The lack of time, difficulties in creating appropriate tasks and the integration into the current lessons are the most mentioned reasons for why MCM had not yet been used. However, the findings also suggest that the task and trail creation processes in the web tool might be too complex at its current state (see Figure 3). All of these reasons could be interdependent. If one has difficulties in finding tasks or difficulties in integrating the mathematics trail into the lessons, it will take more time to solve these problems. Since many teachers report that they are short of time, this might lead to not using MCM (Kuntze, Siller, Vogl 2013, Schneider 2015).

## Conclusions

In our case the reasons for not using the tool (web portal and app) were mainly identified not in the tool itself, but in the mathematics trail concept (creating tasks, implementing the trail in classes). The teacher training events and student courses need adjustments so that they pay more attention to the following identified difficulties:

1. Higher focus on task design – guidance, best practice examples, blueprint tasks which can be easily adopted to the participants' school surroundings.
2. Creating a teaching concept – concrete example of how to integrate mathematics trails in combination with MCM into mathematic lessons for a particular topic.

In addition, 'doing mathematics outdoors' could be integrated into the school curriculum to increase its significance. On the technical side, further research is needed on how to improve the usability of the MCM web portal to make the creation process more intuitive.

# Exploring a framework for technology integration in the mathematics classroom

Patrik Gustafsson

Mälardalen University, Sweden; [patrik.o.gustafsson@mdh.se](mailto:patrik.o.gustafsson@mdh.se)

*The aim of this paper is to investigate the potential of Ruthven's (2009) framework the Structuring Features of Classroom Practice (SFCP) as a tool to analyze empirical data to conceptualize and analyze teachers' reasoning about technology integration in the mathematics classroom. The framework is tested on interview data from a Swedish design research project seeking to develop design principles for Classroom Response System (CRS) tasks. The results show that the framework captures a large part of teachers' ways of reasoning, while the parts it does not capture are related to students' attitudes and behaviors. If the SFCP framework aims at capturing key features of classroom practice, and is to be built on a system of constructs closer to the 'lived world' of teacher experience and classroom practice, it would benefit from an extension.*

**Keywords:** Technology integration, framework, classroom response system.

## Introduction

Recent years have seen a remarkable increase in technology investments in education, and nowadays many teachers and students have constant access to computers or tablets in the classroom (OECD, 2015). The reasons for these investments are likely related to expectations that digital technology can enhance students' learning, and there are several studies that suggest this (e.g., Cheung & Slavin, 2013; Li & Ma, 2010; Lynch, 2006). However, the mere presence of digital technology in the mathematics classroom does not guarantee improved student learning. For instance, a report on PISA 2012 (OECD, 2015) showed that increased time spent with the computer at school can decrease students' learning in mathematics. It may be possible to explain these ambiguous findings by studying how the technology was used in the classroom (Drijvers, 2013; Hattie & Yates, 2014). Nevertheless, integrating technology in the classroom seems to present a challenge, and one of the most important factors influencing successful integration is the teacher's expertise (e.g., Drijvers, 2013; Ruthven, 2013). Hence it is important to learn more about how to successfully integrate the technology within mathematics education. There is a need for practical analytical research tools and frameworks that offer the potential to analyze teachers' technology integration in mathematics. A commonly used framework, derived from Shulman's (1987) pedagogical content knowledge, is Koehler and Mishra's (2009) Technology Pedagogical and Content Knowledge (TPACK), which focuses on the aspects of teacher knowledge that are needed for the effective use of technology in the classroom. Other researchers have used the theory of "instrumental orchestration" as an interpretive framework for analyzing technology-mediated teaching and learning (cf. Drijvers, Doorman, Boon, Reed, & Gravemeijer, 2010; Trouche, 2005). This theory focuses on a process of "instrumental genesis" whereby a tool evolves into a functional tool and, simultaneously the teacher evolves into a proficient user. Another recently developed framework for analyzing and identifying critical aspects of technology integration in the mathematics classroom is Ruthven's (2009) Structuring Features of Classroom Practice (SFCP). TPACK and "instrumental orchestration" are commonly used frameworks for analyzing technology

integration in the classroom, but as Ruthven (2009, 2013) stresses, the SFCP framework includes aspects such as the complexity and importance of a teacher's "craft knowledge", which other frameworks largely overlook. This is the main reason I have chosen to explore the SFCP framework. A second reason is that the SFCP framework is relatively new and needs to be tested using empirical data from other contexts (Ruthven, 2009). Thus, my contribution to research is that I have investigated the potential of this framework using interview data from a Swedish design research project seeking to develop design principles for classroom response system<sup>1</sup> (CRS) tasks in a multiple-choice format. Hence, the aim of this paper is to investigate the potential of the SFCP framework as a tool to analyze empirical data to conceptualize and understand teachers' reasoning about technology integration in the mathematics classroom.

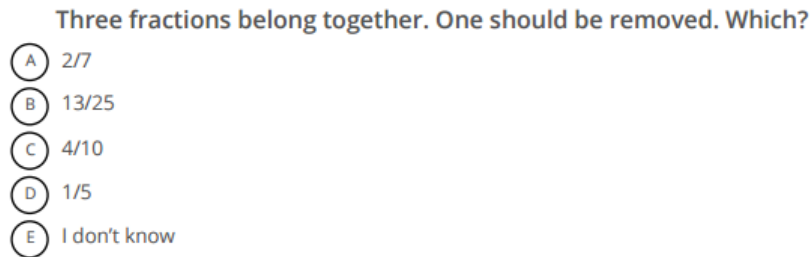

## Participants, context and data

The framework was tested on interview data from two cases of CRS integration in mathematics classrooms within grades 6-9 in lower secondary school in one of Sweden's largest municipalities. One teacher participated in Case 1, and six teachers in Case 2. The reason for working with only one teacher in Case 1 was that this case was a pilot study, which prioritized the depth of the intervention and analysis in the beginning of this design research project. Further, the choice of teachers at these particular schools was partly due to the fact that during these academic years, I was a mentor to mathematics teachers at these schools. In addition, the schools were one-to-one schools, where all students had access to their own computer. These teachers were not explicitly chosen for the research project, they just represent ordinary Swedish teachers in ordinary schools. The reason for working with six teachers in Case 2 was that all of the mathematics teachers at that particular school wanted to improve their teaching and asked me to guide them. Further, the teachers had no (or little) experience in utilizing a CRS, and had received training in how to use the digital resource in practice. In both cases, CRS supported with specific tasks was used to engineer mathematics classroom discussions that could both elicit evidence of learning and also give the teacher an opportunity to advance the students' mathematical thinking. These tasks were often used in the beginning of the lessons or after a short lecture on the topic. Additionally, in Case 1, tasks were also used to evaluate the lessons and obtain information about the students' knowledge at the end of lessons. Based on the teachers' own wishes in Case 2, the teachers also used flipped classroom method to gain more time for classroom discussions, and Peer Instruction method as support for orchestrating the discussions. Based on the teachers' lesson goals and a pilot of the design principles, the researcher constructed and supplied suggestions for tasks to be used with the CRS. In both cases the topic of fractions was chosen, determined by the timing of the study along with the teachers' wishes. The teachers used and evaluated a total of 31 tasks. Figure 1, which follows, shows an example of one evaluated task type with different multiple defensible answers (Beatty, Gerace, Leonard, & Dufresne, 2006).

---

<sup>1</sup> Using a computer or smartphone, students can answer their teacher's question and the teacher can instantly see the results compiled in a chart in the software program and display this for all the students on a shared screen.

**Figure 1: A constructed CRS task with multiple defensible answers**

All CRS tasks were built on the idea that tasks that produce a spread in students' answers, are more likely to prompt a mathematical classroom discussion (e.g., Crouch, & Mazur, 2001). This particular task was developed to be used as a repetition of some important properties of fractions that students had already encountered. Semi-structured interviews were conducted to support one phase of the evaluation of the intervention. In order to explore the SFCP framework, I chose to test the framework using the data from one interview with the teacher in Case 1 and one group interview from Case 2. The interviews were audio-recorded and then transcribed and analyzed in NVivo 10.

## The SFCP framework

The idea of the SFCP framework is to support the identification and analysis of certain crucial features of technology integration (Ruthven, 2009). The framework was developed by synthesizing and extending concepts and constructs from earlier research on classroom organization, interaction and teacher craft knowledge, which resulted in five crucial features (Ruthven, 2009). These features of classroom practice shape the ways in which teachers integrate new technologies (Ruthven, 2013). Ruthven's own summary of the framework is presented in Table 1 (Ruthven, 2013, p. 12).

Structuring feature	Defining characterization	Examples of associated craft knowledge related to incorporation of digital technologies
Working environment	Physical surroundings where lessons take place, general technical infrastructure available, layout of facilities, and associated organization of people, tools and materials	Organising, displaying and annotating materials Capturing or converting student productions into suitable digital form Organising and managing student access to, and use of, equipment and other tools and materials Managing new types of transition between lesson stages (including movement of students)
Resource system	Collection of didactical tools and materials in use, and coordination of use towards subject activity and curricular goals	Establishing appropriate techniques and norms for use of new tools to support subject activity Managing the double instrumentation in which old technologies remain in use alongside new Coordinating the use and interpretation of tools
Activity structure	Templates for classroom action and interaction which frame the contributions of teacher and students to particular types of lesson segment	Employing activity templates organised around predict-test-explain sequences to capitalise on the availability of rapid feedback Establishing new structures of interaction involving students, teacher and machine, and the appropriate (re)specifications of role
Curriculum script	Loosely ordered model of goals, resources, actions and	Choosing or devising curricular tasks that exploit new tools, and developing ways of staging such

	expectancies for teaching a curricular topic, including likely difficulties and alternative paths	tasks and managing patterns of student response Recognising and responding to ways in which technologies may help/hinder specific processes and objectives involved in learning a topic
Time economy	Frame within which the time available for class activity is managed so as to convert it into “didactic time” measured in terms of the advance of knowledge	Managing modes of use of tools so as to reduce the “time cost” of investment in students’ learning to use them or to increase the “rate of return” Fine-tuning working environment, resource system, activity structure and curriculum script to optimise the didactic return on time investment

**Table 1: The SFCP framework components****Method of analysis**

The interview data was used as a means to explore the potential of the SFCP framework. In this exploration, the framework was used as an analytical tool to capture teachers’ reasoning about utilizing a CRS. To support the exploration of the framework’s potential, I used two analytical questions: 1) How much of teachers’ reasoning ends up in the various categories in the SFCP framework? and 2) Are there parts of teachers’ reasoning that do not fit the categories of the SFCP framework? If so, does a new theme emerge? To answer these questions, I conducted a content analysis with systematic quantification (Kvale & Brinkmann, 2009), with text segments in the transcriptions of the interviews coded in NVivo 10 based on the categories in the SFCP framework. I then compiled the text segments from every category and wrote an accompanying narrative.

**Summary of the content analysis**

Due to space limitations, the outcome of this content analysis is not presented in detail here; instead, some of its main findings are discussed.

**Working environment**

The teacher in Case 1 pointed out that when the projector screen is pulled down it blocks a large part of the whiteboard surface. This can constrain the usage of the CRS. When the teacher wants to write students’ solutions to or explanations of CRS tasks on the whiteboard she has to pull up the projector screen and blacken the computer projection, and then pull the screen down again to continue the CRS tasks. This may constrain the possibility to conduct a classroom discussion. Further, in both cases the teachers declared that students sometimes do not bring their computer, and sometimes do not have access to the internet. Students without a functional computer or internet access constrain the work in the classroom. The teachers solved this by letting students work with a peer who had a computer.

**Resource system**

The teacher in Case 1 emphasized the importance of combining CRS tasks aiming at engineering a discussion with a demonstration of methods. This suggests that the teacher needed to coordinate these two curricular elements to achieve the lesson’s goal. The teacher also mentioned that students seemed to be reluctant to work out solutions to the CRS tasks on paper before submitting an answer in the software program. According to the teacher, this constrained her opportunity to identify and see students’ reasoning behind their answers before the discussion. A teacher in Case 2 did not

believe students needed access to paper and pencil before responding to a task, but thought this could be useful afterwards if they were to proof their own or others' answers. Further, teachers in Case 2 told of struggling with the software and launching tasks in the wrong mode. This gave all the students access to all the tasks at once, which resulted in the teachers decision to shut down the CRS work for that particular lesson. They then discussed the possibility of trying out the different modes before the lesson.

### **Activity format**

The teacher in Case 1 said that the CRS tasks were a great way to get all of the students focused. The students interacted with their computer, and were forced to contribute with an answer to the tasks. They then interacted with their peers through peer and whole-class discussions. The activity formats used in both cases were: first alone, then peer discussion, and finally a whole-class discussion; and also first alone and then a whole-class discussion. One teacher mentioned that it was hard to decide whether to orchestrate a whole-class discussion or a group discussion in tasks with multiple correct answers when applying peer instruction, which holds that students benefit from a group discussion if 30-70% of the students responding correctly. Further, the teachers also discussed the importance of allowing time *before* the students are to respond to the CRS task. Several of the teachers let the students take as much time as they needed, which led to some students having to wait a couple of minutes.

### **Curriculum script**

Teachers mentioned that the CRS tasks made them aware of some student misconceptions, and gave them an opportunity to deal with them. Further, the teacher in Case 1 pointed out the improvement of feedback, both the possibility to use instant feedback through the computer in CRS tasks and the feedback in the peer and whole-class discussions related to the discussion tasks. The technology and tasks 1) gave the teacher information about students' knowledge, and 2) added a new form of feedback resource which, together, developed the teacher's curricular script. Moreover, in Case 2, several teachers identified and talked about different types of CRS tasks and their characteristics, and how they had succeeded in engineering a discussion. One teacher realized that you could not always have tasks with several correct answers, because the students quickly realize this. The teachers also stressed that it is hard to conduct whole-class discussions on CRS tasks, and one teacher mentioned the importance of having a clear teaching strategy for every CRS task to improve the whole-class discussion.

### **Time economy**

The teacher in Case 1 believed that having CRS tasks at the end of the lesson makes students more focused on mathematics for a greater part of the lesson. These tasks improved the "rate of return" in two ways: firstly, students worked with mathematics for a larger part of the lesson; secondly, the software program automatically gave students instant feedback on their answers. One teacher said she would continue using CRS, although it takes time to prepare. Thereafter, she mentioned that *"it's worth the time because it activates every student...when I activated one student who usually doesn't participate she said 'ahaaa' in front of the whole class. It was amazing"*. Several teachers pointed out that the discussions take time, and that it is a challenge to decide how long to work on each task and how many tasks to use in one lesson.

## Results

In this section I present the results of the analysis of the framework's potential according to the analytical questions.

### How much of teachers' reasoning can be categorized within the SFCP framework?

Table 2 shows the coverage of the different categories in the transcription of the interviews regarding teachers' reasoning in Cases 1 and 2. Some text fragments were coded in several categories. I have also rounded the figures. All features captured some parts of the teachers' reasoning, and a total of 90% of the interview in Case 1 and 65% of the group interview in Case 2 were captured by the framework.

	Working environment	Resource system	Activity format	Curriculum script	Time economy
Case 1	5%	20%	25%	20%	20%
Case 2	5%	15%	15%	25%	5%

**Table 2: The SFCP frameworks coverage of teachers' reasoning in the interviews**

### Are there parts of teachers' reasoning that do not fit the categories of the SFCP framework? If so, does a new theme emerge?

Approximately 10% of teachers' reasoning in Case 1 and 35% in Case 2 did not fit the SFCP framework categories, and when the parts the framework did not capture were analyzed a clear theme emerged. Almost all reasoning that the framework did not capture was related to students' attitudes and behaviors. I will continue with a summary on this theme.

All teachers reasoned about their students' attitudes and behaviors concerning the lessons. Some classes and students greatly enjoyed working with CRS tasks in mathematics. As one teacher said, *"they think it's fun to discuss things"*. Another teacher reported that *"the students were crazy about the CRS tasks"*, and another talked about how the students want very much to respond correctly to the tasks and demanded to do it again in the next lesson if they failed the first time. In some classes the students were eager to discuss the CRS tasks; the teacher commented that *"the students want to hear their peers' opinion and they want to tell the class about their own perception"*. Further, teachers also mentioned that some students did not want to participate, especially in the discussions, during which they simply sat quietly. Some teachers had difficulty in handling students who wanted to respond quickly and could not wait for others to think and respond to the tasks. All the teachers in Case 2 talked about the difficulty of getting students to do the homework and to be prepared for the work with the CRS tasks in the classroom. One teacher mentioned: *"In one of my classes, only one student had done the homework and watched the flipped movie at home."*

## Conclusions and discussion

The exploration of the SFCP framework showed that it captured a large part of teachers' reasoning about technology integration in the mathematics classroom. Most of the teachers' reasoning was related to features of activity format, curriculum script and resource system. My conclusion is that the SFCP framework could be useful as an analytical tool for conceptualizing and analyzing

teachers' reasoning about technology integration in the mathematics classroom in the context of Sweden and CRS technology. However, the framework did not capture all the teachers' reasoning about important aspects of technology integration. Almost all of the reasoning that did not fit any category was related to students' attitudes, and students' behavior. According to Ruthven (2009), the SFCP framework aims at identifying and making key structuring features of classroom practice analyzable for the integration of technology into a classroom. Further, Ruthven (2009) states that the benefit of the SFCP "is in providing a system of constructs closer to the 'lived world' of teacher experience and classroom practice" (p. 145). This study's results indicate that students' attitudes and behaviors are an important factor that teachers reason about when discussing the implementation of technology in the mathematics classroom in Sweden. Like all five features of the SFCP, I suggest that students' attitudes and behavior are also important factors for successful technology integration in classroom practice. Research on CRS points out that students' attitudes and behaviors are a challenge that teachers face (e.g., Kay & LeSage, 2009; King & Robinson, 2009; Lee, Feldman, & Beatty, 2012). If the SFCP framework aims at capturing key features of classroom practice and is to be built on a system of constructs closer to the 'lived world' of teacher experience and classroom practice, it would also benefit from taking into consideration students' attitudes and behaviors. This could be done by adding a new, sixth construct to the framework relating to teacher craft knowledge for managing different types of student behaviors or attitudes.

The main contribution of this paper is that it investigates the potential of the SFCP framework with empirical data from a new context and new types of data. It was partially tested on data from group interviews in the context of CRS integration in mathematics at Swedish lower secondary schools. Further, this study and the conceptualization of teachers' reasoning about CRS integration can contribute to the knowledge regarding challenges involved with utilizing a CRS in the mathematics classroom. This conceptualization may also be useful for teachers intending to integrate CRS into their practice. For instance, they could gain knowledge about different activity formats and common challenges, as well as how to deal with these challenges. Finally, the results from this study need to be further investigated with empirical data from similar or other contexts.

# Preparing preservice teachers to use instructional technology: How much development can happen in one semester?

Janet M. Herrelko

University of Dayton, Dayton, Ohio, USA; [jherrelko1@udayton.edu](mailto:jherrelko1@udayton.edu)

*Abstract: Knowledge of instructional software programs that can meet mathematical curricula objectives, motivate and engage students in problem-based learning/inquiry is essential for teachers. This is the first of a series of studies tracking the implementation of instructional technology in a mathematics methods course. Data were collected from surveys, power point presentations of an instructional technology lesson, and the reflections written post lesson presentations. The data were used to classify where preservice teachers were on the five steps Apple Classroom of Tomorrow (1994) inclusion of instructional technology in the classroom. Of the 24 preservice teachers, 21 were solidly on Step 2 – limited use of technology. There were 3 who stood at Step 3 creating their lesson plans to use technology on a daily basis.*

*Keywords: Instructional technology, preservice teachers, mathematics education.*

## Introduction

Teaching mathematics in 2016 requires far more than a deep understanding of mathematics. Multiple pedagogical methods and strategies are needed to address student learning needs. Today, teachers need to use instructional technology that applies scientific processes and stored knowledge to solve practical tasks (Earle, 2002). Knowledge of computer software that can meet curricula objectives, motivate students, and engage students in problem-based learning and inquiry is essential. The ground work for applying technology with intent and purpose should be part of the responsibility of teacher preparation programs. Defining instructional technology in education has been evolving since the American Educational Communications and Technology group produced a broad definition in 1963 that matched the elements of pedagogical courses of the time (Ely, 1963, p. 18-19). While the technology sections of learned societies grappled refining the definition of instructional technology, the Association of Mathematics Teacher Educators (AMTE) created standards for the preparation of preservice mathematics teachers for grades Pre-Kindergarten to grade 12 (PK-12). These standards devoted a section of the Adolescence to Young Adult (AYA) grades (C.1.6. Using Mathematical tools and technology) identifying the types of mathematical software preservice teachers should master. AMTE explained C.1.6. with the following statement:

Well-prepared beginning teachers of secondary mathematics must be proficient with tools and technology designed to support mathematical reasoning and sense making, both in doing mathematics themselves and in supporting student learning of mathematics. In particular, they should develop expertise with spreadsheets, computer algebra systems, dynamic geometry software, statistical simulation and analysis software, and other mathematical action technologies, as well as other tools such as physical manipulatives (AMTE, 2017, p.133). The AMTE elaboration aligns with the goals of this research to help mathematics preservice teachers become competent and frequent users.

## **Integration of instructional technology into curricula issues**

Ertmer, Conklin, Lewandowski, Osika, Selo, and Wignal (2003) found that preservice teachers needed specific ideas and examples of how to put instructional technology into their mathematics instruction. Wang's (2004) research noted that goal setting increased self-efficacy. Dexter and Riedel (2003) identified clinical educators use of instructional technology as a key to helping preservice teachers increase their classroom technology self-efficacy. For this research, instructional technology was practiced in the methods course providing teaching ideas and strategies to the preservice teachers. A teaching assignment goal required use of a software program following Wang's (2004) finding.

## **Introduction of technology to pre-kindergarten to Grade 12**

In the 1970's, Apple® created the Apple®II for classroom work. By the 1980s, computers became part of some PK-12 classrooms. School districts developed technology plans to implement the use of computers at each grade level. However, the districts were missing measurable objectives to track and identify the educational impact of computer use by the teachers and student. By the 1990s, schools had a computer on every teacher's desk and computer laboratories. The 2000s students worked with personal devices such as Chromebooks and iPads. Graphing calculators span the decades since Demana and Waits (1988) noted the importance of creating multiple graphs to grasp a mathematical concept.

## **Preservice teachers using technology for knowledge production**

Preservice teachers are well versed in the use of electronic devices as are today's PK-12 students. Applying that understanding beyond word processing, communications, and gaming to using technology for knowledge production should be part of every teacher preparation program. Doering, Hughes, and Huffman (2003) did a five-year study that provided the hardware and software for their preservice teachers and content faculty at the University of Minnesota. Initially, they found that preservice teachers had solid knowledge of technology use, but integrating technology into daily instruction and problem-based learning was not a skill they had. By the end of the study, integrating instructional technology into content and pedagogical classes, preservice teachers became productive users of instructional technology in their field experiences. Franklin (2004) reported on the attitudes of University of Virginia elementary level teacher graduates. The participants noted a clear understanding of classroom technology to foster student curiosity and construct ideas. These teachers had a deep comprehension of electronic pedagogical content knowledge as the reason for their smooth transition to classroom implementation. The use of Web 2.0 tools in the classroom by preservice teachers was examined by Sadaf, Newby, and Ertmer (2016). Use Web 2.0 tools to increase learning, preservice teachers needed: support of their clinical educator; easy access to those tools; and to hold a high level of self-efficacy regarding their ability to help student learning. Only when these elements were met did the preservice teachers use instructional technology in their classrooms.

## **Assessment scales for instructional technology implementation**

A long term study by, Dwyer, Ringstaff, Haymore, and Sandholtz (1994) working with Apple Classroom of Tomorrow (ACOT) examined how teachers adapted their classrooms and pedagogy to using technology when provided with multiple computers, an abundance of software, technical support and training. The researchers identified a five step progression of how teachers developed technology-based pedagogy naming it the ACOT stages of classroom change. Step 1 - Entry. The

teachers are acquainted with the basic tools of the computer and classroom programs. Step 2 – Adoption, the teachers adopted the computer programs for limited use (defined as practice not knowledge building). Step 3 – Adaptation, the teacher thoroughly integrated the use of computers into the curriculum. This step resulted in students learning more, being engaged with the content, and producing better knowledge products. Step 4 – Approbation, teachers who cannot teach without computers. Step 5 – Invention, teachers created their own programming that enhanced student learning. The ACOT (1994) study noted that teachers' development was not done in leaps, but moved forward in increments over time. As the teachers embraced technology, their pedagogical strategies shifted from being teacher-centered to student-centered.

## **Theoretical framework**

The researcher selected the ACOT (Dwyer et al., 1994) steps to serve as the theoretical framework for this study to judge how preservice teachers developed using technology. The ACOT instrument focused on the changes in teacher practice whereas, other instruments focused on the partnership of the teacher and the students. The case study descriptive quality lends itself to using the ACOT descriptions to define advancement on these steps. This research is to learn how far preservice teachers can grow using instructional technology in one semester.

## **Method**

This article is the first report of a long term descriptive case study following American preservice mathematics teachers in a mathematics methods course that required a lesson using instructional technology to be taught during a 90-hour field experience. A case study format fits this research as it describes the conditions necessary to produce knowledgeable preservice teacher's regarding instructional technology. The research question is: How far can preservice teachers develop using instructional technology on the ACOT Steps in one semester?

## **Participants**

The 24 preservice teachers in this study were enrolled in a course entitled Secondary Mathematics Methods, which was required for state licensure to teach. Eleven majored in Adolescence to Young Adult Mathematics Education (AYA). Thirteen were Middle Childhood Education (MC) mathematics. There was one male in each licensure group with 10 AYA females and 12 MC females.

## **Setting**

The university is a private, non-profit school in the south-western, urban section of a Midwestern state in the USA. There are approximately 8,529 undergraduates and 3,117 graduate students. The Teacher Education department conducts classes at the undergraduate and graduate levels.

## **Procedure**

In the methods course, a survey was given asking how frequently students used: 1) word processing; 2) spreadsheets; 3) power point presentations; 4) photomath; 5) Wolfram Alpha; 6) DESMOS; 7) GoogleSketchUp; 8) Polling apps; 9) GeoGebra; added in 2016 10) Kahoot. Likert scales from 0-never used to 5-used all the time were the choices. The course introduced freeware mathematical programs, demonstrated them and provided practice teaching. During the clinical experience, the preservice teachers were required to create and teach an instructional technology lesson.

## **Study history: Equipment survey of partnership schools**

One of the elements needed for preservice teachers to use instructional technology was easy access to Web 2.0 tools in the classrooms (Sadaf et al., 2016). This study interviewed the university's partnership school districts to learn what technology was in their classrooms. The schools reported that they had invested in computers for all teachers and individual laptops, iPads, or Chromebooks for the students. The more frugal districts had multiple computer carts with 30 individual devices for classroom use. Regarding educational software programs, freeware was the programming of choice. The availability of Web 2.0 tools and software programs allowed the researcher to create an assignment goal requiring the use of instructional technology that Wang (2004) recommended.

## **The search for mathematical freeware and program criteria**

The criteria used to evaluate the appropriateness of the instructional technology were the eight Common Core State Standards Mathematical Practices (CCSSM) (National Governors' Association & Council of Chief State School Officers, 2012) and the eight National Council of Teachers of Mathematics (NCTM) Teaching Practices (Leinwand, 2014). Any mathematical program had to require students to perform six of the eight Mathematical Practices and the teacher to use all eight NCTM Teaching Practices. At an NCTM affiliate meeting, in a Skype session by DESMOS creator Eli Luberoft taught the participants to use the program in minutes. At the NCTM Interactive Institute 2015, the program focused on freeware of GeoGebra, DESMOS, and polling programs to engage students in discourse to evaluate the solutions of others. These polling programs required smart phones rather than clickers. Wolfram Alpha could be used for higher levels of mathematics. This program had many more options for teachers to integrate other content areas. This search for instructional technology was not exhaustive. Once these major programs were found, the researcher stopped the search. The study included: DESMOS, GeoGebra, Wolfram Alpha, PollEverywhere.

## **Data collection**

The data collection began with a survey at the start of the mathematics methods class asking preservice teachers how frequently they used software programs. The instructional technology lesson plans with preservice teacher reflections were collected after the six weeks of field experience. The reflections served as a record of the preservice teachers' comfort level, frequency, and self-efficacy using technology. The preservice teachers presented their instructional technology lesson in a power point presentation that included video clips of their teaching with instructional technology, their classes discussing and completing the mathematical work, and voting on the most elegant solutions. The video tape clips verified what was stated in the lesson plans and reflections. Data were recorded regarding the frequencies that the preservice teacher used: instructional technology; had students use that software; and the issues that arose while teaching a technology-based lesson.

## **Data analysis**

### **Analysis of survey**

The Survey of Classroom Technology for Knowledge Production was conducted to learn how familiar the preservice teachers were with use of instructional technology. The Likert scale scores were totaled and measures of central tendency were calculated.

### Assessment of class assignment

The researcher created an assignment with a goal matching the findings of Wang (2004) to learn what level the preservice teachers reached on the ACOT scale of proficiency – could they use and integrate technology smoothly into their teaching? Each preservice teacher created and video-taped an instructional technology lesson plan using a real world problem for their classes to solve by using a mathematical software program. Once the students had solutions, they were grouped and each student explained their solution to the group. The group debated the solutions and modified their work to create their best solution. Each group presented their work to the class. PollEverywhere was used by students to vote on the elegant solution. The projects were graded using the rubric found in Table 1.

*16 points of the total possible of 21 points is the minimum passing grade*

Elements	1	2	3	Score
1. Completed UD lesson plan format	Hard copy of the lesson passed in with the incomplete reflection. The lesson plan lacks the sections and requirements of the AYA/MC UD Lesson Plan format.	Hard copy of the lesson passed in with the completed reflection. The lesson plan follows most of the section requirements of the AYA/MC UD Lesson Plan form	Hard copy of lesson passed in with written reflection. The lesson plan format follows all the requirements of the AYA/MC UD Lesson Plan format. The reflection provides clear and thoughtful responses.	
2. Use of DESMOS, GeoGebra, or GoogleSketch-Up	Your presentation shows your attempt to use DESMOS, GeoGebra, Google-Sketch-Up to present the problem	Your presentation shows your use of DESMOS, GeoGebra, Google-Sketch-Up posing the problem	Your presentation clearly shows your mastery of DESMOS, GeoGebra, or GoogleSketch-Up as the presentation mode for posing your problem	
3. Problem solving with engaging real world problem	Evidence of the students solving a mathematical problem.	Evidence of the students solving a real world math problem.	Evidence of solving an engaging, real world problem. The problem is posted and easily read.	
4.Math discourse: explain,defend, challenge the ideas of others	Evidence of students engaged in classroom discourse, but not on topic.	Evidence of engaged classroom discourse. Types of discourse are not clear.	Evidence of classroom discourse that includes explaining, defending, and challenging the solutions/ideas of others.	
5. Student presentations	Evidence of presenting solutions with no reasoning.	Evidence of solutions with little explanations.	Evidence of presentations explaining/defending their solution.	
6. Student use of polling	No use of polling devices	Some students use polling devices.	Evidence of the students using electronic polling	
7. Clear video of the voted solution.	No clear result to the voting. Or the solution is not clear	Problem solution is correct, but not the voting.	Evidence of the problem solution selected by the class can clearly be read.	

**Total Score**

\_\_\_\_\_/21

**Table 1: Technology and mathematics project rubric**

During the power point presentations, notes were taken by the researcher regarding the frequency of use and the issues that the preservice teachers had when implementing this lesson. Lesson reflections were reviewed for common themes and attitudes.

## Results

The results of the Survey of Classroom Technology for Knowledge Production revealed that the AYA preservice teachers used mathematics instructional technology more than the MC preservice teachers prior to the methods course. All 24 preservice teachers used word processing, 11 used spreadsheets, and 19 used power point presentations. When the preservice teachers reached the specific mathematical instructional technology questions, many scores were zero. See Table 2 for median scores, standard deviation and standard error measure.

**Table 2: 2015 Survey of Classroom Technology for Knowledge Production, N=24**

Question	1	2	3	4	5	6	7	8	9	10
Median	5	1	2	0	2	2	0	0	1	0
S.D.	0	0.65	0.79	0.2	1.57	1.31	0	0	1.4	0
S.E.M.	0	0.13	0.16	0.04	0.32	0.27	0	0	0.29	0

The preservice teachers were able to implement the instructional technology lesson to varying degrees. The AYA preservice teachers were able to create a real-world problem around which they built their lesson using instructional technology. The preservice teachers taught the students how to use their selected computer program on one day and the lesson the next day.

The MC preservice teachers created their real-world problems, but those who taught in grades 4 and 5 were not able to use any program. Their cooperating teachers believed that this technology was not developmentally appropriate for the students. Since a majority of the students in these grades did not own smart phones, many of the preservice teachers used Kahoot. The preservice teachers used this software program to project questions for voting.

**Table 2a: 2016 Survey of Classroom Technology for Knowledge Production Pre-Field, N=15**

Question	1	2	3	4	5	6	7	8	9	10
Median	5	3	4	0	1	0	0	2	2	2
S.D.	0.52	1.26	1.39	0.60	1.21	0.85	0.28	1.72	1.34	1.59
S.E.M.	0.14	0.35	0.39	0.17	0.34	0.24	0.08	0.48	0.37	0.44

**Table 2b: 2016 Survey of Classroom Technology for Knowledge Production Post Field, N=15**

Question	1	2	3	4	5	6	7	8	9	10
Median	5	2	4	0	0	1	0	1	0	2
S.D.	1.3	1.35	1.06	0.52	1.10	1.22	0.74	1.20	1.10	1.46
S.E.M.	0.34	0.35	0.27	0.13	0.28	0.32	0.19	0.31	0.27	0.38

The 2015 scores from the project rubric were reported in the following data for Year 1:

**Table 3a: 2015-Data Results from Technology + Mathematics Methods Project Rubric Scores.**

	Rubric #	1	2	3	4	5	6	7	N=24	
0.51	Median	3	2	3	3	2	3	3	S.D.	0.64
	0.52	0.51	0.26	0.74						0.63
	S.E.M.		0.17	0.16	0.13	0.13	0.13	0.07	0.19	

**Table 3b: 2016-Data Results from Technology + Mathematics Methods Project Rubric Scores.**

	Rubric #	1	2	3	4	5	6	7	N=9	
0.71	Median	3	3	2	3	3	3	3	S.D.	0.0
	0.44	0.0	0.0	0.0						0.0
	S.E.M.		0.0	0.0	0.24	0.15	0.0	0.0	0.0	

Over all, the 2015 and 2016 rubric scores were 2 or 3. There was one student who did not do the assignment. The preservice teachers were successful having the students vote on the elegant solution to their problem. The high mean score with the lowest standard deviation and standard error measure confirm the attention the preservice teachers paid to this element of the assignment. The power point presentations with video clips demonstrated the ease with which the preservice teachers acquainted their classes with instructional technology. This assignment matched the attributes needed for success by preservice teachers learning instructional technology found by Ertmer et al., (2003) specific ideas, Sadaf et al., (2016) available Web 2.0 tools, and Wang (2004) providing goals. The overall theme in the preservice teachers' reflections found that using instructional technology was a positive experience. They solved technology issues including: the internet working only on laptops in half of the classroom; no internet accessible; reserving the cart of tablets then found another teacher took the cart without regard for the reservation list. Observing the power point presentations and reading the lesson reflections for Year 1, the preservice teachers noted the number of times they used instructional technology beyond the assignment. Given the one preservice teacher who did not do the assignment, 20 preservice teachers were solidly on ACOT Step 2 – limited use of technology. Three of the 24 used some version of instructional technology almost every day placing them on Step 3 – Adaptation where they built more lessons implementing instructional technology. For Year 2, there was a wider variation in the levels achieved. Three pre-service teachers were at Step1entry use of technology. They only used technology for this unit. Ten pre-service teachers achieved Step 2 which is defined as limited use of technology. Five pre-service teachers (four AYA, one MC) achieved Step 3 where they incorporated technology as a major teaching tool on a regular basis.

## Discussion

### Implications and connections to mathematics teacher education

Adding program elements for instructional technology into the curriculum for preservice teachers is not a simple fix. Instructional technology needs time to present, model, and practice. The research by Carlson and Gooden (1999) suggests that the responsibility for teaching preservice teachers to integrate technology be done not only in education courses, but also in mathematics classes. If these two departments can collaborate sharing this responsibility, the preservice teachers would witness the power and benefits of teaching with technology. Preservice teachers need to learn how to use instructional technology in order to create student-focused classrooms that engage their students in the learning process from their first day of teaching mathematics.

<sup>3</sup>Johannes Kepler University, Linz, Austria; [markus.hohenwarter@jku.at](mailto:markus.hohenwarter@jku.at)

*The purpose of this paper is to introduce an ongoing Erasmus+ project “Maths Teachers’ Adventure of ICT Integration (MTAI)” and its outputs. The main aim of the project is to provide professional development for mathematics teachers to integrate Information and Communication Technologies (ICT) into their lessons. To achieve this, three intellectual outputs have been designed; an open online course (OOC), open educational resources (OER), and an online teacher community (OTC). In the scope of the OOC teachers should gain insights about ICT integration into mathematics classrooms. Through development and dissemination of OER we aim to help overcome the scarcity of resources. Through support of peer teachers and researchers at participating organizations we hope to establish an OTC including the teachers participating in the OOC. This paper focuses on the design of the three outputs.*

*Keywords: Erasmus+ project, online learning, open educational resources, online community, professional development*

## Introduction

Numerous research studies (Li, & Ma, 2010; Cheung, & Slavin, 2013) have shown that technology integration can play an effective role in tackling the challenges of teaching mathematics. In their study Hew and Brush (2007) have determined several barriers of technology integration for teachers: resources, institutional constraints, subject culture, attitudes and beliefs, knowledge and skills, and assessment. They also describe strategies to overcome these barriers such as: having a shared vision and technology integration plan; overcoming the scarcity of resources; changing attitudes and beliefs; reconsidering assessments; and conducting professional development. Bingimlas (2009) and Kopcha (2012) have also pointed out that professional development activities for teachers play an important role concerning technology integration in education and, in relation to this, several studies indicate the potential of active professional communities (Arkün, & Aşkar, 2013; Duncan-Howell, 2010; Vrasidas, & Glass, 2004).

## MTAI

The project “Maths Teachers’ Adventure of ICT Integration”<sup>1</sup> (MTAI, [www.mtaii.com](http://www.mtaii.com)) aims to help overcome the barriers of knowledge and skills in relation to ICT integration (Hew and Brush, 2007) into mathematics teaching by creating a professional development environment for teachers that

---

<sup>1</sup> The project Math Teachers' Adventure of ICT Integration (2015-1-TR01-KA201-021561) has been funded by the Erasmus+ program of the European Union. The European Commission's support for the production of this publication does not constitute an endorsement of the contents, which reflect the views only of the authors, and the Commission cannot be held responsible for any use which may be made of the information contained therein.

includes several of the abovementioned strategies. To achieve this, three intellectual outputs have been designed, focusing on a different strategy each, and combined with each other, forming a professional development environment for mathematics teachers from different countries.

Addressing the need for direct professional development opportunities, an open online course (OOC) is designed as the first output of the project. The goal is to help teachers gain some insight into the potential benefits of using technology for education, particularly for learning and teaching mathematics. As part of the OOC teachers are guided towards developing interactive instructional materials and integrating them into their own classroom teaching. The second output addresses the scarcity of high quality, yet ready-to-use educational materials through the development and dissemination of open educational resources (OER). The project's third output will provide the infrastructure and expertise to establish and foster an online teacher community (OTC) that is expected to support the participating teachers beyond the duration of the project. Social, instructional, and technical support will be provided to teachers through the OTC by peers (other teachers) and researchers from the participating organizations.

In addition, the project partners will provide a series of face-to-face workshops, with different content targeting the specific needs of mathematics teachers in each of the participating countries. These events will also serve to promote and disseminate the project's outputs.

### **Output 1: Open online course**

The MTAII OOC is underpinned by three modules that address different aspects of ICT integration for teaching mathematics: (a) Module 1 – ICT use for learning and teaching, (b) Module 2 – Design and development of instructional materials with GeoGebra, (c) Module 3 – Implementation, and evaluation of ICT integration.

After a general introduction of ICT integration and its potential benefits for teaching and learning mathematics (Module 1), participating teachers will be guided through the process of analyzing, designing and developing their own instructional materials based on the interactive mathematics software GeoGebra (Module 2), before they are encouraged to implement their designed lesson in their classrooms and evaluate their experiences supported by experts and peers (Module 3).

As Hew and Brush (2007) have highlighted the necessity for teachers to be able to have easy access to technology, the GeoGebra Math Apps ([www.geogebra.org](http://www.geogebra.org)) have been selected for the project. This set of educational mathematics software applications has been developed for teaching and learning mathematics and are freely available all over the world. In addition to the apps being available in a multitude of different languages, the accompanying GeoGebra Materials platform offers additional support and features related to the creation and dissemination of interactive educational materials. The sharing of such materials with students is achieved by the use of GeoGebra Groups, a simplified Learning Management System (LMS) for mathematics educators and their students.

The Technology Integration Planning (TIP) model (Roblyer and Doering, 2014) was selected as the theoretical framework for the OOC. Organized in three phases, the TIP Model provides a practical approach to lesson planning by guiding teachers towards methods and strategies of using ICT for their teaching in an effective way. It also helps them to identify and address the potential challenges involved in this process. Thus, Module 1 of the OOC is based on Phase 1 of the TIP model, the analysis of learning and teaching needs, whilst Module 2 focuses on Phase 2, planning for integration.

Finally, Module 3 will conclude the course by implementing Phase 3, post-instruction analysis and revision, of the TIP model.

### **Module 1: ICT use for Learning and Teaching**

The main goal of Module 1 is to illustrate the purpose and benefits of using ICT for the teaching and learning process, by introducing a variety of suitable technology applications, as well as sharing best practice examples with the participating teachers, in order to demonstrate effective strategies of technology integration. In addition to providing their expertise in ICT integration, the project partner HU (Hacettepe University, Department of Computer Education and Instructional Technology, Ankara, Turkey) will also guide the participants of the OOC through phase 1 of the TIP Model (Roblyer and Doering, 2014). In the second step, teachers are led towards assessing their own technological pedagogical content knowledge necessary for teaching a self-selected topic in their own classroom, based on the Technological Pedagogical Content Knowledge (TPACK) framework suggested by Koehler and Mishra (2009).

TPACK is a model to emphasize the types of knowledge needed by a teacher for effective instructional practice in a technology based learning environment. This framework suggests that ICT integration for teaching specific content like mathematics, requires understanding of the three components Technology (T), Pedagogy (P) and Content (C), as well as of the relationships between them, resulting in seven different knowledge (K) areas: CK, PK, TK, PCK, TCK, TPK, and TPACK. According to Koehler and Mishra (2009) teachers should have technological pedagogical content knowledge in order to be able to effectively integrate ICT into teaching.

In order to support the TPACK framework, each of the project partners contributes according to their area of expertise, with HU providing TPK, JKU (Johannes Kepler University, Department of Mathematics Education, Linz, Austria) contributing PCK and AIGB (GeoGebra Institute Association of Botoşani, Romania) adding TCK. By creating an interdisciplinary OOC, the participants of the OOC should be able to form TPC Knowledge, which represents the intersection of all three knowledge areas. Roblyer and Doering (2014) suggest teachers assess the knowledge they already have and either use this knowledge or identify what they need to learn and broaden their technology-based teaching methods.

### **Module 2 – Design and Development of Instructional Materials with GeoGebra**

Following a general introduction of ICT integration into mathematics teaching and assessment of their TPC Knowledge in Module 1 of the OOC, Module 2 provides an opportunity for the participants to plan their own technology-supported lesson, deepen their technology content knowledge by learning about the basic use of the GeoGebra Math Apps, as well as create their own instructional materials and integrate them into their lesson plans. Both AIGB and JKU will combine their expertise and experience concerning the introduction of teachers to mathematics software, its use for teaching and learning, as well as the development of interactive instructional materials, while developing Module 2.

The main aims of Module 2 of the OOC are: to raise participants' awareness of pedagogical aspects of integrating ICT into their teaching (Bingimlas, 2009) by providing best practice examples for different methods of successful ICT integration into mathematics teaching; and to guide them towards planning and developing their own technology-supported lesson tailored to their own classroom

teaching. The participating teachers are first encouraged to select a mathematical topic relevant for their teaching. They are then guided through the planning process of a technology-integrated lesson by implementing the following steps: (a) deciding the objectives of the lesson and selecting effective assessment strategies to evaluate the success of the lesson; (b) analyzing and preparing their technological teaching environment and inquiring about potential technical support available during the lesson; (c) selecting appropriate instructional strategies and planning how to implement and adapt them to their students' needs; and finally (d) designing and creating appropriate instructional materials and activities that will help their students reach the objectives of the lesson.

Awareness of the different technology-related skills of the course participants, as well as of their potential previous knowledge of using the GeoGebra Math Apps, Module 2 of the OOC will also provide the opportunity to broaden the participants' technology content knowledge by learning about the basic use and features of certain GeoGebra Math Apps, as well as introducing online tools to create instructional materials on the GeoGebra Materials platform.

By providing a series of different tutorial components to introduce the GeoGebra Math Apps, participants will have the option to select the app most relevant to the mathematical topic of their lesson (e.g. geometry, function graphing, manipulation of equations). As suggested by Preiner (2008), the content and structure of the tutorial components are carefully selected, taking into account the potentially different technical abilities and diverse backgrounds of the OOC participants, as well as the difficulty level of mathematical content and the potential complexity of the introduced features of the software. Thus, the content of each tutorial component will be partitioned into a series of interactive worksheets containing one task each, that can be solved quite easily and enable participants to progress steadily through the chosen content. Being aware of the different technological abilities of the course participants, basic tasks will be optional, but will guide the participants towards gaining the skills necessary to also solve more complex, mandatory tasks of the respective tutorial component.

In order to allow for an individual learning pace and the option of selecting content relevant for each of the course participants, each tutorial component will provide automatic and immediate feedback to the user's work on the provided interactive tasks. However, expert course moderators will be available throughout Module 2, providing feedback or assisting with potential technology-related problems participants might encounter.

Furthermore, the participating teachers will learn how to create their own interactive instructional materials by using the online editors for interactive worksheets and online books provided on the GeoGebra Materials platform. Thus, they will explore the option of creating new interactive worksheets relevant for their lesson 'from scratch', as well as experience the possibility of searching the platform for suitable ready-to-use interactive online worksheets of other authors and collecting them in a so called GeoGebra Book. In this process, the participants will be able to decide themselves whether to share their developed materials with their peers or keep them private, only sharing them with the course moderators for feedback purposes. During the entire planning and lesson preparation process, course moderators and experienced GeoGebra material authors from JKU and AIGB will be available to support the participating teachers on a pedagogical and mathematical content level, as well as providing technical support, an aspect that Bingimlas (2009) identified as being a potential barrier for effective ICT integration if lacking. In addition, the course team will offer constructive

feedback about the newly developed materials and lesson plans, increasing the likeliness of a successful and effective implementation of the lesson in the teachers' classrooms.

### **Module 3 – Implementation, and Evaluation of the ICT Integration**

By the end of Module 2, the course participants are expected to have finished the planning stage of their technology-supported lesson, which should be ready to be implemented in their classrooms at the beginning of Module 3. Subsequently, Phase 3 of the TIP Model (Roblyer and Doering, 2014) will be applied in order to guide teachers through analyzing and reflecting about their lesson, as well as to help them to revise and improve their initial lesson plan. During this process, participants will be encouraged to share their lesson plans, as well as reflection about the implementation with their peers, allowing for further revisions and improvements of their instructional materials, based on the expertise of the experts and their peers.

After completion of the OOC, i.e. by the end of Module 3, each of the course participants is expected to have designed and carried out an effective technology-supported lesson, which can be shared among and reused by peer teachers, contributing to an online pool of ready-to-use interactive instructional materials that foster ICT integration into mathematics teaching.

### **Implementation of the OOC**

As the project is a transnational cooperation of the three countries Austria, Romania, and Turkey, the participating teachers are expected to be from diverse backgrounds with different native languages. Consequently, a nurturing and meaningful online environment for the participants is needed. The following guidelines for increased participation in online communities suggested by Çoban and Arkün-Kocadere (2016) have been taken into account for the implementation of the developed OOC: limiting the number of participants and forming communities from small groups; giving the opportunity to interact in their mother tongue; focusing on participants' direct needs; giving feedback; gamifying the online environment; limiting the workload of the participants; expressing the aim of community and expectations from participants explicitly.

Being aware of the local needs of teachers to support communication, feedback and development of educational materials in their native languages, as well as to encourage participation in the accompanying online discussions (Çoban, & Arkün-Kocadere, 2016), the OOC will take place in four language branches - English, German, Romanian and Turkish - as opposed to offering one course requiring all participants to use English for communication. Each of the four language branches will be supported and moderated by the project partners, as well as additional experts fluent in the respective languages. Also, limiting the number of course participants per language will allow for smaller discussion groups as well as individual feedback by moderators and peers, who will be able to directly address the needs of each of the participating teachers, keeping in mind the different educational backgrounds and teaching methods in the respective countries. Each of the four language branches of the OOC will use a different GeoGebra Group as the platform for communication and sharing of materials, providing valuable insights into the needs of different language groups, which will allow us to repeat the OOC in the future and make it available to the educational community in even more languages.

Some gamification elements will be integrated into the OOC to encourage teachers' continued involvement and active participation, as well as to attempt to minimize the drop-out rate during the

course. Gamification can be defined as using game elements in a non-game context. Literature shows that gamification has the potential to solve engagement, motivation, and especially participation problems in online courses (Çağlar & Arkün Kocadere, 2015). In their applied study, Borrás-Gene, Martínez-Núñez, Fidalgo-Blanco (2016) found that participation in online courses can be increased by developing online communities and gamification methodologies, in addition to providing support for students' learning and participation, by increasing their motivation. Being aware of the potential benefits of gamification elements for online courses, like rewards, badges, leaderboards, progress bars, and levels, the project team is currently planning a potentially gamified environment for the different Modules of the OOC, including the subdivision of each Module into levels, allowing participants to keep track of their progress in each level, as well as awarding the successful completion of each level. Furthermore, the course participants might be able to compete among each other, taking into account their current level of progress, their activity level of participating in the course, as well as their readiness to support their peers throughout the duration of the course. Finally, successful completion of each of the tutorial components in Module 2 might result in awarding a badge on the respective participant's GeoGebra Profile page, while MTAl certificates will be awarded for a successful completion of the entire OOC.

As a professional development opportunity for in-service mathematics teachers, the time-frame and duration of the OOC were planned carefully and took account of the limited time available to teachers during the school year in general, as well as the potentially different schedules of the school year in the countries of the participating teachers. Thus, the OOC will be implemented over 6 weeks with an expected workload of about 3 hours per week for the participants (M 1 - one week; M 2 - three weeks; M 3 - two weeks). Since the implementation of the developed lesson plans involves students, the participating teachers will be informed about the general expectations of the course and the required classroom teaching at the beginning of the OOC to allow for sufficient time for organizational issues related to technology-supported teaching methods.

## **Output 2: Open Educational Resources (OER)**

After the OOC, the materials developed by the participating teachers will be reviewed by the GeoGebra experts at JKU and AIGB and selected materials will then be transformed into OER, to help overcome the aforementioned scarcity of resources for ICT integration (Bingimlas, 2009; Hew, & Brush, 2007). The project partners will develop best practice examples and make lesson plan suggestions for different teaching methods that can be added to the interactive GeoGebra materials developed as part of the OOC. By translating these materials into multiple languages involved in this transnational project and publishing them on the GeoGebra Materials platform, a large community of teachers will have access to these high-quality instructional materials. In this way, teachers (and especially those who are new) to the concept of ICT integration in their everyday teaching, can benefit from the outputs of the project by getting access to a variety of ready-to-use interactive instructional materials, as well as to the experiences and expertise of teachers, who are expert ICT users for teaching and learning mathematics.

## **Output 3: Online Teacher Community (OTC)**

The third output aims to establish an online teacher community to complement the OOC and ensure sustainability of the project outcomes. Literature shows the success of online teacher communities

for professional development in general, as well as for supporting the ICT integration into teaching and learning process in particular (Arkün, & Aşkar, 2013).

The OTC will be designed and conducted with the support of the 3 project partners (JKU, HU, AIGB) who developed the OOC and will use GeoGebra Groups as the underlying platform. Again, four different OTC branches will be provided, allowing participants to communicate in their native languages, while the moderators of the OTC groups will also communicate in English across these language groups. In addition, high quality interactive instructional materials developed in either of the languages might be translated and adapted to the teaching methods of the other language OTC branches, making them available to a larger community of teachers across the different countries.

Throughout the lifespan of the project, the OTC will provide a platform for teachers to discuss their experiences with technology-supported teaching and learning, exchange their lesson plans and educational materials, and share their reflections and improvement suggestions. The participating teachers will receive support from peer teachers as well as from the experts in the partner organizations through the teacher community. The OTC is expected to have a long life cycle as it will be supported by the project partners as well as GeoGebra experts, with the goal of becoming self-sustaining community groups by the end of the project, being complementary to other efforts of ICT integration and sharing of high-quality interactive instructional materials. Furthermore, as opposed to the teacher communities on some other subjects, the project's OTC will be a math teacher community focused on ICT integration into teaching and learning, developing ready-to-use high-quality instructional materials in different languages tailored to the diverse needs of mathematics teachers and students in different countries.

## Conclusion

The main aim of the project described in this paper, is to combine the diverse expertise of the project partners for the design and development of a professional development environment for mathematics teachers consisting of an open online course, open educational resources and an open teacher community, and focusing on overcoming a selection of different barriers of ICT integration into teaching and learning of mathematics.

The online course is designed to support the participating teachers throughout the entire process of planning and developing materials, while also supporting them during the implementation of their technology-integrated lessons and subsequent revision of their materials. Through the development of high-quality and ready-to-use resources in different languages, many mathematics teachers will be able to benefit from the project's efforts by joining an online community of mathematics teachers willing to integrate ICT into their everyday teaching. By building a community that combines the expertise of researchers and actual classroom teachers from different countries and languages, the project aims to develop a network providing continuous support for teachers at all stages of ICT integration into the teaching and learning process, that we hope will become self-sustaining and outlast the duration of the actual project.

While the content of this paper focuses on the design and implementation of the described project, further studies will describe the accompanying research design and analyze its outcomes.

# The effect of GeoGebra collaborative and iterative professional development on in-service secondary mathematics teachers' practices

Houssam Kasti<sup>1</sup> and Murad Jurdak<sup>2</sup>

<sup>1</sup>Lebanese University, Lebanon; [houssamkasti@gmail.com](mailto:houssamkasti@gmail.com)

<sup>2</sup>American University of Beirut, Lebanon; [jurdak@aub.edu.lb](mailto:jurdak@aub.edu.lb)

*Integrating technology in education is still not an easy task, teachers' adoption of technology in their teaching is even more problematic and the wide availability of technology made things more challenging. This research is a multiple case study that aims to study in depth the effect of a GeoGebra (a free mathematics software) intervention on the teaching of in-service mathematics teachers in secondary schools who follow the Lebanese curriculum. The type of the study is Design-Based Research that focuses on working closely with practitioners in collaborative and iterative manner in the real context to add principles to theory and practice. Results showed an increase in the extent teachers use GeoGebra in their student-centered teaching approach.*

*Keywords: Technology integration, professional development, in-service secondary teachers, GeoGebra, design based research.*

## Introduction

When new technologies appear in medical or industrial fields, there is often a rush to replace obsolete tools with new ones, the staff get immediate training on their use and the adoption level is high and quick. Why does this not happen in the education field? Answering this question is not an easy task due to the multiple factors are involved in adopting technology and the rate of change in the education field, which is known to be slow.

## Literature review

Research has extensively focused on the problem of technology integration in general and in mathematics in particular. First, research in many countries has shown that technology still plays a marginal role in mathematics classrooms and that access to technology resources, educational policies, and institutional support are insufficient conditions for ensuring an effective integration of technology into teachers' everyday practices (e.g., Cox, Abbott, Webb, Blakely, Beauchamp, & Rhodes, 2004; Cuban, Kirkpatrick, & Peck, 2001; Goos & Bennison, 2008). Second, research studies in general focused on some aspects of the integration problem such as lack of teachers training (e.g., Law, 2008; Tondeur et al., 2008) or lack of theory (Mishra & Koehler, 2006). Others suggested certain solution(s) such as conducting professional development of specific characteristics, working with mentors (Kratcoski, Swan, Mazzer, 2007), working in a community-based inquiry environment (Lavicza, Hohenwarter, Jones, Lu, & Dawes, 2010), or working based on a theoretical framework such as TPACK, but most of these suggestions "have crashed on the hard rocks of the classroom" (Herrington, McKenney, Reeves, & Oliver, 2007, p. 9). Third, in most studies the methodology used is not sufficient for such a complicated multi-faceted problem, and this partially explains why research has had limited impact on practices (Herrington, McKenney, Reeves, & Oliver, 2007). A key factor is that teachers should be able to actively participate in the process of technology integration (Voogt et al., 2011). To summarise, this research aims to study how a collaborative and

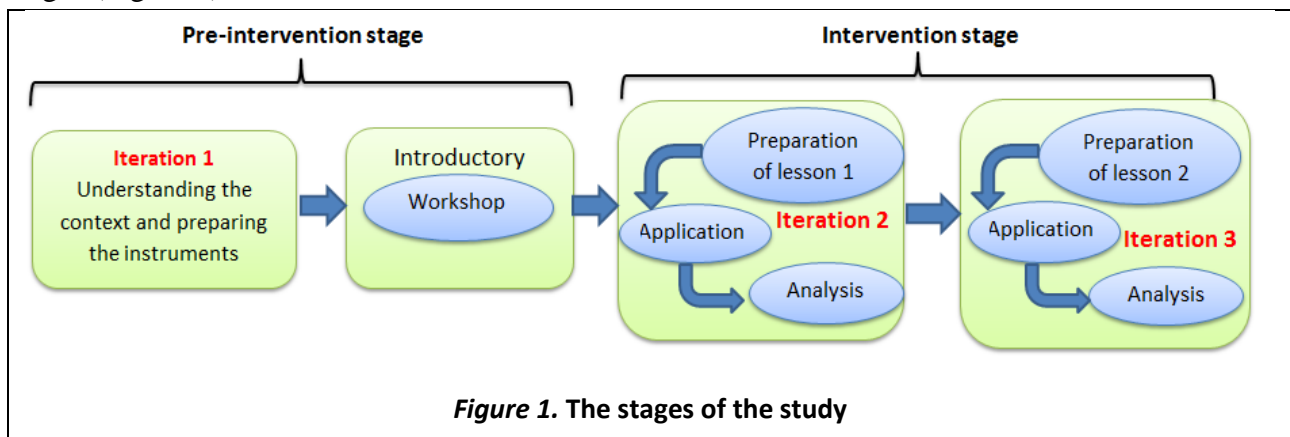

iterative work with in-service mathematics teachers affects their level of GeoGebra integration in their teaching to answer the following research questions:

1. How does a cooperative and iterative intervention affect in-service secondary mathematics teachers' practices regarding the integration of GeoGebra in their teaching?
2. How do participants' Valsiner's three zones mediate the impact of the intervention on teachers' practices regarding the integration of GeoGebra in their teaching?

In this study we have used the Valsiner's zone theory, which states that the factors that affect teachers' use of technology can be categorized into three zones: (1) Zone of proximal development (ZPD) which includes skill, experience, and general pedagogical beliefs; (2) Zone of free movement (ZFM) which includes access to hardware support, curriculum and assessment requirements, students (3) Zone of promoted action (ZPA) which includes pre-service education, practicum courses and professional development (Goos et al., 2010).

## Methodology

Three iterations of a design based research (DBR) methodology were used in this study across two stages (Figure 1).

The first pre-intervention stage was dedicated to understanding the situation of integrating GeoGebra in the Lebanese curriculum, piloting the GeoGebra activities and testing the instruments. Six workshops were conducted over two years and a pilot study with two teachers. At the end of this stage four teachers (other than the ones in the pilot study) were selected as cases for the study. After selecting the participants, a 3 hour-workshop was conducted by the researcher with the four participants to ensure that all participants had acquired the basic features of the software (GeoGebra). In addition, we discussed as a group the topics in the secondary mathematics Lebanese curriculum that could be better taught with the use of GeoGebra. The second stage was the intervention stage, which comprised two iterations. In this stage collaboration was one-to-one between the researcher and each of the participants. In the first iteration, the participating teachers decided which lesson they wanted to teach with GeoGebra in accordance with their school mathematics scope and sequence. They were provided with a ready-made GeoGebra activities (made by the researcher) to be implemented in their classes. In the second iteration, teachers adapted already made GeoGebra activities and/or made their own GeoGebra activities. Three visits were conducted with each participant at his/her own school and according to his/her available time. The first visit was to prepare for the first lesson. The second visit was to evaluate the first lesson and prepare for the second lesson.

Analysis of data collected from the instruments was done before starting the second iteration as required by a design based research methodology. The last visit was to evaluate the second lesson and give a general overview of the whole experience.

### Instruments

For the pre-intervention phase, three questionnaires were administered by the participating teachers: (1) Demographics questionnaire, (2) Instructional Practices in GeoGebra Questionnaire IPGQ (Form 1), (3) Barriers (grouped in zones) in Using Technology Questionnaire BUTQ (Form 1). The purpose of these questionnaires was to measure teachers' current (before the intervention) integration practices of the GeoGebra software in their teaching and the barriers (grouped in three zones) that affect their technology integration. After conducting the first lesson, a semi-structured interview parallel form was used (IPGSI (Form 2) and BUTSI (Form 2) to measure the impact of the intervention on teachers' practices and to find out to what extent the zones could mediate that effect. In addition, another instrument was used to assess the GeoGebra activity itself, the Lesson Assessment Criteria semi-structured Interview (LACI), which is based on instrument by Harris, Grandgenett & Hofer (2010).

The analysis was done in general for the four participants and later individually. The general analysis looked for the general impact of the intervention and for the dynamicity of change in the extent of use in each category of the practices and its subcategories. For the impact of the intervention we were interested in the change in the extent of use of GeoGebra at the end of implementation, whereas for the dynamicity we were interested in the pattern in the extent of use of GeoGebra of change happened in between the implementation stages. The dynamicity could be: (1) static: there was no change in extent of use in between the implementation stages or (2) dynamic: there was a change in extent of use in between the implementation stages.

### Participants

In the sixth (last) workshop conducted by the researcher attendees were given the pre-intervention questionnaires mentioned above. Based on the answers, for the practice instrument, the values were 0 (never use GeoGebra), 1(sometimes use GeoGebra), and 2(most of the time use GeoGebra). The average of all the questions was calculated. Similarly the average for each zone was calculated in the zone questionnaire that consists of 27 questions. Based on these results, four cases were selected (Pseudonyms: Tima, Sara, Amani, and Hazem) in a way that they differ among themselves in practice level and/ or in at least one barrier level. Table 1 represents the characteristics of each participant.

Name	Age	Highest degree	Teaching experience	Practice level	ZFM	ZPA	ZPD
Amani	50-55	BS	25 years	Low	Moderate	Moderate	Low
Tima	23-26	Masters +TD	2 years	Moderate	Low	Moderate	Not*
Sara	33-40	BS	7 years	Moderate	Moderate	Low	Not
Hazem	41-50	Masters	31 years	High	Moderate	Not	Not

**Table 1. Participants demographics, practice and zones level**

*\*Not: the zone is not considered as a barrier to GeoGebra integration*

## GeoGebra modules

The criteria used for lesson selection are based on those identified by Angeli & Valanides (2009) called ICT-TPCK. The GeoGebra activities were prepared by the researcher and tested on both students and teachers. The activities were designed based on the following criteria: Each activity: 1) should be student centered, 2) can be conducted by students in a computer lab or elsewhere (classroom or at home), 3) allows student to discover the concept or theorem under study, 4) includes immediate application of the concept under study, 5) does not require prior knowledge of the software.

Each teacher selected an activity according to his/her scope and sequence, so each teacher applied a different GeoGebra activity. Table 2 shows type and place of activities applied by each teacher.

	Activity 1	Place	Activity 2	Place
Amani	Sign of quadratic polynomials	In class	Derivative	In lab
Tima	Vectors	In lab	3D	In class
Hazem	Equation of a straight line	In class	Thales Theorem	In class
Sara	Translation of functions	In lab	Vectors	In lab

**Table 2. The intervention activities conducted by participating teachers**

## Results

### Stage of Use of GeoGebra

Figure 2 shows that the pattern of impact was the same for using GeoGebra in *lesson presentation*, *lesson implementation*, and *lesson enhancement* but different for *assessment*. For *lesson presentation*, *implementation*, and *enhancement*, in general, participants started with ‘sometimes use GeoGebra’ and ended with ‘most of the time’ after the second lesson. For *assessment*, there was a slight breakthrough from ‘never use of Geogebra in assessment’ to ‘sometimes use’ for each of the four

participants. For all the stages of using GeoGebra, in general, the change was static then dynamic. Probably more time was needed for the change to happen prior to the second implementation, which was due to teachers' need to: become more confident in using the software; be more knowledgeable; and have more free movement.

Concerning the stage of teachers' use of GeoGebra the intervention resulted in: (a) an increase in using GeoGebra in most stages mediated positively by teachers' ZPD, and (b) an increase in teachers' appreciation of GeoGebra as a teaching tool due to the characteristics of the activities. There was interdependence between confidence and the extent of using GeoGebra in each stage. When teachers applied the activities, this led in an increase in teachers' confidence which in turn led to an increase in the extent of GeoGebra use in each of their teaching stages. There was a low impact on using GeoGebra in assessment mediated by teachers' ZFM. Three particular ZFM factors mediated negatively the impact of the intervention on assessment, these factors were: (a) *Lebanese national curriculum* which is so demanding with little time left for discovery, (b) *Lebanese national assessment policies* which assess mostly procedural knowledge, and (c) *school assessment policies* which are mainly set by the school administration and teachers have little impact on changing them. The characteristics of the GeoGebra activities that made impact of the intervention more effective were: (a) the effectiveness of the GeoGebra activity, (b) the ease of operating the software by students, (c) the strong alignment between the activity and the curriculum, and (d) lastly the strong fit of the activity with the instructional strategies each teacher uses.

### Method of use

It is important to use GeoGebra, but what is more important is how to use it. In this category of practices the intervention had, in general, *no* to a slight increase in the extent of use in most subcategories and the general pattern of change was static with minimum dynamicity. For example the intervention did not affect Amani's use of GeoGebra for '*presenting a lesson*' or for '*conducting an activity with the help of students*'. Amani used for the first time GeoGebra for '*discovery activity done by students*' or for '*students to present their work*' but that change was static (never use) then dynamic. The impact of the intervention on Amani's *method of use* was a change in her teaching method to become more student-centered (*activity done with the help of students*) mediated positively by her ZFM and her ZPD. A second example is Tima, despite her ZFM factors that mediated Tima's extent of use of GeoGebra in her methods of teaching she applied for the first, time discovery activities done by students in the computer lab and/or in class. The collaboration between Tima and the researcher increased her self-confidence, skills and knowledge and that mediated positively her GeoGebra application. A third example is Sara. Before the intervention Sara was a moderate user of technology in general, and GeoGebra specifically, but the *lack of a computer lab* in her school and the *lack of hardware* in her class were the main barriers to increase technology integration. Sara used to show her students some applets using her class LCD connected to her own laptop but for the first activity she made a huge effort to take her students to the computer lab to apply discovery activities and she said:

After this experience (applying GeoGebra activity) for the first time and in a lab I will change a lot of things (in my teaching) now I have a lab for secondary. Frankly I will not use that with an LCD in the class to show students such things, there is nothing called to show (not effective)

showing them is like treating them as babies not capable of applying and concluding results, when they do it, it is different even for me I felt different. (Interview 2, November 7, 2015).

The intervention had an important effect on increasing the use of *conducting discovery activities done by students* in the computer lab and that change was not the same dynamicity for all teachers. The barriers teachers faced in this part of the practices were the *accessibility to the computer lab* and *curriculum requirements* (ZFM) but these barriers minimally mediated the impact of the intervention.

### Place of use

Similar to *method of use* category there was *no* to slight effect of the intervention on the extent of use of GeoGebra in their classroom or at home. There was a noticeable impact on the use of GeoGebra in the computer lab since three out of the four teachers tried one or both of the GeoGebra intervention lessons for the first time in the computer lab. This was not a surprise because to use GeoGebra in class or in the computer lab is related to availability of equipment and the way of using GeoGebra. This change was not the same dynamicity for all of the teachers. Amani's change was static then dynamic, Tima's change was dynamic then static, Sara's change was dynamic, and Hazem's change was static then dynamic.

An example is the case of Sara, her first student-centered discovery activity was the activity she applied in her first lesson of the intervention. In this lesson she sensed the importance of discovery activities and how this students motivated the students and she said:

I gave them four cases with aim of acquaint to GeoGebra trace, animation, and sliders. They liked a lot so and got their attention and interest. Gave them the function act printed and they started working, one student volunteered to help me... Students enjoyed a lot the activity and attained all the required objectives. They could see things (Interview 2, November 7, 2015).

A second example is Hazem' case, the intervention did not affect the place where Hazem uses GeoGebra. He mentioned *availability of a computer lab and/or the accessibility to the laptops* (ZFM) to be the only barriers to more extent of using GeoGebra in his teaching. He did overcome that barrier by asking every student to bring his own device mainly tablets. Since his first interview Hazem affirmed his continuous use:

I am willing to use GeoGebra if it is related to my lesson, I consider working with GeoGebra as 'clean work' contrary to board drawing (draw, redraw...). I encourage my students to use it; I already introduced them on its features and how to use. (Interview 1, November 7, 2015)

In his second interview he said: "all students contributed [in the activity discussion], to a certain extent, according to their motivation. If they bring their own device things would be more beneficial." (Interview 2, February 11, 2016)

Summing up, due to the intervention the extent of using GeoGebra for discovery by students in the computer lab increased. For all categories of the practices the *accessibility* and *availability of hardware* were the main negatively mediating factors to higher levels of practices for all participants. The general pattern of change in the practices was more from static to dynamic in the *stages of use*, static in the *method of use* and in the *place of use*.

## Discussion

It seems that unlike the medical or the industrial fields, the educational field is more complex in integrating technology in terms of social and psychological factors of all the stakeholders.

In the medical field for example the instrument for measuring blood pressure is one tool that is used for all people, young or old, under-weight or over-weight... To use this instrument or an updated version of it does not require social acceptance or/and making the medical staff believes of its importance. On the other hand, in the educational field there is no technology that fit all ages, abilities, and intelligence levels... Deciding to use any instrument in a certain class needs to pass many filters in order to be an integral part of the teaching-learning process.

## Recommendations

To see change in mathematics teachers' extent of using GeoGebra in particular and technology in general it seems one day workshop is not the perfect choice according to this study. Maybe with such professional development teachers' knowledge might change quickly but more has to be done in order to change their practices. How should universities prepare their pre-service teachers to be ready to use technology most of the time in their teaching? How should professional development be designed to make sure teachers' practices are changed regarding integrating technology in teaching? Maybe this study answers some of these questions but more work still needs to be done to solidify them.

# **“One of the beauties of Autograph is ... that you don’t really have to think”: Integration of resources in mathematics teaching**

Lina Kayali and Irene Biza

School of Education and Lifelong Learning, University of East Anglia, UK; [l.kayali@uea.ac.uk](mailto:l.kayali@uea.ac.uk)

*This paper introduces part of a larger study on the use of technology, specifically mathematics-education software, by secondary mathematics teachers. It presents some of the data collected with the aim to investigate teachers’ use of mathematics-education software: why are certain settings used, or underused, how are they used, and what are the reasons behind such use? The findings will be discussed by drawing on the documentational approach (Gueudet & Trouche, 2009) and teaching triad (Jaworski, 1994). The data comprised one interview and one lesson observation with a secondary mathematics teacher. While the documentational approach provides an overview of the set of resources being integrated to achieve a specific goal, the teaching triad offers a lens to observe teachers’ considerations when implementing a task in a mathematics lesson.*

*Keywords: Tasks, documentational genesis, teaching triad, mathematics education software.*

## **Introduction**

The complexity of the teaching profession imposes several factors that impact upon teachers’ classroom actions, that include not only their beliefs and knowledge but also their experiences and the educational context in which they act (Biza, Nardi, & Joel, 2015; Speer, 2005). Teachers, while planning and teaching, consider the contexts they work within: their students, school environment, curriculum, etc. In other words, any study of teachers’ practices should take into account the different contextual conditions in which these practices develop to include personalities, institutions, circumstances, epistemology, time issues and materials (Herbst & Chazan, 2003). The study presented in this paper forms part of the PhD research of the first author and it investigates mathematics teachers’ ways of balancing the different elements in their working environment, especially when using technology (in this study mathematics education software, i.e. software designed for mathematics teaching and learning purposes), by looking at their practices or intended practices within specific contexts. Furthermore, our work examines any gaps between intended technology use in mathematics classrooms and actual teachers’ practices. To this aim we invite teachers’ views on hypothetical classroom situations that involve teaching with technology in written responses and follow-up interviews. Then, we observe teachers’ use of technology in their classroom. In this paper we present preliminary analysis from one participant, Adam, by drawing on two theoretical perspectives: the *documentational approach* (Gueudet, Buteau, Mesa, & Misfeldt, 2014; Gueudet & Trouche, 2009) and *teaching triad* (Jaworski, 1994).

## **The documentational approach**

The documentational approach looks at teachers’ interactions with resources where a resource is defined as “anything that can possibly intervene in [a teacher’s] activity”, it can be an artefact (e.g. a pen or a mathematical technique), a teaching material, or even a social interaction (Gueudet et al., 2014, p. 142). Adler (2000, p. 207) adds that “resource” can be also “the verb re-source, to source again or differently”. During their interaction with resources, teachers develop schemes. A scheme

is a set of organised procedures carried out on an artefact (Gueudet & Trouche, 2009). It consists of “the *goal* of the activity; *rules of action*; *operational invariants*; and *inferences*” (Gueudet et al., 2014, p. 140, italics in original). Here, operational invariants are cognitive concepts established throughout the activity to be used in comparable situations (Gueudet et al., 2014). For teachers, these constitute “professional knowledge” (Gueudet et al., 2014, p. 142). The documentational approach describes a two-way influence between a resource and a teacher: a resource affects the teacher’s actions and knowledge; and the teacher’s perceptions and experiences impact on the way the resource is used (Gueudet et al., 2014, p.140). A management process, which Gueudet & Trouche (2009) call instrumental orchestration, is required in order to organise the learning environment (e.g., space, time, dialogue) by the teacher, whose responsibility is to manage the process according to the requisites of the task (Gueudet et al., 2014). When a teacher uses a set of resources according to a specific scheme for a specific goal, s/he creates a document. Such a development of a document is called *documentational genesis*. Thus, the documentational genesis is the process of a teacher developing schemes for adapting different sets of resources to achieve a specific target (Gueudet et al., 2014). The documentational approach studies the development of “structured documentation system[s]” that represent teachers’ work and progress as a result of influencing and being influenced by different resources (Gueudet et al., 2014). In this study we have conjectured that teacher’s schemes are dynamic and are being re-adapted from one situation to another and that the teaching triad (Jaworski, 1994) can help the exploration of those schemes.

## The teaching triad

Jaworski’s (1994) teaching triad (TT) addresses classroom management as an act of harmony between three domains of activity: sensitivity to student (SS), mathematical challenge (MC) and management of learning (ML). These domains are evident when a teacher plans a lesson and starts to think of how to consider teaching a specific mathematical idea (MC), particular students’ needs (SS), the best way to work on the task with the students (ML) (group work, individual work or classroom discussion). The same domains will be in play during lessons, but within a different context as this time the interactions with the students are happening and the teacher should respond on demand, in many cases by diverting from what was planned.

As Jaworski (1994) and Potari and Jaworski (2002) suggest from the “macro analysis” of classroom interactions, alongside the TT domains, teachers’ plans and practices are also influenced by social factors, such as: time pressure; having to complete a set syllabus; the requirement that students know specific things for exam purposes; expectations from the teacher; school ethos; and the training provided for teachers. Such factors seem to be at the centre of teachers’ considerations and they include students’ social culture, teaching resources and materials, syllabus, assessment schemes, time restrictions, room constraints, and cultural considerations of what constitutes good teaching practices (Goos, 2013, p.523). Hence, the TT domains, along with these factors, reflect the range of considerations mathematics teachers have to balance. The TT can be “used as an analytical device (by researchers) and as a reflective agent for teaching development (by teachers)” (Potari & Jaworski, 2002, p. 351). We are conjecturing that the teaching triad domains are related to schemes’ development regarding the use of resources. Sustaining the goals of the resource use, depends on how teaching is balanced by the teacher. Operational invariants can be derived from artefacts, mathematical concepts or social environments. All the above can be used to satisfy a specific goal

and produce a proper usage and inferences, but these are flexible techniques of balancing and rebalancing of the TT domains from one lesson to another. The analysis presented here aims to investigate this conjecture.

## **Technology in mathematics teaching - A view through the lenses of the documentational approach and the teaching triad**

Technology software and hardware devices are “artefacts” (Gueudet et al., 2014, p.141) and can be adapted to provide access to formal mathematical knowledge. They afford “opportunities for additional student actions, such as the manipulation of on-screen objects and the ability to make a range of mathematical inputs, which places an additional demand on teachers as they strive to make sense of a diversity of student activity in real-time” (Clark-Wilson & Noss, 2015, p. 95). Thus, interactions with technological resources influence teachers’ documentational geneses by developing the ways they organise their classroom activities and manage learning situations with impact on the shape of the teaching process and on the way knowledge is communicated. When employing technology, resources become more complex, and so do the TT domains. Sensitivity to student becomes more evident (e.g. if students know more about technology than their teacher). Tasks can be more challenging for teachers to design, and the management of learning becomes more complicated with the higher chances of distraction. We also re-emphasise the importance of social factors when technology is used based on several premises. First, the technology use dependency on the teacher training provided (Gueudet et al., 2014, p.144; OECD, 2015, p.69). Second, the availability of hardware and internet connection (Bretscher, 2014, p. 66; OECD, 2015, p.61 & p. 146). Third, the national curriculum obligations (OECD, 2015, p.70). Fourth, and most importantly, the education policies that aim to embed technology (OECD, 2015, p.50).

## **Methodology**

This paper reports from the first phase of a project that looks at secondary mathematics teachers’ work with technology that involves participants’ written responses to *situation-specific tasks* alongside follow up interviews and classroom observations. Situation-specific task methodology has been suggested by Biza, Nardi, & Zachariades (2007, p. 301) where tasks are given classroom situations that “are hypothetical but grounded on learning and teaching issues that previous research and experience have highlighted as seminal; are likely to occur in actual practice; have purpose and utility; and, can be used both in (pre- and in-service) teacher education and research through generating access to teachers’ views and intended practices”. The study is conducted in England and participants are secondary school mathematics teachers with different levels of experience and training. The work is based on providing qualitative findings established on an interpretative research methodology (Stake, 2010, p. 36).

In this paper we discuss the written response to the situation-specific task presented in Figure 1 (we call it the 3D Task), the follow-up semi-structured interview and the lesson observation (75 minutes) of one participant, Adam. Both interviews and observations were conducted by the first author. The situation described in the 3D Task regards an open investigative question to be given to the students. It did not suggest any specific use of technology, and left that to be decided by the teacher. The situation regards a geometrical problem with a potential consideration of the affordances of software available at the school where the data were collected, such as Autograph

(<http://www.autograph-math.com/>) or Geogebra (<https://www.geogebra.org/>). Adam was invited to offer a written response to the 3D task and, then, he was interviewed, to clarify the answers and offer more elaboration where needed. Then, a lesson was observed of a Year 12 class (17-18 year-old 4 female and 5 male students) and was audio-recorded. The focus of the observation was Adam's use of resources, especially his use of Autograph or Geogebra, which he said he frequently used, and his classroom management. At the time of the data collection, Adam was a mathematics teacher with four years' experience, during which he taught students aged 12-18 years. He held degree in economics, a postgraduate certificate for teaching mathematics at secondary level, and was about to finish his master's degree in educational practice. The school had interactive whiteboards, a computer lab, and Geogebra and Autograph software installed on all computers.

### **3D Task**

A group of Year 11 students are asked the following question:

Design a milk container with capacity of 1L. What dimensions and which design uses less materials? Why?

- What are the mathematical ideas and activities addressed in this question?
- Would you use this question in class? Why or why not? What are the learning objectives for which you would use this question? Would you modify it?
- Would you use technology with this question? If yes, what type of technology? If no, why?
- If you were to use technology, how would you use it?
- What teaching approaches and resources would you suggest for this question?
- Do you anticipate any problems or challenges (either with students or resources)?

**Figure 1: The 3D Task**

A preliminary analysis of teachers' comments and interactions during interviews and lessons was performed for the transcripts (May, 2001). This was coded according to the Teaching Triad (Jaworski, 1994) into SS, ML, and MC. During each interaction, we explored the teacher's interactions with the resources, according to the documentational approach (Gueudet et al., 2014). We then reviewed the results from the interview and observation, and offered a discussion according to TT and documentational approach together.

### **Adam's responses to the 3D Task and follow up interview**

Adam identified mathematical ideas involved in the 3D Task, such as "volume", "surface area" and "calculus". In his response to the task, he frequently repeated the word "scaffold" to state that he would try to adapt the task according to the students' needs and "prior knowledge". He emphasised that he would not use the problem as it is because it needed a lot of scaffolding and it included "too many variables". During the interview, he explained that the scaffolding would include giving hints and examples and even values to work on for weaker students. He said he will not use 1L in this problem, but would use a bigger number:

I think straight away students having to think of a length width and height that times to get 1 will be quite difficult for students... They might be able to go 1 1 1 and they might be able to go 2 ½ 1 or something like that. That will be it, they'll really struggle.

He wrote that he would use technology with the task for "gradient of curves on Autograph" and "to visualise the shapes". During the interview, when asked how and when he would use it during a lesson, Adam suggested "I think as a group activity. It wouldn't be the focus of the lesson though it would just be almost the point at the end". When asked to elaborate he said:

I think it is because one of the beauties of Autograph is that it means that you don't really have to think... I want the student to be thinking about problems and how to approach problems. I think

almost Autograph gives you too much, too much help and then you don't have to think about the shape of the graph because you can just plot it in Autograph. And then other, obviously other reasons a lot of my students have never used Autograph even at key stage five<sup>1</sup>. So, to start understanding it, it will take quite a long time and a lot of effort just to get the students to understand it to start with.

Adam said he will not use the task as it is because although it works well in “an ideal world”, it does not go well with the way the syllabus is set. He anticipated problem with keeping track of calculations, prior knowledge and many involved variables (e.g. Adam suggested if a student chose to design a cylinder container, the case would be very confusing because s/he would have to think of adjusting the radius and height of the cylinder in order to find the minimum surface area).

### Adam's teaching observation

The observation was on a revision lesson about solving simultaneous linear and modulus equations (i.e. equations that include absolute value). Adam started by moving a stick in the air in order to draw a specific graph, and asking the student to recognise the graph. One of these graphs was the *sine* graph, but the students seemed to be confused about what graphs were being drawn. Then, Adam asked his students to solve some problems that were displayed on the board. All the problems apart from one (which was designed by Adam) were chosen from the textbook. During the lesson, Adam used Autograph to check the answers given by the students, he entered the functions and the graphs were projected on the board. Then a discussion/demonstration of the algebraic solution was led by him on the white board. For example, for the simultaneous equations:  $y = |x + 2|$  and  $y = 3$ , he asked students to draw the graphs on their notebooks and see the solution before solving it algebraically: “You will get two points, you can see this graphically”. Then, he started to write one of his student's algebraic answers on the board: “ $3 = x + 2$  or  $-3 = x + 2$ ”. He then commented on the student's answer: “So, math says  $x = 1$  or  $-1$ ... What text book would say is  $y = (x + 2)$  or  $y = -(x + 2)$ . Textbook would just say that, I'll probably do it this way”. Later, with the problem that followed, he commented that: “This is GCSE grade C<sup>2</sup> [...] This is mark C in C1<sup>3</sup>”. He repeatedly encouraged the students to solve another problem he displayed on the board by saying that it is an “exam question”. When the students asked Adam why they should learn modulus equations, he went to his computer and googled “when to use modulus equations in real life” and gave the answers accordingly “Distance, currency exchange...”. Two of the students finished with the problems on the board earlier than the rest of the class and Adam gave them an extension problem which might have been suggested spontaneously in response to the need of extra work. The extension problem was in two parts, the first asked for two different modulus functions that do not intersect, the second asked for two that intersect once. “Is that possible? Can you give me two that intersect once?”, Adam asked the class, and the dialog below followed:

---

<sup>1</sup> Key stage five is post-16 school education in England i.e. for students aged 16-18.

<sup>2</sup> GCSE stands for the General Certificate of Secondary Education. It is the qualification taken by school students aged 14–16 in the UK (except Scotland). Its exams are graded on a scale of A\* to U, with A\* being the highest grade and U the unsatisfactory. A grade/mark C reflects an average progress (pass).

<sup>3</sup> C1 stands for Core1 and it refers to one of the mathematics textbooks, used at Adam's school, for students aged 16-18.

Student A:  $y = |x|$  and  $y = 2|x|$ , shift across

Adam: Oh, ya it is.

Student A: Ya, you've translated it.

Student B:  $y = |x - 4|$  and  $y = 2|x|$ .

*Adam looked at the graphs on Autograph and nodded in what seemed like a hesitant agreement*

Student C: Change the slope.

*Adam amended the equations as student C suggested and wrote  $y = 2|x - 4|$  and  $y = 2|x|$  without commenting on student's B answer*

Adam did not follow up student's B response or student's C correction, but moved straight to a completely different activity by which he concluded the lesson.

## Analysis

From his responses to the task and the observation we notice that Adam's resources were the textbook used at his school, help cards, a computer, Autograph, Excel, Google, interactive whiteboard, the stick he used at the beginning of the lesson observation, information about exam grades and questions, past experiences with students along with the mathematical concepts and methods. Adam's appreciation of Autograph's ease of use as a tool for visual representation was evident, so he used the software to check students' work, and present graphical solutions before going for algebraic ones. So, he would ask his students to solve graphically, check that their graphical solutions are right according to the answers on Autograph, and then ask them to find the same answers algebraically. However, Adam seemed being confused by the Autograph when it came to student B's answer on which he seemed to hesitantly agree. This might be because only one intersection point was visible within the displayed part of the graph. In this case, Adam missed the opportunity to use the full affordances of Autograph in order to improve student's B answer and to explain the correct answer to the rest of the class. There was no evidence that the rest of the class, apart from student C, realised where the problem was and how it was amended.

In terms of the TT, Adam indicated sensitivity to students "they don't know Autograph", "prior knowledge", "scaffold", "weaker students" (SS). In his teaching choices, he also showed consideration of the syllabus he had to follow, exam questions and the timeframe he had to adhere (MC and ML). The way he intended to use resources showed an attempt to balance mathematical challenges (MC) (e.g., change 1L, exercises from the textbook) with students' needs (SS) (e.g. students do not know how to use Autograph, providing extension question when needed), and management of teaching (ML) (e.g., use technology at the end of the lesson as a group activity, encouraging pair work when solving textbook exercises, graphing the equations to see the answers and then doing the algebraic solution because "Putting it in a graph might be easier") with attention to management of learning with technology (e.g. technology takes a lot of time).

Now, we will look at how Adam used the available resources to design and implement his teaching. Along with the textbooks that are being used at his schools, he mentioned he would also use help cards with hints or examples. These will help him "scaffold" and build on "prior knowledge", these terms seem to be adopted during Adam's teaching practice or teacher's education courses for reflection on students' needs (SS). Also, he drew on his teaching experience (as a resource) when he mentioned in the interview that students would struggle to "keep track of their calculations" (ML and SS). In terms of Autograph as a resource, Adam would use it as a graphing software that helps

visualise graphs and shapes and shows answers (ML and MC). The data showed the two-way influence between Adam and the resources. For example, Adam's belief that students do not think when using Autograph (SS) was influencing the way the resources were used, so he used Autograph to show or check answers (MC). Also, the resources available influenced the teacher's decision, so in this instance he used Autograph to show the graphical solution and then asked the students to do the algebraic solutions keeping the answers from Autograph in mind. Additionally, Adam frequently used the textbook as a source for exercises, so the textbook influenced which mathematical challenge he gave the students (MC). At the same time, Adam used the textbook exercises along with Autograph and, by doing so, Adam's way of managing the teaching affected the way the textbook was used. Adam's management of the teaching situation led us to conjecture that his use of resources is connected with a potential scheme developed in order to properly use the resources available and achieve a specific goal, which in the lesson observation was revising the topic of linear and modulus simultaneous equations. We have identified some operational invariants in Adam's schemes, for example the use of Autograph as a class activity managed by the teacher on the board. However, we believe that more data and observations are needed to further investigate Adam's schemes.

## Discussion and summary

The preliminary findings we present in this paper derive from a study on mathematics teachers' practices/intended practices in relation to the used resources and especially mathematics education software.

Adam's attempt to balance the different domains of activity described by the teaching triad was evident in the interview and during the lesson observation; and his interactions with resources were influenced by considerations of these domains as well as considerations of exams' questions and grades, time management, and the syllabus. His use of technology resources was led by him on the board, because of his concern that he would be teaching mathematics and technology use if his students were to work independently or in pairs on computers. Although the teacher used Autograph frequently, his use was mainly for checking answers and displaying visual representations. This is due to his concern that Autograph offers excessive help and would stop students from thinking about the mathematical problems. The pilot observation proved that more clarification about the teacher's actions should be sought from future observations along with pre- and post- lesson interviews. This is because the pre- and post- lesson interviews will give more space for the teachers' interpretations of their classroom actions. More observations are also needed to explore the teacher's documentational work and investigate how the teaching triad helps clarify teachers' considerations when working with resources.

# Identifying and assessing quality criteria for dynamic mathematics materials on platforms

Barbara Kimeswenger

Private University College of Education of the Diocese of Linz, Austria; [barbara.kimeswenger@ph-linz.at](mailto:barbara.kimeswenger@ph-linz.at)

*This paper describes a PhD research project addressing the issue of the quality aspects of dynamic materials. Platforms with user-generated Educational Resources for mathematics teaching show a wide variety in terms of the quality of the materials. The presented project investigates possible quality criteria for dynamic materials based on the opinions of experts in electronic resource development, who describe their views on educationally valuable use of dynamic materials. The relevance of the findings that have emerged is examined through a further quantitative study. Results of this project offer new inputs and ideas for designing manual and/or automatic review systems for dynamic material platforms such as the GeoGebra Materials platform.*

*Keywords: Technology, quality assurance, mathematics materials, empirical study, GeoGebra.*

## Introduction: Quantity vs. quality of resources

Numerous online platforms provide a large number of Open Educational Resources (OER) for teaching mathematics (e.g. GeoGebra Materials, 2016; LearningApps, 2016; I2Geo, 2016). The enormous quantity and variability of quality make it difficult for users to quickly find appropriate resources for their teaching (Trgalova, Jahn, & Soury-Lavergne, 2009). The problem of inconsistent quality particularly appears on platforms with user-generated Educational Resources, not supported by a dedicated editorial team. They are often free or low-cost materials, which are created and shared by different types of users (Camilleri, Ehlers, & Pawlowski, 2014; Ott & Hielscher, 2014).

## An example of a large repository of dynamic mathematics materials – GeoGebra Materials

One example of such a platform is GeoGebra Materials (2016) that already offers more than a half million public dynamic materials (as of November, 2016). Since dynamic worksheets – created using the dynamic mathematics software GeoGebra – can be uploaded, copied, edited and organized into collections by every user, this platform is subject to the aforementioned problem of inconsistent quality (Kimeswenger & Hohenwarter, 2014, 2015). According to interviews with GeoGebra users, it is not always easy to find high-quality resources on this website that comply with users' own quality standards. Thus, it might be desirable to reconsider the review and ranking systems of a platform that might influence the appearance and order of search results.

## Quality and assessment of mathematics materials on platforms

Several platforms with materials for mathematics teaching have different mechanisms to assess the quality of their resources with a similar aim: influencing the search results and ranking the high-quality materials first (Libbrecht et al., 2008; Ott & Hielscher, 2014). For instance, the project Intergeo, Trgalova et al. (2009, p. 1163) characterized nine “relevant indicators” of quality of dynamic geometry resources on their platform I2Geo: “metadata, technical aspect, mathematical dimension of the content, instrumental dimension of the content, potential of the DG, didactical

implementation, pedagogical implementation, integration of the resource into a teaching sequence, [and] usage reports.” For example, one criterion according to the indicator “content” is “validity” with the question “Are the activities in this resource correct from the mathematical point of view?”.

### **Intentional vs. non-intentional reviews**

To facilitate the development of a new review system for the GeoGebra Materials platform I considered combining an intentional and non-intentional review system. Under the project Intergeo, a questionnaire was developed based on the above-mentioned quality indicators. The assessment of the quality of a particular resource on the I2Geo platform requires users to respond to 9 broad statements, which can be extended optionally to 59 questions – using a scale from ‘I agree’ to ‘I disagree’ (Kortenkamp et al., 2009; I2Geo, 2016; Trgalova et al., 2011). Alternative ways for users to intentionally contribute to the evaluation of a resource are through ‘likes’, comments or star ratings, which are also often implemented on platforms with a large number of resources for teaching mathematics – for instance, on CK-12 (2016) or LearningApps (2016). These review possibilities are highly depend on the willingness of individual users to contribute to the review process of certain materials.

In many cases, only a small number of the materials that have been viewed have also been reviewed by a user. For example, on average, only 0.22% of viewed resources on the video-sharing website YouTube have been reviewed by likes or comments (Siersdorfer et al., 2010). Therefore, Ott and Hielscher (2014), who investigated the issue of the quality of interactive exercises on the platform LearningApps, considered assessing quality in an automatic way. For instance, one quality criterion is related to the communication with other users. It turns out that authors of exercises of LearningApps with an average well-rated content (4-5 stars out of a maximum of 5 stars) communicate more than the average authors. Thus, the absolute number of authors’ messages could be used as an evaluation criterion for their created content according to Ott and Hielscher (2014).

In summary, I am interested to identify suitable methods for reviewing dynamic materials that are different to traditional practices, such as solely by questionnaire. It is possible that elements of both approaches, where users assess quality intentionally or non-intentionally/automatically, might be combined within a new conception of a review system for dynamic instructional materials on the GeoGebra Materials platform.

### **OECD results – Does technology provide benefits?**

The recent OECD results highlighted the necessity to regard the quality of mathematics teaching materials supported by technology. According to the report of OECD (2015) there is no evident improvement of students’ achievements in countries that invested heavily on educational ICT (Information Communication Technologies) concerning their performance in PISA. Drijvers (2016) reflected to the state of the art, and questioned OECD's rather generally formulated claims. Assuming that digital technology is generally good or bad is not a proper approach according to Drijvers (2016). He emphasized the necessity to ask HOW technologies should be used to benefit mathematics learning and encourage high-quality teaching. Higgins, Xiao, and Katsipataki (2012, p. 3) also highlighted the urgency to think carefully about HOW technology should be used for teaching mathematics:

We need to know more about where and how it is used to greatest effect, then investigate to see if this information can be used to help improve learning in other contexts.

Drijver's interpretation of the OECD results and the above quote of Higgins et al. (2012) also indicate that technology use does not always result in good teaching. The interpretation within the OECD (2015, p. 3-4) report emphasizes that solely using technology without educational considerations is clearly insufficient. Nabb (2010) highlighted that the availability of different available devices has forced a fundamental question: "How should such devices be used in the teaching and learning of mathematics?". In my research, I investigated the quality of technology-supported teaching materials and their 'valuable' uses in education. I believe that my study will assist to fill the gaps suggested by OECD and Drijvers by offering possible guidelines for identifying high-quality technology materials for teaching and learning of mathematics. In particular, I aim to address how to recognize and create high-quality materials, which leads me to the research questions of this project.

## Research questions

Q1: What quality criteria for dynamic materials exist according to experts?

Q2: How do experts describe the educationally valuable use of dynamic materials?

Q3: How could the conclusions from research questions 1 and 2 contribute to the conceptual design of a new review system and the further development of platforms, e.g. "GeoGebra Materials"?

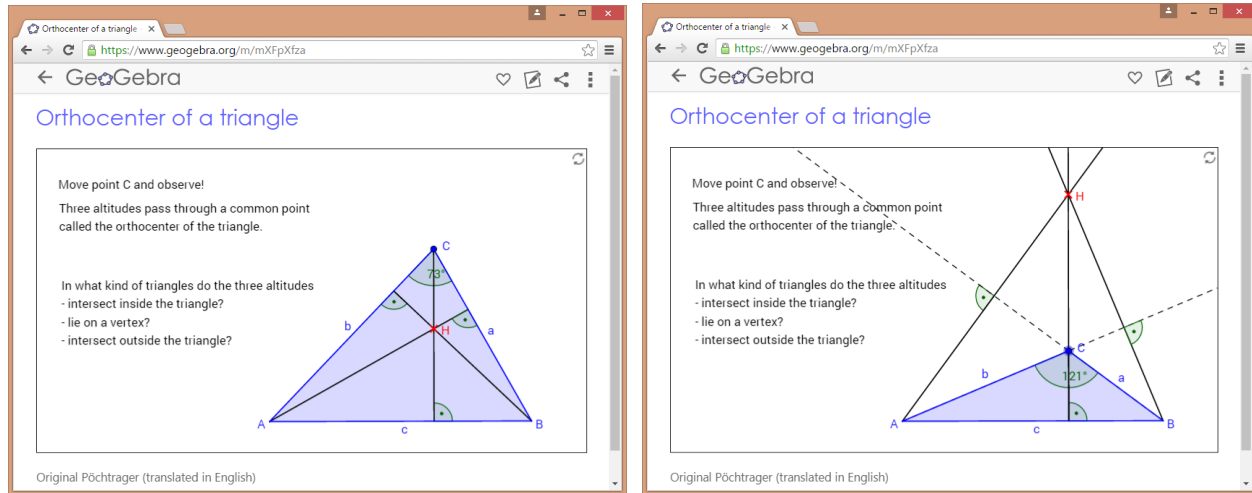

## Research design

I began by investigating the complexity of quality aspects of dynamic materials using qualitative research based on Grounded Theory (Strauss & Corbin, 1996). Experts, in particular mathematics teachers and mathematics educators, were interviewed to enquire about their perspective of quality materials. I selected international participants who were deeply involved in different projects and had been working on the development of instructional materials with GeoGebra for many years, thus they can be named as "GeoGebra experts". I considered different nationalities and cultures to reflect on different perspectives concerning decisive criteria for a high-quality material for mathematics teaching, because the GeoGebra Materials platform is also used by wide-range of users from all over the world. Consequently, I interviewed experts from Hong Kong, Uruguay, England, Austria, Hungary and Germany.

After analyzing the interviews, I created a category system that described core dimensions that contributed to the quality of a dynamic material. In addition, I expressed a list of quality criteria for dynamic resources in a "theoretical and detailed quality catalog" obtained from the expert interviews. These considerations about quality criteria and the educational value of the use of dynamic materials should provide new ideas for a conceptual design of a review system for platforms like the GeoGebra Materials website. and that might combine different elements of existing review systems used by other platforms. Based on the initial results of this stage, I also conducted quantitative research and received responses from 84 Italian and Austrian mathematics teachers using an online questionnaire and investigated the relevance of the emerged results.

## Examples of quality criteria – The orthocenter of a triangle

The following example offers an idea what quality aspects were mentioned by experts, in this case by a highly-experienced teacher and user of GeoGebra, who referred to a specific dynamic resource on the GeoGebra Materials platform focused on the orthocenter of a triangle (see Figure 1).

**Figure 1: Dynamic worksheet, Interview 2014-12-11, <https://www.geogebra.org/m/mXFpXfza>**

The interview with the expert revealed one of many quality criteria for a dynamic resource is “supporting the learning of mathematics”. A related question that could be asked of users concerning the resource shown in Figure 1 is, “Does the dynamic material support the learning of mathematics?”. An answer, from the perspective of the expert, might be, according to the instructions next to the construction, students should move point C and observe the effect of its position to the triangle orthocenter’s shape and position. The potential of the material is from the expert’s point of view that the dynamic worksheet allows students to explore through the dynamic construction. Depending on the location of the vertices of the triangle, the position of the orthocenter changes. For instance, students could discover that the orthocenter lies inside an acute triangle and outside of an obtuse triangle. Such materials are intended to encourage students to come up with their own assumptions and formulate insights, as in Table 1 summarized.

Quality criterion	Question	How?
“Supporting the learning of mathematics”	“Does the dynamic material support the learning of mathematics?”	Allows students to explore with the dynamic construction
		Allows students to discover mathematics
		Encourages students to make their own assumptions
		Encourages students to formulate insights

**Table 1: Quality criterion “Supporting the learning of mathematics”, Interview 2014-11-12**

This example shows that often many different quality aspects come together to influence the overall quality of a particular material. Experts were asked about their opinion and perspectives on the potential of instructional dynamic materials in order to investigate the complexity and different facets of the issue of quality of dynamic materials. Table 1 summarized the aspects that concerned the quality criterion “Supporting the learning of mathematics” considering the dynamic worksheet

about the orthocenter and showing that many aspects could contribute to the quality of this dynamic worksheet. Additionally, I would like to highlight the difficulty to express guidelines or criteria defining the quality of a dynamic material:

[T]he issue of how to maximize the benefits of the integration of technology is hard to capture in overarching guidelines. (Drijvers et al., 2010, p. 86)

Nevertheless, in this paper, I summarize and describe dimensions developed in this study that could contribute to the quality evaluation of dynamic materials.

## **Eight quality dimensions of dynamic materials**

The analysis of the expert interviews revealed eight core “quality dimensions” as crucial factors: (i) author, (ii) mathematical content, (iii) resource type, (iv) supporting the learning of mathematics, (v) integration into teaching, (vi) advantages of dynamic material, (vii) design and presentation, and (viii) technical aspects.

These dimensions were compared to the literature and could significantly influence the quality of a dynamic material created for mathematics teaching. The “author” (i) can be considered as a main quality dimension influencing all of the other above-mentioned items (ii-viii) and is therefore listed first. This importance is due to the fact that the creator has a considerable effect on the resource that she or he has developed and can assist in the decision of what mathematical content is presented to support learning. The creator should consider how to integrate technology to benefit classroom activities and to exploit the potential of the dynamic material. Depending on these considerations and on the available technology in the classroom, the author adopts the dynamic material's design to be as user-friendly as possible and considers teaching aspects related to this kind of material. Next, I present examples showing the importance of the author and how certain conditions – such as available technology and the author’s view on learning – effect the development of GeoGebra resources.

## **Importance of the author of a dynamic material**

The majority of experts stated that there is a strong correlation between the quality of the author and the created material (see Figure 2).

**Figure 2: Correlation between quality of author and dynamic material**

When I asked experts to describe their search strategies to find high-quality materials, the importance of the author was pointed out several times. It seems nearly impossible to decide in general, whether a specific resource is of “high quality” or not: “A given resource can be ‘good’ in one context and ‘poor’ in another.” (Trgalova et al., 2009, p. 1162). Nevertheless, there seem to be certain strategies for searching for “good” dynamic materials on the GeoGebra platform and certain “authors” were often named. For instance, a British expert mentioned an author, whose: “materials are brilliant and if you see something of [him] then it is a guarantee of quality.” (Interview 2015-07-15) Expert users of GeoGebra seem to search particularly on profile pages of already known “high-

quality authors”, which they expect to produce “good” dynamic materials according to their own standards of quality:

If you get to know people who produce quality materials, they don't tend to produce quality materials by accident. Once, you find one or two things by somebody which is good, you can expect pretty much more materials with high quality. (Interview 2015-07-15)

As mentioned in the beginning, inconsistent quality especially occurs, when users with different quality standards share their dynamic materials online. However, this can be regarded not only as a disadvantage, but also as an advantage. These user-generated Educational Resources provide a vast number of instructional materials ready to be used in classrooms created by different authors considering varying circumstances such as diverging curriculums, technical requirements or quality standards.

### **Available technology**

An author's creation of a dynamic material depends on the available technology and the individual classroom situation. In a computer lab, pupils can work independently and actively on dynamic materials, but they require clear instructions and questions complementing the applets. In contrast, dynamic materials do not necessarily contain instructions if it is the intention for the teacher to demonstrate the concepts using a projector. In this case, the teacher can explain the purpose of the resource to students during the presentation. Another example of the influence of available technology on the design of a dynamic material could be derived from mouse driven approaches as opposite to working on touch-sensitive devices. On tablets and mobile phones, learners may directly use their fingers to work with a dynamic resource, while on non-touch devices, dynamic materials are manipulated with a mouse. In addition, displays of these devices are usually smaller than computer monitors and this should be considered within the design of the resource (Kimeswenger & Hohenwarter, 2014). In summary, the classroom situation, especially the available technology, strongly influences the design and use of dynamic material's design to include task instructions and the usability.

### **The author's views on learning – learning theories**

Authors' views on learning and on the acquisition of knowledge considerably affect the use of the created materials. The structure and design is influenced by teachers' intentional or non-intentional views on learning theories such as behaviorism, cognitivism or constructivism.

The value of students' own constructions has been often discussed in educational research papers. Mercat, Soury-Lavergne, and Trgalova (2008) mentioned that principles that draw on a constructivist approach to teaching and learning are commonly accepted in mathematics education. Nevertheless, the development of an instructional material depends on the author's view on learning theories (behaviorism, cognitivism or constructivism). A platform should draw users' attention to high-quality authors who have similar views on learning. On the one hand, this would simplify finding “good” materials within a vast number of resources in repositories. On the other hand, these high-quality authors should be recognized and honored for their effort and top-quality materials.

## Identification and recognition of high-quality authors

Experts suggested to allow users to follow particular authors on the website. Based on these interview results, the "Followers" Badge was released on the resource-sharing platform GeoGebra Materials (March 2016). It seems to be important that a review system of a platform enables users to find materials of specific authors quickly who adhere to similar quality standards. It should also allow following these authors and support finding of these dynamic materials by giving resources of the 'followed' authors a higher priority among the search results.

The "Followers" Badge could help identifying high-quality authors chosen by other users. It represents some kind of recognition outlined by a mathematics educator of Hong Kong:

If the material is good [on the platform GeoGebra Materials], I think the designer has paid a lot of effort. He or she need more encouragement or appreciation. (Interview 2015-07-13)

Caprotti and Seppälä (2007, p. 7) also emphasized that authors should be respected and recognized for their high-quality resources. Users will share more materials if their work is recognized – "Credits to creators".

## Conclusion

This study addresses the key issue: What is a high-quality material for mathematics teaching supported by technology? The internet offers an immeasurably large number of diverse mathematics teaching and learning resources proving it difficult to navigate for ordinary teachers and students. Therefore, it would be beneficial to identify and assess the quality of dynamic materials before using them in the classroom. It seems important that a review system influencing the search result order of a platform enables users to quickly find materials of specific authors who adhere to similar quality standards as well as to allow following these authors. Additionally, the platform should give resources of followed authors higher priority in search results, but it is also important to offer chances for new authors to be represented among the highlighted search results. Further analysis of different expert interviews and 84 responses of an online questionnaire will examine the complexity of the quality of dynamic materials in greater detail resulting in a detailed catalog of quality criteria. With this background knowledge, additional suggestions for intentional and non-intentional review systems for dynamic material platforms such as GeoGebra Materials could be devised. Beyond the PhD project described in this paper, software developers may implement further results of this study on the material sharing platform GeoGebra to improve finding of high-quality materials for mathematics teaching and learning. Further research will be necessary to investigate these new releases and support their continued improvement.

# Teachers designing e-books to foster creative mathematical thinking: the case of curvature

Angeliki Kolovou and Chronis Kynigos

University of Athens, Educational Technology Lab and CTI & Press Diophantus, Greece;

[angkolovou@ppp.uoa.gr](mailto:angkolovou@ppp.uoa.gr), [kynigos@ppp.uoa.gr](mailto:kynigos@ppp.uoa.gr)

*This study focuses on the design of a novel genre of e-books incorporating dynamic constructionist artefacts-widgets that aim to induce mathematical creativity allowing students to interact with their content in significant ways (called 'c-books', c for creativity). The design of the c-books is addressed through collectives of educational professionals with a diversity of expertise. The analysis of the design process of a c-book on Curvature shows that the interactions fostered by the socio-technical environment allowed diverse practitioners to learn from, work with and collaborate across their boundaries supported by collectively evolving artefacts as boundary objects. The end-product of this social creative process, the c-book on Curvature, evolved through the constant versioning of a narrative intertwined with malleable dynamic constructionist artefacts.*

*Keywords: Curvature, design of digital resources, social creativity, documentational approach of didactics, theory networking.*

## Introduction

Curvature is weakly addressed as a conceptual field (Vergnaud, 2009) with respect to its potential to generate environments rich in opportunities for mathematical meaning making by students. In traditional curricula it lies disparately in Euclidean Geometry sections, in Algebra and Calculus depicting systematic co-variation, in 3D Geometry but in simple applications like conic sections. The dynamic and diverse representational repertoire provided by digital media allows us to approach curvature anew with a disposition to re-structure (to use Wilensky & Papert's term, 2010) the ways in which mathematics is conceptualized in education in the quest to make it more attractive to students, affording meaning making, creative mathematical thinking (through problem-solving/posing and constructionist activity) and engagement. Previous research has shown that dynamic digital environments and especially 3D spatial environments support students in constructing meanings about challenging conceptual fields (Kynigos & Psycharis, 2003; Zantzos & Kynigos 2012). In this study, we look at a digital medium affording the meshing of narrative with malleable constructionist artefacts such as *half-baked microworlds* (Kynigos, 2007) and study the ways in which a diverse community of professionals jointly design narratives around curvature with an explicit interest to afford creative thinking in their prospective students. We perceived of the medium which we called the 'c-book', as potentially affording thinking out of the box, allowing for restructuration of mathematical conceptual fields. We also began from the premise that collaborative design by educational professionals with diverse expertise would generate a socio-technical environment more likely to produce creative ways to enhance creative mathematical thinking (CMT) for students. In this study, the designed c-book eventually focused on a story involving comparisons between Archimedes' and exponential spirals. In addition, by involving in-service teachers in all stages of the design process, we aimed to induce their reflection on the affordances and pedagogies incorporated in the tools, the tasks and narratives under

development, as well as the changes to the mathematical content and the classroom practices that the presence of technology brings about.

## Theoretical background

The design of digital educational resources for fostering mathematical creativity and meaning generating in a mathematically rich conceptual field like curvature is a complex task, which brings the issue and study of creativity in the design to the fore. In the design, process and product are inextricably linked in the sense that the former draws its very existence on the pursuit of the creation of some novel products, and that a creative product acquires its substance as the end-result of some design processes. However, the role of creativity in instructional design, or specifically in educational resource design, has been only recently acknowledged (Clinton & Hokanson, 2012). In this study, we looked at the process of designing such a resource collaboratively, focusing on the emergence of Social Creativity (e.g., Fischer 2005; 2014) which we employed as a theoretical frame to both understand and foster creativity in collective design. Our designer communities were engineered to include diverse expertise and personal histories of educational professionals (we borrowed Fischer's term 'communities of interest' or CoI) working together and using digital tools specially designed to amplify the outcome of their collaborative efforts. We hypothesized that social creativity builds on the wealth of diverse individual perspectives brought in by different stakeholders in addressing a design problem of common concern and focuses on the interactions occurring in socio-technical environments (Fischer, 2014) i.e., among the individual members of a community and between them and particular technologies and artefacts.

The diversity within a CoI although being a source of discontinuities and breakdowns in communication, can be also a source of new ideas, insights and artefacts. According to Akkerman and Bakker (2011) boundaries are defined as the “sociocultural differences that give rise to discontinuities in action and interaction” (p. 139), which can be overcome through boundary crossing processes, i.e., efforts made by individuals or groups ‘at boundaries’ to establish or restore continuity in action or interaction across practices, leading to learning, identity development and re-conceptualization of practice. These efforts are facilitated by boundary objects (Fischer, 2005) which are externalizations of ideas that help to establish and maintain a common ground supporting communication and shared understanding. They come in the form of artefacts (such as specially designed computer tools), discourses (as a common language), or processes that allow the coordination of actions. Thus, computational support for CoIs should enable the creation, discussion and refinement of boundary objects that allow different knowledge systems to interact (Fischer, 2005).

In our study, we worked with educational designers and thus needed to also employ a framework to help us understand the context particularly of teachers as resource designers. Thus, we adopted the documentational approach of didactics (Gueudet & Trouche, 2009), which focuses on the interactions between mathematics teachers and resources and their consequences for professional growth. Teachers ‘learn’ when selecting, transforming, implementing and revising resources in the course of their teaching. The documentational approach proposes a specific conceptualisation of this learning as a *documentational genesis*, which jointly generates a new resource and a scheme of utilisation of this resource in an ongoing process. In relation to collectives instead of individual teachers, community documentational genesis describes the process of gathering, creating and

sharing resources to achieve the teaching goals of the community. The result of this process, the community documentation, is composed of the shared repertoire of resources and shared associated knowledge (Gueudet & Trouche, 2012). A collaborative design activity, and more particularly an activity involving teachers as designers of creative educational resources, is thus a process that is expected to trigger collective documentational genesis. The present study aims to unfold social creativity, located in and nurtured by the boundary crossing encounters among the CoI members, and collective documentational genesis processes in the design of digital creative mathematical resources for curvature, which takes place in a socio-technical environment consisting of a community of diverse educational professionals and a digital environment specially designed to allow them coordinate their efforts in designing these resources.

## **Method**

### **The Community of Interest (CoI)**

A wide range of expertise was brought together in the design of the c-book “Curves in Space”. The seven CoI members participating in this joint design were practitioners in different levels of education (from primary to tertiary education) specialized in mathematics, mathematics education, creative writing, computer mediated communication and the design of digital tools for mathematics education. This diversity in knowledge domains, perspectives and cultures was meant to enhance the CoI’s creative potential.

### **The Computational environment**

The C-book environment provides the ‘CoIcode workspace’, a tool for asynchronous online discussions allowing designers to choose between a threaded forum discussion organised in a tree-like structure (see Figure 1) and a mind map view. When posting a contribution, CoI members have to state its nature (i.e., alternative, contributory, objecting, off task or management) by using a specific icon, and can attach and refer to objects like online resources, texts or widget instances that reside in the c-book under construction. In addition, the environment contains a platform which is the space for authoring (the C-book authoring tool) and the space where students interact with the c-book (the C-book player). The platform is designed to incorporate pages with dynamic and configurable widget instances accompanied by corresponding narratives (see Figure 2). In this case, MaLT+, a 3D Logo-Based Turtle Geometry tool affording dynamic manipulation of variable values was used (<http://etl.ppp.uoa.gr/malt2>). Spirals are generated by either constant or incremental curve and torsion changes to a turtle respectively repeating very small displacements.

### **Data and analytical approach**

Our data were the 124 contributions uploaded in the ‘Curves in Space’ workspace from the outset of the design process (6/4/2015) until the final version of the c-book was released (23/7/2015). The analysis of the contributions posted in CoIcode involved the selection and analysis of critical episodes, i.e., relatively brief and uninterrupted periods in CoIcode discussion, shedding light on some important aspect of the social creativity processes and/or products developed, by focusing on the interactions among the CoI members and with the C-book technology. Furthermore, we traced paths of socially creative ideas, which stretch over longer periods of time and include several critical episodes, in terms of the critical moments in their evolution from the initial to the final idea (i.e., an

idea implemented and incorporated into some part of the c-book). The emphasis was on unveiling the social nature of the processes involved in the development of ideas and in the examination of the C-book environment features which added to the formulation, elaboration and cross-fertilisation of the CoI members' ideas.

## Results

### Critical episode: The design of a widget instance

The episode selected (see Figure 1) started one month after the outset of the design process, it lasted 8 days (14/5-20/5/15) and the participants in it were three CoI members: George, Mathematics teacher and graduate student in Mathematics education, Dimitra, Literature teacher and graduate student in ICT in Education, specialised in creative writing and Marianthi, MA ICT in Education graduate and developer. At that time an exchange of resources was taking place on the mathematical idea of Helix-Spiral between a senior mathematician (Stefanos) and George. The discussion is initiated by Dimitra (14/5) who, inspired by the airplane functionality in MaLT+, suggests that students calculate the distance covered by airplanes performing spiral movement during air shows. George (14/5) responds enthusiastically, elaborates on Dimitra's idea and provides a Wikipedia link on jets streams. Marianthi then puts forth a suggestion on a *half-baked* widget instance (i.e., a 'buggy' procedure where students are asked to experiment, figure out what is wrong or superfluous in the code and correct it):

Marianthi (19/5): [...] in MaLT+ I created a procedure where the airplane movement forms the Olympic rings. I am sending you the complete code so that we can half-bake it, e.g. it can turn by a 45-degree angle in the last two turns so that the rings do not come out straight (attaches 'Olympic\_correct.txt')

Marianthi (19/5): I am sending you the one I wrote with the wrong angles (attaches 'Olympic\_wrong.txt')

George (20/5): I like it a lot! I suggest not to half-bake it, but ask students to create it by themselves by looking at an image of the Olympic rings [...]

Marianthi (20/5): [...] I think if it's half-baked it will be more challenging for students to correct it than create it from scratch. Also, we can focus on specific mathematical topics like the turn angle or the distance of cycles.

George (20/5): [...] Since the unit addresses senior students it would more creative to allow them work without such restrictions. If we half-bake it though, wouldn't it be better to use variables for the angles?

George (20/5) refers to drones as a more innovative alternative to airplanes and designs two alternative versions of the widget instance in which he adopts Marianthi's proposal. Finally, one of his versions was incorporated in the c-book without further negotiation including his suggestion of imprinting the traces of a drone instead of a plane (see Figure 2). This episode shows how the collective resource system is enriched through the sharing, reflection and transformation of individual resources to boundary resources. What is more, boundary crossing interactions between CoI members allowed the cross-fertilization of diverse perspectives: mathematics, digital tools development and creative writing. Dimitra, having studied existing resources is inspired to articulate the airplane idea stating in what ways it deviates from what has been heard before. Marianthi turns Dimitra's idea into a 'tangible' object, i.e., a widget instance, while George expresses considerations initiating an interesting exchange on the pedagogical affordances of different types of activities. He brings CMT to the fore and poses the challenge to other members to directly argue on specific pedagogical and technical affordances of the proposed activities. The final version of the instance appears in the c-book as a result of the *coordination* of George's and Marianthi's ideas. Social creativity is thus enhanced by exchanging, discussing on and modifying half-baked curve designs acting as boundary objects, allowing the communication and coordination of diverse perspectives. Mathematical resources thus take a mediational role between diverse perspectives undergoing several transformations and revisions until they are reified as widget instances in the c-book. As teachers negotiate over an emergent mathematical construction, they are challenged to reflect on and reconsider their beliefs and practices as well as their meanings of mathematical objects and relationships, thus expand their learning.

### **The evolutionary path of the narrative**

The path presented below is related to the evolution of the narrative of the c-book. The respective path includes 52 contributions and stretches along the entire workspace. Early on in the design process, CoI members were concerned with devising a narrative that, together with appropriate widget instances, would provide opportunities for mathematization and meaning making around curvature. The mathematical affordances of various digital tools also became an early topic of discussion so that tools, narrative and mathematical concepts were interrelated in the design of the c-book. Below we provide decisive contributions from individual CoI members and stress the social nature of the processes involved in the development of the scenario from its first appearance to its incorporation in the c-book. At that time a number of widget instances designed to afford creativity and meaning making in curvature took the role of boundary objects by evolving through multiple cycles. However, a cohesive narrative that would incorporate and join together these elements was pending, despite the fact that some interesting ideas had been already suggested. The path sheds light into how the CoI members'

conceptions about their productions in terms of didactical design (widget instances and corresponding learning activities) intertwined with their ideas about the narrative of the c-book. Stefanos (22/6) presents a -rather loose- synthesis of his own and other members' ideas on the c-book narrative integrated in a new version of the c-book: the history of curves, two detectives working to solve a crime, a 3d printer laboratory, and solving riddles related to spirals. George (24/6) reacts enthusiastically and attaches an elaborated version of Stefanos' story incorporating Sylvie's comments on enhancing the story: two renown detectives (Hercule Poirot and Sherlock Holmes) try to solve a mysterious robbery in a laboratory, which is connected to constructions related to curvature. Sylvie, a teacher and creative writing specialist who joins the discussion at that time, presents a totally different idea on the structure of the scenario relying on contemporary characters, which fuels an intense debate. Stefanos (25/6) objects to Sylvie's suggestion on the grounds that the storyline should blend with the widget instances so that students follow a learning trajectory working with tools of gradual increase in complexity. He also posts a document in which he justifies his rationale for building his own version in which mathematical concepts are presented in a coherent and meaningful way. George and Katerina (computer mediated communication specialist) react to Stefanos' post:

George (26/6): Very insightful comments, especially in relation to the way the current narrative supports the smooth integration of the learning sequence on curvature. [...] Wouldn't it be better to make some corrections without discarding what we've done until now? [...] (He attaches 'What a strange morning in the laboratory.doc' where he expands his previous version to include logarithmic spirals).

Katerina (27/7): [...] I don't think that the new version rejects previous constructs and ideas [...] but rather promotes them by organically binding them with a fresh, creative story.

Up to this point there are two opposing views on the scenario; a mathematics oriented strict, structured and robust learning scenario mainly supported by a senior member who is an experienced Mathematician, teacher and researcher (Stefanos) and a more innovative one which embodies a set of characters and situations of contemporary culture. This tension is released when George (28/7) replying to Katerina, posts a new synthetic version of the scenario. In the next two versions of the scenario Sylvie, Katerina and George collaborate so that Sylvie presents a more robust synthetic version that organically integrates the designed widget instances. The coordination of the two prevalent perspectives in the design of the c-book, i.e., the mathematics and the creative writing perspective, made possible the infusion of creative elements in the narrative, while not losing sight of its mathematical focus on curvature. It is noteworthy that these two perspectives are not only gradually reconciled after the catalytic intervention of George, they also enrich each other; the senior mathematician later proposes two additional ideas on the scenario much more innovative than his initial ones, while the creative writing specialist, after closely collaborating with mathematicians, comes to adjust her story in a synthetic version. These reflective processes are essential for the interweavement of widget instances with the narrative into a concise whole. Social creativity is thus facilitated by the meshing of the Sherlock Holmes narrative with curvature, which can only have emerged because of the diversity in the CoI. Furthermore, the process of story versioning boosts social creativity as it allows for the generation of new ideas which capitalize on, object to and finally synthesize previous ones. It is an ongoing process where ideas are adjusted, adapted and combined to produce new documents.

## Conclusions

The analysis of social creativity in the design process of a c-book on Curvature focused on the boundary crossing interactions between the CoI members and the role of the narrative and the widget instances as key resources for the development of social creativity. Two important boundary crossing processes, *coordination* and *reflection*, have enhanced social creativity establishing communication between different communities of practice: Mathematics, Literacy/creative writing and Digital tools development. Reflection, on the other hand, is the process which gave ground to the fertile synthesis of different views. Moreover, the story and its versions as a key resource was paramount to social creativity within the CoI. The story versioning process allowed for warm debate and idea exchange to take place: it created common ground for all CoI members to unfold their expertise, as well as the meshing of narrative with constructionist artefacts-widgets on curvature. As a result, a collective document, that is the c-book, was developed, associating various shared resources (activities, widget instances, text, and CMT representations) and a scheme for interweaving all these elements in a coherent whole. The issues that emerged during the construction of successive c-book versions challenged teachers' perceptions with respect to the teaching and learning of curvature resulting in innovative approaches fostering creativity and meaning-making. Embedding the comparison of constant to incremental turn and torsion changes to generate spirals in space within a Sherlock Holmes 'who dun it' story involved stepping out of curriculum structures for curvature and making a new conceptual field available to students connecting curvature with functions and 3D geometry.

The use of different theoretical perspectives, i.e., Social Creativity, Documentational Genesis and Boundary Crossing, has helped us gain a deeper insight in the phenomena in question. In our framework of analysis, the Social Creativity perspective provides the lens through which the social dimension of teachers' documentational genesis process can be approached. Moreover, resources take the role of boundary objects allowing the coordination of diverse perspectives leading to the generation of creative products (the c-book as an end-product). Thus, by coordinating these theoretical approaches, we seek to develop a networked understanding (Prediger, Bikner-Ahsbahr, & Arzarello, 2008) of the collective design of a c-book as a novel digital medium to foster students' creative mathematical thinking; a single theory would not suffice for understanding such a complex process. Even though drawing connections between theories is not a trivial task, such networks are potentially powerful and useful for the further development of mathematics education as a scientific field. (Prediger et al, 2008).

# Planning geometry lessons with learning platforms

Andreas Lindenskov Tamborg<sup>1</sup>

<sup>1</sup>Metropolitan University College, Department of School and Learning,  
Copenhagen, Denmark/ Aalborg University, Department of Learning and Philosophy, Copenhagen,  
Denmark, [alta@phmetropol.dk](mailto:alta@phmetropol.dk)

*This paper investigates how mathematics teachers plan lessons with a recently implemented Danish learning platform designed to support teachers in planning lessons in line with a recent objective-oriented curriculum. Drawing on data from observations of and interviews with teachers, three mathematics teachers' joint planning of a lesson in geometry with a learning platform called Meebook is analyzed using the instrumental approach. It is concluded that the interface in Meebook orients the teachers work toward what the students should **do** rather than what they should **learn**, although the latter is a key intention behind the implementation of the platform. It is also concluded that when the teachers succeed in using learning objectives actively in their planning, the objectives support the teachers to design lessons that correspond with their intentions. The paper concludes with a discussion of the dialectics between learning objectives and planned activities.*

*Keywords: Planning lessons, objective-oriented curriculum, learning platforms.*

## Introduction

Teachers' planning of lessons is an important aspect of teaching as the decisions made at this stage shape students' opportunities to learn (Superfine, 2008). Planning is especially important for mathematics teachers as techniques and tools are closely linked to mathematical conceptualizations (Haspekian, 2005). It is therefore essential that teachers' choices of resources and tasks resonate with the teachers' intentions of what the students should learn. Currently, an increased number of technologies are becoming available that support teachers to plan lessons (Johnson, Adams Becker, & Hall, 2015) by giving teachers access to new resources and allowing them to design their own materials (Gueudet, Pepin, Sabra, & Trouche, 2016). Although such technologies bring new opportunities, they also bring challenges as new resources and materials often require mathematics teachers to reconsider how environments that give the students the right opportunities to learn can be designed (Haspekian, 2005).

In Denmark, learning platforms are currently being implemented that are an exemplar case of new technologies that support teachers in planning lessons. Among other things, the learning platforms serve to give students, parents and teachers access to plans for students' learning progression, and the platforms are designed to support teachers in planning and sharing lessons (KL, 2014). The learning platforms share a number of characteristics with learning management systems (LMSs; see, for example, Watson & Watson, 2007), but learning platforms also integrate affordances that are not typically associated with LMSs. Although LMSs typically are designed to handle all aspects of student learning, the learning platforms also support teachers to design lessons by giving the teachers access to online curriculum materials and enabling the teachers to create their own. Previous research about platforms that support teachers' planning has identified a need to support teachers to design lessons and choose resources that are in line with the teachers' intentions for students' learning (Hodgson, Rønningen, Skogvold, & Tomlison, 2010). Danish learning platforms

were implemented in the wake of a recent curriculum reform that foregrounds learning objectives, and the idea is that learning objectives will support teachers to make choices that reflect the teachers' intentions for student learning. Although the learning platforms are already used widely in Danish primary schools, there is yet little research on *how* teachers plan lessons with these platforms. This paper investigates how Danish mathematics teachers plan lessons with one of the most widely chosen platforms, called Meebook (<https://meebook.com/>). It derives from a small-scale pilot study in an ongoing PhD-project. The paper contributes to the literature as it offers the first empirical analyses of how Meebook mediates teachers' planning and discusses the consequences of this planning for the orientation of their planning and of the foundation on which teachers build their choices of resources and tasks. The data in the study consists of a case of three teachers' joint planning and individual interviews with the same teachers. I begin the paper by explaining the Danish context and some of the key ideas behind the implementation of the learning platforms. I then introduce the instrumental genesis framework and my methodological approach and analyze a case of three teachers' joint planning with Meebook. I conclude with a discussion about the dialectics between learning goals and planned activities in which I draw on a concept of rational and relation modes of planning (John, 2006; Superfine, 2008).

## Context

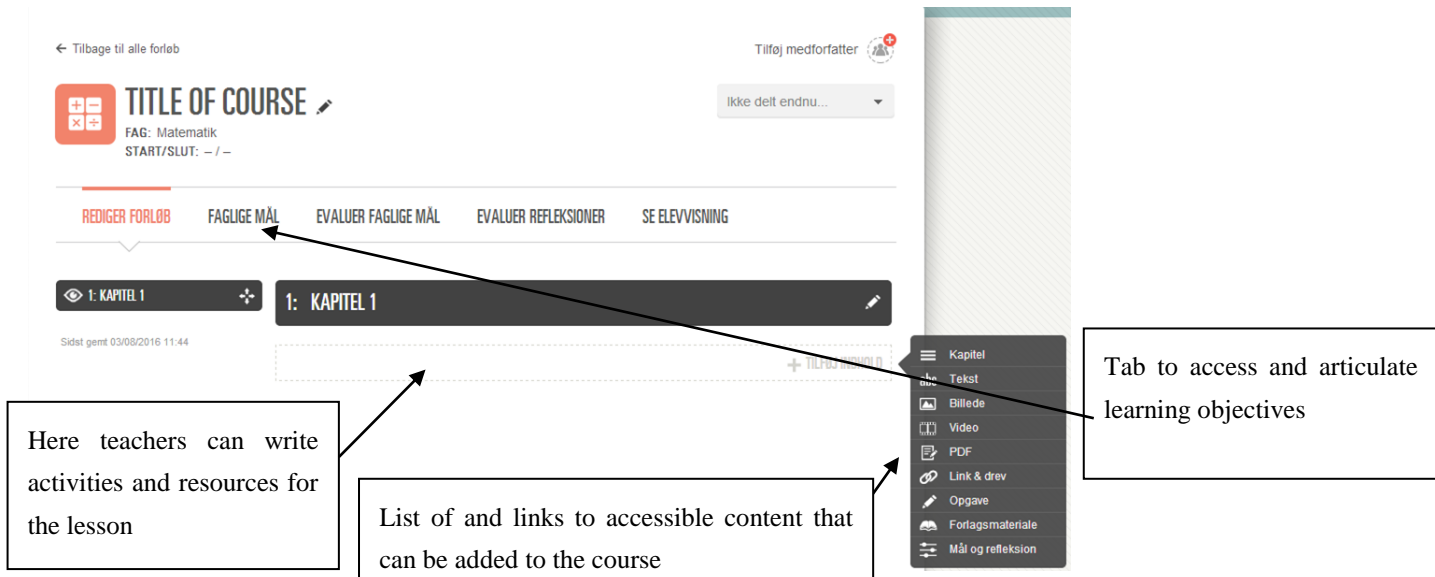

In 2014, as part of building a national digital infrastructure, the national government decided that all municipalities in Denmark would be required to purchase and implement a learning platform during the 2016/2017 school year. Instead of developing a common, national learning platform, the Government and Local Government Denmark (KL) allowed municipalities in Denmark to choose a platform that best meets their needs. As some degree of uniformity was needed, KL stated 64 functional requirements that the learning platforms must fulfill in order to be approved (KL, 2014). Among other things, these requirements included that the platforms should support the implementation of an objective-oriented curriculum reform and that they should support teachers to define the learning objectives for each lesson (KL, 2014). The idea was that teachers would begin their planning by defining a learning objective and then design or choose activities and resources that will enable the students to attain the objectives. Currently, six platforms are available that fulfill the 64 functional requirements of Local Government Denmark. These platforms differ in design, the amount and type of support that teachers are offered in planning lessons and how the national curriculum is considered as part of teachers' planning.

The school in which the present study took place is in a municipality that has chosen Meebook, one of the most widely chosen platforms. In contrast to some of the other available platforms (for example, <https://minuddannelse.net>), Meebook is characterized by an interface that allows teachers to choose how and when to integrate learning objectives in their planning. For example, MinUddannelse requires teachers to define a learning objective as the initial step of planning a lesson. The school had begun a gradual implementation of Meebook in December 2014 when the teachers initially were encouraged by school leaders to experiment with the platform. In August 2015, school leaders made it mandatory for teachers to use Meebook to plan lessons in both mathematics and native language education.

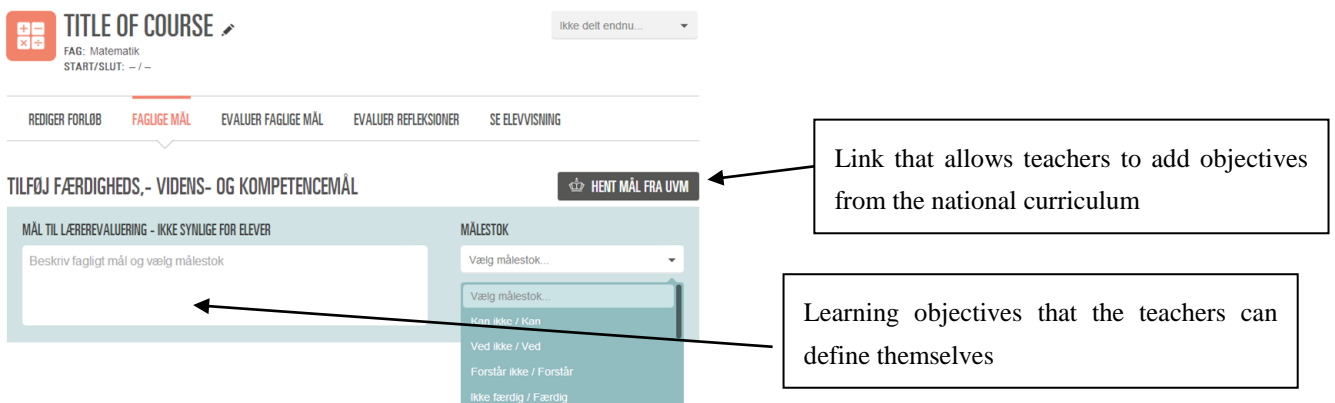

## The Meebook interface

Figure 1 illustrates Meebook's interface to create a course and add a chapter, text, picture, video material, a PDF document, a hyperlink, a task or activity, e-textbook material or a student reflection. In this interface, the teacher defines what should happen in the lesson and which resources should be integrated. The learning objectives are in a separate tab that is illustrated in Figure 2 and can be accessed at individual teachers' convenience. However, a learning objective must be defined before the course can be saved.

**Figure 1: Meebook's interface for teachers to plan a course/lesson**

Figure 2 illustrates the interface in Meebook where teachers can define learning objectives for the course. Here, the teachers can also access the learning objectives from the national curriculum through a link and select those addressed by the course or lesson. Teachers can also define their own objectives.

**Figure 2: Meebook's interface in the tab called "Add skill, knowledge and competence objectives"**

## Theoretical framework and research questions

In this paper, I draw on the instrumental approach (Guin, Ruthven, & Trouche, 2005). The instrumental approach is a framework developed to study the consequences of different kinds of tools, technologies and software for learning and teaching mathematics (Gueudet, Buteau, Mesa, &

Misfeldt, 2014). A key aspect of this approach is the assumption that the relation between design and use is dialectic rather than one-sided (Haspekian, 2005). When a subject uses an artifact in an activity with a specific objective in mind, the artifact can shape the appearance of the activity or even force the subject to redefine the objective of the activity. The subject's use of the artifact can, however, also exceed the intended uses of the artifact. The latter is referred to as design that continues in use (Ejsing-Duun & Misfeldt, 2015).

The instrumental approach distinguishes between artifacts and instruments. An artifact is defined as a cultural social construct that offers mediations of human activity, and an instrument is defined as the product of a subject's use of the artifact for certain activities with a certain objective (Gueudet & Trouche, 2009). An artifact therefore *becomes* an instrument when the artifact is used by a subject. This process is called instrumental genesis and results in a change in the mediating artifact and in the activity the artifact is used for. These two opposite processes (the shaping and the being shaped) are referred to as instrumentation and instrumentalization (Haspekian, 2005). Instrumentation is the process in which the subject's use of an artifact shapes the artifact, while instrumentalization is the process in which the artifact shapes the subject's activity (Gueudet & Trouche, 2009). The approach also distinguishes between pragmatic and epistemic mediations (Rabardel & Bourmaud, 2003). Pragmatic mediations are the use of technology to perform a task (Rabardel and Bourmaud use the hammer as an example) while epistemic mediations are the use of technology that allows the subject to learn about the object through the use of the technology (Rabardel and Bourmaud use the microscope as an example). Finally, the framework distinguishes between different orientations of instrumentations and proposes three main orientations: orientations toward the object of the activity, toward other subjects or toward oneself (Rabardel & Bourmaud 2003). I use this framework to address the following research question: Which mediations of the teachers' work occur as they plan lessons with Meebook, what are the consequences for the orientation of their work and for the foundation on which they build their choices of resources and tasks for the lesson?

## Method

The data in this study comprised observations of two 2-hour meetings during which three teachers collectively planned lessons, and of individual interviews with the three teachers. In general, the teachers expressed a positive attitude towards Meebook, although none of them had previous experience of using LMSs. The observations focused on: 1) the materials and task that was chosen by the teachers; 2) whom or what their planning was directed towards; and 3) what the foundation of their decisions seemed to be. The meetings, which took place at the school where the teachers worked, were documented by video recordings and field notes taken during the session. The video was recorded with a high-resolution camera that showed how the teachers maneuvered in Meebook. All video recordings were subsequently transcribed as closely to the spoken word as possible and supplemented by the notes taken during the observation.

The interviews were carried out after the observations and supplied data about what the teachers found important to consider when planning lessons—in general and related to the observed sessions. The interviews also collected data about the teachers' educational backgrounds and their seniority.

For this paper, I use a single case (Yin, 2014) that was selected as it gives insight into the relation between the teachers' planning practices and their use of the different interfaces in Meebook.

Although the amount of data in this study is sparse, the case reveals important problems and prospects associated with supporting mathematics teachers' planning with technologies, such as learning platforms. The case also identifies issues that future research in this area could consider.

## Case

This case took place during three teachers' joint planning of a lesson on geometry in middle school (students aged 10–11). The three teachers were Karen, Miriam and Gina. At the time this session took place, the teachers were two weeks into a three-week course on geometry. Karen is 29 and has 2 years of teaching experience, Gina is 40 years of age and has 5 years of experience and Miriam is 46 and has 22 years of experience teaching.

During the meeting, the teachers alternately discuss how to plan the lesson and write their decisions in Meebook in the tab illustrated in figure 1. While working in this tab, they decide that the students should work in groups and categorize the geometric figures they had been working with for the last two weeks (rectangles, squares, trapeziums, parallelograms and rhombuses). The teachers agree that each group should be given cardboard figures in the shape of these five figures and that the students should categorize the figures by placing them on an A2 piece of paper. Gina then openly poses the question whether the students should categorize the figures 'freely' or whether they should follow certain instructions. As the teachers discuss this matter without immediately reaching an agreement, Karen turns to the tab in Meebook where they have written the learning objectives for the course (illustrated in Figure 2). Karen reads the objectives aloud to her colleagues: "According to the objectives, the students should be able to distinguish between the five figures and categorize different types of figures according to their side lengths and angle sizes." Miriam argues that if these objectives should be addressed, then the students should identify the figures *from* their properties and that they therefore should be given instructions to do so. The two other teachers concede. Gina then comments: "If we give them figures to categorize, how do we make sure that they actually talk about the properties of the figure?" This comment makes the teachers aware that there is a risk that the students will categorize the figures from what they spontaneously believe the figures look like. The teachers find this likely, as the students have been working with the same five figures for two weeks at this point. This method of categorizing the figures would not target the objective for the lesson. The teachers therefore agree to hinder this from happening by cutting the cardboard figures into shapes that are unlike the figures the students have been exposed to during the last two weeks (for example, a 'crooked' trapeze, as Miriam calls it). They believe that this will make it difficult for the students to recognize the figures and that this will prime the students to actually investigate the properties of the figures and to do their categorization from this. The teachers also decide to instruct the groups to take turns picking a figure from a pile of cardboard with the figures facing downward, then place the figure in the category on the A2 paper where they believe it belongs and explain to the rest of the group why they believe it belongs there.

## Results

The teachers' planning of the lesson initially takes place in the interface illustrated in Figure 1. This interface in Meebook displays an overview of the resources available to the teachers and presents a blank field for them to fill. This blank field refers to the content of the lesson: which resources they will draw on and which activities they will include in the lesson. Meebook's visualization of the

content as the first aspect of the lesson to consider seems to be reflected in the teachers' initial decision that the students should categorize laminated geometric cardboard figures and that this activity should be carried out in groups. At this stage, the teachers' activity is oriented toward the object (the lesson to be planned), and their objective seems to be to decide which resources and task to include in the lesson. This priority of the content contradicts all three of the teachers' statements in the interviews where they emphasized the importance of beginning their planning by defining the objectives for the lesson. Miriam expresses it in the following way: "We always begin our planning with the learning objectives. That way, we can find or design the resources and tasks that fit the objectives. That's the whole starting point when we plan lessons." This suggests that the teachers' use of Meebook leads to a shift in the orientation of their activity from being oriented toward learning objectives toward being oriented toward defining the content. A consequence is that the choice of the cardboard figures does not reflect considerations about which specific geometric learning the students should obtain. This choice seems rather to reflect that the current topic is geometry. In the interviews, Karen and Miriam stated that they found it important that students have the chance to verbally express themselves in mathematics, as they believe that this creates good opportunities to learn. It is possible that the teachers' choice of organizing the lesson in groups is a reflection of this belief. The teachers' choice of using cardboard figures and that the students should categorize the figures, however, rather seems to reflect an objective of deciding what the students *should do* than what the students should *learn*. As previously stated, a subject's use of an artifact in an activity can shape the appearance of the activity or even force the subject to redefine the objective of the activity. In this case, Meebook's visualization of the activity 'planning lessons' seems to instrument the teachers' activity and orient it toward deciding the content for the course instead of prompting discussions about what the students should learn and which resources and tasks would enable this learning to occur. The case does not clearly illustrate an epistemic nor a pragmatic mediation. The case however illustrates that the teachers' use of Meebook does not lead to a new understanding of how the lesson could be planned according to their intentions.

As the teachers' meeting continues, they discuss whether the students should categorize the figures freely or whether their categorization should be guided by specific instructions. This decision requires a basis, and to find this basis, Karen turns to the tab in Meebook's interface where the teachers previously have written the learning objectives for the course. By turning to the objectives, the teachers become aware that the setting requires certain instructions if the learning objectives should be addressed. In this manner, the teachers use their knowledge about the students to anticipate how they would engage in solving a task and what learning in which this would result. This can be seen as an instrumentation of Meebook as the teachers merge two otherwise separate interfaces in Meebook. This results in the opportunity for an epistemic mediation of their activity that did not occur when the teachers worked in Meebook's *content* interface. As the learning objectives in Meebook become available for the teachers to use, they are enabled to explore their design of the lesson and modify it according to their intentions. At this point, the teachers' activity is characterized by a shift in orientation from the content of the lessons toward other subjects: the students, and more specifically, the students' learning. In other words, the teachers' activity shifts from being oriented toward what the students *should do* toward designing a lesson that creates opportunities for the students to *learn* something specific.

## Discussion and conclusion

One of the main ideas behind implementing learning platforms in Denmark is the assumption that integrating learning objectives in the platforms will support teachers in choosing resources that correspond to the teachers' intentions for student learning. However, this pilot study suggests that it is not sufficient that learning objectives are integrated as a part of teachers' planning in the platforms, but that *the ways* the learning objectives are integrated in the design of technologies are important. In the case presented here, Meebook's interface separates the objectives from the content of the course that in this case implies that the teachers' choice of resources is separate from the learning objectives. Considering the importance of techniques and tools for mathematical conceptualizations, it is crucial that the choice of resources and tasks is carefully considered. This does not seem to be the case here. The case demonstrates that learning objectives can be valuable assets and work as epistemic mediators for teachers when they plan lessons. The teachers' use of the learning objectives enables the teachers to explore their lesson design and modify it so it corresponds with their intentions. However, it is remarkable that this opportunity arises as a consequence of the teachers' instrumentation of Meebook rather than of Meebook's instrumentalization of their activity. In addition, the initial choices (that the students should categorize cardboard figures in groups) are not changed or reconsidered during the session. In the case presented here, the teachers succeed in building a lesson with the cardboard figures and group organization a way that reflects the teachers' intentions. However, it remains to be known whether the teachers would have changed or discarded the cardboard figures or not if it turned out that these resources were incompatible with the learning objectives. This point suggests that this is an issue to be aware of in future research.

Previous research in mathematics teachers' planning distinguished between a rational and a relational mode of planning (John, 2006; Superfine, 2008). The rational mode views education as a linear input-output relation in which the planning begins by defining the objectives and resources/activities then are decided. The relational mode is planning focused on how students encounter each other, the mathematical content and with the teacher in a specific setting and the opportunities to learn arising thereof (John, 2006). The rational mode has been criticized for resulting in lesson plans that overlook and fail to anticipate the complexity and contingency of educational contexts while the relational mode is often referred to as a 'better alternative' (John, 2006). The results in this paper challenge that these modes should be separated sharply. It is exactly when the teachers foreground the learning objectives that they are able to engage in a relational mode of planning and design tasks and resources in ways that reflect the teachers' intentions. Through combining these modes, this potential is exploited, and neither the rational nor the relational mode in itself would enable this process. This result suggests that future research in this field could benefit from considering *how* learning objectives are integrated in technologies that support teachers' planning and *what kind* of planning modes these objectives enable or disable.

# What can we assess using multiple choice problems that involve learner generated examples?

Shai Olsher<sup>1</sup> and Michal Yerushalmy<sup>2</sup>

University of Haifa, Faculty of Education, Haifa, Israel; [olshers@edu.haifa.ac.il](mailto:olshers@edu.haifa.ac.il),  
[michalyr@edu.haifa.ac.il](mailto:michalyr@edu.haifa.ac.il)

*Multiple choice (MC) items are the natural choice for automated online assessment. Ideally, making a choice should be based on knowledge and reasoning. Nevertheless, studies demonstrate that often various techniques (e.g. guessing) are the common practices. In the last decade technology has been employed to support real-time feedback as formative assessment for teaching and learning. This study examines whether and how learner generated examples, when required as support to the choice made in MC task, could be automatically identified to give insights into learners' understandings. Results show discrepancies between chosen correct statements and their supporting examples. Other automatically assessed characteristics are related to learner's approaches and strategies.*

*Keywords: Reasoning with examples, geometry, multiple choice questions, automatic online assessment, formative assessment.*

## Theoretical background

Multiple choice (MC) tasks are the most well-known tasks when it comes to automatic assessment (Farrell & Rushby, 2016; Sangwin & Kocher, 2016). They are used for testing various topics of study as well as different levels of abilities from basic through high order thinking. They hold several advantages including objectivity of scoring, and availability of more items in each assessment due to short solving times (Farrell & Rushby, 2016). However, MC tasks are often criticized for being biased (Hassmen & Hunt, 1994), for sometimes being measurements of how fast a student could make an educated guess or use elimination techniques, and not necessarily assessing what the MC tasks were designed to assess (Lau, Lau, Hong, & Usop, 2011).

Recent use of technology has made it possible to automatically assess responses by not only using MC tasks (Stacey, & Wiliam, 2012; Sangwin & Kocher, 2016). Immediate presentations of information on tasks performed in a technological environment are used as means to formative assessment: serving as feedback to modify teaching and learning activities (Black & Wiliam, 1998). One of these avenues is by automatically assessing learner generated examples (LGE) in a dynamic geometry environment (DGE) (Leung & Lee, 2013). Example generation tasks may serve as possible means to show conceptions of mathematical objects, or concept images (Vinner, 1983), informing about possible difficulties and inadequacies (Zaskis & Leikin, 2007). Another use of examples is for determining the validity of mathematical statements (Nagari-Haddif & Yerushalmy, 2015), in which systematic analysis of LGE could shed light on the evolving understanding of the status of examples in proving or refuting a mathematical claim (Buchbinder & Zaslavsky, 2009). Combining the accessibility of MC tasks in assessment with the potential reasoning abilities and demonstration of understanding by generating examples in a technological environment has the potential to enhance formative assessment in the mathematics classroom.

## Methodology

This study is part of a long-term project aiming to explore ways in which automatic assessment could give more insight about student understanding in mathematics (Olsher, Yerushalmy, and Chazan, 2016). Specifically, we ask whether the requirement to provide examples to support a chosen answer gives the assessor additional insight into students' understanding in MC tasks. The participants were 32 secondary Israeli geometry teachers, from all over the country who taught different levels and ages ranging from 7<sup>th</sup> to 12<sup>th</sup> grade. The study was conducted as part of a broader national professional development effort to expose teachers to innovations in mathematics education.

## Tasks

The study included three tasks and the context was mathematical similarity. The tasks were designed as interactive diagrams describing a geometrical context, using the STEP platform<sup>1</sup>. The interactive diagrams were constructed using GeoGebra and they enabled the participants to drag a set of elements in the diagram, according to the predefined characteristics determined by the designers of the task. The context was described in the task, and several statements were provided for the participants to consider. The participants were required to select the statements that are correct in regards to the diagram. More than one statement could be correct in relation to the interactive diagram in any single task. The tasks were similar to conventional multiple choice tasks accompanied by an interactive diagram, with one main difference: In these tasks the participants were expected to experiment and manipulate the interactive diagram into a state that fits one or more of the statements. In order to add another layer of reasoning, we asked the participants to attach a screen capture of the applet in a state that exemplified each of the statements they have chosen, thus requiring the participants to add an example instead of just select a statement as in traditional multiple choice tasks.

## Automatic checking of tasks

The STEP platform enabled an automatic analysis of the predefined mathematical properties of the submitted solutions in order to characterize these solutions pedagogically and mathematically (Olsher, Yerushalmy and Chazan, 2016). The tasks in this study were designed so that the system would indicate if the corresponding example fits the criteria in the relevant statement<sup>2</sup>, and enable the teacher to immediately have access to filtered answers accordingly. Yet, it is important to state that at the present time technology cannot determine correctness on its' own for these types of rich tasks. For each task, a well-defined set of conditions should be applied in order to determine the type of feedback affording formative assessment. Meeting the conditions of the checking algorithm does not mean correctness. It just means that this is what was automatically checked, and any

---

<sup>1</sup> Seeing the Entire Picture - STEP – is a formative assessment platform developed at the University of Haifa's Center for Mathematics Education Research and Innovation (MERI). For more detail about this platform, see [www.visustep.com](http://www.visustep.com).

<sup>2</sup> When automatically checked, a margin of accuracy was determined by the teacher in which solutions are considered sufficiently accurate. For example, in this case, parallel lines, or coinciding points.

interpretation about correctness is purely suggestive, and should be carefully examined by both the assessor and the assessee.

## Analysis

Our unit of analysis was the task. The first stage included locating discrepancies between a correct choice and the accompanying interactive example. We checked which participants chose the set of correct statements and compared it with the number of participants to correctly attach examples for all of the statements. The second step included a refinement of the analysis. We counted how many correct statements were chosen per-task (more than one choice could be correct for a single task), and compared it with the number of incorrect examples that do not meet the required answers' conditions. The third stage included the coding of the discrepancies according to pre-set categories (e. g. *familiar mistakes* or *additional reasoning*) in order to study the characteristics which could be subsequently assessed automatically.

## Results

Table 1 shows the distribution of answers (consisting of chosen statements and supporting examples submitted by the participants (n=32) to the 3 different tasks.

Task (number of correct statements)	No. of participants which submitted an answer (n=32)	Sum of correct statements chosen by submitting participants	Sum of correct examples attached to correct chosen statements	No. of participants with all correct statements chosen (n=32)	No. of participants with correct answers and correct supporting examples. (n=32)
1 (3)	30	66	49	13	5
2 (2)	28	40	32	11	7
3 (3)	21	39	27	7	5
Total	N.R*	145	108	N. R.*	N. R.*

\* N. R = Not relevant

**Table 1: Answers submitted, statement choices, and examples provided for 3 tasks**

As can be seen in Table 1, a total of 145 correct statements were chosen and submitted. For 108 of them (74.5%) correct examples were submitted. The remainder (25.5% of the correct choices) were submitted with incorrect or no examples. We now investigate the work related to two statements of task 3 in order to learn the nature of the examples that did not seem to be coherent with the choice of statement. In this task (Figure 1), the topic is the recognition of similar triangles, and ratios between areas of similar triangles. The context of the dynamic figure is presented to the participants in multiple representations: a verbal description in the task description, starting with: "point D is the midpoint ...", a symbolic representation in the digital geometry environment (DGE):  $ED \perp AB$ ,

$AD=DC$ , and a DGE construction: A draggable triangle  $ABC$  with point  $D$  and  $E$ . Measurement tools and numerical feedback are not supported in this task.

In the dynamic figure below, point  $D$  is the midpoint of segment  $AC$  in triangle  $ABC$ .  $ED$  is a line segment perpendicular to side  $AB$  of triangle  $ABC$ . Explore the dynamic figure considering the ratio between the areas of triangles  $ABC$  and  $ADE$ .

Below are three statements. For each statement for which you have a supporting example, please save the example as a way to show that you think that this statement is true. Leave the statements that you do not think are true as they are.

1  $S(ABC):S(ADE)=4:1$

2  $S(ABC):S(ADE)=2:1$

3  $S(ABC):S(ADE)=k:1 \quad k>10$

Save

Save

Save

---

$ED \perp AB$   
 $AD = DC$

**Figure 1: Multiple choice with supporting example task**

In terms of correctness, the red points in the diagram could be dragged to create an example for any of the three statements in this task, making all the choices potentially correct ones. In order to construct a supporting example for the first statement, the lines  $ED$  and  $BC$  should be parallel<sup>3</sup>, in order to construct a supporting example for the second statement points  $E$  and  $B$  need to coincide. A supporting example for the third statement would be any position where  $AB > 5AE$ . But in order to construct such examples (mostly for statements 1 and 2) participants are required to have some understanding regarding similarity and ratios of areas of similar triangles.

Automatic assessment of this task was performed with the STEP platform, which is designed to present the submitted examples in several representations, including a visual representation of all examples attached to each of the statements (Figure 2), while enabling the assessor to automatically

<sup>3</sup> There is also another option to construct this where  $E$  is outside  $ABC$  and  $AE=AB$ .

filter the results according to mathematical and pedagogical criteria (Olsher, Yerushalmy, and Chazan, 2016), as will be demonstrated for this task.

**Figure 2: A sample of supporting examples for statements presented on the STEP platform**

### **Incorrect examples that do not meet the required answers' conditions**

Analyzing the collection of examples per-statement suggest a finer categorization. Statement 3-1 (the first statement in task 3) stated that the ratio between the area of triangle ABC and the area of triangle ADE is 4:1. Triangles ABC and ADE are similar as ED is perpendicular to AB. In addition, AD has the same length as DC. Thus, any example in which ED is parallel to BC, which means AE has an equal length to EB and vice versa provides a supporting example. There were a total of 17 examples submitted for this statement. 13 of which met the criteria for correctness. In Figure 3 appear the 4 submitted examples that were automatically marked as incorrect, as the automatically calculated ratio between the relevant triangle areas was not approximately 4:1.

Figure 3: Incorrect submitted examples for task 3-1

The main characteristic that could be automatically assessed with this representation is the possibility that these participants did not address the characteristics relevant for this statement in their submitted examples - ED is not even approximately parallel to BC.

### Incorrect examples in line with familiar student mistakes

Statement 3-2 stated that the ratio between the area of triangle ABC and the area of triangle ADE is 2:1. Triangle ABC and ADE are similar. Thus, any example in which points E and B coincide provides a supporting example. There were a total of 12 examples submitted for this statement. 8 of which met the criteria for correctness. In Figure 4 appear the 4 submitted examples (a, b, c and d from left to right) that were automatically marked as incorrect, as the automatically calculated ratio between the relevant triangle areas was not approximately 2:1.

Figure 4: Incorrect submitted examples for task 3-2

In Figure 4, we see two incorrect examples (4a, 4b) that were further automatically categorized as "familiar mistakes". In these examples, the ratio between the lengths of BC and DE is approximately 2:1. These examples are a possible indication of holding the image of "linearity" between ratio of lengths and ratio of areas, a familiar phenomenon from the literature and teacher practice.

### Examples with additional verbal, symbolic or free-hand graphic reasoning

Figure 4c shows an example that includes a correct verbal explanation but without any matching change to the dynamic diagram. One of the functionalities of the STEP platform is a free-hand pen tool which can be used for making annotations and marks, or any other use that the participant might find helpful. The participants were aware that the platform automatically checked their figures, and that text or graphical markings, if submitted, are presented for the teacher to review but not analyzed automatically. The example above is one of 18 submitted examples (across all three tasks in this study) that were accompanied with free-hand markings on the interactive diagram. Apart from verbal explanations, the examples also included annotations in the form of either symbolic writing or in graphical marks on the diagram. There are numerous possible explanations

for such responses. The participant might not have been able to construct the example, but thought about its mathematical properties, and wanted to demonstrate his knowledge. Annotation could also indicate that the participants needed to justify their example in a more robust, mathematical fashion, not fully accepting the diagrammatic example alone as a valid justification for a statement, which is closer to Israeli standard classroom practice.

The example in figure 4d was not automatically categorized beyond its' incorrectness, as it did not fit the predefined filter for a familiar student mistake.

One other aspect of the automatic assessment of MC tasks is the correctness of the entire task (e. g. choosing all of correct statements *and* providing them with correct supporting examples). In this study 13, 11, and 7 participants made a correct choice of statements in the three tasks respectively (Table 1). The number of participants who chose both the relevant statements and also provided a correct corresponding supporting example is lower: 5 (of 13), 7 (11), and 5 (7) (Table 1). This might be because the tasks were not clear enough, not specific about the relevant conditions; or perhaps ill-defined in terms of level of accuracy required. In order to enable efficient formative assessment these analyses are presented to the assessor in various graphic (e. g. Figure 2) and analytic (e. g. Venn diagrams) representations for further investigation.

## Conclusions

This study provides initial information about discrepancies between choosing a correct statement, which could be a result of a guess or good examination tactics (Hassmen & Hunt, 1994; Lau, Lau, Hong, & Usop, 2011; Sangwin & Kocher, 2016), and providing an example to support this statement, which requires the translation of the conditions into a DGE context.

Many of the automatically assessed characteristics of submitted examples were not related to the correctness of the example in supporting the claim, but to other aspects such as student approaches and strategy (e.g. construction of prototypical figures, unexpected solutions). Although, due to space limitations, this report has focused on the limited analysis of discrepancies between chosen *correct* mathematical statements and their supporting examples, it has provided several additional insights into the MC tasks. Some of the solvers did not attend to significant characteristics required to support the answer (e. g. a line that needs to be a mid-section therefore to connect mid-points of two sides of the triangle and to be parallel to the third one), or the fact that they construct an example in line with a familiar student mistake (e. g. the ratio between the areas of similar triangles is the ratio of their sides squared, not the exact same ratio as reflected in the submitted example). These types of phenomena could help teachers better assess the performance level on these types of tasks, in the relevant mathematical topic, providing meaningful real-time analysis in the service of instruction. The automatic analysis and categorization alongside the visual representation methods played a key part in discussions of the results with teachers. This practice is well aligned with what Olsher et al. (2016) claim that the viability of this assessment in the mathematics classroom lies within the ability to automate the assessment process as much as possible, and to provide the teachers with suggestive insights as part of a better picture of their classroom example space and answers.

*The main aim of this paper is to analyse the experience of a MOOC for mathematics teacher training implemented in France, in parallel with a similar experience in Italy<sup>1</sup>. The study focuses on teacher collaboration within such an online learning environment, in terms of co-working and co-learning. The Italian and the French teams outlined a common starting point for the research and some common research concerns. Each team then reformulated the research questions and sought to answer them through specific theoretical lenses. In the case of the French MOOC eFAN Maths, we study the trainees' collaborative design of a pedagogical resource, by focusing on the efficiency of an evaluation grid designed by trainers to be used within a global process of peer evaluation. A comparison with the results of the Italian experience is shown in the conclusion.*

*Keywords: MOOC, teachers' professional development, meta-didactical transposition, community, collaboration.*

## Introduction

Internet communication tools provide the opportunity to develop new types of teaching methods that combine online courses, resources and discussions. MOOCs (Massive Open Online Courses) were conceived in 2008 at the initiative of prestigious American Universities (MIT, Harvard, Stanford, ...) that sought to enlarge the courses they offered to a wider audience. Since then, the MOOC phenomenon has been growing steadily and worldwide, the number of MOOCs doubled between 2014 to 2015 (Shah, 2015). Although there is a wide choice of many different topics, when looking specifically for a MOOC aimed at teacher training, the range is limited, especially in mathematics. Nevertheless, there is a growing interest in MOOCs involving mathematics teachers as participants, as shown by the TSG44 work during the 13th ICME<sup>2</sup>. In particular, from our experiences, there is a need for designing and implementing a MOOC for teacher training in mathematics education with a particular focus on the development of communities of practice (Wenger, 1998) and collaborative work among teachers as the basis for their professional development. Indeed, when people co-work (work together collaboratively) they can also co-learn (learn together collaboratively), as highlighted in the ICME survey of Robutti et al. (2016). The authors found that teachers can learn through discussion, conversation and reflection on their own teaching, on students' learning and the teaching of others. The methodology of the French MOOC eFAN Maths aims to create collaborative contexts

---

<sup>1</sup> See Taranto et al. (2017). Since the French MOOC and the Italian MOOC were delivered at the same period of time, even if the contents were designed independently, our teams had the opportunity to discuss and exchange about them.

<sup>2</sup> For more information, see [http://www.icme13.org/files/tsg/TSG\\_44.pdf](http://www.icme13.org/files/tsg/TSG_44.pdf)

for teachers' work, where they can learn from these kinds of practices. Taking into account the necessity for teachers to be supported in exploiting the affordances of technology, the shared objectives of both the French and Italian MOOCs are shared, namely: accompanying teachers in the production of teaching resources, by examples of activities and reflection on their ongoing resource design; fostering a reasoned use of technology, encouraging teachers to choose appropriate digital tools for the classroom. Such aims are related to the interest in the design and the implementation of teacher professional development programmes to include the role of teachers working and learning in communities (Wenger, 1998; Jaworski & Goodchild, 2006).

The originality of our research based on the data collected from two MOOCs (in Italy and in France) that share similar aims and objectives, is twofold. First, it focuses on the specific dynamics of online interactions – among trainees and between trainees and trainers – to study the trainees' use and appropriation of a tool (an evaluation grid) designed by trainers, for supporting peer evaluation of collaborative projects. It is topical and urgent to analyse the efficiency of such tools and interactions in the context of distance learning, because of the increased interest in this approach in recent years. Second, it analyses such dynamics according to the cultural constraints that shape MOOC design and development. French and Italian school environments have some remarkable differences and one of the most palpable is a wider freedom that institutional regulations traditionally give to the Italian teachers, compared to the major institutional constraints met by the French teachers. The Italian *Indicazioni*<sup>3</sup> (guidelines) highlight for each discipline the fundamental learning goals that students have to achieve at the end of each cycle of instruction (two or three scholastic grades). These guidelines have the character of general didactic guidelines and require teachers to take the responsibility to choose and link the specific mathematical contents to be developed in the classroom in order to reach the required learning goals. The French *Programmes*<sup>4</sup> (syllabus) are also based on competences for a given cycle of instruction, but they appear to be more detailed and normative: for each mathematical content, they provide some examples of activities. Moreover, they are accompanied by several additional resources intended to support the curriculum implementation in the classroom.

In this paper, and in parallel with the Italian contribution to the symposium, we draw on the common theoretical element of the Meta-Didactical Transposition (Arzarello et al., 2014) to highlight how the concepts of community and of collaborative work evolve, taking new and different forms, and how these processes impact on teachers' professional learning. As members of the French team, we are working together with members of the Italian team to compare data from the two MOOCs. In our conclusion, we will discuss the relevance of cultural and institutional aspects to the specific dynamics of the two experiences.

## Description of the MOOC eFAN Maths

The MOOC eFAN Maths<sup>5</sup> was delivered on a French national platform (FUN, France Universités Numérique) and its target was the world-wide French-speaking community, namely mathematics teachers and teacher educators willing to improve their practices in using technology in their classrooms. The second season of the MOOC, which is reported in this paper, lasted from early March to mid-April 2016 over a period of five weeks. The MOOC eFAN Maths is part of the *Stratégie Mathématiques* of the French Ministry of Education, which stresses the relationship of mathematics with other sciences and with the world, and aims at training teachers in this perspective in order to give students a refreshed image of mathematics. More specifically, this season of the MOOC was created with a dual institutional aim: to support teachers and teacher educators to understand and implement the new French curriculum (introduced in September 2016 in all French primary and secondary schools); and to promote collaboration within the French-speaking community. Courses, activities and discussion were especially focused on the new themes involved in the French curriculum, namely algorithmics and interdisciplinary work. The MOOC was grounded on a project-based pedagogy, aimed at the design and the analysis of a classroom activity involving the use of digital tools. Every week, trainees took courses on specific topics of mathematics education from three video-based lessons, answered the related quizzes and worked on specific activities. The courses were constructed to provide trainees with elements to develop their reflections and projects about teaching and learning mathematics with technology. They showed brief episodes of classroom observation and their analysis, or were based on existing resources, showing and commenting animations or programs created with technology. Collective work was strongly encouraged among trainees. For this purpose, they were invited to join the “MOOC eFAN Maths 2016” group, created on Viaéduc<sup>6</sup>, a professional social network specifically designed for teachers’ exchanges. Viaéduc essentially allows members to post comments, to create subgroups, to create and publish documents and to comment/recommend/share them. Group members can work collaboratively either asynchronously, being authors of the same online document, or synchronously, writing on the same online collaborative board (*padlet*).

During week 0, on Viaéduc, trainees were invited to propose a theme, an idea or a project to work on and to start to establish relationships with others. Week 1 was devoted to the characterisation of digital or non-digital resources that can support teachers’ and teacher educators’ work. On Viaéduc, trainees gathered together around a project constituting public subgroups of the main “MOOC eFAN Maths 2016” group, so that any trainee could read the work of any subgroup and follow any discussion. Week 1 activity involved the selection of resources to constitute a “toolkit”, deemed relevant to the group project. Week 2 was devoted to the analysis of students’ activity using technology in mathematical situations. On Viaéduc, each group had to design a mathematical situation and to analyse it from the students’ point of view using an analysis grid proposed by the trainers. Week 3 was devoted to the analysis of the teacher’s role in the designed mathematical situation. An analysis grid that focused on instrumental orchestration was presented through the courses and trainees were

<sup>5</sup> eFAN Maths stands for *Enseigner et Former avec le Numérique en Mathématiques* (Teaching and Training in Mathematics with technology). See <https://www.fun-mooc.fr/courses/ENSDeLyon/14003S02/session02/about>

<sup>6</sup> See [www.viaeduc.fr](http://www.viaeduc.fr)

invited to apply it to their situation. During week 4, trainers organised a process of peer evaluation of the different projects (submitted as versions 0) and proposed an evaluation grid grounded on the theoretical frames presented in the course, underpinned by the analysis of digital resource quality (Trgalová & Richard, 2012). Finally, every group was supposed to use the feedback received to refine and revise their project, submitted as version 2.

## Theoretical framework

The MOOC eFAN Maths was analysed using a combination of three main theoretical frameworks: the Meta-Didactical Transposition (Arzarello et al., 2014), the documentational approach to didactics (Gueudet & Trouche, 2009) and the concept of communities of practice (Wenger, 1998).

The Meta-Didactical Transposition (MDT) model and the documentational approach to didactics, which places a major emphasis on the collective aspects of teachers' work, both required a theory to support the analysis of the development of teachers' (and researchers') collective work. Both approaches adopted the theory of communities of practice (CoP), mainly because these communities are structures where learning occurs. CoP are formed by people who engage in a process of collective learning in a shared domain of human endeavour. For Wenger (1998), a condition for the development of such communities is to balance participation and reification, where reification means producing resources, symbols, stories etc., recognised by the whole community as common products. Such communities may develop by themselves, or be "cultivated" (Wenger et al., 2002), i.e. encouraged, supported by an organisation. Indeed, organisational knowledge develops in a constellation of CoPs, and each CoP plays a specific role in this organisation.

The MDT model captures the dynamic interactions between teachers' and researchers' practices when these two communities interact, typically in training contexts, and in particular in the case of training programmes in mathematics education. Using the MDT lens, we can address research questions that infer the influence of the practices of one community on the other. Such practices are described through the notion of praxeology (Chevallard, 1999): a praxeology for a given task consists of a practical block comprising techniques to accomplish the task, and a theoretical block justifying and supporting these techniques. In a teacher education programme, trainees and trainers bring into play the components of their respective praxeologies. The objective of the programme is to transpose, in the sense of Chevallard, some components of the trainers' research practices into the teachers' practices, taking into account the classroom reality and teachers' expertise for effectively enacting such components. Thus, the two communities together contribute to creating a shared praxeology, which both communities can adapt in their future practices. This occurs through the phenomenon of *internalisation*: a community internalises a component of the praxeology of the other community, that was previously external to it, entailing an evolution of practices.

The documentational approach to didactics (Gueudet & Trouche, 2009) analyses teacher professional development through the interplay of practices and resources. This interplay is modelled as a *documentational genesis*, extending the notion of instrumental genesis introduced by Verillon and Rabardel (1995) between artefact and instrument. A documentational genesis involves different steps, such as looking for resources, selecting/designing mathematical tasks, planning their sequence, managing available artefacts, etc., to achieve a given teaching goal. This genesis gives birth to a document, which is a mixed entity composed of the revised and recombined resources and the

associated usage schema. Each documentational genesis is then a means to trigger teacher professional development. The genesis of a document combines two processes: *instrumentation*, when the affordances and constraints of the resources influence the subject's activity, and *instrumentalization*, when the subject shapes the resources that he/she appropriates. The documentational approach to didactics, from its beginning, and even more in its recent developments (Pepin et al., 2013), gives a major importance to the collective aspects of teachers' work with resources, evidencing the importance of interactions within teacher collectives for spurring documentational genesis and teachers' professional development.

The combination of these three frameworks supports our analysis of what happened during the MOOC, seen as a constellation of cultivated CoPs. These communities are not created at once, they emerge in the dynamics of a shared project. First, the community of trainers emerges as they design and implement a new teacher education programme. Then the communities of trainees emerge, each one developing through the advancement of the individual projects. The elaboration of a project involves the design of a pedagogical activity from selected existing resources that are subsequently adapted, modified and combined by the group members. Thus, this process can be seen as a collective documentational genesis. In such a process, we are interested to analyse the efficiency of the tools designed by the trainers, as elements of their meta-didactical praxeologies, to foster both collaboration and project development. We study the phenomenon of internalisation in interaction with the process of documentational genesis as a reification process, addressing the following research questions: How does each trainees' CoP emerge through the process of documentational genesis according to CoP criteria? How do the CoP of trainers and each trainees' CoP interact through the MDT lens?

## Methodology of the study

In this paper, we focus on the final week of the MOOC and in particular on the trainees' use of the evaluation grid. This tool had been constructed by the trainers to include all of the phases of the pedagogical design, developed in the MOOC week after week. Analysing the way trainees used it can provide insights into the way they have understood and internalised the principles underpinning each phase of design. Moreover, the final week revealed an interesting dynamic between individual activity (the evaluation of another project through the grid) and collective work (of each group on the delivered version 0 for improving it). The evaluation grid was structured around the following four criteria: 1. Accuracy of the definition and description of the project; 2. Relevance of the mobilised digital resources with respect to the educational goal of the designed mathematical task; 3. Relevance of the analysis of the students' activity; 4. Relevance of the analysis of the teacher's role. For each criterion, aimed at evaluating the work done by a group during a specific week, some guiding questions were proposed with a double objective: to foster the production of justified feedback; and to deepen the reflection carried out in the previous weeks of the MOOC. The grid finally asked for a brief global feedback on the project and some suggestions to improve the work. Trainers provided this tool to support trainees in the process of peer evaluation, with the implicit aim to facilitate the internalisation of the evaluation criteria. Each trainee was invited to use the grid individually to evaluate the project of another group, by answering each guiding question with an appreciation: very good, satisfactory, weak or insufficient, accompanied by a justification. Trainers gradually collected feedback and comments in a table and shared it in a specific space on Viaéduc, called "Project evaluation", so that all the trainees could access them.

## Data analysis

2500 people were enrolled in the MOOC, and more than 700 registered on Viaéduc, of which approximately 11% contributed to the work of a group, generating a large amount of data from multiple sources. In this paper, we analyse some discussions on Viaéduc related to how trainees used the evaluation grid and illustrate the main finding of our study: the trainees' internalisation of the evaluation criteria, through the tools provided and the process established by the trainers.

The evaluation grid became a resource for trainees. It was used both to provide feedback to other projects (instrumentation) and for reflecting on and refining their own project (instrumentalization). We illustrate this double action, that of the grid on the trainees and that of the trainees on the grid, through some excerpts of Viaéduc discussions. The comments, written by some trainees (CC, CM) on the wall of the "MOOC eFAN Maths 2016" group, show a formative value of the peer evaluation and specifically refer to an introspective use of the grid.

- |    |  |
|----|--|
| CC | It is clear that the peer evaluation of the projects is also an exercise [...] I think that the aim is not marking "very good" everywhere, so I try to use the grid with its criteria that I start to understand [...]. A difficulty that I encounter is that, when I perceive a small flaw in one of the aspects of the whole structure of the project, this flaw seems to impact on several items of the grid...? [...]" |
| CM | Indeed, by evaluating another project, you discover much better how to improve yours. The evaluation grid is a great support but I join CC on the domino effect of some points.  |

In particular, CC's and CM's comments show a well-thought-out use of the grid, especially the awareness that the evaluation criteria are interrelated. The double process of instrumentation and instrumentalization of the grid shows that trainees internalise the evaluation criteria using the grid also for reflecting on the quality of their own document.

Moreover, the remote collaboration on Viaéduc allowed trainees to evolve version 0 of the document into the version 1, taking into account both peers' external feedback and each member's introspective feedback. An example of this step in the collective documentational genesis is represented by the use of the padlet "TO DO List" within one of the groups. In this padlet, the group members organise the different tasks to be done in order to make the common document (version 0), seen as a resource, evolve into a new document (version 1). When a comment is ticked off and an author and a date are specified, this is the sign that the task has been done. This to-do list consists of feedback coming from peers but also of some personal comments, such as "For the resources I think that we must orient the reading of the first ones according to the soma cube activity". We can reconstruct the story of this proposal to reorganise the project resources, due to the parallel discussions that had occurred in the group. Such discussions show that trainees (JP in this case) benefited from both peers' feedback and introspective feedback, coming from the action of evaluating other projects.

- |    |  |
|----|--|
| JP | [on the wall of the group] Hello, after having read several projects I actually expected that someone "criticises" a little bit our profusion of resources. [...] Perhaps, we could prune it in the v1 of the project by keeping only those that are actually usable in the SOMA cube activity. What do you think? |
|----|--|

In terms of remote collaboration, it is worth noting that some groups used such collaborative tools for organising their remote work. This organisation guided the transformation of the version 0 into the version 1 of the project, as a reification of the collaborative participation within the CoP.

## Discussion

Each community of practice benefited from the feedback of others and from the introspective reflections that the members, who were engaged in the design process, made during the evaluation process. Crossing the external and the introspective feedback allows the trainees to work collaboratively on the refinement of their version 0 and to produce the version 1 of their project. This new version of the document is both a stage in the documentational genesis and the result of the internalisation of the evaluation criteria which occurred through the participation in the evaluation process. On the one hand, the evaluation grid is a technical tool of trainers' meta-didactical praxeologies, based on the theoretical concepts tackled in the courses and justified within the global process of peer evaluation. On the other hand, the trainers' choice of collaborative tools, seen as a trainers' technique, is grounded on the trainers' objectives to foster the emergence of communities of practice among trainees. Our analysis shows how these praxeological choices influence the trainees' work when they improve the version 0 of their project into the version 1. In return, this analysis influences the trainers' meta-didactical praxeologies in the perspective of a re-design of the new season of the MOOC. In particular, the organisation of the MOOC schedule will be modified taking into account the emergent question of time. Communities of practice need time for establishing an effective remote collaboration, so that participation and reification equilibrate as much as possible. At the same time, the evaluation process and the documentational genesis need time for being effectively carried out. In that sense, we can observe the double phenomenon of internalisation: from trainers to trainees as well as from trainees to trainers.

## Comparison with the French experience and conclusion

As French team, we observed local communities of practice. We studied the phenomenon at a micro level, intervening in the groups' discussions to support and encourage the development of the collaborative work. The Italian team (Taranto et al., 2017), instead, observed a general community. They studied the phenomenon at a macro level, that is to say not intervening in the interactions between trainees.

During MOOC Geometria (the Italian MOOC) local groups are generated "emerging from chaos" (Siemens, 2004), namely they are subject to a spontaneous generation. During MOOC eFAN Maths trainers induce the generation of local groups and regulate peer relationships. Despite the fact that the cultural aspects affect these differences for sure (as we underline in our similar introduction), for both MOOCs there is an affinity that relies on the fact that trainees' learning is often generated by self-feeding discussions and instrumentalization processes.

# Using a flipped classroom approach in the teaching of mathematics: A case study of a preservice teachers' class

Theodosia Prodromou

University of New England, Australia; [theodosia.prodromou@une.edu.au](mailto:theodosia.prodromou@une.edu.au)

*This study investigates the usefulness of a flipped classroom approach in tertiary education. This exploratory study was conducted to understand the efficacy of the flipped classroom approach that was implemented by a lecturer teaching mathematics education. The study was conducted with the lecturer and her 185 pre-service teachers who attend her online course. Data collection instruments included a survey designed to investigate the dynamics of the flipped approach, semi-structured interviews for the pre-service teachers and the lecturer. The study adds to the literature related to the flipped classroom approach and the role of the lecturer in a flipped classroom.*

*Keywords: Digital technologies, flipped classroom, flipped learning, mathematics education, tertiary education*

## Introduction

The integration of digital technologies is becoming central in our mathematics classrooms. Some schools use digital technologies to replace or supplement teaching resources (Geiger, Goos, & Dole 2015). Multiple studies have been conducted that show that teachers and schools find it challenging to integrate such resources within mathematics lessons (Gueudet, Pepin, and Trouche 2012; Clark-Wilson, Robutti, and Sinclair 2014). Flipped classrooms integrate digital technologies allowing the teacher to implement the restructuring and re-organisation of teaching materials in both synchronous and asynchronous modes. The facilities of the classroom approach can be accessible from anywhere, in both real time or otherwise. How to best take advantage of digital technologies implemented in flipped classrooms is a challenge while attending at the same time to the dynamics of a flipped classroom and what is entailed in flipped learning. Given that research on the flipped classroom approach is in its infancy, there is limited research that has examined the approach under a pedagogical microscope.

## Flipped classroom and flipped learning

Bergmann and Sams (2012) distinguished between the terms 'flipped classroom' and 'flipped learning', pointing out that they are not synonymous and that flipping the classroom does not necessarily lead to flipped learning (FLN 2014). There are different interpretations of this approach and associated variations in implementations strategies. According to Bergmann, Overmyer and Wilie (2013), the characteristics of flipped learning are:

- increased interaction and personalized contact time amongst students and teachers;
- students take responsibility for their own learning;
- the role of the teacher is not the 'sage on the stage', but the 'guide on the side';
- a blending of direct instruction with constructivist learning;
- students who are not able to attend the class due to illness or extra-curricular activities such as athletics or fieldtrips, don't get left behind;
- content is permanently achieved for review or remediation;

- all students are engaged in their learning;
- all students can receive a personalised education.

Abeysekera and Dawson (2015, p. 3) defined the following typical characteristics of a flipped classroom within higher-education settings:

- a change in use of classroom time;
- a change in use of out-of-class time;
- doing activities that were traditionally considered as ‘homework’ in class;
- doing activities that were traditionally considered as in class work out of class;
- in-class activities that emphasise active learning, and problem-solving;
- pre-class and post-class activities;
- use of technology, especially video;

For this article, I will use the term ‘flipped classroom’ as defined by the Flipped Learning Network (FLN) to refer to the mode of teaching and learning ‘in which direct instruction moves from the group learning space to the individual learning space, and the resulting group space, and the resulting group space is transformed into a dynamic interactive environment where the educator guides students as they apply concepts and engage creatively in the subject matter’ (FLN 2014 para. 1). The FLN propose the ‘Four Pillars of Flip’ that recognise the significant features that are essential for learning to occur in a flipped classroom: (1) flexible environment, (2) a shift in the learning culture, (3) intentional content, and (4) professional educators (FLN 2014). This framework was considered to account for diverse learning modes, and its implementation necessitates the arrangement of flexible learning environments that may include, for example, the rearrangement of learning spaces and the use of digital technologies.

The Four Pillars of Flip framework is appropriate for gaining a better understanding of how the flipped classroom approach is implemented in practice. This framework is appropriate when analysing data about the teacher’s role in organising the teaching materials in the flipped classroom. Abeysekera and Dawson (2015) proposed a theoretical model for the flipped classroom (see Fig. 1) that identifies the capacity of the flipped classroom to help students have a sense of competence, relatedness, and autonomy that will lead students to increased extrinsic and intrinsic motivation.

**Figure 1 Theoretical model for the flipped classroom**

Moreover, a flipped classroom approach is characterised by tailoring teaching material and activities to students’ different expertise that allows students’ self-pacing of pre-recorded lectures that may reduce cognitive load and help learning in a flipped classroom.

The theoretical model for the flipped classroom was considered appropriate for interpreting data pertaining students' engagement and motivation while it is required measurement of the cognitive load and motivation that are useful mechanisms for learning. The flipped classroom approaches are being adopted with enthusiasm despite the lack of specific evidence about their efficacy. However, substantial research questions remained unanswered. This article is particularly interested in university lecturer's implementation of the flipped approach in her practices. A small-scale localised intervention, including an experimental study, was conducted to understand the significant features of the lecturer's role against the essential criteria for learning to occur in a flipped classroom approach.

## Methodology

An exploratory case study methodology was chosen as it involves a detailed study of a group of pre-service teachers' experiences. The data collected for the case study was both qualitative and quantitative. Analysis methods were employed (Creswell 2003) to provide richness and depth to the empirical investigation of a single university unit within its real context using multiple sources of evidence such as the lecturer, the entire cohort of preservice teachers who enroll in and attend the unit of study, and the teaching and learning resources that were used by the pre-service teachers.

The choice of the lecturer and her class was purposive in that the lecturer had indicated a strong desire to improve aspects of her online teaching related to student engagement, motivation, and self-pacing. The lecturer used a flipped classroom approach, and the appropriate technological infrastructure and digital technologies was in place to provide students with access to all teaching resources.

The study was conducted with the lecturer and her 185 pre-service teachers who attended an online unit that was required for a bachelor in Primary education or master in teaching Primary Education. The unit covered the content and pedagogy appropriate to teaching primary school students at stage 3 (year 5 or Year 6) in the strands of Data, Chance, Patterns and Algebra, and Number (numeracy). Students were asked to demonstrate their personal content knowledge in these strands, discuss associated teaching strategies, and create developmental learning sequences. The prescribed textbook, (Siemon, D., Beswick, K., Brady, K., Clark, J. and Faragher, R., 2015) was used to guide decisions about the sequence of mathematics topics to be taught. The textbook was used in combination with the Australian Curriculum (ACARA, 2016).

The lecturer prepared lectures recorded by Echo360, and offered two interactive online tutorials that were offered in real time by Adobe Connect. Each online tutorial was scheduled for two hours and students were able to ask questions and complete the tutorial activities with the help of the lecturer. Students who were not able to attend the online tutorials had access to the recording of the tutorials (in asynchronous mode). Additionally, demonstrations, electronic resources and relevant readings were available for students' use on the Moodle learning platform, which served as an online learning space where students interacted with each other, posted questions and engaged with collaborative activities (i.e. students were constantly experiencing feedback).

All students had access to the internet, and the online materials were also available for downloading in their own computers. The students were encouraged to assess the recordings of the online lectures, online tutorials, resources and assessment tasks for each topic.

Participants included one lecturer (Dr. April, pseudonym) and 185 students who attended the online unit. 142 students completed the online survey and 5 (3 females and 2 males) volunteered to participate in the semi-structured interviews. Dr. April, the lecturer had been teaching tertiary education for 7 years and was qualified to teach mathematics education to pre-service teachers and in-service teachers within primary and secondary and post-graduate programs. She had experience in using features of flipped classrooms for 7 years.

Data collection instruments consisted of an online survey that contained 18 questions about the use of the lecturer-prepared online resources. Responses were recorded against a five-point Likert scale. Semi-structured interviews were developed by the researcher to allow the lecturer to probe the pre-service teachers' experiences of the flipped classroom approach in this discipline. Pre-service teachers' online activities, postings, pre-service teachers' participation per day and the semi-structured interview of the lecturer were used to triangulate the data collected from pre-service teachers. All interviews were audio-taped and transcribed. Pre-service teachers' responses were coded and ascribed to five thematic categories as identified by Abeysekera and Dawson (2015). Lecturer's responses were also analysed and coded in four thematic categories based on the four Pillars of FLIP framework.

## Results

In this section we present an analysis of the data collected from interviews with the lecturer, which was analysed using the Four Pillars of FLIP as a framework to recognise the significant features of the lecturer's role against the essential criteria for learning to occur in a flipped classroom: (1) flexible environment, (2) a shift in the learning culture, (3) intentional content and (4) professional educators. The data is supplemented with survey and interview data from the pre-service teachers.

### Flexible environment:

When the lecturer was asked about the flipped teaching environment in an interview, she commented:

Dr April: Students are expected to view the online lectures and the online resources (videos) any time that is best for them because they are mature students who study this online unit and they prefer working during night hours.

Dr April: I am trying to extend classroom into their home where students cover the weekly teaching content and work the routine tasks and examples at home prior to the weekly lecture.

Students reported to making very good use of the online resources prepared by the lecturer and the recordings of the online tutorials at home, indicating that both were helpful for their mathematical learning and the completion of their assessment. As stated by two students, George and Sarah:

George: I do not worry if I missed the real-time online tutorial due to my family commitments. I have the capacity to access the recordings of the online tutorials and lectures at any time I wish.

Sarah: It is fantastic because I can watch the entire online tutorial or lecture without pausing it. But sometimes, I will watch it and pause it to write my notes about it. If I would like to repeat a part of it, I will simply go back to the part I need to listen again. I refer to certain parts many times because they are very essential for the online course.

## A shift in the learning culture

Dr April relegated the more procedural demonstrations of solving a mathematical problem or constructing a mathematical application using mathematical software for the pre-service teachers to watch outside of the online tutorial time. As she commented:

Dr April: It is fantastic because it frees up teaching time instead of spending half of the time of the tutorial to show students the procedure of solving a mathematical problem with or without the use of mathematical software. I am trying to maximise the tutorial time by covering the key aspects of the weekly content taught and the teaching techniques of teaching school students a target content.

The students reported that they make good use of Dr April's video based procedural presentations and demonstrations. For example, John and Jill (pseudonyms) said during an interview:

John: I first listened to the online tutorials. I do find the online tutorials very helpful because the lecturer explains the mathematical content by applying the mathematical concepts in real life situations and solving mathematical problems. If you first watch the online tutorial very carefully it explains the mathematical content, application of mathematical content, primary students' difficulties in understanding specific concepts and pedagogical approaches and appropriate to teaching these primary students.

Jill: Dr April's video based resources are very helpful to understand the content at home on my own without attending traditional classrooms.

George: The online tutorials allow me to interact in real time with a group of other students and the lecturer, so I do not feel lonely during my studies. I post my questions on Moodle platform when I am stuck or unsure of the correct process.

## Intentional content

Dr. April selected the content, decided on ways to present this content, and what resources (e.g., interactive whiteboard activities, or interactive games) would be appropriate for the online tutorial. As Dr April said:

Dr April: In the video-based resources that students are expected to view before the tutorial, I demonstrate how to use technology when they teach, for example I demonstrate how they insert data in a table using Tinkerplots and create various graphical representations of data and analyse data. Or I explain the use of interactive board activities or educational games that would help pre-service teachers to teach students how to compare fractions using computer based interactive tasks.

Dr April's approach included the use of technology to transform the teaching content from the textbook into video format that allowed her to unpack mathematics in more depth during the online tutorials and lectures. She also prepared materials and videos that related mathematics more directly to cross curriculum priorities such as Aboriginal and Torres Strait Islander history and cultures, Asia and Australia's engagement with Asia, and sustainability.

Moreover, pre-service teachers commented that the digital technologies employed by their lecturer to teach mathematics had provoked rich discussions amongst the pre-service teachers, allowing them to access the step-by-step instruction as the lecturer intended.

## Professional educators

As Sarah noted, when asked if there was anything about the online teaching of Dr April that helped her particularly to develop her mathematical learning:

Sarah: The technology she uses helped me to visualise abstract mathematical concepts ... the presentations help me to visualise the graphical presentations as she manipulates the graphical representations to help me to observe the impact of dragging the graph to the algebraic equation of the function. She is explaining very well and clearly all the step-by-step procedures and their dynamic behaviours. I am really amazed by the animations that she provided to show the dynamic behaviour of mathematical concepts.

John also pointed out:

John: I feel that Dr April's videos are giving mathematics life. They explain mathematics better than the textbook does. I really prefer the recordings of the online tutorials because Dr April explains in detail what she is doing step-by-step using a very simple language.

George and Sarah also mentioned that:

George: the presentations are very professional and the quality of the sound is perfect. The recordings of the online lectures and online tutorials were easy to follow and although mathematics was not my strongest subject of study, I enjoyed my study. I found those recordings very engaging.

Sarah: I had all the online resources on my laptop and I study them while I am writing my assignment. I listen also to the online tutorials and lectures to write my assignment, but I do not use the prescribed textbook.

As indicated, the online resources were more appealing to the pre-service teachers and preferable to the prescribed textbook. The preparation of the online materials used for the pre-service teachers to access on their own exemplifies the enactment of the first, second, and third pillars of the flip framework. There was a shift from a static to a dynamic representation of the content and an intentional selection of the aspects of direct instruction that could be assessed in students' individual spaces.

## Summary of 142 pre-service teachers' responses to the Likert items

Pre-service teachers indicated that they found the online resources prepared by Dr April to be very helpful for their mathematical learning (Q1, 96%). They also indicated that the online resources prepared by the lecturer are easy to follow and flowed well (Q2, 97%) and they agreed that they are engaging and interesting (Q3, 100%). The resources prepared by their lecturer were favoured over other online resources (Q4, 89%). Responses to the survey also indicated that pre-service teachers did not use the internet resources to help them with their mathematics learning (Q5, 73%). Pre-service teachers indicated that they found the online lectures relevant and meaningful, and they assist them with their mathematics learning (Q6, 96%). They also indicated that the online lectures were easy to follow (Q7, 99%) and they were about the right length (Q8, 95%). Significantly, respondents also found that the online tutorials offered them a great opportunity to answer questions about the mathematical content (Q9, 95%), fitting nicely into their schedule (Q10, 87%), being interesting and engaging (Q11, 89%; Q12, 2% boring). Interestingly, responses indicated that they make use of the

'Online tutorials' to explore mathematics (Q14, 5%) and they rarely use the 'Online tutorials' as a last resort when they were stuck on problems (Q15, 12%). However, they seemed to believe that they did better on the assessment because they watched the online tutorials (Q16, 82%). Importantly, pre-service teachers also believed that the step-by-step 'Demonstration of Mathematics software' was simple to use and it was beneficial (Q17, 93%), with only 1% of the responses indicated that the 'Demonstration of Mathematics software' was lacking and it required more technical tools (Q18, 1%); a possible consequence of the selection of the intentional content that Dr April expected students to cover before attending the online lectures and tutorials.

## Conclusion

Dr April's attempt to implement aspects of a flipped classroom approach to her online course was made possible within a highly structured teaching and learning content because of the robust technological infrastructure in the university. Nevertheless, the pre-service teachers' engagement with their study of the online course was a consequence of the online resources developed by the lecturer to support her students' online learning. It would appear that pre-service teachers appreciated the opportunity they were offered to progress through materials at their own pace exercising a degree of autonomy in developing their own mathematical competence.

The four Pillars Framework afforded insights into the specific features of Dr. April's implementation of the essential features of flipped learning. The analysis of the data showed that Dr. April has provided students with a *flexible environment* that provided students with a *sense of autonomy* and *self-pacing*. Reflection on lecture's practice indicates a *shift in the learning culture* by transferring direct instruction from the classroom environment to home. The flipped classroom approach was implemented without removing the synchronous interaction of pre-service teachers with other students and the lecturer. It is noteworthy to point out that the interactive online tutorials aided in preventing students from being alienated from other students, the lecturer and the teaching materials. The selection of the intentional content was challenging in order to *tailor* the content to different *students' expertise*. Pre-service teachers appeared to be motivated to access the online resources prepared by Dr. April stressing the importance of *relatedness* between students and materials prepared by the lecturer to foster a version of an online flipped classroom. There was evidence that pre-service teachers engaged in rich mathematical discussions about the content of the teaching materials, showing that a flipped classroom can increase motivation and interaction amongst students and learning of ideas aimed by the provided teaching materials. The fourth Pillar of the flipped learning, the *professional educator*, appeared to be the agent of the flipped classroom approach. A *professional educator* (as Dr. April demonstrated) could foster the implementation of the flipped classroom approach in teaching and learning practices without making radical change to their current pedagogical approaches— a finding consistent with research conducted by Muir and Geiger (2016) who found that a flipped classroom approach could be implemented without radically reforming a teaching practice. Future studies could examine the suitability of flipped mathematics classroom approaches in different teaching contexts, such as inquiry learning contexts, teaching school mathematics, and whether or not it would be effective in improving students' learning outcomes.

*In this paper we report an experimental activity involving working with functions and graphs in a grade 6 class in a Norwegian primary school. We argue that working with graph loggers in the form of an echo sound system enhances student conception of mathematical graphs.*

*Keywords: Mathematical concepts, mathematics activities, mathematics education, educational technology.*

## **Background and literature review**

The research reported in this paper was part of the EU FaSMEd project<sup>1</sup>, which brings together seven European countries and South Africa, researching the use of formative assessment and technology in mathematics and science education. Part of each country’s work has included case study interventions in ordinary classrooms in close cooperation with school teachers. In this paper, we focus on a particular set of lessons concerning functions and graphs, and how one particular type of technology was used to increase student activity and engagement, leading to enhanced learning.

The function concept is generally regarded as a difficult concept for students to grasp (Dreyfus & Eisenberg, 1982; Sajka, 2003; Sierpinska, 1992). Dreyfus and Eisenberg (1982) point out that the function concept is not a single concept by itself, but has several aspects and sub-concepts associated with it. DeMarois and Tall (1999) connect this to the learning of functions, saying that “for many students, the complexity of the function concept is such that the making of direct links between all the different representations is a difficult long-term task” (p.264). Also in Norway, national and international tests have shown that mathematical functions is a problematic topic area. It took humanity several thousand years of mathematical activity until functions were introduced in the 17<sup>th</sup> century; and even then it took time to place functions on a solid foundation within mathematics. It is therefore not surprising that pupils struggle with functions and how to respond to this struggle has been addressed in various ways. During the “New Math” movement in the 1960-70s, it was believed that school mathematics should resemble research mathematics, and attempts were made to introduce functions during the first years of primary school. Eicholz, Martin, Brumfiel and Shanks (1963) did exactly that. This American textbook was translated into several languages, including Norwegian. The pendulum turned away from this with the “back to basics” movement, and, in Norway, functions were moved to the secondary school. As a consequence, most research on students’ understanding of functions and graphs is conducted with secondary school students. In this paper, we report on work done in primary school.

<sup>1</sup>FaSMEd = Improving Progress for Lower Achievers through Formative Assessment in Science and Mathematics Education, see <https://research.ncl.ac.uk/FaSMEd/>

According to Duval (2006) we can only gain access to mathematical objects by semiotic representations. Janvier (1984) distinguished between four representations of functions: situations; graphs; tables; and formulae; and how to work with transitions between these. Duval (2006) stresses that “What matters is not representations but their transformation” (p. 107). That is, when learning about a mathematical concept, students deal with a representation of the object, and the main difficulty is to change between different representations of the same object. Duval distinguishes between conversions and treatments. Here, treatments take place between the same registers (e.g., changing  $y = 2x$  from one particular form to another), while conversions take place between registers (e.g., reading a table and using the numbers within it to interpret a situation). The latter seems to be far more difficult, while the former is the most common activity format in school. Consequently, Janvier’s framework helps teachers to focus on the change of registers rather than algebraic manipulation alone. To support the learning of functions, many different kinds of digital tools have been developed and used. Regardless of any particular view on learning outcomes from using technological tools, it is important to realize that use of technology is more than the introduction of new tools. In a survey on mathematics teachers’ use of technology in England, Bretscher (2014) found that while ICT might contribute to change, the direction of this change was as likely to be towards “more teacher-centered practices rather than encouraging more student-centered practices” (p. 43). The tools used in our study are a particular type of data loggers. These are mainly used in science, but we claim that inclusion of these types of tools may be beneficial also in the mathematics classroom, and may contribute to more student-centered practices. According to Newton (2010) “data-logging methods involve the use of electronic devices to sense, measure and record physical parameters in experimental settings.” (p. 1247). Measurements and results of the logging can be displayed on a computer screen, either subsequently or simultaneously. We used this type of technology to study students’ early understanding of graphs. The use of motion experiments in the learning of functions has been studied by several authors. Nemirovsky (2003) conjectures that “mathematical abstractions grow to a large extent out of bodily activities” (p. 106). Arzarello and Robutti (2004) claim that students can grasp mathematical concepts through meaningful sensory-motor experiences if they are encouraged to communicate and have the necessary support (p. 308). Arzarello, Pezzi and Robutti (2007) point out that teachers can use new technology to design experiences for students “where graphs can be presented in a dynamical and genetic way” (p. 135). Robutti (2009) conducted research on time-distance graphs with kindergarten children using motion sensors and calculators, finding that even very young children were able to make connections between the movements they made in front of the sensor and the graph sketched by a calculator.

The research question addressed in this paper is: How can a primary school teacher use data logger technology to enhance primary school students’ engagement and conceptual knowledge about function graphs?

## Method

The teaching experiment was carried out in a grade 6 class (students around 11 years old) in a primary school in Norway. The number of students in the school is close to 600, and the number of teachers around 35. The participating teacher has background from general teacher education, with specialization in mathematics and history. At the time of the experimental sessions, he had been working as a teacher for 7 years, the last three years at the school in question. He had been teaching

mainly mathematics, and also some science. During his participation in the FaSMEd project he was teaching the same group of students, which began in grade 5 and continued with the same group of students into grade 6. There were 31 students in his class, 15 girls and 16 boys.

The theme of the teaching sessions was time-distance graphs. Several technological tools and software had been introduced to the participating teachers at FaSMEd meetings at the university. Teaching material from the FaSMEd toolkit that addressed time-distance graphs had also been introduced. The planning of the experimental lessons began at this meeting. The teacher would give one lesson introducing the students to graphs and to the connection between graphs and real life situations. Working with mathematical graphs connecting situations and graphical representations is usually not done in Norwegian primary schools. According to the national curriculum, functions and graphs is not a specified learning goal for students until after grade 10. This would therefore be the first time this teacher had worked with students in primary school on graphs. Because of this, he wanted to first pilot the lesson on a small group of students that he considered high achieving and with an interest in mathematics. Subsequently the lesson was repeated with a group of students considered to be lower achievers.

The technology used was two echo sounder devices developed by Pasco. This was chosen as the entry level for using it was not too high, and therefore the teacher considered it could be experimented with grade 6 students. It facilitated students to walk back and forth in relation to a logging device, such that a graph was immediately drawn on the computer screen indicating how near they were the device during a time lapse of ten seconds. The immediate live update of the graph distinguishes this activity from most regular science data logging activities. The computer was loaded with an app with premade tasks that were presented to the students. When students walked in front of the echo device, the computer would give a live display of graph in a time – position coordinate system. The tasks<sup>2</sup> were a mix of practical tasks: “Walk a graph”, and open-ended questions about interpretation of the graphs from the “walks”. All the results were saved and could be used by the teacher for assessment and feedback to the students. These data were e.g. used by the teacher at the end of the sessions to determine which student groups should present their work in a plenary. Students were chosen deliberately to give good examples of graphs made and how to interpret them.

Data sources collected during the experiment include a) observation sheets from two sessions; b) audio recordings from two sessions, from teacher pre- and post-interviews, post-lesson reflections, interviews and q-sorting activities with students; c) video recordings from two sessions; d) transcriptions of audio and video recordings; e) photos taken at sessions and of student work; f) files and screen shots from PC during student activity; g) teacher lesson plans for two sessions.

After the “walking a graph” activity, students were interviewed in a q-sorting<sup>3</sup> activity; i.e. they were presented with a set of statements printed on cards and asked to sort the cards according to

---

<sup>2</sup> The echo sound activity used some tasks taken from the software bundled with the Pasco software. Instructions for using the software and tasks were translated into Norwegian by the FaSMEd team. Some additional tasks were added.

<sup>3</sup> [https://en.wikipedia.org/wiki/Q\\_methodology](https://en.wikipedia.org/wiki/Q_methodology)

whether they agreed, disagreed or were undecided about, the statement on the card. This activity was carried out in groups of 3 to 4 students.

## Findings

The echo sound activity made this lesson stand out from an ordinary mathematics lesson. One student said,

Student A: It was very different (...) In maths lessons we never move, we sit at our seat; except sometimes we go out to do measurements, but that is always during summer.

The tasks were also considered different to normal mathematics exercises on two accounts. First, students were not used to doing mathematics tasks using computers. Second, in the classroom they usually have to compute things, whereas in these lessons

Student B: There were word problems and we had to do things.

The q-sort revealed that students generally agreed to statements that connected mathematics to real life. E.g., students agreed to the statements “Mathematics helps us to understand our surroundings” and “Mathematics is used in everyday life”, whereas they disagreed with the statements “Mathematics is only for the classroom, not for real life outside school”, “I can do without mathematics” and “Mathematics is not relevant for my future life”. The q-sorting activities were completed around two weeks after the time-distance graph lesson. We may therefore claim that there is some evidence indicating that the lesson had made students aware of, or strengthened their awareness of, connections between mathematics in school and real life situations that can be described by mathematics or where mathematics is used. Students agreed that “Mathematics is important”, claiming that

Student C: We use it all the time. Everywhere. In the shop. (...) On trains. Airplanes. The bus.

It seems that these groups of students held positive attitudes towards mathematics, and that they were able to see mathematics as relevant for themselves and for real life situations. During the echo sound activity, the students had to relate what they were doing, i.e. the way they were walking in front of the sensor to the graph the software would display on the PC screen. We can see evidence that students were able to connect the pace of their walking to the slope of the graph:

Student E: It rises earlier because you walk faster.

This relates the time (horizontal axis), distance from the sensor (vertical axis) to speed (how steep the curve is), a fundamental relationship in understanding time distance graphs, and a fundamental relationship in physics, and of course in everyday life. There were several student utterances showing the same kind of understanding:

Student F: It will be more slanted the faster you walk. So you start slow, then you walk faster.

The teacher asked another student how you can find from the graph where you walked faster. The student said that

Student H: You can see, because, first it is quite slanted, and then it goes straight up.

Students also developed understanding of the fact that a graph does not have to start at the origin. When trying to walk in a way that would produce a W as graph:

Student I: You have to start far away [from the sensor] because then it goes downwards and then it goes upwards and then it goes downwards.

We see here that they understand that a graph can cross anywhere on the vertical axis, and the relationship between distance from the sensor and time passed. Their descriptions and discussions did not use mathematical vocabulary or concepts. Rather, they described what they saw in everyday terms, which shows that they are able to change registers and not only operate within the same register. These examples show how such an activity helps students in the process of conversion. The activity offers two aspects of working with graphs. On the one hand, students had to translate a given situation into a movement in front of the echo sound device, observe the graph being plotted on the computer screen and adapt their movement to change the graph as needed. On the other hand, students would interpret a graph plotted on the screen into what kind of movement that this would correspond to. In the interviews, students said the tasks in this lesson were more challenging than the mathematics tasks they normally work with, e.g., in that they had to explain how they did things. Being challenging is not really a bad thing, and students said they found the sessions to have been great fun and exciting. They claimed that they had learned a lot about graphs. During q-sorting, students who agreed to the statement “I can better understand when I use the technology tools in our mathematics lessons” also agreed that the statement referred to learning about graphs:

Student E: I learned a lot about graphs and how they change with the computers

When the lesson was repeated with students that were considered to be lower achievers, the setup remained unchanged, making it more relevant for comparison. Notably, we found that it was not possible to distinguish any big differences between the first session with higher achievers and the second session with lower achievers.

Teacher: It was indeed very similar (...) maybe these were a bit slower. And I would be tougher, push the others more. (..) But I think they were clever, they were good at cooperating, learning on each other. (...) It shows that if you have open and good tasks, you have a lot of differentiation included.

The activity prompted student communication and discussion. The teacher found that students who normally keep quiet were engaged in discussion.

Teacher: In particular, some of the girls in the last group, they were talking, usually they are very quiet. Now they talked, without me having to point at them, prompting them; now they gave their opinion (...) And I was positively surprised at how easy it was for them, to listen to each other's arguments.

It was obvious that, even if these types of activities with graphs are common in Norwegian primary schools, it had not been too difficult and that this is a topic that could easily have been done with the whole class. The teacher said that

Teacher: I think, interpreting graphs, it could have been done quite easily. (...) I think this might be more fun in primary than in lower secondary school. They still find it exciting with graphs (...) they are more curious and less biased.

In the interviews, all students said that they had enjoyed taking part in the project and performing the lessons with graphs.

Student: In my opinion everything was good (...) We learned a lot about graphs.

## Discussion and conclusions

The echo sound graph plotting activity was very useful to give the students hands-on experience in using modern technology and use their own physical movements to create something to talk about mathematically. Acquiring experience with new technologies can be an educational goal in itself, and in particular, echo sound technology is not common in the classroom, but it is well known in other aspects of life. In the interviews, students claimed this was an important part of what they had learned and which distinguished these lessons from ordinary mathematics lessons. In traditional data logging experiments, students might see the data collection and the data analysis as two separate entities as these are separated in time (Barton, 1997). In our experiment, the gap between the collection of the data and the displayed graph is narrowed down to practically zero. In this respect, this activity also resembles working with dynamical graph tools, like GeoGebra<sup>4</sup>. These software tools allow students to explore graphs by manipulating parameters within designated bounds, while walking a graph changes freely the look of a graph only limited by the range of the echo sound device. This is more in line with work by e.g. Arzarello and Robutti (2004) and Robutti (2009).

When looking at the Janvier table we see that what the students had engaged in was making a transition between a situation and a graph. However, the typical sketching activity proposed by the Janvier framework when working with functions usually has a different feel than in this experiment. Not only is the sketching part of the activity itself done in a kinesthetic manner. There is also a dual aspect in that the students continually interpret the graph whilst the graph is sketched by the program on the screen. This way we can say that students work simultaneously with two elements of Janvier's framework, giving further evidence that changing registers is a difficulty that can be overcome by giving appropriate teaching materials.

The kinesthetic part of the activity, the walking, is in itself an important aspect of the experiment. As it turned out, the designated low achievers were able to perform well and display great enthusiasm during the session. This can be related to the way learning through movement can be an alternative approach to put students in a receptive state, ready for learning. Learning through actually moving your body is rarely an aspect of mathematics lessons, but can certainly encourage engagement, as seen in this experiment.

The type of activity exemplified in this experiment is completely devoid of focus on algorithms or procedural performance in the form of computations. Students do not know in advance how to solve the problems presented, and so focus is on developing conceptual knowledge about function graphs. From their statements, we also see that they relate mathematical concepts, like slope, to real world experiences, like speed. This is similar to findings in Robutti (2009, p. 68). A well founded conceptual understanding of functions and graphs in a time-distance setting will contribute to better understanding of functions on a more general level. When students encounter functions at higher

---

<sup>4</sup> <http://www.geogebra.org>

grades, their conceptual foundation will make it easier to grasp other aspects and algorithmic approaches to functions.

The literature suggests that teachers need support of different kinds in order to conduct teaching with new technologies in a meaningful manner. For example, building on a large teacher survey in Singapore, Tan, Hedberg, Koh and Seah (2006) suggest that teachers need support from laboratory technicians, data logger training, and instructional material to use data loggers effectively. In our case, none of these were present. We do however acknowledge the collaborative effort between teacher and researchers as instrumental to the success of the sessions. It is also important to stress that learning is not an automatic outcome from playing with technological tools, no matter how sophisticated the tools are. The role of the teacher is instrumental in bringing about learning, as highlighted by Clark-Wilson, Robutti and Sinclair (2014, p.396).

*“Pépité” is an online automated assessment tool for elementary algebra for students in secondary education (12-16 years-old) in France. Pépité was initially developed for students at the end of compulsory schooling in France (16 years-old). At CERME9, we presented its transfer at different school levels and illustrated it with the design of Pépité test for grade 8<sup>th</sup> students. Information provided by Pépité allows identifying students’ consistent reasoning and calculation in order to organize teaching corresponding to students’ learning needs. In this paper, we focus on the use of Pépité test for grade 8<sup>th</sup> students to learn the domain of equations. We defined an epistemological reference of the algebraic domain that allows us not only to build the tasks selected for the test and to analyze students’ responses but also to propose suitable courses adapted to students’ learning needs.*

*Keywords: diagnostic assessment, Information and Communication Technology (ICT), elementary algebra; equations, student’s profile, teaching suggestions.*

## **Context of the study**

This paper deals with the issue “Digital assessment of and for learning” of TWG16 “Students Learning Mathematics with Technology and Other Resources”. Since the 1990s, our team has developed several multidisciplinary projects (Delozanne & al., 2010; Grugeon-Allys & al., 2012) concerning the design, development and use of online tools for diagnostic assessment and student learning. One of these tools, named “Pépité”, is relevant for learning elementary algebra for students of secondary education (12-16 years) in France. We have disseminated *Pépité* online tool on platforms<sup>1</sup> largely used by teachers and students.

In this paper, we deal with the use of *Pépité* online assessment for learning the domain of equations for grade 8<sup>th</sup> students. First, we revisit the theoretical foundations of *Pépité* online assessment. Then, we illustrate it with *Pépité* assessment for grade 8<sup>th</sup> students in France (13-14 years). We specify both the didactical model and the computer model that automatically generates generic tasks, analyses students’ work and provides descriptions of students’ profiles. Finally, we discuss the potentialities

---

<sup>1</sup> Pépité tools are available on LaboMep platform (developed by Sésamath, a French maths’ teachers association): <http://www.labomep.net/> and on WIMS environment (an educational online learning platform spanning learning from primary school to the university in many disciplines).

of *Pépité* online assessment to propose suitable courses adapted to students' learning needs for the domain of equations for grade 8<sup>th</sup>.

## **The theoretical and methodological framework**

In the educational system, assessment is a complex issue. Usually, assessment results are generated from standardized and psychometric models. Studies highlight the strengths and limitations of such approaches to make instructional decisions (Kettelin-Geller & Yovanoff, 2009). To identify the features of appropriate online assessment for learning, we have chosen both a cognitive and epistemological approach and also an anthropological approach, the potentialities of which are described in Grugeon-Allys & al. (2012).

### **Epistemological and cognitive approach**

Designing a test requires the selection of a set of tasks that enables the assessment to be realized. We agree with Vergnaud who stated, "Studying learning of an isolated concept, or an isolated technique, has no sense" (Vergnaud, 1986, p. 28). Furthermore, Vergnaud introduced a strong assumption: dialectics between genesis of a student's knowledge and mathematical knowledge structure. Beyond a quantitative analysis of responses, we have to define a qualitative didactical analysis (based on a collection of students' responses to the tasks) to identify the type of procedures and knowledge used by students in solving the tasks. To provide descriptions of a student's consistent reasoning, it is necessary to define a reference for modelling the mathematical competence, in a mathematical domain, at a particular school grade.

### **Anthropological approach**

The epistemological approach is not sufficient so as to take into account the impact of the institutional context on students' learning. According to the anthropological approach, mathematical knowledge is strongly connected to the institutions where it has to live, to be learnt and to be taught; it is strongly connected to mathematical practices (curricula, etc.). Chevallard (1999) analyses knowledge in terms of praxeology, that is to say in terms of type of tasks, techniques used to solve these tasks, technological discourses developed in order to produce, explain and justify techniques, and last, theory that justifies technological discourses.

### **A reference epistemological praxeology for algebraic knowledge**

For a given mathematical domain, we defined a reference epistemological praxeology (Garcia, Gascon, Higuera & Bosch, 2006) that makes it possible to create an *a priori* design that describes features of an appropriate assessment. For algebraic knowledge, such reference is based on results from didactics of algebra (Chevallard, 1989; Artigue & al., 2001; Kieran, 2007). In its *tool* dimension (Douady, 1985), there are tasks for *generalizing*, *modelling*, *substituting*, *proving*. In its *object* dimension, there are tasks focused on calculus with algebraic expressions (*calculating*, *substituting* a number for a letter, *developing*, *factorizing*) or equations (*solving*). This reference makes it possible to define appropriate technology for an intelligent and controlled algebraic calculus, based on equivalence of algebraic expressions and the dialectic between numeric and algebraic treatment modes.

## The domain of equations for grade 8<sup>th</sup> students

The three following types of tasks are specifically related to equations (we will give some precise examples later about our experimentations):

- Modelling and putting a problem into equation (tool dimension). These tasks motivate the production of an equation in order to solve modelling problems and require semiotic conversions (Duval, 1993).
- Solving an equation using an algebraic technique; proving that two equations are equivalent (object dimension). These tasks use the concept of equivalence and require transformational activity (Kieran, 2007).
- Testing if a number is a solution of an equation; identifying the degree of an equation (object dimension). These tasks are based on substitution and polynomial properties.

## Features of *Pépité* online assessment

The *Pépité* online diagnostic assessment is based on a reference epistemological praxeology of the algebraic domain, both for designing tasks and for analyzing responses to the test. We will base this on the *Pépité* test for grade 8<sup>th</sup> students.

### The didactical model

#### *Pépité* test

The test (targeting 13-14 years old students) is composed of 10 diagnostic tasks and 22 individual items covering the types of tasks defined below (Table 1). The tasks may be multiple-choice or open-ended items (Figure 1).

Types of tasks	Number of items	Test items
Calculus	4 / 22	7.1 / 7.2 / 8.1 / 8.2
Producing numerical expressions	1 / 22	5
Producing algebraic expressions	2 / 22	3.1 / 6
Translation or recognition	14 / 22	1.1 / 1.2 / 1.3 / 2.1 / 2.2 / 2.3 / 3.2 / 4.1 / 4.2 / 9.1 / 9.2 / 9.3 / 9.4 / 10
Problem solving in different mathematics frameworks	1 / 22	6

**Table 1: Organization of the 8<sup>th</sup> grade level test in terms of types of tasks**

**Exercise 6: Proof and calculation program**

A student says to another student: “You will always find the same result if you take a number, you add 6 to that number, you multiply the result by 3, you subtract triple the initial number”.

Is this statement true for any number? Justify your answer.

Justification

Result

The statement is true for any given number: true or false?

**Figure 1: Example of generalization task**

*Responses analysis: the multidimensional model of algebraic assessment*

At the local assessment level (for each task), students' responses are not only evaluated as correct/incorrect, but also according to their technological discourse, that justifies the techniques. The analysis concerns validity of response (V) and seven dimensions: meaning of the equal sign (E), algebraic writings produced during symbolic transformations (EA), numerical writings produced during symbolic transformations (EN), use of letters as variables (L), algebraic rationality (J), connections between a semiotic register to another (T) and skills with negative and decimal numbers (N) (Table 2) (Grugeon-Allys, 2015). We code the responses with assessment criteria, which depend on knowledge and reasoning involved in the techniques<sup>2</sup>.

Assessment dimensions	Assessment criteria
Validity of response	V0: No answer V1: Valid and optimal answer V2: Valid but non optimal answer V3: Invalid answer Vx: Unidentified answer
Algebraic writings produced during symbolic transformations	EA41: Incorrect rules make linear expressions $a^2 \rightarrow 2a$ EA42: Incorrect rules gather terms ...
Connections between a semiotic register to another	T1: Correct translation T2: Correct but non optimal translation T3: Incorrect translation taking into account the relationships T4: Incorrect translation without taking into account the relationships Tx: No interpretation

**Table 2: The multidimensional model of algebraic assessment (partial view)**

We illustrate the multidimensional model of algebraic assessment on the task “Proof and calculation program” (Figure 1). In order to solve this task, two *a priori* strategies are possible: an arithmetic strategy using a number or an algebraic strategy mobilizing a variable. Several incorrect techniques can illustrate an arithmetic strategy (Table 3) according to the rules used to translate or transform numeric expressions. Algebraic strategy may be incorrect (J3) if the conversion rules (T3 or T4) or algebraic transformation rules (EA3 or EA4) are inadequate (Table 4).

Solutions	Reasoning and technological discourse	Coding
For number 5 $(5 + 6) \times 3 - 3 \times 5 = 18$	Correct arithmetic strategy with global expression that uses parenthesis	V3, L5, EA1, J2, T1
For number 5 $5 + 6 = 11$ ; $11 \times 3 = 33$ ; $3 \times 5 = 15$ ; $33 - 15 = 18$	Correct arithmetic strategy with partial expressions	V3, L5, EA1, J2, T2
For number 5 $5 + 6 \times 3 - 3 \times 5 = 8$	Erroneous arithmetic strategy with global expression that uses no parenthesis	V3, L5, EA3, J2, T3
For number 5 $5 + 6 = 11 \times 3 = 33 - 3 = 30 \times 5 = 150$	Erroneous arithmetic strategy with calculus by step (procedural aspect)	V3, L5, EA3, J2, T4

**Table 3: *A priori* analysis for arithmetic strategies**

<sup>2</sup> Contrary to usual practices in assessment, we do not attribute a code by technique for each task. This would lead to a multiplicity of codes on various tasks and would be unusable for a cross analysis on all the tasks of the test.

Solutions	Reasoning and technological discourse	Coding
$(x + 6) \times 3 - 3 \times x$ $= 3x + 18 - 3x$ $= 18$	Correct algebraic strategy with global expression that uses parenthesis	V1, L1, EA1, J1, T1
$(x+6) \times 3 = 3x + 18;$ $(3x + 18) - 3x = 18;$	Correct algebraic strategy with calculus by step (procedural aspect)	V2, L1, EA1, J1, T2
$x + 6 \times 3 - 3 x$ $= x + 18 - 3 x$ $= - 2x + 18$	Erroneous algebraic strategy with global expression that uses no parenthesis	V3, L3, EA32, J3, T3
$(x + 6) \times 3 = 3x + 18 = 21x ;$ $21x - 3x = 18x;$	Erroneous algebraic strategy with calculus by step (procedural aspect)	V3, L3, EA42, J3, T4

**Table 4: *A priori* analysis for algebraic strategies**

#### *Student's profile, groups and differentiated strategies*

The *Pépité* diagnostic assessment proposes both individual and collective assessment. The individual assessment, at the global assessment level (on a set of tasks), builds the student's profile which aims to identify features of algebraic knowledge and skills for the seven dimensions. The collective assessment locates a student on a scale with four components: skill in Algebraic Calculus (CA), skill in Numerical Calculations (coded CN), Use of Algebra for solving tasks (UA) and flexibility in Translating a semiotic register to another (TA). For each of those four components, different technological levels and appropriate benchmarks have been identified (Grugeon-Allys & al., 2012). Regarding to a class, students are divided into three groups according to their skill in Algebraic Calculus: CA1 (group A) - reasoned and controlled calculation preserving the equivalence of expressions -, CA2 (group B) - calculation based on syntactic rules often in blind, not always preserving the equivalence of expressions - and CA3 (group C) - meaningless and non-operative calculation. Therefore, for a given learning objective, it is possible to assign tasks to each group, depending to didactical variables related to the associated technological levels (Delozanne & al., 2010, Pilet & al., 2013).

#### **The computer model**

An iterative process between educational researchers, computer scientists and teachers was used to design and test different *Pépité* prototypes in order to improve the didactical model. We defined the conceptual IT model of classes of tasks, which allows the characterizing of equivalent tasks (Delozanne & al, 2008). The software *PépiGen* (Delozanne & al., 2008) automatically generates the tasks and their analyses, at different grade levels. It uses *Pépinère*, a computer algebra system, to generate anticipated student correct or incorrect answers (according to the *a priori* analysis). *Pépité* automatically calculates a student's profile as well as profiles for groups of students. According to a learning objective defined by the teacher, *Pépité* generates tasks adapted to the related technological levels (Grugeon-Allys & al., 2012).

#### **Results and discussion**

The information provided by *Pépité* diagnostic assessment allows the teacher to identify students with close profiles in algebra. Then, *Pépité* automatically generates differentiated routes corresponding to these algebraic profiles. As mentioned above, these routes were designed on the basis of a reference epistemological praxeology.

### Differentiated routes for learning equations

Three differentiated routes were created concerning equations. The first route “Motivating the production of an equation and solving it with an equation solver” motivates the production of an equation. It includes tasks like “*equalizing two calculation programs*” (see the example below). Students have to solve them using an equation solver. The second route “Algebraic resolution of an equation” requires technologies for solving equations by algebraic methods (by using the concept of equivalence of equations). In the last route “Algebraic resolution of problems that lead to an equation”, tasks that require a problem to be expressed as an equation and then solved, such as, “*equalizing two perimeters of dynamic figures*”, are proposed.

We give now two examples of tasks for the first route. The first one aims to introduce equations and to highlight the inadequacy of arithmetic techniques to solve problems of first degree. As we can see, thanks to a thoughtful choice of the didactic variables, this task prevents arithmetic strategies – because of the presence of the unknown in both calculation programs – or “trial and errors” methods – because the solution of this problem which is  $\frac{7}{3}$  cannot be easily obtained by successive trials. Algebraic techniques are necessary.

For groups A, B and C		
Program A	Program B	Alex and Brenda choose the same start number. Alex tests the calculation program A and Brenda tests the program B. Then, Alex and Brenda find the same final result. Which start number did they choose?
Choose a start number Multiply it by 3 Add 5 to the result	Choose a start number Multiply it by 6 Subtract 2 to the result	

**Table 5: Task for motivating the production of and equation and solving it with an equation solver**

The second task is differentiated (Table 6) to take into account students' algebraic activity and makes the students work on semiotic conversions (from the representation register of algebraic writing to the representation register of calculation program). Differentiation relies on didactical variables: the left member of the equation for group A is a product and solving the equation needs to use the distributive property, while the equation for groups B and C do not require it to be solved. Moreover, the multiplication sign is used for groups B and C to suggest that one or more multiplications are expected in the expression.

For group A	For groups B and C
Write a problem with two calculation programs that correspond to the equation $2(x + 7) = 5 - 3x$ .	Write a problem with two calculation programs that correspond to the equation $2 \times x + 7 = 5 - 3 \times x$ .

**Table 6: Task for working on semiotic conversions solver**

### Experimentation in a grade 8<sup>th</sup> class

We now present the results of research carried out in 2016 with a mathematics teacher we will call M2. M2 has been working in a REP establishment (high-priority education network) for three years. We chose him because he is not an expert. After an observation phase (6 hours) of his teaching practices, we proposed a whole teaching sequence to him on equations that takes into account the main epistemological aspects of the reference epistemological praxeology. M2 was free to adapt this sequence to his practices; however, both teacher and researcher have worked together to plan the implementation in the class.

M2 is required to introduce equations in his grade 8<sup>th</sup> class. First, his 20 students (14 years old) completed the *Pépîte* test. Then, they were been divided into three groups A, B and C. Only one student belonged to group A (reasoned and controlled calculation preserving the equivalence of expressions). The others students belonged to groups B (15 students who can calculate correctly expressions but without using semantic rules) and C (4 students who do not understand the calculus on algebraic expressions). M2 proposed to his students the three routes mentioned above, in the same order. Due to the fact that most of his students were in group B (15/20), M2 chose to give the same tasks to the whole class. After working on the three routes, the 20 students completed a written test on equations. We chose to focus on two tasks from this test to present our results. The first task was about solving three first-degree algebraic equations. Depending on the equation they solved, 7 to 11 students among the 20 students found the correct solutions. We particularly studied how many students used an algebraic technique. We observed that 17 out of 20 students solved the equations using the equivalence of equations. Even if they did not find the right solution, they had a strategy and transformed the equations in order to “eliminate” the unknown; they respected the concept of equivalence to do so. For the second task, equalizing two calculation programs (as presented above in table 5), 11 out of 20 students succeed for putting the problem into an equation.

## Discussion

The *Pépîte* assessment tool, based on an epistemological reference of the algebraic domain, allows the teacher to identify students’ consistent reasoning and calculation in order to plan differentiated courses adapted to grade 8<sup>th</sup> students’ learning needs for the domain of equations. The mathematics routes tested in our experimentation seemed to have effects on the students’ technological level: most of them used algebraic techniques to put a problem into equation. But this experimentation only concerns one teacher. So, in the ERASMUS + project “Advise me” which has just started in September 2016, we aim to carry out a larger scale research study.

We intend to validate these results for the field of arithmetic of integers for grade 3-4 pupils. Grapin (2015) carried out a multidimensional model of assessment for this new domain in elementary school. She defined an epistemological reference of arithmetic of integers to design an assessment tool in order to define pupils’ profiles and to highlight the epistemological aspects of arithmetic to work according to pupils’ learning needs. She organized an experimentation to study the evolution of pupils’ profiles according to differentiated routes adapted to students’ learning needs for the domain of arithmetic of integers. Data analysis is underway.

*The main aim of this paper is to analyze the experience of a MOOC for mathematics teacher training implemented in Italy, in parallel with a similar experience in France<sup>1</sup>. The study focuses on teacher collaboration within such an online learning environment, in terms of co-working and co-learning. The Italian and the French teams outline a common starting point and set of concerns for the research (the two papers have a similar Introduction for this reason). Each team then reformulated the research questions and tried to answer them through specific theoretical lenses. The Italian team used a fresh theoretical framework called MOOC-MDT. We concentrate on practices implemented by teachers who attend the MOOC, in particular on their contributions to communication boards and the consequent conception and growth of their particular community. In the conclusions, we contrast our results with those of the French experience.*

*Keywords: MOOC, teachers' professional development, meta-didactical transposition, community, collaboration*

## Introduction

Internet communication tools provide the opportunity to develop new types of teaching methods that combine online courses, resources and discussions. MOOCs (Massive Open Online Courses) were born in 2008 at the initiative of prestigious American Universities (MIT, Harvard, Stanford, ...) that sought to enlarge the courses they offered to a wide audience. Since then, the MOOC phenomenon has been regularly growing and the worldwide number of MOOCs has doubled from 2014 to 2015 (Shah, 2015). Although there is a wide choice of many different topics, when looking specifically for a MOOC aimed at teacher training, the range is limited, especially in mathematics. Nevertheless, there is a growing interest in MOOCs involving mathematics teachers as participants, as shown by TSG44 work during the 13th ICME<sup>2</sup>. In particular, from our experiences, there is a need for designing and implementing a MOOC for teacher training in mathematics education with a focus on the development of communities of practice (Wenger, 1998) and the collaborative work among teachers as a basis for their professional development. Indeed, when people co-work (work together collaboratively) they can also co-learn (learn together collaboratively), as highlighted in the ICME

---

<sup>1</sup> See Panero et al. (2017). Since the Italian MOOC and the French MOOC were delivered at the same period of time, even if the contents were designed independently, our teams had the opportunity to exchange and to discuss about them.

<sup>2</sup> For more information, see [http://www.icme13.org/files/tsg/TSG\\_44.pdf](http://www.icme13.org/files/tsg/TSG_44.pdf)

survey of Robutti et al. (2016). The authors found that teachers can learn through discussion, conversation and reflection on their own teaching, on student learning and on the teaching of others. The methodology of the Italian MOOC Geometria aims to create collaborative contexts for teachers' work, where they can learn from these kinds of practices. Taking into account this necessity for teachers to be supported in exploiting affordances of technology affordances, the objectives of both the French and Italian MOOCs are shared, namely: accompanying teachers in the production of teaching resources, by examples of activities and reflection on their ongoing resource design; fostering a reasoned use of technology, encouraging teachers to choose appropriate digital tools for the classroom. Such aims are related to the interest in the design and the implementation of teacher professional development programmes to include the role of teachers working and learning in communities (Wenger, 1998; Jaworski & Goodchild, 2006). The originality of our research based on the data collected from two MOOCs (in Italy and in France), that share similar aims and objectives, is twofold.

First, our new framework (MOOC-MDT: see below) facilitates the study of the specific dynamics of the interactions among trainees and between trainees and trainers, which occur online and in totally virtual environments. It is topical and urgent to analyze these interactions in the context of such distance learning due to the increased interest in this approach in recent years. Consequently, we reviewed and revised an existing framework that had been used to describe face-to-face meetings for teacher professional development, namely the Meta-Didactical Transposition (see below).

Second, our new framework analyzes such dynamics according to the cultural constraints that shape the MOOCs' design and development. The French and Italian school environments have some remarkable differences and one of the most palpable is a wider freedom that institutional curriculum regulations traditionally give to the Italian teachers, compared with the major institutional constraints met by the French teachers. The Italian *Indicazioni*<sup>3</sup> (guidelines) highlight for each discipline the fundamental learning goals that students have to achieve at the end of each cycle of instruction (two or three scholastic grades). These guidelines have the character of general didactic guidelines and defer to teachers the responsibility of choosing and linking the specific mathematical contents to be developed in the classroom in order to reach the established learning goals. The French *Programmes*<sup>4</sup> (syllabi) are also based on competences for a given cycle of instruction, but they appear to be more detailed and normative: for each mathematical content, they provide some examples of activities. Moreover, they are accompanied by several additional resources intended to support for the curriculum implementation in the classroom.

In this paper, and in parallel with the French one, we draw on the common theoretical element of the MDT to highlight how the concepts of community and of collaborative work evolve to new and different forms, and the impacts on teachers' professional learning. As members of the Italian team we worked alongside members of the French team to compare the data from the two MOOCs, so in the conclusion we will discuss the relevance of cultural and institutional aspects in the specific dynamics of the two experiences.

## The description of MOOC Geometria

The “MOOC Geometria” is the result of a long development process over many years by the researchers of the Mathematics Department of Turin University, and characterized by many previous experiences of teacher education projects in which the team has been involved (e.g. the M@t.abel project <https://goo.gl/Q30Dn0>) alongside years of research into teacher education. The MOOC was delivered on a Moodle platform (<http://difima.i-learn.unito.it/>) between October 2015 to January 2016 (6 modules in 8 weeks), and the 424 participants, all teachers in secondary school, were from all over Italy. 36% of the teachers completed all of the MOOC activities, which compares with reported average completion rate of about 5% (Bayne & Ross, 2013).

The MOOC team comprised 13 people (university researchers and expert in-service teachers). The MOOC had two main teacher education aims: professional training and raising awareness of the possibilities for technology use in schools. Every week the trainees worked individually to become familiar with different approaches. These activities included: watching a video where an expert introduced the conceptual knot of the week; watching a “cartoon video” with some guidelines to carry out the units; reading the geometry activities based on a mathematics laboratory (and the option to experiment with these in their classroom). Trainees were invited to share thoughts and comments about the activities and their contextualization within their personal experience, using specific communication message boards (forum, padlet, and tricider: see Table 1 for an outline description of each). The team of trainer chose to limit their own interventions in these message boards to a minimum in order to support the birth of a trainees-only community. The trainers were more active within the webinars: educational online event for trainees.

TOOL	AFFORDANCES	REASON OF THE CHOICE	IN WHICH MODULE WAS IT THERE?
Forum (web 1.0 tool)	For public discussion, where everyone can read and answer to messages, using nested replies.	To give teachers a friendly and known tool for discussion.	1, 2, 3
Padlet ( <a href="https://it.padlet.com/">https://it.padlet.com/</a> ) (web 2.0 tool)	Board of collaboration/sharing material (images, videos, documents, text) on common tasks.	To give a communication mode different from the forum, for supporting teachers in participatory methods.	1, 2, 3, 4, 5, 6
Tricider ( <a href="https://www.tricider.com/">https://www.tricider.com/</a> ) (web 2.0 tool)	For easy brainstorming and voting. For decision making, crowdsourcing and idea generation.	To facilitate decision making after any discussion by the request of a vote.	2, 3

**Table 1: Collaborative a-synchronous tools for interaction**

## Theoretical framework

As previously mentioned, we developed the MOOC-MDT framework to suitably describe and analyze the MOOC’s dynamics (presented by Taranto in TSG 44 of ICME 13). It integrates three

theoretical frameworks in a new form: the Meta-Didactical Transposition<sup>5</sup> (MDT: Arzarello et al., 2014), Connectivism (Siemens, 2004; Downes, 2012), and the Instrumental Approach (Verillon & Rabardel, 1995). In what follows we give a synthetic idea of this framework.

First, a MOOC can be considered as an *artifact*, that is a static set of materials. Connectivism allows us to picture the *MOOC-artifact* with its own network-based knowledge: its nodes are the content, the ideas, the images and videos used; the connections are the links between their node pairs. When a MOOC module is activated, it dynamically generates a complex structure (Siemens, *ibid*; Downes, *ibid*) that we call *ecosystem*: “all the relations (exchange of materials, experiences and personal ideas/points of view) put in place by participants of an online community thanks to the technological tools through which they interact with each other, establishing connections within the given context”. The network-knowledge of the *MOOC-ecosystem* is dynamic: it evolves as the MOOC-artifact’s network, thanks to the participants’ contribution. Also, the network-knowledge of individuals evolves as a personal self-organization (Siemens, *ibid*, p. 4) of the ecosystem. The process of transformation from artifact to instrument (Verillon & Rabardel, *ibid*) is here replaced by the evolution artifact-ecosystem-instrument.

In a MOOC there are two communities, a community of inquiry (the researchers and designers of MOOC) and one of practice (in the sense of Wenger, 1998), that is teachers as trainees in the MOOC<sup>6</sup>. The trainers evolve from their meta-didactical praxeologies (*m-dp*), to new ones, to deal with the MOOC’s training in Geometry. These new *m-dp* are based on a double awareness. One is that learning within the MOOC is connectivist: each trainee is part of a community, with the opportunity to share her/his own views, self-organizing information, with which (s)he comes into contact, for creating new connections, and questioning the existing ones. The second is that what is shown in the MOOC should encourage experimentation. The trainers’ *m-dp* constitute the network of the MOOC-artifact. During the implementation of the MOOC-artifact’s network-knowledge, in fact, trainers foster its nature of ecosystem, sharing tools and posing appropriate key questions. Moreover, the tasks designed by trainers suggest to trainees, in a more or less explicit way, to use the proposed material in their classes. In such a way, the MOOC is enriched with reports about trainees’ teaching experiences: this process increases a virtuous circle that encourages other trainees to experience the same materials. For this, the trainers’ *m-dp* evolve themselves, because trainers analyze, observe and monitor the MOOC activities as an ecosystem, to understand what did work or not.

The community of trainees is not a unitary subject of learning: the MOOC-ecosystem is an *instrument* that belongs to each single trainee. The trainees have to solve multi-tasks, through multi-techniques, properly justified. In fact, they must look at the proposed material, share their thoughts through sharing tools, and experience their activities. These tasks are not predetermined, depending on the

---

<sup>5</sup> MDT is a model that describes the process of teachers’ professional development with the aim of grasping its complexity. It is a tool to analyse the dynamic aspects of this process, namely the evolution of teachers and researchers’ activity over time. This activity is described through teachers’ and researchers’ meta-didactical praxeologies (Arzarello et al., 2014, pp. 353-355), which consist on the task in which they are engaged in the educational programme, with the techniques used to solve it, along with its theoretical justification.

<sup>6</sup> In the following we use *trainers* to indicate both researchers and designers and *trainees* for participants of the MOOC.

time, approach and depth with which trainees address them. The multi-techniques are the ways in which the trainees extend and modify their network-knowledge, drawing on that of the ecosystem, and influencing it in turn (thus affecting all other trainees). The *m-dp* of each trainee trigger a “**double learning process**”: firstly the MOOC-ecosystem is a specific learning tool for the individual, and secondly the use of MOOC-instrument by the individual generates learning for the whole ecosystem. The dynamic process has the following components, intertwined and self-feeding each other:

- i. **Instrumentation/Self-organization** (from the ecosystem to the individual): process by which the network of MOOC-ecosystem expands the individual’s network-knowledge. In particular, the **instrumentation** (Verillon & Rabardel, *ibid*) is the process by which the chaos (Siemens, *ibid*) of the ecosystem network reaches the individual. The many novelties of views and experiences make sure that the individual compares himself with new usage schemes. A phase of **self-organization** (Siemens, *ibid*) of the MOOC’s information follows this process: when the individual selects which usage schemes proposed by the MOOC are valuable and which are not.
- ii. **Instrumentalization/Sharing** (from the individual to the ecosystem): process by which the individual’s network-knowledge expands the network of MOOC-ecosystem. The **instrumentalization** (Verillon & Rabardel, *ibid*) is the process by which the individual, with her/his renewed network-knowledge independently builds new connections. The individual is stimulated by a task requested by MOOC and (s)he caters to the ecosystem to turn it according to her own (new) usage schemes. (S)He wants to integrate it with her/his own cognitive structures. **Sharing** is the process by which the MOOC welcomes the contribution of the individual and makes it available to all: information goes towards all members.

Within this complex, iterative learning process lies the inherent difference between the frame of the MDT and the MOOC-MDT. In fact, in the MDT, the trainers shape their proposal according to the practices they think appropriate, and so they can realize how much the trainees learn such proposal. On the contrary, inside the MOOC-MDT the process appears to be more difficult to control. The trainers do not know “what” the user has really looked at among the presented materials, nor they can know how (s)he interpreted them. At the same time, the trainees benefit from material provided not only by trainers, but also by other trainees that share some of their own materials and ideas using the communication boards. The process evolves stochastically: a determining role is played by the individual trainees, and by their feeling as a community with whom to collaborate, to inspire and to share results. Basing on such a theoretical framework, it is now possible to suitably formulate a specific research question as follows: *How effective and in which form is the collaboration between involved teachers (trainers and trainees), and how does it develop because of the support of tools designed by the trainers?*

## Data analysis

The accesses of the trainees in the MOOC (distinct from watching videos, reading materials and interventions in communication boards) have been in the order of tens of thousands. Accessing the MOOC, each trainee enters into an ecosystem, living in it through the use of free collaboratively asynchronous tools (as shown in Table 1), through which (s)he interacts with a community. Each of these interactive tools has been carefully monitored by the trainers’ team during the weeks of the MOOC delivery. The trainers’ team met regularly and, at the end of each module, they shared what

they had observed during that specific module. In particular, the most significant trainees' interventions or sharing actions were discussed. After the first few weeks we realized that we were dealing with a unique community of trainees, which we will expand on in the last section. We explain below how the trainees have used these interactive tools, showing some examples (in italics).

The forum played a predominant role with respect to the other tools. Despite being an almost out-dated mode (based on web 1.0), the trainees were very fond of it and used it to share their experiences of learning or of working. There was no moderator in the discussions: each trainee had the opportunity to read a diversity of opinions and experiences, and when (s)he understood how it worked, then (s)he introduced her/himself, became an author of posts, influenced other colleagues, or appreciated the idea expounded by a colleague. For example, in the second module of the MOOC, the geometrical topic was the widespread (at least in Italy) misconception that students have between angle and arc. Several activities have suggested to teachers to tackling this problem and a forum was inserted in this module. It collected 31 discussions, each of them with from 1 to 21 response replicas. In the following, just an extract: *"The proposed activities have made me think about (a) how the conceptual articulation "Angle vs. arc" is delicate. When the guys study trigonometry at high secondary school (b), they know the Radian that [...]allows you to no longer distinguish between (width of) angle and (length of) arc. I would like to know your thoughts (c), especially those who teach at lower secondary school"*. In (a) there is an evident phase of Instrumentalization: the trainee is creating new connections between his network-knowledge and that of the ecosystem. He was stimulated by the activities that he saw in this module and he is connecting this thinking to his classroom (b). In particular, he invites another person to share their thoughts about this topic (c).

If the forum was the right place for the trainers to talk about themselves, including their strengths and weaknesses, the Padlet was the place where the trainees began to share photos, videos and, spontaneously, their own materials. It is clear that the Padlet did not help to structure the exchange, but many trainees obtained inspiration from the exchange of materials in this place. For example, it was re-used and proposed by a participant as a tool to track her training programme with the construction of a Learning Diary: *"I am reviewing all of the course materials ... Because of my age, I can hardly remember the various proposals, ideas offered in this course surely professionally enriching and among the best I've attended to! So I thought to produce a Learning Diary with Padlet. Step by step it will enrich it, even with external links, with the materials I have looked for during this course or suggested by colleagues in the forums. Can it be useful to anyone?"*.

The Tricider had the goal of triggering simple threads, most of all confined to the approval or not of ideas, by voting through "likes". However, the participants used it more for collecting ideas and comparing their didactical experiences – as a forum – rather than for the expected use. Practically, the trainees realized a *catachresis* (Verillon & Rabardel, 1995): an artifact is used to do something it was not conceived for. Due to the fact that they explored the tool for the first time, and also because they usually need to explain and to go in depth when they express an idea, so the simple vote would not have let them satisfied. The posts written in Tricider are rich of ideas for both trainees and trainers. The trainees were introduced to a new tool for them. The trainers acquired awareness about the necessity to be clear in writing the tasks, in exemplifying the use of the tools and in providing tutorials on their affordances.

Beyond some trainers' interventions in the forums, or email communications with administrative aims, the actual contact between trainees and trainers was realized through three online webinars (using the chamber BigBlueButton of Moodle): they supported the community with synchronous interaction. While the trainers in the webinar could use video and chat, the trainees could use only the text chat. The trainers (in this case, only the academic professors) presented themes linked to the didactics of geometry and from mathematics education research. In all the three webinars there was a high participation (from 90 participants in the first one to 50 in the last one) of trainees, who posed questions and doubts.

## Discussion

The complex ecosystem structure developed as soon as the trainees had begun to access the MOOC. They are asked to enter into what, at first glance, may look like *chaos*, because of the multitude of materials and available technological resources. In fact, initially the trainees may not have enough self-confidence with the situation (*instrumentation*). Gradually they implemented the *self-organization* phase: appropriating the use of the MOOC's usage schemes, they began to use resources and materials (*instrumentalization*) and also to contribute comments to the communication boards (*sharing*). A community, in the sense of Wenger (1998), began to take shape. It is a community comprising individuals who are both looking for answers and helping others, by sharing their practices - a community that seeks to grow collaboratively. The will to establish the threads often leaks out, though it is very difficult that they take shape in a broad and articulated manner. In fact, the threads tend to split into different groups, which are formed and split locally and for a certain period of time, depending on the needs felt by the individual, but generally they contribute to give to all trainees the sense of a common participation in one unitary event, precisely the MOOC. Using a term from neuroscience, we call this property *plasticity*, which makes it possible to adapt to various situations in different groups and times. It is true that situations and times change, but within a community that preserves its global unity. This unity consists in the collaborative sharing of what happens, even if the active participation converges on more than one local theme. The sharing processes (of materials, thoughts, ideas, experiences) in fact gives life to the ecosystem, enhancing the materials and expanding the individual's network-knowledge. Even the "contact points" with trainers via webinars contribute to this purpose. Through sharing processes the ecosystem becomes more and more structured; fragments from the history of web communication (from web 1.0 on) coexist and complement each other, and are used by the trainees. This aspect is interesting and little pointed out in the literature. It is something similar to the multimodal interactions that take place in the classroom thanks to the activation of different registers: we call it *technological multimodality*.

*Plasticity* and *technological multimodality* are the two main properties distinguishing the evolution of a community in a MOOC from that in a traditional training course. It is primarily for this reason that we needed to change the framework of the MDT elaborating the lens of MOOC-MDT: it allowed us to give a first answer to our research question.

## Comparison with the French experience and conclusion

The Italian team worked to observe a general community, studying the MOOC phenomenon at a macro level and they did not intervene in the interactions between trainees. By contrast, the French team (Panero et al., 2017) observed local communities of practice. They studied the phenomenon at

a micro level, intervening in the groups' discussions to support and encourage the development of the collaborative work. During MOOC Geometria local groups are generated "emerging from chaos" (Siemens, 2004), namely they are subject to a spontaneous generation. During MOOC eFAN Maths (the French MOOC) trainers induce the generation of local groups and regulate peer relationships. Despite the fact that the cultural aspects affect these differences for sure (as we underline in our similar introduction), for both MOOCs there is an affinity that relies on the fact that trainees' learning is often generated by self-feeding discussions and instrumentalization processes.

# Coaching and engaging. Developing teaching with CAS in High School

Henrik P. Bang<sup>1</sup>, Niels Grønbaek<sup>2</sup> and Claus R. Larsen<sup>3</sup>

<sup>1</sup>Christianshavns Gymnasium, Denmark; [hb@cg-gym.dk](mailto:hb@cg-gym.dk), <sup>2</sup>Dept. of Mathematical Sciences, University of Copenhagen, Denmark; [gronbaek@mathematics.ku.dk](mailto:gronbaek@mathematics.ku.dk), <sup>3</sup>Christianshavns Gymnasium, Denmark; [cl@cg-gym.dk](mailto:cl@cg-gym.dk)

*Keywords:* CAS, mathematics teaching, coaching

The extensive use of CAS at upper secondary school in Denmark provides a laboratory for research on the development of standards for CAS teaching. The poster focus on action research into teachers' development of lessons and student activities in an ongoing collaboration between university and high schools on use of CAS in mathematics teaching. Coaches mediate design processes, reflection and documentation, and enable sharing. We discuss coaching as a valuable part of action research, and how to draw findings from such collaboration.

## Danish CAS context

Starting with handheld devices in the 90's, the use of CAS in upper secondary mathematics education has accelerated. The reform in 2005-07 of Danish high schools opened the door to extensive use of computers, resulting in a move to PC based programs like Maple or TI-Nspire, used in the classroom as well as for homework. Powerful CAS tools such as Maple drastically change the teaching environment, but have only led to minimum adjustments in the final examinations since the earlier CAS-days. Early adopting teachers *do* give access to their own material, but there is no systematic sharing of experiences or standards for use of CAS within Danish mathematics education.

## CMU's<sup>1</sup> Agenda

Many teachers experience instances where CAS provides new insight or furnishes new possibilities to handle examples that are more interesting or more realistic. CAS can also provide possibilities for extensive drill and practice of taught methods. However, and especially when use is allowed in the final exams, CAS can turn mathematics into merely an instrumental enterprise and thus trivialize mathematics education. Moreover, this trivialization is hard to see, outside looking in. From a policy maker's, school leaders, parents or even students point of view, you hardly know what is missing. Understanding that CAS *can* work in ways where skilled students learn less because tasks are too easy, while at the same time the less able students are performing poorer, because they try to rely on a tool they do not know how to use, demands insight. Addressing these issues, lead to establishing CMU.

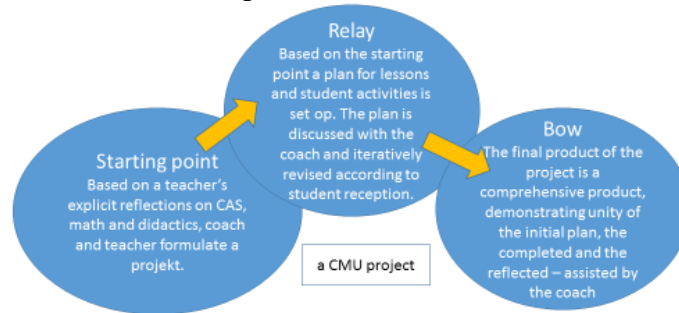

## Principles for coached teacher training

CMU collaborates with teachers interested in developing and sharing their experience with the use of CAS as an instrument for learning. We used a bottom-up approach, drawing upon models for action research (Asiale et al., 1996, Borba & Skovsmose, 2004), to designed a project management model (Figure 1). In Denmark, teachers have wide latitude to organize their teaching, but a limited tradition

---

<sup>1</sup> CMU, Center for Computer Based Mathematics Education, Department of Mathematical Sciences, University of Copenhagen, Denmark, founded in 2013.

for addressing teaching and learning in didactical terms. Through individual or group coaching<sup>2</sup> we support teachers to develop their own ideas about mathematics with CAS. The coaches play an important role to promote teachers' reflections before, during and after teaching - our goal being twofold; to draw on teachers' experience and to promote teachers' professionalism (Dale 2003). We have designed a project report template to capture teachers' reflections alongside the teaching material, and made the projects available on our website (<http://cmu.math.ku.dk/projekter/>). The coaches also assist in this documentation process.

**Figure 1: Systems model for a CMU project**

Participants present their projects, goals and standards on an annual basis. It is essential to develop a common language and understanding of how mathematical content, and student activity changes in a CAS environment. From the discussions at our seminars, we can point to themes such as:

- which non-CAS activities should be introduced when working with CAS?
- what is the value of students mastering (details of) the CAS program or put in another way – how well should students know the CAS program in order to make real investigations?
- How can you work in ways that students both acquire useful skills and concept knowledge?

CMU has a double agenda of promoting sound use of CAS and of in service teacher training, so we pose our own research questions: 1. How to draw *general* conclusions about CAS standards based on individual projects? 2. Which teacher competences - CAS, didactical and mathematical - should coaching promote?

# **A study of the development of mathematics student teachers' knowledge on the implementation of CAS in the teaching of mathematics -a praxeological analysis.**

Louise Meier Carlsen

Department of Education, University of the Faroe Islands, The Faroe Islands,  
Department of Science Education, University of Copenhagen, Denmark; [LouiseC@setur.fo](mailto:LouiseC@setur.fo)

*Keywords: CAS, student teacher knowledge, praxeology, lesson study.*

## **Introduction**

The implementation of CAS in the teaching of mathematics introduces new challenges that concern: content, technology and didactics. There is a change in the mathematical focus from pragmatic to more epistemic, since the routine work is taken over by digital tools (Artigue, 2002). Furthermore the didactic changes, not only by the change in the mathematical knowledge, but also due to the need for the teacher to orchestrate a new component in the classroom (Drijvers, Doorman, Boon, Reed, & Gravemeijer, 2010). In the course “Numbers, Arithmetic and Algebra” for mathematic student teachers for lower secondary school on the Faroe Islands we implement the format of lesson study as a tool for the student teachers to develop their knowledge on teaching with CAS. This is a preliminary study of the transcripts from a reflection meeting, which will later form the basis for a more detailed study as part of my work towards the PhD.

## **Theoretical framework and research question**

The anthropological theory of the didactic (ATD) suggests considering human activity as an amalgam of praxis and knowledge: praxeology. The praxis, also named the praxis block of the praxeology, consists of the constituting task and the corresponding technique. A technique can consist of several actions. The task and technique are in one-to-one correspondence. The knowledge, also called the logos block, is the discourse of the techniques and the theory that explains and verify the discourse. For more details see (Bosch & Gascón, 2014). This study considers the didactical praxeology and the mathematical praxeology of mathematics student teachers when implementing CAS in research lessons. Within ATD the task of solving an equation with CAS is categorized as mathematical praxeology, while the task how to teach the students to solve an equation using CAS is categorized as a didactic praxeology. The research question is “What didactical logos developed during the reflective meeting of a lesson study cycle?”

## **Context and study**

The study is situated within a course focused on numbers, arithmetic and algebra. As part of the course, groups of three to four students participate in four lesson studies where CAS has to be implemented in the teaching of algebra in grade 7 and 8 (14 - 15 year). Each lesson study cycle consists of a planning phase resulting in a lesson plan, a research lesson, a reflection meeting and a new lesson plan. In the lesson plans, the student teachers will not only describe the intended lesson but also have to justify the instrumental orchestration, part of the didactical technique, in relation to the mathematical praxeology of the lesson. Reflection meetings in lesson studies are a rich environment for the development of knowledge for teaching (Miyakawa & Winsløw, 2013;

Rasmussen, 2015). As part of the protocol for these meetings, the student teachers reflect on the relationships between the instrumental orchestrations used during the research lesson, the development of the mathematical praxeology of the students and the mathematical praxeology of the teacher.

## Conclusion

As an example, the mathematical praxeology of making two integer sliders in GeoGebra and the related didactical praxeology of how to teach students to make two integer sliders in GeoGebra is considered. As a didactical technique, the student teachers chose to hand out a booklet with step-by-step instructions in order to guide the students through the lengthy technique. Focusing on the didactical logos related to the technique of handing out a booklet during the reflection meeting the teacher students concluded that if the student did not get the exact same picture as in the booklet such as slider  $b$  above slider  $a$  instead of slider  $a$  above slider  $b$ , they would consider it an error and not usable. Additionally, the students were discouraged by having to read text in addition to carrying out the GeoGebra technique. It was agreed upon by the student teachers that a booklet is still a good didactical technique but has to be complemented or preceded by a board-demonstration for the students.

# A study investigating how mathematics teachers view and use tablets as a teaching tool

Kinga Petrovai

University of Oxford, Faculty of Education, United Kingdom; [kinga.petrovai@education.ox.ac.uk](mailto:kinga.petrovai@education.ox.ac.uk)

*Mobile digital technologies, such as tablets, hold great potential for teaching and learning, but they are being introduced into schools with little evidence to guide how they are implemented. With little impact on learning outcomes there is increasing attention on the need for greater focus on the role teachers play in the use of digital technology in the classroom. This study investigates the way teachers at an English school, which has one tablet per student, view and use tablets in teaching mathematics. The results of my study form a framework on how tablets are used in teaching.*

**Keywords:** Teaching, mobile technology, mathematics.

## Introduction

“Despite considerable investments in computers, Internet connections and software for education use, there is little solid evidence that greater computer use among students leads to better scores in mathematics and reading” (OECD, 2015, pp. 145). Mobile technologies are increasingly being introduced in schools with little evidence to guide how they are implemented (Kiger et al., 2012). With the technology available today, some argue that there is a need for renewal of pedagogy (Jouneau-Sion & Sanchez, 2013), and greater understanding of the teachers’ perspectives and practice regarding the integration of technologies in schools (Ertmer, 2005). Using a paper poster, I outline how my study addresses this by investigating how a group of lower secondary school mathematics teachers in the south of England – who meet regularly as a group to reflect on and develop their practice – view, use, and develop their use of tablets in their teaching.

## Theoretical Lens

Within the second facet of Ruthven’s (2008) examination of the incorporation of new technology into educational practice - the process of integrating a tool at the level of a community - Laborde (2001) identifies four stages of increasing degrees of mathematical/pedagogical innovation. This is the base of my analysis.

## Methods

My study ran in two phases over the course of one year. Phase one established the context of the study. In phase two data was gathered by (1) group meetings in which teachers reflected on, and developed, their practice; (2) classroom observations; (3) post observation interviews with teachers.

## Findings

I developed a framework of how mathematics teachers use tablets in their teaching. I adapted Laborde’s (2001) framework of *instrumental evolution*, to which I developed new categories that are organized in the two distinct groups of *efficiency* and *engagement*. Efficiency includes tasks that help to organize the class structure to give more time to focus on the mathematics. An example includes the use of quick response (QR) codes, which speeds up the distribution of online material to students.

Engagement includes tasks that help to capture the attention of students so that they focus more intently on the mathematics. An example includes using virtual games to practice numeracy skills.

My study addresses the criticisms of education research that it does not investigate questions that are important to teachers, thus impacting on the lack of disruptive change in schools (Pring, 2002). Other studies have investigated the use of technology in mathematics education by (Ruthven et al. 2009; Galligan et al. 2010). However, the combination of a natural school setting, regular collaboration among teachers, observation of use over a longer period of time, focusing on the use of tablets, and focusing on multiple lessons per teacher, makes my study unique. This research can help guide future implementation of new technologies in schools and the associated teacher professional development.

### Acknowledgment

I would like to thank my supervisors Dr Gabriel Stylianides and Dr Niall Winters for their support.

# The role of automated reasoning of geometry statements in mathematics instruction

Francisco Botana<sup>1</sup>, Tomás Recio<sup>2</sup> and M. Pilar Vélez<sup>3</sup>

<sup>1</sup>Universidade de Vigo, Spain; [fbotana@uvigo.es](mailto:fbotana@uvigo.es). <sup>2</sup>Universidad de Cantabria, Spain; [tomas.recio@unican.es](mailto:tomas.recio@unican.es). <sup>3</sup>Universidad Antonio de Nebrija, Spain; [pvelez@nebrija.es](mailto:pvelez@nebrija.es)

*Keywords: Mathematics instruction, elementary geometry, automatic reasoning with GeoGebra.*

## The tools ...

By “automated proving of geometry statements” we refer to tools that mechanically output a mathematically rigorous (e.g. not based upon a probabilistic proof) yes/no answer to the conjectured truth of a given geometric statement. By “automated derivation of geometry statements” we refer to tools that, rigorously, output some/all geometric relations verified by a collection of selected elements within a geometric construction. Finally, by “automated discovery of geometry statements” we refer to tools that systematically find complementary, necessary, hypotheses for a conjectured geometric statement to become true.

The community of mathematicians and computer scientist has been working on these goals for the past 50 years, with a variety of approaches, outcomes and popularization results (cf. the pioneer work of Gelertner (1959) in the Artificial Intelligence context, or the algebraic geometry framework to automated reasoning in geometry disseminated by the book of Chou (1988)). On the other hand, although we can mention the development of some intelligent tutorial systems designed to assist students to construct proofs in Geometry such as GRAMY (Matsuda and Vanlehn, 2004) or GeoGebraTutor (Tessier-Baillargeon, Richard, Leduc and Gagnon, 2014), it is fair to say that, up to now, the dissemination, use and impact of these findings in the educational context is very limited. Thus, the very recent survey by Sinclair et al. (2016), on geometry in education, although it includes a full section on the role of technologies and another one on “Advances in the understanding of the teaching and learning of the proving process”, does not refer at all about automated reasoning tools.

## ...and the issues

Hence, we consider it quite relevant to address, in our poster, two issues: one, to announce the very recent implementation (2016) of tools for the automatic proving and discovery of geometric theorems over a free dynamic geometry software, with tens of millions of users worldwide, and a great impact in mathematics education. See Abánades, Botana, Kovács, Recio and Sôlyom-Gecse (2016) and Hohenwarter, Kovács and Recio (2016).

Then, recalling that the program where we have implemented our automatic reasoning tools (ART) is available over computers, tablets, smartphones, with and without internet connection, the second issue we would like to pose here is the consideration of the following questions: what could be the role, in mathematics instruction, of the ample availability of such tools? It was already 30 years ago (cf. the visionary ICMI Study “School Mathematics in the 1990's” (Howson and Wilson, 1986) or the inspiring paper by Davis (1995), with a section that refers to the “transfiguration” power of

computer-based proofs of geometry statements) when educators started reflecting about the potential role in education of software programs dealing with automatic theorem proving (automatic discovery and derivation were inexistent at that time). But these reflections were formulated rather as considerations about the future than as proposals for the present time of their authors...

Thus, in view of the current implementation of ART in well spread, dynamic geometry programs, our final goal is to make an open call to the community of math teachers and math education researchers, in order to join us preparing a research project to address the following questions: Are ART in geometry education good for anything? If yes, what are they good for? What should be the necessary changes and requirements in the educational context, if ART are to be considered good for anything?

# **A study of the Cornerstone Maths project teachers' classroom practices: Geometric similarity using the Cornerstone Maths software**

Ali Simsek<sup>1</sup> and Nicola Bretscher<sup>2</sup>

<sup>1</sup>UCL Institute of Education, London, UK; [british.simsek.15@ucl.ac.uk](mailto:british.simsek.15@ucl.ac.uk)

<sup>2</sup>UCL Institute of Education, London, UK; [n.bretscher@ucl.ac.uk](mailto:n.bretscher@ucl.ac.uk)

## **The rationale of the study**

More recently, a need for further studies examining the process of integrating digital technology into classroom practice in order to support the development of a better, more comprehensive understanding of classroom practice with digital technologies, and to refine evolving frameworks has been emphasised by a number of researchers (Artigue, 2010; Hoyles, Noss, & Kent, 2004). In this context, the present research is useful in various different areas. First, the study is concerned with the concept of geometric similarity in geometry teaching using Dynamic Geometry Software (DGS). This particular topic makes our study beneficial, specifically because geometric similarity has been overlooked in recent studies. Given the significance of geometric similarity to benefit students' spatial and geometric reasoning skills (Watson, Jones, & Pratt, 2013), the fact that this key area of mathematics has not received sufficient attention seems surprising. Secondly, this study uses and adapts a contemporary theoretical framework (the Structuring Features of Classroom Practice (SFCP) framework) (Ruthven, 2009) that aims to assist researchers in the identification and analysis of classroom practice using digital technology. Our study, therefore, helps identify how the SFCP framework supports and/or hinders the researcher in the process of such identification and analysis. Furthermore, an exploration of teachers' classroom practice using the new technological tool provides deeper insight into the issue of digital technology integration through the detailed analysis of two case studies.

## **Research design**

The purpose of this research is to develop a holistic understanding of how the Cornerstone Maths (CM) software is integrated by teachers into their classroom practice when teaching geometric similarity. This entailed conducting a qualitative research study in order to gain a detailed in-depth understanding of teachers' use of the CM tool in the classroom. We adopted the case study approach where data is collected through multiple sources of information; i.e. in this study, observation followed by semi-structured post-lesson teacher interview based on the observations made during the lessons. While the more experienced teacher's classroom practice was observed in two lessons, the less experienced teacher's classroom practice was observed in one lesson. With each teacher, one follow-up teacher interview took place.

In addition, a multiple-case study design was used, so that a better holistic understanding of teachers' technology integration into classroom practice could be accomplished by comparing the teachers' two cases. Between the teachers who participated in the CM project professional development programmes, the participants were chosen based on their different experiences of teaching using digital technology because this offers a productive comparison that will highlight the

variables in the teachers' integration of technology in the classroom (see Bozkurt & Ruthven, 2015). The data analysis was made according to the five factors in the SFCP framework, namely: working environment, resource system, activity structure, curriculum script, and time economy.

## Findings

Data analysis suggests several key findings related to five structuring features of classroom practice using digital technology. For instance, the varying levels of teachers' experience in using digital technology to teach have a considerable influence on the degree and type of their technology use during classroom activities. In addition, teachers think that pre-designed technological resources with good ideas support them to better exploit the didactic potential of digital technologies in classroom practice because they do not have enough time to prepare such resources. The evidence shows that teachers' preparation for integrating technology into classrooms leads them to not use their time productively enough on the mathematical content to be taught in the course of planning their lessons. Lastly, despite some technical difficulties appears during classroom practice, the use of digital technologies facilitates and accelerates students' learning of mathematical ideas.

## Acknowledgment

This study is based upon first author's master's thesis. We would like to give special thanks to Dr Alison Clark-Wilson, who allowed the first author to attend the Cornerstone Maths professional development programmes for teachers.

# Resource systems of English teachers as they appropriate mastery approaches

Michael Achile Unameh  
University of Leeds, UK; [edmau@leeds.ac.uk](mailto:edmau@leeds.ac.uk)

*Keywords: Mathematics teaching, resources, digital tools, appropriation.*

## Introduction

I report on the resource systems (Gueudet & Trouche, 2009) of a sample of mathematics teachers' in England. An influence on these teachers' appropriation of resources for learning and teaching is current mathematics education reform that is focused on how mathematics performance in England compares to the highest attaining systems internationally. The OECD's Program for International Student Assessment (PISA, 2012) ranked England in the 25<sup>th</sup> position in mathematics achievement, with the assessment table headed by a clutch of south-east Asian jurisdictions. PISA results also showed that England's performance in mathematics has stagnated over the years. There is a government-backed mandate to explore, adapt and embed the Singapore/Shanghai model of mastery teaching and assessment for learning approaches across England (Hodgen, et al., 2014; NCETM, 2014). "Mastery learning can be described as a set of group-based, individualized, teaching and learning strategies based on the premise that virtually all students can and will, in time, learn what the school has to teach" (Anderson, 1975 p.4). Although mastery learning has morphed into various adaptations, essential elements remain the feedback, corrective and enrichment (Drury, 2014). Extant research points to the potential of well-implemented mastery teaching as enabling higher levels of achievement, deep understanding and confidence (Drury, 2014).

This study combines an activity theoretic approach with the more recent 'documentational approach' (Gueudet and Trouche, 2009) from French didactics as theoretical tools for developing an understanding of the teachers' appropriation of digital resources and building up a coherent explanation for its impacts on classroom practices. In this investigation, I document the context for the current motivation for adopting mastery teaching and examines the emergence of the resource systems of seven English mathematics teachers' as they 'resource for mastery', and the potential impact of this on classroom practices. The major aims of this study are to:

- Analyze how teachers' appropriate digital resources for classroom practices.
- Explore teachers' resource systems for mastery teaching.
- Contribute to the discourse on teachers' appropriation of digital resources.

## Research design, methodology, data collection and analysis

A qualitative case study approach (Creswell, 2013) was adopted. Purposive sampling was used to select seven teachers from three schools based on the use of digital resources, access, proximity and the opportunity to observe rich and real life-context of teacher practice with digital resources. Data collection was undertaken during the 2015-2016 school year through periodic whole day school visits. Data were collected through: audio-recorded semi-structured interviews; classroom observations using an adapted *systematic classroom analysis notation* for mathematics lessons (SCAN, Beeby, Burkhardt & Fraser, 1979); screen capture software; and collation of documents.

Data analysis is ongoing at the time of writing and includes: coding and analyzing transcribed interviews using thematic analysis and taking into account key concepts from the literature and information emerging from the data alongside the SCAN analysis of classroom observations. Data is organized by teacher and by data type. The thematic mappings will be constantly grouped and regrouped into categories and themes for discussion.

## Emergent results and implications

Preliminary results from ongoing data analysis includes:

1. Teachers' appropriation of digital tools for formative assessment (student seat-work is e-analyzed during lessons which allows the teacher to enact changes in the tasks).
2. The reality of 'emergent (in lesson) task design' afforded by access to multiple resources.
3. The emergence of Twitter as a key platform for 'massive live staffrooms' (teachers are constantly collaborating, developing task, and sharing expertise and resources on mastery approach).
