In almost all situations, the groups address (direct) comparisons of sizes. When it comes to someone's own body length, competitive situations emerge quite often. For the children it is important to know "Who is taller than the other?" or "Who is the tallest?". This aspect of rivalry is especially obvious in Situation E, when Irvin and Torben compare different things with a beam balance. The kindergarten teacher has prepared different building blocks and plastic figures, which possess certain weight proportions. The main idea of Linda's arrangement seems to be producing balance with these special objects. Both children use one scale together and each child fills the balance pan on their side. In their first attempt, in Irvin's balance pan there is one green stone and two blue ones in Torben's balance pan. The scale is in balance. The kindergarten teacher asks the children to compare the stones:

Irvin	ahh / that that is small and I am big /
Linda	right \ this is a bit smaller / and this is a bit bigger \

Irvin's sentence structure is perfectly correct from a syntactic point of view and in principle as a statement as well, since Irvin really is big in contrast to the building block on the scale. However, he probably wants to express that the green stone on his side is "big" in contrast to the blue stone on Torben's side. In this sense, Linda paraphrases his statement. She indirectly corrects his verbal expression (Brandt & Keuch, in Press), by formulating the relational connection "smaller – bigger" on the one hand, and the personalization "I'm big" connected with the pointing gesture to the actual object of comparison. While Torben uses correct possessive pronouns with corresponding comparisons ("then mine are / heavier\"), Irvin consequently uses the personal pronoun and therefore figuratively makes himself the object of comparison. Finally, Torben picks it up. With the following utterance, Irvin and Torben alike refer to the fact that the content of 'their' balance pan is heavier. Nevertheless, through the context of actions, both children are able to understand each other:

Irvin	then I'm heavier \
Torben	now I'm stronger hihahaha \
Irvin	yooo I'm the strongest \
Torben	no / I'm stronger \
Irvin	there I'm heavier \

Using the words *strong* and the related forms of comparison *stronger* and *the strongest*, the children focus on the idea of competition. However, at least Torben would be able to express himself correctly in such situations. Irvin as well uses the correct possessive pronouns at the end of the situation to explain, why "his" balance pan with the smaller (and therefore lighter) piece of cardboard is up: "Because this is very big / and mine is very small \ " – interestingly this is a

situation in which he would not be the ‘strongest’. This competition, generated through language, gains momentum and prevents the original request to balance out the different objects through skillful placing.

### Scale values and their verbalization

In most situations, the kindergarten teachers measure the children’s body length and name and record them in different ways (some write them down, others document them with woollen strings, (Brandt & Keuch, in Press). When you capture body length with standardized measuring tools, you read the numbers on the measuring tools as a scale value. With measuring tools, the scale value indicates the corresponding measuring value based on a certain scale unit; for ordinary leveling boards or carpenter’s rules, that is centimeter.

When using measuring sticks and carpenter’s rules, the kindergartners on the one hand are confronted with measuring units (meter and centimeter), whose meaning they rarely comprehend and only hesitantly take over into their active vocabulary (Brandt & Keuch, in Press). On the other hand, they also have to deal with numbers that exceed their actively mastered range of numbers. The kindergarten teachers seem to be willing to make the numbers consciously perceivable as scale values with different circumscriptions and complements. In the following example, the focus on the meaning of the scale becomes obvious, when Doris refers to the animal symbols on the leveling board:

Doris	okay / look here \ one meter are you \ (.) hee \ one one meter one \ up to there \ [unintelligible] at the monkeys right \
Nikola	up to here \
Doris	exactly at the monkey \ and Uwe / (.) at what have you / [unintelligible] [at the sea lion\]

The kindergarten teacher therefore uses the animal symbols here as scale values; the connection with the local preposition “up to there” points to the distance from the floor to the symbol as a representation of the body length. The children take up the animal symbols on the leveling board for their comparisons of size:

Regina	the biggest ehm \
Uwe	is the duck

The generated verbal co-construction is a grammatically correct utterance: The duck is the biggest one in relation to a (not further specified here) selection of reference objects. This statement, however, is neither correct for the mentioned animal symbols (sea lion, monkey, duck) nor their real counterpart. Still, Uwe does not formulate a ‘wrong’ statement. A few minutes before, Nikola determined that the duck stands for the scale value 116 (Regina’s body length). Therefore, Uwe related with “the duck” to the corresponding scale value without using the corresponding local preposition. Regina is indeed the tallest child, as Doris confirms shortly after “Regina has [unintelligible] is the tallest”. The statement “The biggest is the duck” stands for the comparison of body length and gives an answer – at first with reference to the measured values – to the question: Who is the tallest? Concerning the linguistic means, Uwe treats the scale value ‘duck’ syntactically

like a representation of the measured length: “The biggest is 116 centimeter.” Interestingly, we also find comparable deviations in the language usage of our kindergarten teachers:

Sabine                      now I measure you \ that means the hand is now on this / (.) und you are one meter and ten centimeters \ look \ and you are exactly (.) as big as this red number is \

Here as well Sabine is eager to make the numbers comprehensible for the children. On the carpenter’s rule used in this situation, the scale values are marked in red every ten centimeters, while all other numbers are black. The red number thus references the measured body length. Similar to Uwe, Sabine syntactically uses the red number as a representation for the measured size value 110 centimeters.

## Conclusion

In this article, we looked at semantic deviations concerning verbal constructions with *to measure*, the use of personal pronouns in comparisons and the verbalization of scale values. Each of the analyzed sentences were syntactically correct, the semantic deviations, however, emerge from prepositions, pronouns; and additions and omissions of phrases. In everyday situations and action settings, these sentence constructions rarely lead to misunderstandings. In the analyzed situations too, the action flow is preserved. However, it remains unclear which conceptual understanding of measuring, comparing or scale values the children develop, which goes beyond the actual action context. The vague and imprecise use of *to measure* immediately concerns the meaning of measure as an activity, as well as the associated behavior patterns in relation to measuring devices. “Measuring” becomes the hypernym for the whole situation and is not delimited from other activities. By means of personalization, the comparison in the balance beam situation becomes a competition, and the semantic deviation becomes a play on words with its own dynamics. For linguistically less competent children, the pun might not be accessible and therefore they do not get a chance to improve their linguistic competences. The negotiation process related to the mathematical content stays at the surface, since it is overlapped by the play on words.

Ambiguity and change of meaning by using different prepositions as well as adding or omitting certain objects can lead to confusion in more in-depth negotiation processes. With regard to the development of less context-dependent language registers, one has to look critically at the observed reactions by the kindergarten teacher. Although all kindergarten teachers show pedagogical as well as didactic competences, in relation to our investigated difficulties and deviations we only observed minor language awareness. On the one hand, we just find a few reactions to semantic deviations in the children’s language productions. On the other hand, even our kindergarten teachers produce such deviations. Especially for learners of German as a second language, figurative language constitutes a specific problem. In this area, we still perceive a major challenge in order to establish educational equality via early education.

*The focus of the paper is the analysis of written argumentation in solving logical-linguistic riddles by 6<sup>th</sup> and 7<sup>th</sup> grade students. This is part of a larger path dealing with the introduction of some logical contents, in which all the activities are immersed in a narrative framework. In analyzing students' productions, we pay great attention to the interplay between logical-scientific thinking and narrative thinking, with the awareness that a rigorous mathematical argumentation can be obtained only at the end of a path starting from different, often not rigorous, forms of reasoning.*

*Keywords: Language, written argumentations, logical riddles, narrative and scientific thought.*

## Introduction

In this paper we focus on the analysis of written argumentations produced by 6<sup>th</sup> and 7<sup>th</sup> grade students to solve logical-linguistic riddles. This kind of activities is part of a path carried out within a project in a secondary school near Salerno (Italy), during the year 2014-15. The aim of the whole project was to reconcile students with low level of mathematical skills with the subject. In accordance with the teachers of the school, the focus was on linguistic competences in a scientific environment, with particular attention to the development of the argumentative competence.

The starting point was the didactic path described in Tortora (2001), consisting of 15 structured worksheets. Its aim was to bring the contents of classical propositional logic to the students, through a fantastic and attractive way. The innovation with respect to the initial idea, favoured by the introduction of the logical-linguistic riddles (Smullyan, 1978), is the great attention devoted by us to students' reasoning. To give importance to students' answers, we have let them naturally emerge from a learning set in which discussion had a central role. In analysing students' productions, we can observe how their spontaneous reasoning is a first step toward the development of their argumentation skills. We are aware that a rigorous mathematical argumentation can be obtained only at the end of a long path that starts from different forms of reasoning, often not scientifically rigorous. This does not mean that different forms of rationality should be dismissed in favour of the specific mathematical rationality. We know that for each of us all the forms of rationality coexist more or less in our life, but what is important is the possibility given to all students as early as possible to acquire the special kind of mathematical rationality.

This is the specific purpose of this work, where we analyse some of students' productions in solving the riddles and we trace the development of their reasoning. Therefore, our main research question is to what extent, and by means of what specific didactic mediations, the use of logical riddles with their linguistic challenges, can favour the development of argumentative competences and of scientific language and thought.

## Theoretical background

Language and in particular linguistic competencies are considered very relevant issues in mathematics learning. For example, Sfard (2000), to quote just a single seminal work, interprets thinking as a form of communication and considers languages not only as vehicles of pre-existing

meanings, but as builders of the meanings themselves. These competencies are the basis of many cross abilities, argumentation, communication, problem solving and so on, recommended as essential in all the official documents (for example, MIUR, 2012, Italian Ministry of Education).

In our works (e.g., Coppola, Mollo & Pacelli, 2010) we have often used logic in educational contexts, just because, in addition to being an important learning goal in itself, it has a special role in relation to language. In fact, logic appears as a privileged field for analysing the relation between language and interpretation, for identifying, studying and using linguistic manipulation rules and especially for the dual role of object and tool of investigation that language plays within logic (Ferrari & Gerla, 2015). The attention to the distinction between language and metalanguage is evident in our study, where the language is in the logical riddles and the metalanguage occurs in the discussions and the written argumentations used to solve them. However, no educational use of mathematical logic can be exhausted in its strictly disciplinary or formal aspects. These aspects may at most be considered a point of arrival, bearing in mind that in any case the way leading to the formalization is long and arduous. Along this road, the language takes on different forms and levels and the argumentations meet various needs. The importance of the contexts in which communication occurs and of the different forms of language has been widely recognized by the research that has put into the foreground the pragmatic aspects of language (Ferrari, 2004).

In general, the topics of pragmatic are deeply connected to the critical points of the research on learning and teaching mathematics (Ferrari, 2004). In our study, we use these tools to interpret some of the students' behaviors, elsewhere classified as 'irrational'. On the contrary, according to (Zan, 2007), we believe that the behaviors of the subjects 'getting wrong' may appear consistent when considered in relation to contexts and purposes other than those strictly adhering to rigorous logical reasoning. For this reason, we prefer to speak of two forms of rationality, rather than counter the rationality of mathematics with other behaviors that obey to different pulses. For example, according to one of the central issues of the pragmatic (Grice, 1975), in a particular context it is possible to make interpretive inferences based on the belief that who speaks or writes respects the Principle of Cooperation, according to which the communication is a collaborative process among those who are involved. These inferences, called conversational implicatures, differ by the logical implication, which relies only on the semantic content. Moreover, in making inferences in a certain context, it is frequent and legitimate to resort to one's own *encyclopedic knowledge*, that is the general knowledge of a person about the world (Zan, 2007).

The aspects of language brought to the fore by the studies on pragmatics are intertwined with the Bruner's distinction between two kinds of language or thought, the narrative and the scientific ones (Bruner, 1986). The scientific thought categorizes reality, recognizes the order of things, and produces demonstrative argumentations. It comes up in linguistic forms which are typically impersonal and timeless. Narrative thought, instead, interprets human facts: actions, intentions, desires, beliefs and feelings. It comes up in linguistic forms in which actions are performed by individuals and are accomplished in time. The acquisition of the first kind of thought and language, necessary for the understanding of science and mathematics in particular, is slow and it requires a careful didactic mediation, whereas the narrative way is more spontaneous and within everyone's means. For this reason, in many researches there are several suggestions for using narrative forms or even invented stories as a way to present mathematical contents (see, e.g. Zazkis & Liljedahl,

2009). Hence our decision to use a fantastic setting to introduce abstract concepts and present logical tasks. Our choice also depends on other reasons. It prepares the students themselves for using narrative modes. This establishes a working setting in which teachers and researchers can use and interpret students' answers in order to guide them through the gradual acquisition of forms of scientific language. Moreover, a third reason, regarding the logical contents we introduce, led us to design a fantasy narration. In fact, we agree with what Eco (2009) says about the relationship between narration and the notions of true and false:

“[...] every statement in a novel draws and constitutes a possible world whence all our judgments of truth or falsity will refer not to the real world but to the possible world of that fiction [...] The epistemological function of such fictional statements is that they can be used as a litmus paper for the irrefutability of any other statement. They are the only criterion that we have to define what the truth is” (Eco, 2009, translated by the authors).

It is only in the context of an invented story that true and false are incontrovertible: for example, Rome could stop being the capital city of Italy, but Juliet will never stop loving Romeo.

## Methodology

The study involved eighty 6<sup>th</sup> and 7<sup>th</sup> grade students of the same school with medium-low level of mathematical skills for about two months. The activities were carried out outside school time, in the presence of a mathematics teacher and a researcher (one of the authors of this paper). In a Vygotskian perspective, according to which the reasoning ability increases in the interaction among peers under the guidance of an expert (Vygotsky, 1934), the children participated in the activities working in small (2, 3 or 4 people) cooperative groups. Moreover, in accordance with the notion of *didactical cycle* (Bartolini, Bussi, & Mariotti, 2009), the activities were carried out with the alternation of different phases: exploration of the artefact, problem solving and collective discussion guided by the researcher. In our case, the artefact is the text of the riddle, so a linguistic artefact.

The students alternated their work with structured worksheets and with logical riddles. All the texts are adapted from the tales of “the knights and knaves island” (Smullyan, 1978): an imaginary island populated by two kinds of inhabitants, the knights who always tell the truth, the knaves who always lie. The activities on the structured worksheets, already used in the original path (Tortora, 2001), were proposed in the first part of every lesson. Their aim was to introduce in each lesson some of the basic elements of logic, e. g. the notion of proposition, the truth values, the distinction between simple and compound sentences, the logical connectives. The worksheet activities also gave to the researcher the opportunity to involve students in reflections about the differences between mathematical logic and common sense, as well as about the relativity of the notions of true and false and their dependence on the available information, the context and in some cases the judgment of the evaluator. The second part of every lesson was devoted to the solution of logical-linguistic riddles, as an application of the notions and the abilities acquired. From a formal point of view, the resolution of this kind of riddles requires that the students succeed in determining the only model<sup>1</sup> coherent with the dialogues in the text of the riddle.

---

<sup>1</sup> We use here the term ‘model’ to mean a correspondence that assigns to each character in the story the category he belongs to (knaves or knights).

All the collected data, that is, the students' written argumentations and the audio-recordings of their interaction within the group, have been analyzed. Here we refer only to the analysis of some written protocols, produced as answers to a single riddle. The task we examine is the solution of the first riddle, proposed at the end of the first lesson, after having introduced the notions of logical proposition and true values. We find this task the most interesting in order to reflect on how the students switch from one kind of thought and language to another, since in this first phase they were totally free from the influence of any didactic contract in solving linguistic riddles. Protocols have been examined on the basis of the awareness that different contexts and aims activate different forms of rationality and different linguistic styles (narrative vs. scientific). This aspect is crucial since we required students to logically solve linguistic riddles situated in a narrative environment. The analysis was carried out recognizing students' behaviors just on the basis of these categories.

The task that we examine is the solution to the riddle described in Figure 1.

Team:

Riddle 1

*Oreste is in the knights and knaves island and he meets two persons, Alberto and Bernardo.*

*Alberto claims: "One of us is a knave, at least"*

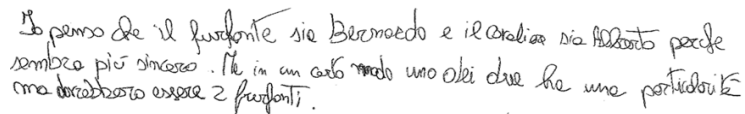

What can we say about Alberto and Bernardo? Can we establish which kind of inhabitant is Alberto? Can we know what kind of inhabitant is Bernardo? Discuss about this with your team mates. Then, write your reasoning.

**Figure 1: Riddle 1 - The right answer is: Alberto is a knight and Bernardo is a knave**

## Analysis of protocols

We report four protocols<sup>2</sup>, which seem to be meaningful and representative. We have selected them among the others, to show a spectrum of resolutions starting from a completely narrative approach until a prevalently scientific one. In them we have found also many interesting examples of conversational implicatures.

Protocol G1 (Fig. 2) gives us an example of completely narrative resolution of the riddle, without any explicit argumentation. In the first part, the students attach to Alberto the identity of a knight: probably, since Alberto speaks with Oreste, they affirm that "he seems sincerer". From that they deduce that Alberto is a knight and Bernardo is a knave.

Io penso che il fudefante sia Bernardo e il cavaliere sia Alberto perché sembra più sincero. Ma in un certo modo uno dei due ha una particolarità, ma dovrebbero essere 2 fudefanti.

**Figure 2: Protocol G1 - Answer: Alberto is a knight and Bernardo is a knave**

G1: [First part] I think that Bernardo is the knave and Alberto is the knight because he seems sincerer. [Second part] In a certain way one of the two has got a particularity, but they should be 2 knaves.

<sup>2</sup> The labels G1, G2,... indicate the protocols of the different groups (Group 1, Group 2,...). In Figures 2 to 5 we show the original protocols (including some erasures), and then just below we report our English translations.

Many groups attribute conversational purposes to knaves and knights. In particular, here students seem to believe that the knaves prefer not to intervene in the dialogues, because they do not want to risk, exposing themselves to reveal their nature, whereas the knights speak freely, because they have nothing to hide.

In Protocol G2 (Fig. 3), the possibility that Alberto be a knave is excluded on the basis of encyclopedic knowledge: in fact, the group imagines that in that case Alberto would have said something different. Thus we have an example of narrative thinking, with an argumentation.

**Figure 3: Protocol G2 - Answer: Alberto is a knight**

G2: Alberto is a knight because, if he were a knave he would have said the opposite i.e., that ~~both~~ neither of them was a knave.

Very often the students' priority in solving their first linguistic riddle seems to be to preserve the coherence of the story, based on their daily life experience. In this protocol, for example, we note a *change of script*, which is one of the most frequent phenomena we found in the first approaches to the riddles. By this we mean an argumentation used to exclude cases that appear to the students inconsistent with the narrative. When the students judge a case as inadmissible, they try to make examples of what the characters would have said in a case coherent with the narration (*"this case is not possible, because otherwise the character would have said so..."*). This change of script is in accordance with the cooperative purpose often attributed to the knaves.

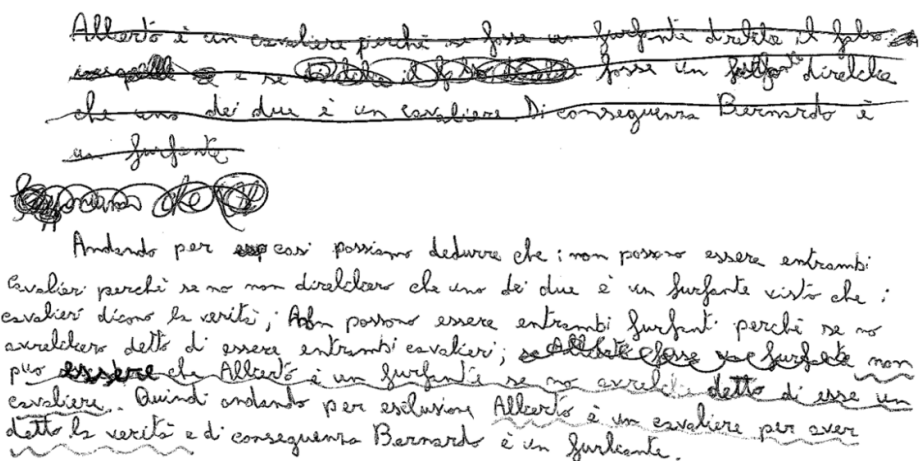

Nevertheless, already within the activity of resolution of the first riddle, it is possible to notice the emergence of a different form of rationality. In many protocols, there is a transition from a first response, corresponding to an involvement of only the narrative thinking, to subsequent responses, in which the students bring into play simple forms of logical-scientific thinking. This evolution was supported by collective discussions, which took place during the activity. For example, in Protocol G4 (Fig. 4), we can read three successive different kinds of resolutions: exactly what we intend for a complete spectrum of different approaches to the riddle resolution.

**Figure 4: Protocol G4–First version answer: Alberto and Bernardo are both knaves.**

**Second and third versions answers: Alberto is a knight and Bernardo is a knave**

- G4: [First version, erased in the protocol] Alberto and Bernardo are both ~~knights~~ knaves, because, after that saying, Bernardo does not rebut, therefore this means that the proposition is true.
- [Second version, erased too] Alberto is a knight and Bernardo is a knave, because, saying what he says Alberto affirms that one of them is a knave and so, among them, there is necessarily a knave.
- [Third version] Let us suppose that Alberto is a knave. By saying this, his sentence will be true. But, since he is a knave, he should not tell true things. Therefore Alberto is a knight; and Bernardo is a knave.

In the first version the answer is wrong and the argumentation seems ascribable to a totally narrative approach, with reference to personal encyclopedic knowledge. By saying “*Bernardo does not rebut*”, he wants to express that “*Bernardo does not justify himself*”: according to their life experiences the students interpret this attitude as an admission of guilt. In the second version the answer is correct. Nevertheless, in their attempt to argue, the students only explain the meaning of the sentence pronounced by Alberto, with special attention to the crucial expression “at least”, which was examined during a short collective discussion. Finally, the third version, which maintains the correct answer, contains a “scientific” argumentation. It comes after a longer collective discussion, in which the researcher, comparing the productions of the different groups, pursued two principal objectives: to support students in re-situating the activity in the mathematical context, introduced in the first part of the lesson; and to build a shared more rigorous language. It can be said that the discussion favored the appearance of words like “*sentence*”, “*true*”, “*true things*” and, at the same time expressions like “*let us assume*”, “*but*”, “*since*” and “*therefore*”, in this way supporting a complete “*reductio ad absurdum*” form of reasoning. A similar evolution can be found also in other groups, as we can see in Protocol G7 (Fig. 5).

~~Alberto è un cavaliere perché se fosse un furfante direbbe il falso.   
 ~~invece se è un furfante direbbe il vero.   
 ~~quindi se Alberto è un furfante direbbe il vero.   
 ~~che uno dei due è un cavaliere. Di conseguenza Bernardo è   
 ~~un furfante.~~~~~~~~~~

*Andando per ~~caso~~ casi possiamo dedurre che: non possono essere entrambi   
 cavalieri perché se no non direbbero che uno dei due è un furfante visto che:   
 cavalieri dicono la verità; non possono essere entrambi furfanti perché se no   
 avrebbero detto di essere entrambi cavalieri; ~~se Alberto fosse un furfante non   
 più ~~direbbe~~ che Alberto è un furfante se no avrebbe detto di essere un   
 cavaliere. Quindi andando per esclusione Alberto è un cavaliere per aver   
 detto la verità e di conseguenza Bernardo è un furfante.~~*

Figure 5: Protocol G7 - The answer in both versions is: Alberto is a knight and Bernardo is a knave

- G7: [First version, erased] Alberto is a knight because if he were a knave he would tell the false and if he were a knave he would say that one of them is a knight. Consequently Bernardo is a knave.
- [Second version] Going by cases, we can deduce that: they cannot be both knights, otherwise they would not say that one of them is a knave, since the knights say the truth; they cannot be both knaves otherwise they would have said

to be both knights; ~~if Alberto was a knave~~ it cannot be that Alberto is a knave otherwise he would have said to be a knight. Therefore by exclusion Alberto is a knight having told the truth and consequently Bernardo is a knave.

In both versions the answer is correct. In the first argumentation, we can notice a clear predominance of the narrative thinking over the logical one, leading to a change of script, coherent with the conversational purposes attributed to the characters. On the contrary, in the second one, which comes after the long collective discussion, we notice the use of a scientific language, while the content is at the same time narrative and logical. In fact, the possibility that Alberto and Bernardo are knights is ruled out by means of a logically correct argumentation. The other two non-admissible cases, instead, are excluded on the basis of narrative argumentations, through changes of script. For example, the change of script “*they cannot be both knaves otherwise they would have said to be both knights*”, is based on the conversational purpose that the knaves team up to hide.

## Discussion and conclusions

It is well known that the logical formalism, although necessary, to a certain extent, for a full acquisition of mathematical notions, may constitute a difficult obstacle for students, due to its distance from common sense and to its exasperated exactness. The awareness of this risk was the starting point of our research and experience. For this reason, a first decision was to introduce the didactic activities by means of riddles, which are a sort of game. Secondly, these puzzles were immersed in a fictional context, using explicitly a narrative mode. But in the experimentation analysed in this study, the role of narrative has been twofold. On the one hand, as we have said, following a well-established research trend, we have benefited from the context of an invented story and its appeal to introduce some not easy logical-mathematical concepts; on the other hand, we have paid special attention to the narrative mode adopted by students in their oral and written productions. It seems to us that our experimentation has brought some interesting results. First, the path supported the students toward a strengthening of the metalinguistic control over the texts, spurring a reflection on the relationship between language and metalanguage. In our context, the object language corresponds to the sentences pronounced by the knights and the knaves, whereas the metalanguage is the one used in group discussions and in the production of written argumentations. Thus the students became aware of the dual role of language, as a communication tool and an object of manipulation. In addition, our way of introducing the activities allowed the students to grasp a first sense of the logical formalism, although deliberately not rigorous. Addressing the proposed activities, the students were gradually able to experience directly how a rational management of statements, at a first glance uninformative, could be very efficient. The narrative dimension has played a key role in providing a criterion of truth, which was naturally accepted by the students and which allowed to (partially) approach what logicians call a ‘model’.

During the steps towards the resolution of the riddles, alternated with the collective discussions about the students’ argumentations, it seemed to emerge a gradual evolution from a purely narrative approach toward an approach where some form of scientific thinking appears. Even in the solution of the first riddle, where the two kinds of rationality are intertwined, it emerges a shift towards a more conscious management of the two forms of thinking, spurred by the resolution of the logical tasks. This kind of evolution is supported by the emergence of a more and more rigorous language.

Our further step will include a deeper analysis of the oral discussions among the students, in order to try to better understand if and how the peer discussion, the comparison of different views and the necessity to write down the shared conclusions favour the transition toward a more and more sophisticated use of a scientific language. If this will be the case, there will be room for designing and experimenting further didactic proposals also in order to observe whether, in a longer period of time, there are positive repercussions on mathematical competences.

### Acknowledgment

We thank Pier Luigi Ferrari for the suggestions and stimulating discussions on this argument.

# Implicit and explicit processes of establishing explaining practices – Ambivalent learning opportunities in classroom discourse

Kirstin Erath

TU Dortmund University, Germany; [kirstin.erath@math.uni-dortmund.de](mailto:kirstin.erath@math.uni-dortmund.de)

*Participation in mathematical practices is widely accepted as important for students' meaningful learning of mathematics. But how do students learn to adequately participate in these practices? This paper addresses the question for the specific case of oral explaining practices in whole class discussions. The study is theoretically based on merging an interactionist and an epistemological perspective to describe explaining practices as interactive processes in a classroom microculture while simultaneously keeping in mind the development of the broached mathematical content. The identified implicit and explicit processes of establishing explaining practices are exemplified and discussed with respect to ambivalences in the differing learning opportunities they offer.*

**Keywords:** *Explaining practices, student participation, discourse, interaction, implicitness.*

## Introduction

This study is based on the assumption that students' learning is inseparably linked to participation in classroom interaction, which is mainly based on verbal communication. Therefore, learning of mathematics is conceptualized as “a process of enculturation into mathematical practices, including discursive practices (e.g., ways of explaining, proving, or defining mathematical concepts)” (Barwell, 2014, p. 332). In this study, the discursive practice of explaining in whole class discussions is further investigated. Erath, Prediger, Heller, and Quasthoff (submitted) show that explaining is the most frequent discursive practice in German grade 5 mathematics classrooms. Furthermore, explaining has an important role for the meaningful learning of mathematics since it serves to communicate about more isolated pieces of knowledge, including talking about meanings and connections (Prediger & Erath, 2014). But how do students learn to participate in explaining practices and the corresponding epistemic processes? This question is investigated in this paper on the level of the interactive processes of establishing explaining practices in four microcultures.

## Theoretical background: Explaining as practices of navigating through different epistemic fields

Following Interactional Discourse Analysis, explaining is understood as multi-turn units which are interactively co-constructed, contextualized and serve to convey or construct knowledge (Erath et al., submitted). This definition is extended and intertwined with an interactionist and an epistemological perspective from mathematics education: From an *interactionist perspective*, explaining can be conceptualized as a mathematical practice (Cobb, Stephan, McClain, & Gravemeijer, 2001) that is interactively established in a classroom microculture and that allows talking about collective mathematical development. Here, this concept is used descriptively to talk about identified ways of collective explaining processes in whole class discussions that are interactively established by students and the teacher. But not every explanation constitutes an own practice. To clarify this point, the notion of mathematical practices is enriched by the following definition from general educational science: “Practices are [...] understood as rule-governed, typecasted, and routinely recurring

activities” (Kolbe, Reh, Fritzsche, Idel, & Rabenstein, 2008, p. 131; translated from German by the author). Therefore, mathematical explaining practices are conceptualized as *recurrent* ways of explaining that are treated as matching the classroom microculture from the participants’ perspective.

The *epistemic matrix* was derived from research in mathematics education from an *epistemological perspective* (Prediger et al. 2014) and is used to further specify the notion of ‘recurrent ways of explaining’. Different possible objects of explanations in mathematics are systematized in the lines of this matrix (not readable in Figure 1 that focusses on the depicted pathways), called *logical levels* (from top to bottom): Concepts, propositions, representations, and models (conceptual logical levels) and conventional rules, procedures, and concrete solutions (procedural logical levels). Each of these mathematical aspects can be explained by different means that are distinguished in the columns of the matrix (Prediger & Erath, 2014), called epistemic modes (from left to right): Labeling & naming, explicit formulation, exemplification, meaning & connection, and purpose & evaluation.

**Figure 1: Three explaining pathways contributing to the practice of explaining ‘good’ representations**

On the one hand, the epistemic matrix is used to characterize the utterances of students and teachers in explanations by analyzing which cells (called *epistemic fields*) of the matrix they address. On the other hand, the matrix is used to depict the *explaining pathways* that are interactively established by mapping these characterizations of utterances in the matrix (see Figure 1): Students’ utterances are depicted as rectangles (including turn number and name), the teacher’s utterances as circles with turn numbers. These pathways give access to the underlying mathematical structure of explaining sequences, which are especially characterized by the teacher’s navigations through different epistemic fields (indicated by arrows in the pathways). Therefore, the matrix is used as tool of analysis and at the same time the associated language of ‘explaining pathways’ serves to specify the definition of explaining practices: Altogether, explaining in mathematics classrooms is conceptualized as practices of navigating through different epistemic fields, which are identified by building categories of pathways with similar structures (Erath, 2017). Hence, different practices are constituted by different defining patterns of their pathways describing the ‘recurrent ways of explaining’. For example, all three pathways in Figure 1 have entries in the lines of “representations”, “procedures” and “concrete solutions” in common and after working in the column of “purpose & evaluation” (more on the right) the teacher navigates towards the column of “explicit formulation” (more on the left). This recurring pattern defines the practice of explaining ‘good’ representations in one classroom: “navigating from the evaluation of a student’s concrete solution and suggestions for improvement to deriving more general hints for drawing and characteristics of good representations”.

But how do students learn to adequately participate in these interactively established explaining practices? Studies on the establishment of related norms in mathematics education (e.g. Yackel & Cobb, 1996) and discourse analysis (Heller, 2015) identify implicit and explicit processes as oppor-

tunities for students learning how to explain in their classroom. This work is extended to the processes of establishing explaining practices in this paper.

## Methodology of the study

*Larger data corpus.* In the larger project INTERPASS, video data was gathered in 10 x 12 mathematics and language lessons (each 45-60 min.) in five different grade 5 classes (age 10-11 years) in an urban area of Germany. Eight lessons were observed in the beginning of the school year directly after the transition from primary school since it could be expected that processes of establishing practices are more explicit in this time of getting to know each other. Further four lessons each were gathered in the middle of the school year in order to get a long-term impression.

*Sampling for the case study of this paper.* The presented study builds on data of four mathematics classrooms chosen due to the following different characteristics in order to observe a broad range of interactions (Erath, 2017): Two higher tracked secondary schools (German: “Gymnasium”) and two normal secondary schools (German: “Gesamtschule”) and within each of these subgroups one classroom with students from a privileged and one with students from an underprivileged quarter.

*Data analysis.* This paper is based on analyses done for the PhD thesis “Mathematical discursive practices of explaining in different classroom microcultures” (Erath, 2017) enrooted in the larger project INTERPASS. In this context, all explaining sequences in whole class discussions were transcribed and analyzed by means of the epistemic matrix resulting in explaining pathways for each sequence. In a second step, explaining practices were identified in each classroom by developing categories of pathways with similar structures. In this way, three to five different explaining practices were explored in each of the four classrooms. In order to answer the question “How do students learn to adequately participate in the explaining practices of their classroom?” the interactive processes of establishing practices were further investigated. More precisely, it was explored if these processes were explicit or implicit and which turn teachers use in order to express their expectations and if this makes any difference for students learning opportunities.

All presented transcripts were translated from German and simplified (capital letters indicate stressed words, round brackets indicate phrases difficult to understand in the video data).

## Empirical results: Processes of establishing explaining practices

The investigation of processes of establishing explaining practices in four German grade 5 classrooms (Erath, 2017) shows that there are some explicit but primarily implicit processes that contribute to the establishment of explaining practices. Furthermore, it comes to the fore that teachers (implicitly or explicitly) explicate their expectations in the turn of demanding an explanation as well as in the turn of responding to a student’s utterance.

### Explicit processes

Out of 16 identified explaining practices, only the practice of “explaining a concrete solution by means of a conventional rule” in Mr. Maler’s classroom is recurrently established in an *explicit* way. The following transcript from the sequence “rounding on tens” (see Prediger & Erath, 2014 for a longer extract of the sequence) exemplifies how the teacher explicates his expectations for a ‘good’ explanation in his response to Kosta’s explanation why 63 can be rounded on 60:

- 8 Kostas: °hhh [*articulated clearing his throat*] Well, if you are rounding DOWN the sixty-three on TENS; then it comes, it gets, there must be ALWAYS a zero at the end, it MUST be,
- 9 Teacher: [hm\_hm ]
- 10 Kostas: [when you are rounding.]
- 11 Teacher: On TENS yes.
- 12 Kostas: And then there, if you take AWAY the three and shift the ZERO to it. So, you could DO that, but actually it's WRONG. You just have to round down and nea.. nearest number with a ZERO you have to write there.
- ...
- 20 Teacher: [...] and you already implied WHY; but does any of you know a RULE, HOW one has to proceed here, and when one here, when the ten stays the SAME? In this case, and the place BEHIND, which is rounded, goes to ZERO? Ha; [4.5 sec. break] Katja.
- 21 Katja: With zero one two three FOUR you are rounding down and with five six seven eight NINE you are rounding (up). [3.5 sec. break]
- 22 Teacher: Did EVERYBODY understand that?
- 23 Class: YES [*affirms in choir*]

Kostas explains his solution by referring to the meaning related model of distance and closeness on the number line. This is implicitly rejected as a matching explanation by the teacher in #20, immediately followed by questioning the class about a rule that could be applied to explain the solution. In this way, Mr. Maler explicates his idea of a 'good' explanation of a concrete solution, which is underlined by his reaction to Katja's formulation of the corresponding rule. This sequence is an example of explicating expectations in responding to a student's explanation by navigating to the epistemic field (explicit formulation of a conventional rule) that would match for an explanation from the teacher's perspective and directly demanding an answer in this epistemic field. Another conceivable possibility would be that the teacher explicitly talks about which mathematical aspect of an explanation he values or which part did not match from his perspective.

These kinds of explicit processes can also be observed in Mr. Maler's demands for explaining a solution. The following extract from "rounding on thousands" in the context of a homework on rounding the length of rivers illustrates the case of explicating expectations in the turn of asking for an explanation by pointing to the expected epistemic field (explicit formulation of a conventional rule):

- 6 Tabea: SIX thousand
- 7 Teacher: GOOD; but now my QUESTION is, HOW did you arrive at this six thousand? Since we also want the RULE
- 8 Tabea: Because from e:r,
- 9 Teacher: to be CLEAR
- 10 Tabea: Well up to five, well up to four, you have to round DOWN, and from five six seven eight nine you have to round UP.
- 11 Teacher: EXACTLY. [...]

After naming the right number (#6), Tabea is asked by the teacher in #7 to explain her solution. In this turn of demanding an explanation he directly states that she should refer to the conventional rule (shortly interrupted by Tabea): "HOW did you arrive at this six thousand? Since we also want

the RULE [...] to be CLEAR” and in this way explicitly points to the expected epistemic field. Tabea follows this navigation (#10), which is explicitly evaluated positive by Mr. Maler in #11.

In both ways, the teacher explicates his expectations and reveals the recurring, typical structure of explaining a concrete solution by means of stating the related conventional rule. That is, this structure is made accessible to all learners and not only to those who can interpret the implicit processes of establishment (see below). Hence, the teacher’s explication of expectations in the turns of demanding for and responding to an explanation are major learning opportunities for explaining a concrete solution adequately in this classroom (this must not hold for other classrooms since every microculture establishes different practices). Especially the way of explicating in the demand for an explanation seems to be important: This allows all children to contribute in the subsequent explanation even though they might not yet recognize the recurrent pattern of the underlying practice.

### Implicit processes

Explicit establishments (see above) have only been found in rare cases in the data corpus. Instead, processes take course implicitly. Three different ways of *implicit* processes contributing to establishing explaining practices were identified and are exemplified in the following: (1) marking match or mismatch in responding to a student’s explanation without giving reasons for the evaluation, (2) picking up only particular aspects of a student’s explanation without explication, and (3) navigating recurrently to specific epistemic fields without revealing the underlying (intended) pathway.

An example for evaluating a student’s explanation without further comments is the sequence “distinguish lists” from Mrs. Bosch’s classroom. During revision at the beginning of the lesson, students are asked to distinguish the concepts of tally sheets and frequency tables.

- 12 Teacher: [...] Now, WHAT was tally sheet, WHAT was frequency table, this PART, Barbara,
- 13 Barbara: Tally sheet is where you did strikes; and frequency table is er [4.0 sec. break] er-
- 14 Teacher: Can you HELP Maria?
- 15 Maria: YES, when you did it all count up and then wrote it DOWN with numbers
- 16 Teacher: EXACTLY. Well CAUGHT. [...]

Mrs. Bosch marks Maria’s explanation explicitly as matching (#16) but does not reveal the underlying pathway in her response: The analysis of several sequences on explaining concepts in this classroom unfolds that in this microculture a concept is adequately explained by means of addressing an epistemic field on the level of procedures, which means formulating an instruction for generating a representation of the concept. Therefore, the sequence is an example of an implicit process that contributes to the establishment of an explaining practice by marking an explanation as matching or mismatching without commenting on the reasons for the evaluation.

The second kind of implicit processes (picking up only particular aspects of a student’s explanation in a response without explication) is concretized by the sequence “function of diagrams” from Mr. Schroedinger’s classroom in the context of talking about different ways of presenting data.

- 1 Teacher: [...] WHY they’re doing quite frequently in printed media but also um on TV in the news, um why they’re not giving a LIST like that [...]

- 2     Nikolas:     um because maybe because this CATCHES one's eye much faster and um well that you can SEE this faster; so that something is BIGGER; because this is also bigger from its SIZE. So it's MORE because it's BIGGER from its size.
- 3     Teacher:     [nods] [Markus     ]
- 4     Marcus:       [Because you] can CATCH it very fast. For example um now up RIGHT I think there are such PERCENTAGES; because (that they) CATCH that well it's actually even BETTER than this; (also how many) PEOPLE;
- 5     Teacher:     hm\_[hm ]
- 6     Marcus:       [How] many SIBLINGS they have, because then in parts they would maybe have to always go THROUGH our classroom that small.
- ...
- 9     Teacher:     THIS exactly meets the point, these two utterances. THEREFORE you normally do it in the form of such diagrams, because of the clarity actually [...]

In his evaluation in #9, the teacher explicitly marks that the students' answers match but in his subsequent summary, only specific aspects are picked up: The teacher takes on the aspects related to functionality but he does not refer to the further issues of meaning (#2, "it's MORE because it's BIGGER") or examples (#4/6, number of siblings) addressed by the students. This selection is in line with the practice of explaining that is established during several sequences: In Mr. Schroedinger's classroom, concepts are adequately explained by referring to purposes and functionality.

The third way of implicit processes contributing to establishing a practice is the teacher's repeated steering to specific epistemic fields without revealing the underlying (intended) pathway. This directly refers to the definition of explaining practices that forms the basis of this study. Figure 1 shows three pathways of sequences that show the same regularities. These kind of pathways are identified five times in Mr. Schroedinger's classroom in the context of explaining how 'good' representations are designed. But, as with the two ways illustrated before, the underlying pathways are not revealed. The following extract from the sequence "lists of pets" exemplifies the navigation from evaluating a concrete solution to formulating hints for generating 'good' representations.

- 1     Teacher:     What would you SAY which ADVANTAGES, DISADVANTAGES [*break 1.3 sec*] have these particular ways of writing it down; [...]
- 34    Büsra:       Well, in my POINT of view number two is BEST [*break 1.7 sec.*]
- 35    Teacher:     WHY; [*break 1.2 sec.*]
- 36    Büsra:       Yes because it doesn't that much TIME and em like Monir-Zohir already SAID em it only takes you like two MINUTES or so-
- 37    Teacher:     hm\_HM, [*break 1.3 sec.*] But with number two TOTALLY obvious- something is MISSING in order to make it as clearly arranged as POSSIBLE [...] WHAT is missing TOTALLY obvious with number two so you can SAY yes THIS makes somehow sense- this there you need LITTLE time- this is SOMEWHAT clearly arranged
- ...
- 40    Uwe:         the NUMBERS; [*break 1.7 sec.*]
- 41    Teacher:     SAY again- WHY does it make sense to write numbers behind it?
- 42    Uwe:         So that you don't always have to count THROUGH;

43 Teacher: [writes on the transparency] EXACTLY; [...]

Mr. Schroedinger initiates (#1) the evaluation of the representations and after some students stated pros and cons for the different representation, he navigates to formulating suggestions for improving the lists (#37), which helps clarifying how good lists should be designed. By repeatedly starting from a student's concrete solution and navigating from its evaluation and suggestions for improvement to deducing more general hints for drawing and characteristics of good representations this explaining practice is established across several sequences.

Although the three presented ways of establishing explaining practices must be characterized as implicit processes, they serve as opportunities to learn how to participate adequately in whole class explanations, at least for some learners. But the examples also show how challenging it is for other students to interpret these implicit processes (see e.g. Gellert, 2009, for further discussion of divergent learning opportunities related to implicitness). In the cases of marking matches and mismatches or picking up particular aspects without further comments, it might be challenging for students to follow since they must relate the teacher's evaluation to a classmate's utterance that is not present any more. The third way (recurrent teacher's navigations) allows all students to contribute in the explanations as long as the teacher explicitly demands for the shifts of epistemic fields. However, it probably takes students several sequences of one practice to recognize that there is a pattern and that knowing "how explaining works" is important for adequately taking part in whole class discussions.

## Conclusion and discussion

The distinct dominance of implicit processes found in the qualitative analysis of the video data corpus is in line with research that identifies criteria of "successful participation" and "expected student contributions" (Gellert, 2009, p. 131, translated from German by the author) as often staying implicit. The presented study deepens these findings for explaining practices. Furthermore, the epistemic matrix offers a possibility to talk about mathematical aspects of 'good' explanations and to make the hidden regularities visible and discussable by means of the pathways. The dominance of implicit processes also suits the observation that explaining (as well as oral communication in general) is not treated as an explicit *learning goal* by the teacher (Erath, 2017). Instead, explaining serves as *learning medium* that is used without talking about adequate participation beyond general social behavior, i.e. the mathematical aspects of 'good' explanations. Moreover, it becomes apparent that learning how to adequately participate in whole class explanations is a learning process (across several sequences and lessons) and hence especially not a feature that students bring to the classroom but a competence that can be acquired in the interaction of collective explanations guided by the teacher.

The explicit and implicit processes of establishing explaining practices relate to different learning opportunities for students as explicated above: More explicit processes are eligible since they reveal the underlying patterns of the pathways and provide more students access to this mathematical aspects of participation, not only those who are able to also interpret the implicit processes. However, this does not imply a call for direct instruction: Talking about language on meta-level while simultaneously talking about mathematical content may ask too much especially from weaker students. Instead, it is about making the criteria for matching and mismatching utterances in relation to a practice accessible in responses to explanations or in the turn of demanding for explanations. Therefore, teachers need to be sensitized for the role of oral explaining as a learning goal in order to be able

to deliberately initiate particular practices. But as a first step, research in mathematics education should further specify which explaining practices are reasonable (also related to general discourse acquisition) or rather necessary in which grade in order to help teachers to enable even more students to actively participate in oral explanations and the corresponding epistemic processes.

# Young children's appropriation of mathematical discourse: Learning subtraction in a plurilingual classroom

Marie Therese Farrugia

University of Malta, Malta; marie.t.farrugia@um.edu.mt

*I describe a teaching experience I carried out in Malta with a class of 5-year-old children of different language groups. The language of instruction was English and the topic subtraction. I explicitly taught mathematical expressions and sentence frames and planned class and paired activities wherein the children themselves would use the language to express the concepts at hand. The theoretical framework underlying my interpretation of the children's efforts is learning-as-participation. More specifically, I used Krummheuer's empirical model designed for interpreting classroom interaction in terms of producers and recipients. My teaching experience illustrates that with careful attention to both mathematics and language objectives, young learners in plurilingual Maltese classrooms can appropriate and use mathematics discourse within structured activities. However, more research is needed with regard to how students might use this language to author novel contributions.*

*Keywords: Learning-as-participation, mathematical discourse, subtraction, elementary education.*

## Introduction

Although the academic language for mathematics in Malta (an ex-British colony) is English and written texts are in English, interaction in classrooms is usually conducted through both Maltese and English. However, the number of non-Maltese students in classrooms is increasing over time, prompting teachers to use more English during lessons; although English may not be the non-Maltese children's home language, it is more likely that they would be familiar to some extent with English rather than Maltese. Anecdotal evidence suggests that teachers generally view this situation to be problematic, as they need to cater linguistically for Maltese and non-Maltese children. I carried out a study in the form of a teaching experience with a mixed language group of children with the aim of encouraging students to learn and use topic related language. My reasons for carrying out the study were (1) to apply to the Maltese context, the recommendation from the field of mathematics education for teaching mathematics language explicitly; (2) to focus on specific aspects of the mathematics register. I hoped that the reflections would aid me in my discussions with local colleagues, trainee-teachers and policy-makers on medium-of-instruction issues. My research question was: *How can children of different language groups be supported to learn English mathematical language?* By 'learning' I mean that the children would be able to express mathematical ideas through appropriate language during and after a series of lessons wherein specific language structures were emphasized.

## Learning mathematical discourse

Several researchers, among them Gibbons (2015) and Murray (2004), make a strong case for teaching students explicitly how to talk about mathematics. Learning the language of mathematics allows individuals to express the ideas and concepts that form the discipline of mathematics, and by learning the language pupils begin to be enculturated into it (Lee, 2006). Thus, children learn the *discourse* of the discipline. This includes more than just learning subject specific vocabulary. Rather, it involves

learning - and using - the ‘ways of saying’ particular to the subject. For example, Sammons (2011) states that students need to learn how to formulate questions, make inferences and predictions; Murray (2004) and Gibbons (2015) recommend reflective journal writing as part of learning mathematics while Gerofsky (2004) considers word problems to be a genre forming part of the discourse. Whereas learning mathematical discourse is important for all learners, second-language learners have the dual task of learning the second language and content simultaneously (Bresser, Melanese & Sphar, 2009). Consequently, the teacher of second-language learners faces the challenge of not only making the mathematics lessons comprehensible for students, but also of ensuring that the students have the language needed to express their grasp of mathematics concepts. Coggins, Dravin, Coates and Carroll (2007) and Melanese, Chung and Forbes (2011) offer suggestions for classroom activities to support these students in learning ‘academic’ language, while Gibbons (2015) suggests that when planning lessons, both subject and language objectives should be listed.

In her consideration of mathematical language as a ‘register’, Morgan (1998) highlights grammatical features such as the imperative (command) and nominalization (nouns derived from verbs like *rotation* and *construction*), the passive voice (e.g., a line is drawn), being concise and the use of symbols. Whereas Morgan referred to written mathematics, these features also contribute to spoken mathematical discourse. Prediger and Wessel (2011) link the verbal register with what they call non-verbal registers including concrete, graphical and symbolic-numerical representations. They note that cognitive development of mathematical concepts is deeply connected to the ability to relate concepts in different representational modes. In this study, particular features of the register were addressed and developed by using them alongside non-verbal representations.

## Theoretical framework

Lave and Wenger (1991) proposed that learning can be considered as participation in a community of practice. As students progress in their learning of an apprenticeship, they move from what Lave and Wenger call ‘peripheral’ to ‘full’ participation (p. 37), which involves learning the tools of the activity and gaining autonomy. Dealing with a similar theme of apprenticeship, Rogoff (1995) writes about two concepts: *guided participation* and *participatory appropriation*. The former refers to the mutual involvement of individuals, including communication, in a collective valued activity. ‘Participatory appropriation’ refers to the process by which individuals transform their understanding of, and responsibility for, activities through their own participation. In the context of the mathematics classroom, ‘learning’ may be taken to be the participation in the practice of the discourse of mathematics. Krummheuer (2011) has queried how the sensitizing notion (Blumer, 1954) of learning-as-participation can be described or represented on an empirical level and he proposes a framework for this purpose. He widens the dyad ‘speaker/listener’ to *multiple* roles so as to account for the multiple individuals normally participating in a group conversation such as that of a classroom context (ibid, pp. 84-85). For participants who are listening (recipients), he proposes the following roles; the first two refer to direct participation, while the latter two to indirect participation:

- Conversation partner (addressed by the speaker);
- Co-hearer (unaddressed by the speaker);
- Over-hearer (tolerated by the speaker);
- Eavesdropper (excluded by the speaker).

For participants who are speaking (producers), Krummheuer suggests these roles:

- Author (responsible for the content and the formulation of an utterance);
- Relay (not responsible for either content or formulation; echoes the author);
- Ghost (takes over the identical formulation and uses it to try to express an original idea);
- Spokesman (expresses the same idea with his or her own formulation).

As Krummheuer points out, this model has the advantage of accounting for the process of moving from ‘legitimate peripheral participation’ (as evidenced by the roles of eavesdropper, over-hearer, co-hearer and relay) to ‘full participation’ (role of author), through the intermediate stages of spokesman and ghost. Using this model, it is possible to interpret classroom interaction and participation, and hence learning, in a more specific way. Whereas Krummheuer (2011) used the model to interpret a small-group discussion, I apply it to a whole-class setting.

## Research context and method

An ethnographic approach was considered suitable since I wished to describe the practices of an educational community. Since my focus was the details of a teaching/learning context, I considered the case study method to be appropriate (Yin, 2014). I approached a school where the Head of School was an acquaintance of mine, and she put me in touch with a Grade 1 teacher, whom I call Ms Jenny. Most of her children were 5 years old at the time of the study. The class comprised 22 children and exemplified a ‘superdiverse’ context (Barwell, 2016). There were nine children of whom both parents were Maltese; seven children had one parent Maltese and the other non-Maltese, namely Australian, Irish, Bulgarian, Serbian, South African, two Libyans. Five children’s parents came from varying countries: Italy, Greece, Hungary, Ecuador, South Africa. One boy had a Finnish father and a Kenyan mother. All the non-Maltese children understood English with different levels of confidence; I am not in a position to know their exact language experiences through which they learnt English, but from the conversations I had with some of the children it transpired that those who had one Maltese parent used English with this parent. Some of the non-Maltese children understood some Maltese and could say a few words. The Maltese children spoke Maltese fluently and understood English, but their speaking proficiency varied. Ms Jenny’s class situation prompted her to use English as the medium of instruction. Some of the Maltese children used Maltese when communicating on a social level. I did not hear any of the other languages during my time in the classroom, although I cannot exclude that the two Libyan children might have used Arabic to communicate outside the classroom. Ms Jenny and I agreed on the topic to be taught: Subtraction. 9 one-hour lessons were given and these were video-recorded. The focus of this paper is on the 5 lessons on subtraction as separation or ‘take away’. Parental and the child’s own consent was sought for children to show up on the cameras. If either withheld consent, the child was placed out of camera view. I interviewed some children individually before the lessons, asking them about the languages they spoke; I also confirmed that Subtraction was going to be new to them as a school ‘topic’. Three days after the lessons ended, I spoke to the children again, asking what they recalled. Children were chosen on the basis of consent obtained from both themselves and their parents; six were interviewed prior to the lessons, seven after. The interviews were audio-recorded.

I wished to present the children with mathematics/language and to see if, and how, they would appropriate the targeted discourse. The mathematical objectives of the lessons were: subtraction as

separation using pictures, blocks and fingers; symbolization ( $5 - 2 = 3$ ) and translating story problems into subtraction operations. The related language objectives included the following structures: making statements using specialist vocabulary with regard to items (“Five [blocks] take away one is four”), using the imperative (“Take away two!”), asking a mathematical question (“How many left?”), ‘reading’ concisely symbolization ( $5 - 1 = 4$  read as “five minus two equals three”), and formulating story problems orally (“Ms Jenny has 5 cookies. She eats 2 cookies. How many are left?”). Resources included a story book, pictures, blocks and fingers. As suggested by Bresser et al (2009), I modelled sentence frames during whole-class discussion, then set paired tasks during which the children were encouraged to use similar language. Some pairs (based on consent) were recorded using an audio-recorder. Individual worksheets were also set, of which photos were taken after the children completed them. In order to analyse the data, I studied the lesson, pair-work and interview recordings in detail, together with the completed worksheets. I focused especially on children’s contributions, now interpreting my original, general aim of getting children to use mathematical language in terms of Krummheuer’s framework.

## Teaching and learning subtraction as separation

Classroom interaction is a complex activity, with participants’ roles interweaving. However, for the sake of presentation, I here tackle the roles separately. Names are pseudonyms. In the transcripts, the language is presented as stated by the children, and so in some cases may differ from standard English.

### Teacher as author, children as recipients and relayers

In order to introduce the children to the new expressions, I first authored them myself within a whole-class discussion. In these situations, the children took the roles of either conversation partners or co-hearers, since I could not interact with all children simultaneously. In a typical ‘whole-class’ style of interaction, I sometimes drew on particular children (“This one’s for Andrea”) while at other times I selected children with raised hands, or allowed a chorus answer.

The following is an illustration of how I introduced an expression and encouraged the children to relay it back. The conversation follows Ms Jenny’s reading of the story ‘Monster Musical Chairs’ (Murphy & Nash, 2000) during which I had used statements such as “Three monsters take away one monster leaves two monsters”, while showing up large number cards.

- |                    |  |
|--------------------|--|
| MTF:               | <i>(Referring to the monster pictures attached to the whiteboard).</i> I’m going to say something important: “Six take away one leaves five”. <i>(MTF simultaneously removes one card).</i> Now I need Dragan to say “five take away one leaves four”. |
| Dragan:            | <i>(As MTF removes another card).</i> Five take away one leaves four.  |
| (Serbian/ Maltese) |  |
| (...)              | <i>(A short while later with reference to three attached monster cards).</i>   |
| David (Maltese)    | Take away ...  |
| MTF:               | <i>(Indicates the three cards attached to the whiteboard).</i> First say how many there are. <i>(Slowly)</i> Three – take – away – one – leaves – two.   |
| David:             | <i>(Saying it with me).</i> Three take away one leaves two.  |
| Children:          | <i>(Some children in the class say it with myself and David).</i>  |
| MTF:               | I want to hear you say it.   |
| Children (chorus): | Three take away one leaves two.  |

For some children, relaying was not a trivial matter. For example, in the second lesson I introduced the question “How many left?” or “How many are left?” During this lesson, Lili (Hungarian) relayed this as “How many is?” but the following day I overheard her ask the question correctly to her task-partner. Initial difficulty may be due to the fact that English might not be a child’s first language. Age may also have an impact on how quickly a child might pick up a new expression; these young children were still developing general language communication skills. Once a key phrase was practised a number of times, I encouraged children to offer their own examples, thus giving them the opportunity to act as ghostee or spokesman.

### Children as ghostees and spokesmen

Taking the role of ghostee (identical formulation, original idea) first occurred during class discussions. For example, in the second lesson I showed up picture cards, starting with six, decreasing to zero, each time asking a child to express what we had observed during the monster story. By this stage in the lesson, we were using both expressions *take away leaves* and *take away is*.

MTF:	What shall I do with the picture?
Kylie:(Australian/Maltese)	Take away!
MTF:	So what shall I say?
Kylie:	Three take away one is two!

Although Kylie’s idea was not ‘original’ as such, I still consider that Kylie had progressed a step ahead of simply repeating after me, or with me. By Lesson 3, the children had picked up a lot of confidence, sometimes using the formulation to ‘jump the gun’. For example, in one activity I was asking children to show up a certain number of fingers, then take away (put down) a number of them. I had previously set two examples, guiding them with questions.

MTF:	OK, another example. Seven fingers...
Child 1 (unseen):	Take away four!
Sofia (Bulgarian/Maltese):	It’s three!
MTF:	Listen carefully!
Child 2 (unseen):	Five! Five!
Child 1 (unseen)	No, four!
Children (chorus):	Seven take away four is/leaves three.

Another context in which the children took the ghostee role was during a structured paired activity. For example, in the excerpt below Sofia and Lennie were using monster pictures.

Sofia (Bulgarian / Maltese)	( <i>Puts out six pictures, removes one</i> ). Six take away one is five.
Lennie (South African/Maltese)	( <i>Removes a picture</i> ). Take away /
Sofia:	( <i>Interrupts</i> ). FIVE take away.
Lennie:	Five take away one is four.
Sofia:	( <i>Removes a picture</i> ). Four take away one is three.
Lennie:	( <i>Removes a picture</i> ). Three take away one is two.

It took some time for some children to get accustomed to stating the original number; as Lennie did, they might say “Take away two is three”. I drew their attention to stating the first number; this was important as a preparation for the standard symbolization  $5 - 2 = 3$  that was introduced in Lesson 4.

It is not possible, nor necessary, to insist on identical formulations when working with mathematical discourse, since it would render the language-use artificial. Indeed, taking the role of spokesman (same idea, varying formulation) played a crucial part, since it allowed the children to express themselves freely and to draw on English *as they knew it* to express the mathematics at hand. This helped create an inclusive context, build up their confidence in English and mathematics, and allow me to gauge their understanding. For example, during a paired activity with blocks, the children were required to give an instruction to their partner (use of imperative, e.g. “Show six blocks”), then ask “How many (are) left?” Some children asked the question differently, for example: “How much is there?” (Sofia, Bulgarian), “How much is there now?” (Andrea, Ecuadorian), “How many blocks there left?” (Shania, Maltese) and “How many is the answer?” (Ritienne, Maltese). During the paired activities, Ms Jenny and I had monitored the children’s work, using the new expressions as we interacted with them and, through questioning, encouraged them to use the expressions themselves. Plenary sessions in which we reviewed a lesson also allowed the children to express themselves as they wished, while using the new expressions.

- |                       |   |
|-----------------------|---|
| MTF:                  | What was that special word we were using today?   |
| Ian (Maltese):        | We were taking away.  |
| MTF:                  | Can somebody remember what we were doing when we were playing teacher?                      |
| Sven (Finnish/Kenyan) | We was ... we was ... we was asking to show ... to show ... to show ten blocks.             |
| MTF:                  | Good! We were asking our friend to show blocks. And then, Sven, what did we ask them to do? |
| Sven:                 | To ... to ... to ... to take away.  |
| MTF:                  | And then what did we ask our friend? ... Luca?  |
| Luca (Italian):       | How many there left?  |
| MTF:                  | Very good! How many are left?   |

A number of the children had another opportunity to take the role of ghostee or spokesman during informal individual interviews I carried out with them. In this context, I asked open questions like “Tell me what you remember”, prompting them to use the language – or similar - that we had focused on in the lessons. Following are two examples. In relation to word problems, Dragan used the story problem formulation to offer an example about himself, while Mohammed articulated a story sum with varying formulation, drawing on his knowledge of English as best he could.

- |         |   |
|---------|---|
| Dragan  | Dragan has five cookies and he ate three, and it’s two. |
| MTF:    | Do you remember that question we were asking?           |
| Dragan: | Yes. ‘How much are left?’                               |

- |           |  |
|-----------|--|
| Mohammed: | Ms Farrugia is, have a ... like ... eleven biscuits and he eats ... em ... six biscuits. |
|-----------|--|

### Children as authors

The role of ‘author’ is one that implies original input by the speaker and hence the role implies a certain autonomy. In the lessons on subtraction as ‘take away’ I did not recognize instances when children acted as authors in the sense of them coming up with novel input that could shape the

discussion, or influence other children's learning of subtraction. I believe that the reason for this was the structured nature of the activities. Due to my intention to stress and develop specific mathematical language, the whole class conversations were shaped by myself. Furthermore, the paired activities had particular instructions to follow. Although children offered their own subtraction examples on the worksheets, including drawings of their choice, I would still say that they were following quite closely the structures I had taught them. Of course, the children did digress in their talk during the pair work and as they worked out the written examples on the sheet. However, this alternative talk tended to be social talk, such as "Look, my monster is green" or "Hey! Don't take our blocks" and so on, as one might expect from children this age.

## Conclusion

From a researcher perspective, my study served the purpose of supporting international research that highlights the benefits of giving explicit attention to academic/English language with non-English speakers. It provides an example of focusing on specific features of the register. My study also illustrates an attempt at addressing mathematical language in a plurilingual classroom, and an application of Krummheuer's (2011) framework. From a teacher perspective, I concluded that the strategies I had planned had been effective in reaching my aim which was to enable the children to use features of mathematics discourse, namely specialist vocabulary, the imperative, asking questions, interpreting symbolization and the story problem genre. Thus I went some way in guiding a group of children with very different language backgrounds and differing proficiency levels of English to appropriate the 'academic' mathematical discourse and hence to increased participation in the discipline (Lave & Wenger, 1991). However, according to Krummheuer (2011), *full* participation in the practice is achieved through authorship. Due to the structured nature of the class activities, I cannot say that the children fulfilled the role of authors; it is likely that open-ended style activities are required to allow for authorship opportunities.

In conclusion, I note that on one hand the explicit attention to language can help to set up a reciprocity of conversational English and mathematical discourse, with potential benefit for both aspects. This would seem to be an important teaching strategy for mixed-language groups. On the other hand, the attention to language in itself can be restricting unless further opportunities are provided for more open-ended tasks. In the latter tasks, one might hope that the language expressions learnt during structured activities might then be utilized as students offer novel ideas. This would result in students' authoring by using the mathematics register - surely the 'fullest' verbal participation that one can expect from mathematics learners. Of course, appropriating mathematical discourse is not something that can be achieved over a few lessons, especially in the case of very young children learning mathematics in a second or foreign language. The next stage in my line of research is to explore how newly learnt language structures can be encouraged in a plurilingual classroom to author original contributions to the development of the mathematics at hand.

# Language in argumentation and solution of problems with graphs

Pier Luigi Ferrari

Università degli Studi del Piemonte Orientale, Dipartimento di Scienze e Innovazione Tecnologica,  
Alessandria, Italy, [pierluigi.ferrari@uniupo.it](mailto:pierluigi.ferrari@uniupo.it)

*The paper reports an investigation about undergraduates' argumentations to justify answers to elementary calculus problems involving the recognition of relationships among graphs, verbal texts and formulas. The examination of the texts produced over more than ten years highlights serious language difficulties and suggests that we cannot exclude that language is a key factor for the quality of arguments. The main goal of this study is to gain a better understanding of how language difficulties (depending on both competence and attitudes) affect argumentations.*

*Keywords: Language, problem solving, register, argumentation.*

## Introduction

The paper focuses on how undergraduates justify their answers to elementary calculus problems involving relationships among graphs, verbal texts and formulas, in the frame of an introductory mathematics course delivered in Italian to biology freshman students. The course is short (48 hours of lectures and 24 hours of optional tutoring sessions) and taught by two instructors, one of whom is the author. It is usually attended by more than 400 students, coming from various regions of Italy and Eastern Europe. The students' language competence is much varied. Due to the goals, the attendance, and the lack of time, I did not develop a standard course moving from the basic definitions of Calculus to get to theorems and applications, but focused instead on a few concepts such as graph symmetries and slope. Most of the tests administered as working material or examination papers require the linking of different representations of functions (symbolic expressions, graphs, verbal texts, tables of numbers). Through these activities participants are systematically asked to explain and justify their answers in writing, even informally. This requirement is aimed at discouraging guessing or rote learning and help the students to better understand the concepts involved. Morgan (1998) provides a description and discussion of the 'writing-to-learn' paradigm, and highlights the benefits of the use of writing as a means for learning. Very appropriately, she suggests (with the expression 'learning-to-write') that nobody needs to assume that students of any age have achieved the level of linguistic competence required in order to produce texts adequate to their goals, and challenges the assumption, more or less implicit in a number of studies, that language naturally develops and there is no need for deliberate language teaching (Morgan, 1998, pp. 37-49).

The scrutiny of the papers written by students over the years highlights serious difficulties with language and suggests that we cannot exclude at all that language competence is a key factor for the quality of arguments. If we admit that there is a link between language and thought, there is no reason at all to rule out the hypothesis that the quality of the texts a subject can produce or interpret could deeply affect the quality of her/his thinking, and thus of the arguments s/he can produce.

An investigation of this topic requires dealing with the texts involved as objects, not only as means to develop a discourse within a given context. The focus should be on the organization of the texts, not just on the corresponding communication process.

The main goal of my research is to get a better understanding of how language difficulties (depending on both competence and attitudes) affect the production of arguments by undergraduates. In this specific study I focus on problems involving graphs.

## Theoretical framework

Research on argumentation has produced a large number of papers from a wide range of perspectives. Some researchers, such as Crawshay-Williams (1957) and van Eemeren et al. (1996), in different ways, have underlined the role of context in argumentation and the links between argumentation and language. Crawshay-Williams (1957, p.3), for example, claims that his work on argumentation “enquires how we use language as an instrument of reason” and argues that “[i]t is only possible to determine whether an empirical statement is true or false if the context of the statement is known.” On the other hand, van Eemeren et al. (1996) relate the theory of argumentation to the pragmatic theory of speech acts (Austin, 1962), which takes into account not just the *propositional content* of a statement (i.e. the part of its meaning, based on vocabulary and grammar, that allows the receiver to identify the referents and possibly to establish whether the statement is true or false), but also the *speech act* (i.e., the fact of expressing a proposition in a specific context, which conveys also speaker’s (or writer’s) beliefs, attitudes and commitments, possibly influencing the hearer’s (or reader’s) ones. Toulmin’s framework (2003), on the contrary, although it is widely adopted in research on argumentation in the context of mathematics education, seemingly pays very little attention to language and context.

As far as language is concerned, I adopt Halliday’s (2004) account of the relationship between scientific language and science and his Systemic Functional Linguistics (SFL) (Halliday, 1985, 2004; Leckie-Tarry, 1995; O’Halloran, 2005). Halliday, whose research is in the field of pragmatics started by Austin (1962), argues that there is no learning of science without some learning of its language (2004, p. 160). The adoption of the SFL framework is justified by the opportunity of focusing on the functions of language in mathematics education, where the needs for effective representations of concepts and their relationships and algorithms is unavoidably at odds with those of effective communication. Multisemioticy is an important feature too, as the interplay among verbal, figural and symbolic representations is stronger in mathematics than in other fields.

In order to analyze the protocols, I am using the idea of *register* as a linguistic variety related to use (Halliday & Hassan, 1990). An enlightening discussion on registers in an SFL framework has been provided by Leckie-Tarry (1995). Morgan (1998) and Ferrari (2004) have applied this idea to mathematical language. Any individual has at her/his disposal a range of registers that s/he uses according to circumstances. The most relaxed registers, used in spoken (but sometimes also written) everyday communication are classified as *colloquial*, while those adopted in written (but sometimes also spoken) communication among educated people, for example in institutional, educational, literary, research contexts are referred to as *literate*.

Colloquial registers, in short, are characterized by their strong dependence on the *context of situation* (i.e., according to Leckie-Tarry, 1995, the space and time in which the exchange takes place, the participants...), which allows participants to negotiate meanings and makes it unnecessary to produce accurate and unambiguous statements from the beginning. Literate registers are less related to the context of situation. In colloquial registers the meaning of words is mainly taken from previous

experience, and most often much precision is not required to achieve the goals of the exchange, whereas in literate ones words have precise meanings, based on definitions (the so called *lexicalization*). In colloquial registers syntax is customarily relaxed, while in literate ones it is tighter. In colloquial registers there is an extensive use of *iconicity*, i.e. the analogy between the form or organization of a representation and its meaning. Iconicity is opposed to *arbitrariness* and can involve factors such as order (the order of facts matches the sequence of the representations). In literate registers representations are less iconic and more conventional. As a consequence, the interpretation and production of texts and representations in colloquial registers are quite unstable, since they depend on factors difficult to control (how the subject is accustomed to use words, how s/he interprets images, the mental models s/he uses in place of the definitions, the personal experiences s/he tries to recall, ...). In literate registers, the lesser dependence on the specific situation, the reference to defined meanings (thus more objective and verifiable) and the role of syntax (objective and verifiable too) make the interpretation and production of texts more stable.

Even a quick analysis of what is described above should make it clear that most of the registers used in mathematical settings share the features of a literate register in an extreme way: in mathematical registers the interpretation of a text depends little on the context of situation in which it is produced. I am not referring to the processes of learning or communicating mathematics, but on the organization of mathematical texts, as they can be found in any mathematics textbook from primary to graduate schools. The dependence of mathematical language on the *context of culture* (any kind of systems of knowledge related to the participants and the topics of the exchange), on the contrary, is very strong (think of definitions, conventions, theorems...), as well as lexicalization and conventionality (there are not many other semantic domains where definitions play as important a role as in mathematics). The same holds for syntax: in a mathematical text, either symbolic or not, a minor variation (e.g., the displacement of a parenthesis or of a comma) can change its meaning. The interpretation of texts in mathematical registers is stable: in some cases it can be performed automatically. The use of colloquial registers is essential for learning as well: nobody could ever learn anything if s/he should use literate registers only. So, in learning mathematics the trouble is not the use of colloquial registers, but the failure to adopt literate ones when necessary.

## Methodology

A large number of argumentative texts produced by freshman students to justify their answers to problems involving the interpretation of graphs, both in examinations and in tutoring sessions (including online ones) have been scrutinized. In this paper I take into consideration only texts produced for one specific examination. To understand the argumentations it is necessary to regard them related to the problem-solving context they are produced within, considering the solutions produced as well. This study is not aimed at testing a particular model but rather at understanding the difficulties of a relevant number of students with different backgrounds, cultures, attitudes, and levels of competence, also in order to improve our teaching and tutoring strategies. For these reasons I have used a large number of protocols taken from a real examination, as most often the weakest students are not willing to take part in other activities, such as special tutoring sessions.

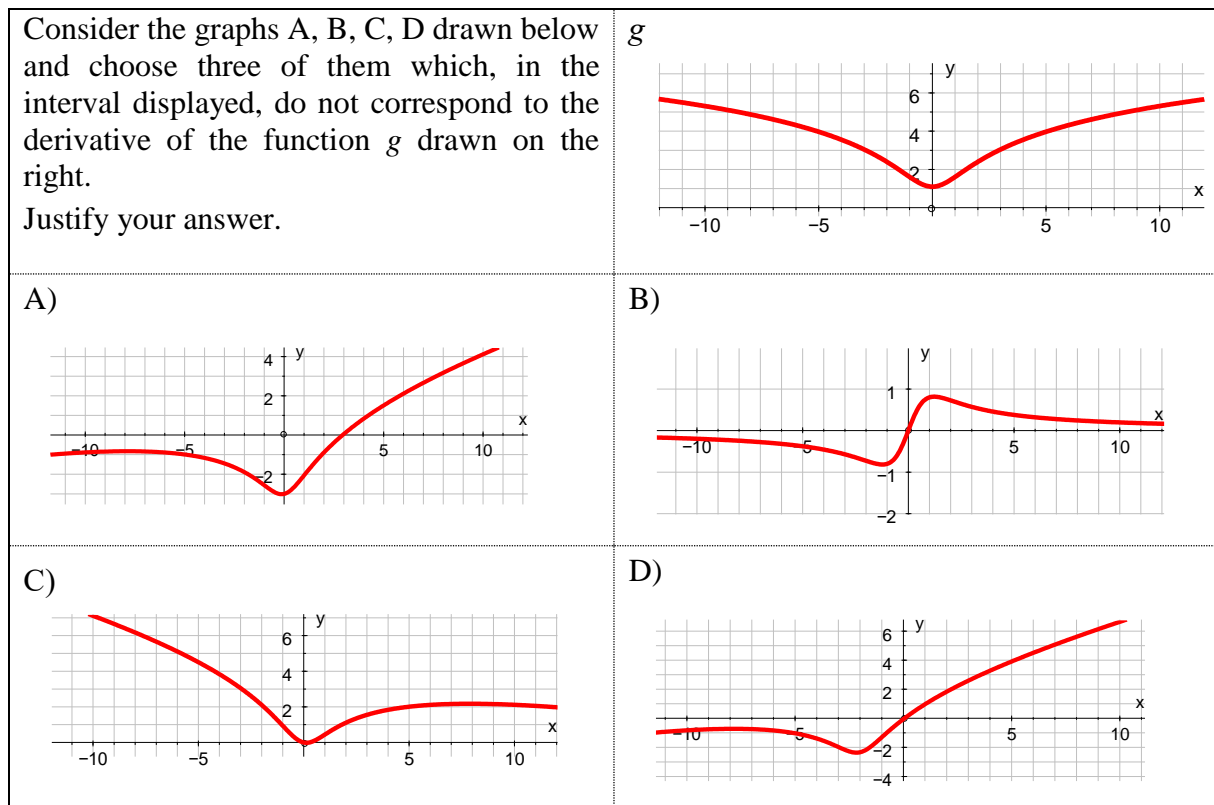

Some of the participants have been interviewed after the test. For each participant I tried to classify answers and errors, if any, such as: use of pseudo-rules or of mathematically inappropriate models, wrong reading of the data, miscalculations, and language errors. I have also classified the kind of text

produced (basically, the register adopted, by means of the indicators suggested by Leckie-Tarry, 1995) to see if and how linguistic competence might have affected the answers. In some of the excerpts both the original Italian text and an English translation are given. The kind of analysis I want to carry out does not allow me to refer to an English translation only, which, even if it may convey with fair approximation the ideational component of the text, unavoidably it cannot but fail in conveying other aspects of the text, such as register or improper uses.

It is never easy to understand whether an error depends on the language (e.g., a proper idea wrongly expressed), on contents (e.g., a wrong idea truly expressed) or on both. For example, the (wrong) claim that function  $g$  below is decreasing in  $[0, 10]$  might depend on a poor understanding of the definition, or on the improper use of ‘decreasing’, or even on a wrong interpretation of the graph. This in turn might be affected by the everyday use of the same words. The analysis of cohesive devices (i.e., the linguistic resources used to link the parts of the text), as carried out by Alarcon and Morales (2001) is a classical way to deal with argumentation in a SFL setting. In the analysis of the protocols, I have applied two criteria: the appropriate use of cohesive devices (contrasted to improper use or no use at all) and the vocabulary (lexical vs colloquial use of words).

## The problem

Here I focus on problems involving graphs, such as problems requiring to associate a formula to a graph, or a graph to a formula, or to link the graph of a function to the graph of its derivative. All the protocols (about 200) used in this study come from the following problem.

**Table 1. The problem**

The problem is in negative form, as participants are required to identify three graphs that do not correspond to the derivative of the function  $g$ . It is manifest that in a problem of this sort it is not

possible, from the scrutiny of the graphs only, to decide that a graph does correspond to the derivative of a given function. On the other hand, it is possible, in many cases, to decide that a graph does *not* correspond to the derivative of a function. Considerations of this kind hold for a great deal of mathematical problems involving graphs. The negative wording of the problem has proved a source of trouble although it explicitly refers to the need for excluding three graphs.

I have regarded as acceptable all answers excluding the three appropriate graphs with appropriate justifications, i.e. argumentations where the properties of  $g$  and of the graphs the answer is based on are explicitly mentioned. For example, a text like “ $g$  is increasing in  $(0, +\infty)$ , so its derivative must be positive in the same interval, so I exclude graph A, which is partly negative in the same interval”, has been considered a sufficient justification in order to rule out graph A, although the student has made no explicit reference to any theorem or rule. It is uncommon among freshman students to find explicit reference to some general property to justify an inferential step.

## Outcomes

Although this is not a quantitative study, I often give some quantitative indication about the size of the groups adopting some behaviors. It might be interesting, from a teaching perspective, to know if a behavior is adopted by a small group of students or it is more general.

Correct answers equipped with acceptable arguments usually range from 20 % to 40 %, according to the sample and the task. In this experiment correct answers have been a bit less than 25 %.

Student A02 marks the graphs A, B, D and gives the following argument:

“Non corrisponmono, perché  $g$  è in positivo mentre A, B, C sono sia in positivo che in negativo.”

[“Do not match, because  $g$  is in positive while A, B, C are both in positive and in negative.”]

The argument, which seems aimed at ruling out graphs A, B, C, is inconsistent with the marks on the diagram, which rule out graphs A, B, D. The argument adopted seems to fit graph D better than graph C, and one can imagine that the subject wrote ‘C’ in the argument by mistake. Errors of this kind are quite frequent. Second, the subject only deals with what s/he is looking at and makes no reference to mathematical properties connected to the problem, nor any attempt to link to each other the data s/he has mentioned. In other words, the argument is completely bounded within the context of situation, with no attempt to put it in a framework of knowledge, i.e., in a context of culture. Third, the text is inaccurate: the main verb has no subject, the expressions “in positivo”, “in negativo”, which are circumstantials of (spatial) location, are used in place of the more correct attributes (‘positivo’, ‘negativo’) and the expression “sia in positivo che in negativo” is vague.

Student A03 marks graphs B, C, D and produces the following argument:

“in  $x > 0$  la *fne* della derivata dev’essere positiva quindi non è sicuramente la B, in  $x < 0$  la *fne* della derivata dev’essere negativa (decrescente) quindi non può essere la D e la C non è sempre crescente nell’intervallo  $(0, +\infty)$ . Penso sia il grafico a.”

‘fne’ is an informal abbreviation for ‘funzione’ (function). In order to help reading, I translate it as the whole word.

["in  $x > 0$  the {function} of the derivative must be positive so surely it is not B, in  $x < 0$  the {function} of the derivative must be negative (decreasing) so it cannot be D and C is not always increasing in the interval  $(0, +\infty)$ . I think it is graph a."]

In this text some connection is hinted at but not developed, the student states (in her/his way) that the derivative must be positive for  $x > 0$  and negative for  $x < 0$  but s/he does not explain why. S/he seemingly identifies "increasing" with "positive" and (explicitly) "decreasing" with "negative", as s/he rules out graph B which is positive for  $x > 0$  but not increasing in most part of that interval. Moreover, s/he inconsistently does not rule out graph A, which is the only one with negative values for some  $x > 0$ . The identification of "increasing" with "positive" and "decreasing" with "negative" may depend on poor understanding of the subject matter, but most likely it has linguistic roots, as this student seemingly makes no distinction between the words and most likely s/he refers to everyday-life uses, according to which "positive trend" might mean "increasing trend".

Student A36 marks graphs A, B, C (with some erasures) and writes:

"La funzione tra  $[0, +\infty[$   $f(x) > 0$  quindi la funzione è crescente quindi la B non è crescente. *[erased words]* funzione  $g(x)$  è tutta positiva da da  $]-\infty, 0]$  è decrescente mentre da  $[0, +\infty[$  la funzione è crescente l'unico che cresce sempre di più è la D."

["The function between  $[0, +\infty[$   $f(x) > 0$  so the function is increasing so B is not increasing. *[erased words]* function  $g(x)$  is all positive from from  $]-\infty, 0]$  is decreasing while from  $[0, +\infty[$  the function is increasing the only one that always increases is D."]

The linguistic quality of this text is very poor. There is a bad coordination between the verbal and symbolic parts, the given function is referred to as ' $f$ ' instead of using its proper name ' $g$ ', the conjunction "quindi" ["so"] is used twice inappropriately, in the second occurrence to introduce some data taken from a graph. There are a number of erasures and repetitions, and some of the last clauses are linked neither by discourse markers nor by punctuation.

Student A39 marks graphs A, C, D and writes:

"Escludo la C perché nell'intervallo  $(10; 0)$ , la funzione decresce perciò la sua derivata dovrà essere negativa. Escludo la D perché la funzione è pari mentre il grafico D è dispari. Escludo la A perché la funzione  $g$  è crescente nell'intervallo  $[0; 10)$  e quindi il grafico A dovrebbe essere positivo mentre è negativo per  $x \in [0; 3]$ ."

["I rule out C because in the interval  $(10; 0)$  the function decreases so its derivative will be negative. I rule out D because the function is even whereas graph D is odd. I rule out A because function  $g$  is increasing in the interval  $[0; 10)$  and so graph A should be positive, whereas it is negative for  $x \in [0; 3]$ ."

In this case the choice of graphs is the correct one. Most likely in the expression  $(10; 0)$  the subject has forgotten to write the sign '-' before '10' (although other participants wrote reversed intervals too). The motivation to rule out D is inappropriate, for it would have been necessary to recall that the derivative of an even function, if any, is an odd function and that graph D does not correspond to an odd function but it is neither odd nor even). On the contrary, the subject proceeds by analogy ( $f$  even  $\Rightarrow f'$  even), missing the classification of graph A: s/he claims it is odd. Maybe s/he means that it is not even, but is misguided by the meaning of odd/even in the frame of integers.

Student A17 marks graphs A, C, D and writes:

“Non corrispondono i grafici A-C-D. Possiamo escludere il grafico C perché per esempio nell’intervallo  $(-10;0)$ , la nostra funzione  $g$  risulta decrescente mentre in quel tratto il grafico C risulta positivo (dovrebbe invece essere negativo). Possiamo escludere la A perché per esempio nell’intervallo  $(0;3)$ , la funzione  $g$  risulta crescente mentre il grafico A in quell’intervallo è negativa anzi ché positiva. Escludiamo anche il grafico D perché nella funzione  $g$  la concavità è verso il basso tra  $(1;5)$  quindi nello stesso intervallo il grafico dovrebbe essere decrescente mentre la D è crescente.”

[“Graphs A-C-D do not correspond. We can rule out graph C because, for example in the interval  $(-10; 0)$ , our function  $g$  results decreasing while in that stretch graph C results positive (it should be negative instead). We can rule out A because, for example in the interval  $(0;3)$ , function  $g$  results increasing while graph A in that interval is negative instead of being positive. We rule out graph D too because in function  $g$  the concavity is downwards between  $(1; 5)$  so in the same interval the graph should be decreasing, while D is increasing.”]

This excerpt underlines the difference between those who can use language in a mathematical setting and those who cannot. The text of A17 is not perfect, but language for her/him is a tool good enough to understand the problem, find a solution and justify it. The text is explicitly organized with conjunctions and discourse markers (“while”, “so”, “for example”, “instead”) and each statement is equipped with its own domain of validity (“...in the interval  $(-10; 0)$  ...”). The general properties the argument is based on are not explicitly mentioned, but the subject adds some remarks that highlight the connections between the parts of her/his argumentation and make it unambiguous (“... it should be negative ...”, “... while D is increasing.”). Although the subject does not write down some general rule or property, s/he underlines the critical points of her/his argumentation and uses language (including grammar) to organize and clarify her/his answer.

In the optional interviews performed in the week following the experiment, subjects A02, A03, A36 and A39 could not reconstruct their thinking and explain their answers. This is a general behavior: a great number of students cannot reconstruct the meaning of the text they have produced, even if they have it before them and are given time to read it with no pressure.

## Discussion

The protocols examined have been chosen as representatives of diffused patterns of argumentation. In particular, the lack or improper use of connectives and discourse markers (i.e., of cohesive devices) is a serious problem: the links between the clauses are not made explicit or are expressed in a vague and improper way; even if the subjects, while writing down, may have some nice idea in mind, the lack of an explicit and effective objectification through language, prevents them from reconstructing and developing it afterwards. Behaviors of this kind are common.

Some students (such as A02) seem not to be able to recall the necessary pieces of knowledge and work on the data of the problem by creating pseudo-rules (e.g.,  $g$  increasing/positive/even  $\Rightarrow g'$  increasing/positive/even). Models of this kind are very robust. It is possible that these models are consequence of the practice of not interpreting the text of a word problem in order to reconstruct the problem situation, but to search for keywords that might suggest the proper.

The difficulties mentioned above all increase the instability of the processes of interpretation and production of texts, which might explain some apparently inconsistent behaviors; an example is protocol A39: the student answers correctly and correctly rules out graphs A and C reasoning on the basis of known properties of functions; to rule out D as well, s/he properly focuses on the evenness of  $g$ , but, probably in the attempt to apply the pseudo-rule “ $g$  even  $\Rightarrow g'$  even” claims that D is odd; a number of students (more than 30 % of the sample in this experiment) correctly rule out A and C but use wrong or inconsistent arguments to rule out D too; the fact that in order to rule out D some ‘rule’ different from “ $g$  increasing  $\Rightarrow g'$  positive” is required is enough to trouble the subjects and induce them to provide wrong answers.

Although much research is needed to determine the exact role of language in argumentation processes, it seems to me that the outcomes of this study suggest that it cannot be disregarded at all, in spite of the fact that a number of current studies on argumentation do not take the role of language into account. On the other hand, SFL seems a promising framework to better understand students’ linguistic behaviors in a mathematical setting, disregarding neither the factors related to interpersonal communication nor those related to the specific features of mathematical language.

*Both language and objects seem to play an important role in mathematics learning. In our research, we focus on their interplay: How do language and objects support students' development of mathematical ideas? In order to develop a framework of 'talking with objects', we draw on three approaches. First, we adopt the idea from Bauersfeld that learning is a domain specific process. It is always bound to a very specific situation and context. Second, Aukerman's approach of re-contextualization supports our insight in the link between language and context. Third, Latour's Actor-Network-Theory helps us to better understand, how concrete objects take part in the process of constructing social reality in mathematics lessons.*

*Keywords: Language, objects, recontextualization, domains of subjective experience (DSE).*

## Introduction

Children are supposed to learn what a 'number' is or what we mean by 'addition'. The challenge of mathematics learning is to construct abstract mental objects that can neither be touched nor seen. Even if we cannot see the mathematical objects themselves, there is a lot acting and handling of and with concrete objects to be observed in everyday mathematics classes: Children write, read, and work with different concrete objects like bead frames, hundred boards or Dienes blocks. And they speak: They ask questions, explain their ideas and discuss about different mathematical interpretations. Obviously, both objects and language play an important role, when students are learning mathematics. Children and teachers use physical representations of mathematical objects in order to clarify what they are talking about and what they are referring to. These physical objects help to coordinate children's mathematical communication and their learning processes (Sfard, 2008, p. 147).

As mathematics educators, we see already quite clearly that language is an important aspect of mathematics learning. But how do objects come into play? And how do language and objects interact as means of representation? These questions lead our main research interest. In our research project, we intend to reconstruct mathematical learning processes with a special focus on the interplay of language and objects (Fetzer & Tiedemann, 2015). To begin with, we concentrate on primary school children who learn arithmetic in different German primary schools. We collect data in several schools so that we cover different social and cultural backgrounds and get an impression of our research topic that is as broad as actually possible.

Theoretically, our study is based on two main assumptions. First, we assume, together with many other researchers, that *mathematics learning is a social process* (Bauersfeld, 1988; Jungwirth & Krummheuer, 2006; Miller, 1986). Children do not construct abstract mathematical objects without any suggestions from their environment, but rather in permanent exchange with it. In processes of social interaction and collective argumentation, mathematical objects are constructed, negotiated, and clarified. In this sense, children create abstract mathematical objects on the basis of social

processes. But who are the players in these social processes? Usually, mathematics educators think of students and teachers as actors. However, concrete objects influence the ongoing interaction, too. And, in our opinion, it will mean missing important opportunities to support mathematics learning if we neglect them. Especially in primary classes, objects play an important role in the process of abstraction.

Second, we conceptualize mathematical abstraction as a process of *becoming aware of similarities in different experiences* (Skemp, 1986). According to that assumption, children have to grasp the similarities in different representations, which they encounter in the context of arithmetic. To make this clear, we can consider children playing with little game figures. Four are sitting in a train and two more are getting on. What do these little figures have to do with the drawing of a number line, with six fingers of our hands, with the arithmetical task “ $4+2$ ” written on a sheet of paper or with specific arrangements of didactical material in mathematics classrooms? (Compare Fig. 1)

**Figure 1: Different representations of  $4+2$**

In order to express what is similar in all those representations and to come to a social agreement on those similarities, children and teachers need language. It is a tool, which allows individuals to share their interpretations of reality with each other. They can express what they ‘see’ in a certain representation and can, in this way, develop a shared interpretation. Within that interplay of language and objects, children construct their concepts of addition or number. It is for that reason that children have to develop appropriate language skills in mathematics classes, i.e. that their language has to become suitable for describing similarities in different representations.

We present the theoretical framework that we have developed so far for our research project. It consists of three parts. First, we refer to Bauersfeld’s (1988) framework of domains of subjective experience (DSE). He points out that learning is a domain-specific process, i.e. that children’s mathematical constructions are always bound to the situation in which they were developed. Second, we focus on the aspect of language and our fundamental assumption that every linguistic utterance, how concrete or abstract its content may be, always refers to a context (Aukerman, 2007). Third, there is the question of objects and the role that they may play in the process of mathematics learning. In this regard, we refer to Latour’s Actor Network theory (ANT) (2005) which offers a new perspective on objects and their contribution to mathematical communication.

### **On domain-specific learning: Bauersfeld (1988)**

Bauersfeld’s (1988) approach of Domains of Subjective Experience (DSE) elaborates how individuals organize their construction of mathematical knowledge. He assumes that children do not organize their remembrance of experiences in a hierarchical way, but rather accumulatively in separate domains. Each experience is stored with reference to the very specific and complex situation in which it was made and, accordingly, in its own domain. These different domains of

knowledge are called “domains of subjective experience (DSE)”. They include their own meaning, language, actions and objects. To illustrate this approach, Bauersfeld (1983, p. 3) reports from Ginsburg’s (1977) work about eight-year-old Alexandria. She is not able to solve the task “ $8:4=$ ” which is written on a piece of paper. She only suggests 0 or 1 as possible solutions. But, surprisingly, she can solve another task without any apparent effort: “Imagine you have 5 dollars and there are four children. How many dollars will each child get?” In fact, this second task is more difficult from a mathematical point of view. So we might ask why Alexandria did not transfer the initial task “ $8:2=$ ” to the money-world herself. Why did she not solve it with reference to the domain that is obviously much more familiar to her? Bauersfeld’s answer points to an important characteristic of DSEs: They are not linked automatically. Thus, from Alexandria’s point of view, two different DSEs are affected which are unconnected up to now. In the paper-world, you have to cope with mathematical signs that are written on a piece of paper. In the money-world, you have to cope with banknotes and coins and think about buying attractive goods. Language, actions, objects, but also interests, motivations and feelings are fundamentally different in both DSEs. For that reason, Bauersfeld (1983, p. 6) doubts fundamentally, whether Alexandria regards the number word ‘eight’ which appears in both domains as the same at all.

According to Bauersfeld, mathematics learning can be understood as a process of constructing, deepening and connecting DSEs. However, how can those separate domains be linked? How does mathematics learning proceed? Bauersfeld (1983, p. 31) describes that individuals cross the borders of a DSE by trying, creating and negotiating. In order to link two different DSEs, they have to build a third DSE that exclusively aims at comparing the two already existing ones. Solely in such comparative DSEs, it becomes reasonable to develop a comparative language. In fact, it is this comparative language that allows students to talk about similarities, which they ‘see’ in different representations. This means that all parts of a DSE, including language and objects, can help children to link DSEs and to get access to abstract mathematical objects. In the following paragraph, we focus on the language at first.

### **On language and context: Aukerman (2007)**

Aukerman (2007) points out that it is quite misleading to talk about a ‘decontextualized’ language because no “text, and no spoken word, ever exists without a context” (p. 630). This approach puts the main emphasis on the content level of a linguistic utterance: Every utterance refers to a context, no matter whether this context is concrete or abstract, close or far, accessible to observation or only hypothetical. It is important to notice that Aukerman does not make any statement about the setting in which language is used or how language is used in it, but rather about the point of reference. Utterances in mathematics classes may be produced in many different ways, e.g. with gestures or not, with a parallel action or not, with pointing at something in the closer environment or not, etc., but they are all produced with the intention of talking *about* something. Subsequently, we always talk and listen to others with regard to a specific context. We think about a specific context and produce an utterance. We hear an utterance and interpret it against a background that we deem appropriate. Thus, no matter whether we are the ones who speak or the ones who listen, we relate every utterance to a context that we regard as adequate at that very moment. Aukerman (2007) refers to the process of connecting utterances with contexts as *recontextualization*. In the process of recontextualizing, speaker and listener have to agree to a certain extent on the context of their

conversation: What are we talking about? Thus, when students are expected to talk about mathematical objects, they have to re-contextualize their language and match it with rather abstract contexts. Seen from that perspective, the question is no longer, whether a student is able to decontextualize his or her language, but the question is whether students and teachers succeed in finding a shared context: Do their *recontextualizations* fit together sufficiently?

### **On objects as actors: Latour (2005)**

When students and teachers are negotiating a shared context for their constructions of DSEs, they can get help from concrete objects, which have a lot to offer. Objects as actors? This conceptualization appears to be unfamiliar at first sight. Nevertheless, we think that it can be very useful to adopt Latour's (2005) sociological proposal for accepting objects as actors in the course of action. According to him, they participate in the emergence of social reality.

Latour (2005) goes beyond the traditional understanding of the social, widens the perspective and redefines the notion of 'the social'. He takes a closer look on who and what assembles under "the umbrella of society" (p. 2). As a consequence, he defines sociology as „the tracing of associations“ and thus “reassembles” the social (p. 5). In his view, the social refers to any kind of networking: humans with humans, but also humans with any kind of things. Heterogeneous elements that are not necessarily social themselves associate in different ways. According to Latour, all these different associations create social reality. Thus, in his *Actor Network Theory* (ANT), he extends the list of potential actors in the course of action fundamentally and accepts all sorts of actors: “Any thing that does modify a state of affairs by making a difference is an actor” (p. 71). Consequently, objects *participate* in the emergence of social reality, too. In this sense, Latour asks for a broader understanding of agency. “Objects too have agency” (p. 63). They are associable with one another, but only momentarily. To say it with Latour's words, they “assemble” (p. 12) as actor entities in one moment and combine in new associations in the next one. Following Latour, there are no longer stable and pre-defined associations and actor entities.

Again, following Latour (2005), objects participate in the emergence of classroom reality. In fact, this is true for *all sorts* of objects: Paper and pencil, as well as manipulatives or even the bottle of water on the table. Should we as researchers in mathematics education not focus on a certain kind of object, on didactical material? From a theoretical as well as from a methodological point of view, we clearly deny that restriction. Just imagine that the bottle was open, and would drop. Not only the table, but also the paper would get wet, the pencil might fall on the floor. This would surely influence any process of social interaction. “Any thing” (p. 71), a human or non-human actor, might become associated with other actors in the course of action, but only momentarily. The association might be dissolved the next minute. However, in that very moment these actors, no matter who and what they are, contribute to the ongoing process of social interaction.

Looking through Latour's sociological glasses, we can see clearly that concrete objects do play a role in the emergence of social reality. This appears to be especially true for manipulatives and other didactical material. They participate in the negotiation of a shared context and, in this way, offer help in the social process of constructing and connecting DSEs. However, how *do* they contribute? Earlier research revealed different modes of participation that objects might take or have in ongoing classroom interactions (Fetzer, 2013). Our current research on the interplay of language and objects

goes one-step further. Now, we try to get hold of objects' contributions on the content level. In our opinion, their most important contribution is to offer various contexts for re-contextualisation from which students and teachers may choose. A short example that we could observe in a second grade class might illustrate this variety of possible offers. The students and the teacher talk about the question what *the* diagonal might be on their hundred board. On that special hundred board (compare figure 2), the numbers from 1 to 100 are covered with red and blue pieces of paper.

**Figure 2: Hundred board covered with red and blue pieces of paper**

Here are some of the offers that the students accept and express in linguistic utterances - always in association with the hundred board in front of the classroom:

- 1) "The diagonal runs from 10 to 91."
- 2) "The diagonal runs from one corner of the hundred board to the opposite one."
- 3) "The diagonal runs from one corner of a square to the opposite corner."

We see that the hundred board suggests a wide variety of contexts, which might be suitable for re-contextualization. Most important to us is the fact that those offers range from "concrete" to "abstract". Thus, on the one hand, objects support the opportunity to construct new DSEs because they make a very concrete offer. They are concrete in nature so that students can associate with them and refer to their rather concrete offer: The 10 is at the top right, the 91 is at the bottom left. On the other hand, they make offers that appear to be suitable for comparing. The hundred board has properties that other geometrical forms have as well. It is a square and in every square, "the diagonal runs from one corner [...] to the opposite corner." However, in order to grasp that similarity in different representations, you have to construct a DSE of a specific square at first and then a comparing DSE, which aims at comparing different geometrical forms. Those offers of objects may support the construction and connection of DSEs and may support the language development which goes along with it, too.

### **Integrating the concepts: Talking with objects**

According to Bauersfeld (1988, p. 178), the subjective realization of a mathematical object remains always bound to the context of experience, i.e. to the objects and language used in the situation of construction. This approach gives us a clue that we will understand mathematics learning better, if we concentrate not only on language or on objects but on the interplay of both. How do language

and objects interrelate in the process of mathematics learning? How can we talk with (the help of) objects? Aukerman's (2007) approach of re-contextualization and Latour's (2005) Actor Network Theory seem to be useful background theories to tackle these questions.

According to Aukerman, every spoken word in mathematics classrooms refers to a context and is re-contextualized by the recipient. In order to achieve a shared understanding, the interlocutors have to agree on the 'right' context. What can serve as a solid ground, which a linguistic utterance can be related to? At this point, objects come into play. According to Latour, humans and non-humans associate with one another and create social reality. In terms of mathematical learning processes, children and objects interact in the social process of learning. Objects make offers that students and teachers can accept and refer to in order to coordinate their mathematical communication. The "steely quality" (Latour, 2005, p. 67) is a solid ground that allows individuals to experience reality. Objects are not a mere tool in students' hands that can easily be manipulated. Objects are participants in their own social right and contribute to the ongoing classroom interaction: Objects make offers and students 'listen' to those offers. Students talk *to* objects, and become associated with one another. At this point students 'talk' together *with* objects in a combined action.

But how does that work? Objects are concrete in nature. Nevertheless, in their concreteness they prove to be not a limitation, but a chance for development of (mental) mathematical ideas. Indeed, objects offer a variety of possible contexts for re-contextualization ranging from concrete to abstract. Sometimes, objects may provide the context for very specific experiences. In these cases, objects can help to construct a new DSE or to deepen already existing DSEs. At this stage, students try to find words with which they can express the particularity of this specific context and to negotiate it with others. Language is probably the most important tool for such a negotiation: What do I 'see' in that object? What do you 'see'? In a second step, students have to become aware of similarities in different experiences. They are in permanent exchange with their social environment. They listen to as well as talk to and with participating actors. In doing so, they construct new DSEs that aim at comparing already existing DSEs. Again, objects profoundly contribute. They offer a context for comparisons: What do I 'see' as the same in different objects (or in different actions with objects)? What do you 'see' as the same? Where are differences? Do we agree? In this sense, objects help not only to coordinate mathematical communication, but also to develop language more and more. Students are challenged to match their language with a concrete experience at first and with a comparison afterwards.

On closer inspection, we see that objects are actors that students can talk *to* and talk *with*. In fact, objects contribute to the process of negotiating mathematical meaning. In most interactional situations, it is not only the child who is responsible for a linguistic utterance. Words are not the only means to negotiate mathematical meaning. Instead, students and objects often associate and convey a mathematical idea together. In these cases, the object actor takes over part of the act of re-contextualization (Fetzer & Tiedemann, 2016). Students talk together *with* objects. The boundaries between language and objects almost seem to merge.

## Discussion

The theoretical framework that we have sketched in this paper raises awareness of some aspects that are not new in mathematics classes, but that are new in our thinking about content-related language

use. When students want to express their mathematical interpretation of reality, they are not restricted to the words they have at their disposal. Thus, they can accept one of many offers that the objects in their close environment make. In this process of assembling, the objects achieve two things. They offer their help, but at the same time, they challenge the children to move further in their mathematical development and in their improvement of content-related language use.

For that reason, the framework does not only make us sensitive to the importance of objects in the process of language development, but it points in a direction that might be productive for our further research. We have not only to analyze objects that we use in mathematics classes, but we have to analyze children's associations with them, too. Which offers do the children accept? Moreover, how do these offers support their language development in mathematics classes? These are the questions, which will lead our further steps in that project about the interplay of language and objects.

# Occasions for productive interactions in inclusive mathematics classrooms that arise following mistakes

Uta Häsel-Weide

University of Paderborn, Institute of Mathematics, Germany;  
[uta.haesel.weide@math.uni-paderborn.de](mailto:uta.haesel.weide@math.uni-paderborn.de)

*When learning mathematics, mistakes can serve as productive occasions if a mistake is followed by a process of negotiation and insight. This paper addresses the question of the extent to which the informal occasion of a “mistake” leads to productive interactions in inclusive mathematics classrooms. Within the context of the project LUIS-M video-based qualitative analysis of cooperative learning situations in inclusive classrooms are made with focus on formal and informal occasions for productive interaction. In the paper the negotiation processes which follow mistakes are exemplified and discussed with respect to opportunity for learning processes.*

**Keywords:** Cooperative learning, discourse, interaction, inclusion, mistakes.

## Introduction

Learning mathematics requires interaction; cooperative learning leads to interaction. This is the hope which is associated with cooperative learning in teaching mathematics. Therein, learning is understood as a co-construction process in the context of social processes and/or interactions. As such, not only social learning objectives but also cognitive learning objectives are of importance in cooperative learning. From a mathematical-didactical point of view the epistemological learning processes based on the exchange of different interpretations are of interest (Steinbring, 2005).

Cooperative forms of learning also gain in importance in the context of fostering teaching, both for children with and without (mathematical) learning weaknesses. Meta analyses in the elementary school area prove that cooperative forms of learning and peer-supported learning show stronger effects with respect to subject matter performance than traditional forms of teaching (Rohrbeck, Ginsburg-Block, Fantuzzo & Miller, 2003). However, the effects are dependent on both the composition of the pairs as well as the degree of structure of the cooperative learning environment.

For the inclusive teaching of mathematics, the expectation being associated with cooperative learning environments is that children support and correct each other. Further it can be assumed that children with a lower learning performance develop their own interpretations due to the more elaborated interpretation of other children.

This report focuses on the question of in which way children's mistakes in cooperative learning settings of inclusive mathematics teaching can serve as an occasion for productive interactions. For this, transcribed interaction flows are analysed in the sense of a qualitative research paradigm, and theoretical insights are derived in an abductive process. However, before the research design and the results are presented, the essential theoretical foundations and empirical insights will be outlined.

## Theoretical and empirical starting points

### Cooperation and interaction in mathematics education

When students learn mathematics, they can benefit from sharing their ideas with their peers, especially when their peers have a different point of view. Several studies mention that differences between students' explanations and procedures can increase mathematical understanding and create new insights (Pijls, Dekker, & van Hout-Wolters, 2007). However, not every interaction leads to new insight, the interaction must take place in a productive discourse. Dekker and Elshout-Mohr (1998) work out that verbalising, explaining, defending, asking and arguing are key activities for productive learning processes. Cooperative learning situations seem to be suitable to make such key activities come up. It is expected that children associate ideas, discuss solution possibilities and discover mistakes when they work in small groups.

Especially, it seems to be productive to develop ideas collaboratively and to find a common way for problem solving. In these phases of cooperative learning a high frequency of communication can be observed and the interacting partners change within the group (Brandt & Tatsis, 2009). It can be assumed that the children show a high rate of key activities like verbalising, asking or arguing by sharing ideas. Therefore, the cooperative learning situation should be based on tasks and problems which allow a range of solution procedures, so that children *need* to verbalise and argue with their partner. This could be achieved when the problem is complex and the students do not have a routine which allows them to solve the problem easily (Dekker & Elshout-Mohr, 1998). Open problems, which allow solutions on different levels, can lead to many key activities as well.

In an epistemological view Nührenbörger and Schwarzkopf (2015) mention that it is helpful to use tasks which create a “productive irritation” concerning the experiences of the children. While working on the tasks the children discover something surprising which then becomes an amazing phenomenon. As a consequence, the children may provide phenomena that they do not expect, so that “they have to reflect on the given structures and see the need to re-interpret the experienced mathematics behind the problem” Nührenbörger et al. (2015). Activities like »comparing« and »sorting« can help initiate such processes e.g. when children reason about the criteria for sorting (Häsel-Weide, 2015). Only if children feel the need or the pleasure to share ideas, mathematical communication takes place.

In addition to the cooperation processes initiated through the cooperative learning technique, the tasks and the work assignment, mistakes can lead to interactions and discourse between children (Götze, 2014; Häsel-Weide, 2016). Götze analysed interaction processes of children in so-called “math conferences”, where the children share and discuss their solutions. She points out, that a suggestion of a wrong solution can induce an exchange of arguments and a verbalisation of prior statements - as such key activities take place, that are initiated by the incorrect solution. In my own study regarding the replacement of persistent counting strategies, the children verbalised different interpretations of a structure initiated by mistakes. This interaction had a productive effect and enabled new insights for some children (Häsel-Weide, 2016). The expectation, furthermore, is that non-comprehension or non-knowledge leads to questions and then, as a result, to explanations, and therefore moments of »gaps« and/or »helping« become productive.

## **Cooperative mathematics learning in inclusive beginners' classes**

Inclusive teaching always is in between the poles of common ground and individualisation. It is necessary to take the individuality of each child into account, his/her competences and difficulties, and to foster it individually. At the same time, inclusive teaching has the objective of joint learning, i.e., an objective of participating in content, of the joint learning of mathematics that goes beyond [just] being a part of a class.

In order for children to be able to work together on content, the learning environment must allow working on different levels. At the same time, a joint focusing on a core idea that can be worked on by all children and that is at the centre of the exchange is necessary. Concepts of cooperative learning furthermore recommend a significant methodological structuring as well as the creation of a positive dependency between the cooperating children, e.g. through role distribution, limiting of the material, or time allowances (Johnson, Johnson, & Holubec, 1994). As such, a field of tension exists between a limitation and a common focus for a successful outcome of cooperative processes and the enabling of working on an individual level. In addition, the mathematical competences and verbalising and presenting interpretations, as well as interpersonal competences such as a constructive dealing with conflicts that are necessary for the interaction and cooperation must first be learned.

## **Objective and design of the study**

In project “Learning environments for inclusive mathematics teaching –LUIS-M”, learning environments were developed for the entry phase of elementary school and tested in six classes of the first and second school year (children age 6 to 8). The focus in each class is on a cooperative learning environment which is processed in partner work and accompanied by other offers for individual and cooperative learning. Thematically, the learning environments pick up the basic mathematical topics, which means in the first and second school year the presentation of numbers and operations. Children with different competences in mathematics are supposed to interact and cooperate with each other. Two objectives are being pursued by this: in the spirit of mathematical didactics as a design science (Wittmann, 1995), learning environments are developed for and with teachers and scientific insights are gained via the analysis of the learning processes of the children. We are interested to explore if and how children work together, which different levels of understanding can be reconstructed, and which occasions during the cooperative learning lead to a productive interaction. In this paper the following questions are discussed:

How can aspects and moments causing a productive discourse be characterised? In what way do mistakes induce productive interactions?

The teachers were asked to choose pairs with different competences in order to work together. Two pairs were video recorded in each of the six participating classes. Chosen for the video were pairs of children where one child shows low mathematical competences. The corresponding transcripts were interpreted by a group of researchers. The analysis was compared in an interactive way with empirical findings of other studies and theoretical approaches. As a result, insights about the communication of children in heterogeneous groups could be constructed. This procedure allows the development of new theoretical elements analysing individual cases.

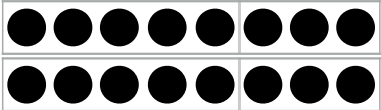

## Analysis of episodes

In the following two examples are presented and analysed where it was possible to reconstruct mistakes. Based on the interpretation of the examples, the theoretical conclusions are being worked out and subsequently presented, going past the examples. In this, analyses of additional scenes are included in the development of a theory.

### Case 1: Jana's incorrect interpretation of the dot-strip image

The episode is from the second school year and was recorded during the introduction to the multiplication tables. The children work in a learning environment that aims at comprehension of multiplication as repetition of equal groups, and the connection between addition and multiplication. The children lay out dot images with strips of two, four, and eight dots and interpret them additively and multiplicatively. For each dot image only one type of strip may be used. The children work focused on each other, i.e., one child lays out a dot-strip image and the other child states the matching addition and/or multiplication task. These are jotted down and then sorted in a second step. In this process the children can already recognise first relationships between the tasks.

In this scene, Kadir – in accordance with the assignment – lays out two strips of eight in the following dot-strip image. Jana is now required to state the task.

- |      |        |   |  |
|------|--------|---|--|
| 1    | Kadir: | <i>(lays out 2 strips of eight)</i>   |  |
| 2    | Jana:  | <i>(counts the dots individually). Sixteen.</i>   |  |
| .... |        |   |  |
|      |        | Okay, sixteen times two.  |  |
| 3    | Kadir: | <i>(lays his head on table)</i>   |  |
| 4    | Jana:  | <i>(laughs)</i> Sixty times two?  |  |
| 5    | Kadir: | Oh God! You can't read that. Five <i>(points to the first five dots of the strip of eight)</i> plus three <i>(points to the last three dots of the strip of eight)</i> two times the eight, oh God. |  |
| 6    | Jana   | <i>(notes down <math>2 \cdot 8</math>)</i>  |  |

In her first statement, Jana mentioned the total number of dots, “sixteen”, and the multiplication, “times two.” Since she determined “sixteen” dots by counting, she appears to link the number of dots with the operation in her phrasing. In this, she is phrasing a typical sequence of »number operation number«. Kadir – probably as a reaction to Jana's statement – lays his head on the table. Jana seems to interpret this as a sign that he considers her statement to be incorrect. She then corrects herself and states “sixty times two”. She does not change the structure of her statement, but rather the number.

Jana is able to determine the number of dots correctly and seems to know the sentence structure of a multiplicative phrase. Besides, she shows a behaviour that is typical for children with mathematical learning difficulties: She determines the quantity by counting in ones, but she seems to have difficulties to find a fitting multiplicative expression and to distinguish between the number words sixteen (“sechszehn”) and sixty (“sechzig”) (Anghileri, 1989; Gaidoschik, 2015).

Kadir's statement (5) makes it clear that he considers Jana's interpretation to be incorrect and furthermore shows that he is applying a different way of reading (“You can't read that”) the strips than Jana. As such, a disagreement exists between Jana's interpretation and his own. Kadir now interprets the dot-strip image himself and in the process phrases a matching multiplicative

interpretation. At first glance, this approach seems to be of little help. Kadir does not provide Jana with any indications how she can correct her interpretation, but rather solves the task himself. However, taking a closer look at his remark, it becomes apparent that he formulates two aspects that can be a learning opportunity for Jana in the spirit of co-construction.

First, he explicates a structured way of grasping the number of dots on a strip. Jana has determined the total number by counting them in ones. Kadir points out to Jana the power of five in the strips, because he separates the dots in the five dots on the left hand side of the mark and the three dots on the right. So he explicates the part/whole structure  $8=5+3$ . He demonstrates and verbalises an option of the structured grasping of the quantity. Through his gesture he additionally makes it clear that only the number of dots on one strip needs to be grasped since these are strips of equal magnitude. In the second part of his statement, Kadir formulates the multiplicative structure and phrases “two times *the* eight”. With the nominalisation, he emphasises the two elements “number of strips” (multiplier) and “number in each strip” (multiplicand).

Therefore, at second glance, it becomes apparent that Kadir is not only providing the correct result, but that there are opportunities of insight for Jana located in his verbalisation and his gesture. The key activities of verbalisation, explaining, and pointing out, described as productive by Plijs et al. (2007), can be reconstructed in the case of Kadir. He shows an understanding of multiplication and an elaborated strategy in the grasping of the quantity. His statement is caused by Jana’s solution, which he recognises as being incorrect, and which he introduces in the interaction. To what extent Kadir’s interpretations are picked up by Jana cannot be identified in this scene since Jana notes down the solution without it becoming apparent to what extent she is exclusively translating the verbalisation into a term or to what extent she can comprehend it with respect to the dot-strips.

## **Case 2: Marie suspects a mistake in Milene’s solution**

In the first school year, the children were given tasks to create “simple” subtraction problems with the subtrahends 1, 5 and 10. In this, the children freely select the minuend, by laying down corresponding dots in the field of twenty, draw an action card, »minus 1«, »minus 5«, or »minus 10«, solve the problem by removing the number of dots or mentally, determine the result and note down the problem on a card. After a while, the cards are sorted in accordance with self-selected criteria, which could be e.g. the minuend or the subtrahend or the size of the numbers. The relationships between the problems become apparent by sorting them, e.g. according to the minuend, the subtrahend, the difference or the size of numbers. So, on the one hand, the focus is on the basic topic of »simple subtraction problems«, on the other hand the structure between problems can be discovered and described. Both the activity of sorting, as well as the potential discoveries are suited to stimulate productive interactions. The step to find the problems can be worked on either individually by each child or the children work with distributed roles. In this case, one child specifies the minuend with dots while the other does the subtraction by taking away one, five or ten dots and notes down the term. Working while focused on each other allows for more cooperation between the children and for a direct reaction in case of erroneous solutions or questions, but also leads to a limitation of the individual level of processing.

Marie and Milene are working on the assignment with distributed roles based on the division of labour, i.e. one pupil lays out the minuend on the field of dots and draws the card with the subtrahend

(c.f. Figure 1); the other pupil finds the difference and notes down the task. Maria has already placed a strip of 10 and 3 chips on the field of twenty in the following way:

**Figure 1: Depiction of the assignment situation**

- 1 Milene: *(lifts away the third dot from the bottom row of the field of twenty)*
- 2 Marie: Now you have to guess how much that is
- 3 Milene: One, two. Twelve! *(looks at Marie, puts the chip back onto its original spot on the field of twenty)* So, and now I write down the assignment *(takes a piece of paper and a pen)*
- 4 Marie: *(4sec) (shakes her head)* You got this wrong, you misunderstood.
- 5 Milene: *(notes down the task  $13-1=12$  on the piece of paper)* Thirteen minus one equals twelve. *(places the piece of paper on the stack with the other tasks)*
- 6 Marie: *(5sec) (points with the finger to the dots)* That equals thirteen *(grabs Milene by the arm and points to the 3 dots in the bottom row of the field of twenty)*. That equals thirteen.
- 7 Milene: *(lifts away the third dot from the bottom row slowly once more, directly looks at Marie, and nods)*
- 8 Marie Oh *(turns away from the field of twenty)*.
- 9 Milene: Understood?

Milene, in accordance with the action card, »minus 1«, takes one dot away from the field of twenty, holds it in her hand and states the correct difference (1 & 3). She then places the dot back onto the field of twenty so that thirteen dots lie on the field once again. Marie voices the suspicion that Milene has made a mistake (4) and phrases “That equals thirteen” (6) which probably traces back to the thirteen dots lying on the field. In this situation, there is disagreement between the children.

Both pupils defend their interpretation in the further process: Marie grabs Milene's arm, maybe in order to be heard, repeats her interpretation, and points to the dots in the field of twenty. By taking away one dot, Milene seems to illustrate the operation »minus 1«, looks at Marie and nods and thus demonstrates that the difference of the task is twelve. The sequential carrying out of the actions corresponds to the process of subtraction so that Marie potentially recognises that the 13 dots represent the minuend, one dot was taken away correctly, and the difference of 12 dots was determined. However, due to the replacement of the dot (3) it was not the difference that was visible, but rather the minuend. Marie seems to be able – through the gesture of Milene (7) – to comprehend that the difference was determined correctly, nevertheless. Her statement “Oh” and her turning away from the task could be a sign of agreement and an acceptance of the result.

The suspected mistake with respect to the solution of the subtraction task leads to the connection between quantity, change, and result being demonstrated on the material. The trigger of this elucidation was the dissent between the interpretation of the 13 dots that Milene considered to be the minuend whereas Marie saw the difference in the field of dots. Here, the supposed mistake leads to negotiation and defence of different interpretations. Both children show key activities, pointing out

and verbalising their interpretations of the material. In this way, they appear to defend their respective point of view and to negotiate the correct interpretation.

### Interpretation and conclusion

Both scenes exemplarily show that mistakes and suspected mistakes can cause verbalisations, demonstrations, and defensive actions. If (supposed) mistakes are recognised in the interaction, they appear to not only be corrected but key activities also take place in the negotiations (Table 1). The children utilise, for example, the material to illustrate something, or (re)phrase it so that other aspects become clear. In this way, (supposed) mistakes function as a trigger for a productive interaction process. Therefore, it does not seem to matter whether a mistake was actually made or if this was only suspected. The children not agreeing in their interpretation – meaning that there is dissent – is of central importance. In this, two cases could be distinguished. (1) One solution is incorrect and this is recognised by the partner child who in the context of the cooperation has therefore solved the task himself (correctly). (2) A correct solution is interpreted as incorrect by the partner child. Here too, the partner child must solve the task herself. Prerequisite is, in this case, that both partners solve the task and arrive at different results.

Trigger	Prerequisite	Effect	
		Occasion for negotiation	Negotiation
(supposed) incorrect statements or approaches are being verbalised	recognising the (supposed) mistake in one's own / parallel solution of the task	verbalising the irritation / non-agreement	explaining, defending, demonstrating the point(s) by one (both) child(ren)

**Table 1: Productive interaction triggered by a mistake**

The activities in the negotiation are gestures and verbalisations which are utilised as justifications and defences. Properly formulated chains of reasoning are not observed in the inclusive beginners' classes. This could be because the children are not yet equipped with respective competencies or also because this does not correspond to the interaction of children among each other and requires a focusing and moderation by a teacher (Gellert & Steinbring, 2012).

Regarding inclusive mathematics teaching, it can also be assumed that the cooperation of children is productively becoming an informal learning occasion through mutual helping and correcting. The analyses show that children in the first and second school year not only take corrective action but also display key activities in their correction which can lead to learning processes for themselves and also potentially for the partner children. This, however, requires that mistakes are recognised during the learning process. Yet, this prerequisite does in no way always exist, not even when pairs of children with different competences work together. On the one hand, the children are in part simultaneously busy with their own tasks, while on the other hand even in case of working focused on one another not all mistakes are being recognised and explored. As such, it is not sufficient to trust in informal occasions. Productive interaction should rather be stimulated through suitable activities and through phenomena yet to be discovered.

# Revisiting the roles of interactional patterns in mathematics classroom interaction

Jenni Ingram, Nick Andrews and Andrea Pitt

University of Oxford, UK. [Jenni.Ingram@education.ox.ac.uk](mailto:Jenni.Ingram@education.ox.ac.uk)

*The ways in which teachers and students interact about mathematics in lessons can be more powerful in influencing learning than the materials and resources that teachers use. Interactional patterns structure all interactions and there are many such patterns that occur frequently in mathematics lessons. This paper focuses on one such pattern, the funneling pattern, which is widely discussed in the literature. Three distinct examples described in the literature as a funneling pattern are examined in order to examine the different roles sequences of closed questions can have and the opportunities these patterns can provide or constrains to students in the learning of mathematics.*

*Keywords: Interactional patterns, funneling, questioning.*

## Introduction

The aim of this paper is to contribute to the discussions around the roles different interactional patterns have in the teaching and learning of mathematics. The simplest, and most prevalent, pattern that is discussed widely in the mathematics education literature is the IRE pattern of teacher initiation, student response, and teacher evaluation (Mehan, 1979). Many authors describe this pattern as doing little to encourage students to reason, give explanations or articulate their thinking (e.g. Cazden, 1988; Nystrand, 1997). Yet the discussion has now moved on, with authors pointing out that it is not the IRE pattern itself that is the issue, but rather how it is used. This IRE pattern continues to dominate classroom interaction because it enables students to know when to speak, how to speak and about what to speak (Ingram, 2014; Wood, 1998). This pattern can be used by mathematics teachers to convey and establish different norms. It creates opportunities for students to communicate in classroom interaction, but it is largely teachers who can both constrain or enhance their students' opportunities to communicate mathematics or to communicate mathematically.

This paper focuses specifically on another interactional pattern called the 'funneling' pattern (Bauersfeld, 1980; Wood, 1998) that comprises of a series of IRE sequences. Four extracts that have many of the features of the 'funneling' pattern are discussed with a view to illustrating here that again it is not the pattern itself that focuses student thinking on "trying to figure out the response the teacher wants instead of thinking mathematically himself" (Wood, 1998, p. 172), but rather it is the way that it is used by the teacher that can affect student thinking.

## The funneling pattern

The funneling pattern was initially described by Bauersfeld (1980, 1988) and consists of a series of teacher questions and student responses that has particular features. The sequence follows an incorrect answer from the student, or some other form of difficulty with the mathematics. The teacher uses "more precise, that is, narrower, questions" (Bauersfeld, 1988, p. 36) to lead the student to the correct answer. This narrowing effect of questions towards a particular correct answer (hence the term funneling) contrasts with sequences of questions that leads students step-by-step through a process (e.g. Herbel-Eisenmann, 2000), however both invite students to do little more than complete the

teacher's sentences (e.g. Franke et al., 2009). These different examples have led to further terms, such as leading questions (Franke et al., 2009), guiding questions (Moyer & Milewicz, 2002) and scaffolding (Wood, Bruner, & Ross, 1976), becoming associated with funneling. The distinction between these terms and the precise relationship with funneling is often not made but we believe it is an important one as we outline below. As a result, funneling has become used more broadly in the literature to describe any sequences of IRE patterns that lead students through a series of specific narrow questions, often only requiring short factual response from the students.

Particular concerns have been raised about the implications of such funneling interactions. For example, Brousseau (1984) refers to the Topaze effect in which the sequence of 'funneling' questions disguise the mathematical knowledge that is being targeted by the interaction as a whole. Indeed such interactions in which students do not need think about mathematical relationships, patterns or structures in order to answer the teachers' questions (Wood, 1998) the most frequently cited instantiations of 'funneling' patterns. Wood (1998) argues that in funneling patterns of interaction students are only responding to the surface linguistic patterns in order to respond appropriately to the teacher's initiations. However, Temple and Doerr (2012) have shown how this aspect of the funneling pattern can be used by mathematics teachers to activate prior knowledge and offer them opportunities to talk about newly learned concepts. This indicates the possibility that the funneling pattern can have a variety of roles within the classroom, some of which support students' learning and communication of mathematics. Wood also connects funneling to "certain beliefs about the nature of mathematics and the relationship between teacher and students" (p. 175) but we would suggest that it is not the pattern itself that indicates these beliefs, but how it is used by teachers.

## **Data and methods**

The data used in this paper to illustrate the different functions of a funneling pattern of interaction comes from two sources. The first is transcripts from two videos of mathematics lessons collected as part of a larger project looking at the role and use of language in mathematics teaching and learning. Both lessons were from the same school, a small inner-city comprehensive secondary school with high levels of students in receipt of free school means and over 50% of the students with English as an additional language. The lessons are taught by two different teachers and the students are aged 11-12 years old. The second source is transcripts from a published article (Drageset, 2015) focusing on categorizing language use in mathematics classrooms that also uses conversation analysis as its methodology. A conversation analytic approach is taken in the analysis of the transcripts, which is an approach that focuses on the identification of patterns of interaction. Conversation analysis (CA) looks specifically at what participants are doing in their turns at talk through a careful analysis of how the turn is designed, both in terms of its content but also in terms of how it is spoken, i.e. quickly, hesitantly, emphasizing particular words. A key feature of any analysis based on CA is the reflexivity of turns at talk. Each turn is designed in response to the turns that it follows and affects the turns that follow. This makes it a particularly useful approach for examining the relationship between teacher questions and student responses.

## **The roles of funneling**

In this paper we will outline three distinct patterns of interactions described in the literature as funneling. The first is used by the teacher to make assumed knowledge publicly available. The second

offers students the opportunity to use recently introduced vocabulary. The third involves two extracts that are used in combination to draw attention to structures within a sequence of mathematical interactions.

### Making assumed knowledge publicly available

The funneling pattern of interaction does not occur very often in the lessons collected as part of the larger project, which contrasts with other studies looking at mathematics classrooms (e.g. Temple & Doerr, 2012; Franke et al. 2009). Yet using a conversation analytic approach in the analysis of this pattern reveals that each instance of the pattern is doing different things. For example, in the first lesson the students have discussed the meaning of some key words on the whiteboard associated with probability. The extract in Figure 1 follows this discussion and then is followed by an activity where students are tossing a coin twenty times and then combining the results. No connection is made between this interaction and the tasks that came before it or after it.

T: ...lovely. so what would be the probability of rolling an e:ven (.) number. how many e:ven numbers are there? s1 (0.4) how many even numbers are there (0.3) o:n a: dice.  
(1.1)

S1: u:m ↑three  
(0.6)

T: what are the total (0.4) numbers on a dice?  
(0.5)

S2: six?  
(0.8)

T: okay so the probability (0.6) of rolling an e:ven number would be what,  
S3: three sixths.  
(0.9)

T: pardon  
S3: three ... or [a half]  
S4: [half. ] a ha[lf]  
T: [thr]ee sixths. (1.2) which you're quite right i:s a half. (1.9) okay are we happy with that? are we ha:ppy with how to find the probability of an event.  
S: ye::[a[h ] ]  
S: [yeah]  
T: [(beautiful)] okay. ...

### Figure 1: Calculating the probability of getting an even number

See Jefferson (2004) for details of the transcript conventions used here

The teacher asks a series of questions requiring short factual answers, which are given by the students. These questions lead the students through a step-by-step process for calculating a probability. The fact that these responses are given hesitantly, as indicated by the pauses, ums and phrasing the response as a question, is ignored by the teacher. The sequence of questions focuses on the identification of the numerator and the denominator when identifying the probability and this is emphasized through the teacher's choice of accepting the answer three sixths rather than the half, which is acknowledged but not treated as the answer to the probability of rolling an even number.

The interaction ends with the teacher checking that the students are happy with this process and treating them as such by moving on to the next task. Yet there is little in the interaction to indicate that the students as a whole could calculate the probability themselves. This is a feature of the funneling pattern that Wood (1988) draws attention to: that it can give the impression of learning even though it is the teacher that has done the cognitive work. However, what the teacher has done through this interaction is explicitly to make the process public and has involved the students in this process (as opposed to just telling them how to calculate the probability). The ability to calculate the probability of an event is taken as assumed knowledge in the following task where the students have to calculate the relative frequency of getting a head when tossing a coin. So, whilst there is no evidence that the students are doing more than responding to the immediate initiations, the funneling pattern of questions and responses does make public knowledge that is needed later in the lesson. So the teacher's questions are doing something other than just assessing whether students have the required knowledge. This is demonstrated further in other examples where incorrect responses are ignored such as the second student's suggestion of larger in the second extract (Figure 2), which comes from a lesson focused on solving linear equations.

### Opportunities to use terminology

The majority of the lesson on linear equations is spent with students working independently through a set of differentiated exercises. At the start of the lesson a student asks a question about the difference between an expression and an equation and the extract follows this question. Again, the teacher leads students through a series of closed questions requiring short factual responses from them. This example shows the teacher using questions that offer students opportunities to talk about newly learned concepts and new terminology in a similar way to the example offered by Temple and Doerr (2012). The questions serve to support the students in recalling processes and words introduced in previous lessons such as simplifying and collecting like terms. Each use of a technical word is connected to the specific example,  $3x + x$  becoming  $4x$ , and  $3x + x = 4x$  being an expression is contrasted with  $4x = 12$  being an equation. Throughout the interaction student responses that do not fit with the use of the language the teacher is focusing on are ignored or built on by the teacher who turns them into a form that does fit. This sequence of questions again is doing other than assessing students' knowledge. The questions are providing students with the opportunity to use mathematical terminology and hear it used in a mathematical way by the teacher. This sequence could be considered a form of scaffolding (Wood, Bruner & Ross, 1976) if the support the teacher is giving, through his questioning and phrasing of his responses, is withdrawn over time until the students are using the language in their own descriptions of their work on mathematical tasks.

T: ...wha- I mean what process, what mathematical process essentially has,  
has S1 demonstrated here by doing three ex and ex

S1: addition.

T: addition. and in which case what's happened to that expression.

(1.0)

S1: i[t's been answered]

T: [it's become, ]

(0.5)

S2: ↑larger

(1.5)

S3: um

S5: °it wha[t° ]

S4: [simpli]fied.

T: ↑simplified. absolutely S4. you've got three ex plus ex, (0.8) we've si:mplified that. by collecting our,

(0.9)

S: like [terms].

S: [terms]

T: like terms good. and we've managed to say three ex plus x has become fou:r ex. so that's simplified. but it's ↑still an expression. (1.2) whats- how can I turn this fou:r ex here, how can I turn that four ex from an expression (.) into an equation.

S: make x three.

(0.7)

T: right, so if I make ex three, four times three would be twelve. that's still an expression.

(2.0)

S6: give er: would it be give what ex i[s ]

S7: [↑oh] take away  
the e[x and ((inaudible))]

T: [so (.) go on then S8] hang on

S8: would it u:m you would do ex equals, °you would- can't remember°

T: so (0.6) if I did four ex equals: (2.8) twelve?

S: yeah

(0.9)

T: that's no:w (.) an equation.

**Figure 2: The difference between an expression and an equation**

### **Drawing attention to regularities**

The last two transcripts are taken from Drageset (2015) and have been coded as “closed progress details” which is one of the “main elements of funneling” (Drageset, 2014). In each extract the teacher takes a step-by-step approach in posing questions and students are only required to give short factual responses to the question asked immediately before:

Teacher: How much is one of... one-fifth then of ... of twenty-five?

Student: Five.

Teacher: It is five, yes. How much is two-fifths?

Student: ...ten.

Teacher: Then it becomes ten. How much is three-fifths  
 Student: Fifteen.  
 Teacher: How much is four fifths?  
 Students: Twenty.  
 Teacher: And how much is five fifths:  
 Students: Twenty-five.  
 Student: One whole.  
 Teacher: One whole, yes. Yes, good. Great.

**Extract 1: Extract 1 from Drageset (2015, p.260)**

Teacher: Yes. So if I have thirty chips here and then divide them into six equal piles, then how many are there in each pile then?  
 Student1: There are five (hold up five fingers).  
 Teacher: Five. But how much is two-sixths of thirty, then?  
 Student2: Ten.  
 Teacher: Ten. How much is three-sixths?  
 Student2: Fifteen.  
 Teacher: And four sixths?  
 Student2: Twenty-five.  
 Student1: Twenty, twenty  
 Teacher: and f...six sixths?  
 Student 2: Thirty.  
 Teacher: Yes. And... six sixths, how much do I have then?  
 Student2: One whole.  
 Teacher: One whole. And then, this time the entire quantity was?  
 Student2: Thirty.  
 Teacher: Thirty yes.

**Extract 2: Extract 5 from Drageset (2015, p. 265)**

Extracts 1 and 2 are not just narrowing sequences of questions, but are also specific, structured, and lead to a mathematical regularity within the sequence of questions itself. It is also the repetition of the pattern of interaction itself that offers students an opportunity to see the relationship between the fractions and the quantities. This is pointed to by the teacher in their penultimate turn with the phrase “and then, this time”. So, whilst the teacher does not explicitly talk about the meaning of ‘one whole’ the sequence of questions identifying each of the fractional parts goes in order, and stops when one whole is reached. The teacher does not ask what seven sixths is, and also does not stop at four sixths

for example. In both extracts the total number, twenty-five and then thirty, is said alongside one whole. The sequence of closed questions is leading students through a process in a similar way to the example offered by Herbel-Eisenmann (2000, p. 182). However, it is also the repetition of the sequence that makes this process more explicit and affords students' attention to be drawn to it.

## Conclusion

In this paper we have explored three different interactional patterns referred to in the literature as a type of funneling pattern: one example of a narrowing pattern, one example of step-by-step pattern, and one example of connected step-by-step patterns. Each pattern includes a sequence of closed questions requiring short factual responses from the students. Each sequence is leading the students to a particular answer. However, we question whether the mathematical knowledge is always being disguised (c.f. Brousseau, 1984). Each pattern is doing something different to the other patterns and, in the final example the repetition of the pattern itself can be used to support the students' thinking. We have shown the possibilities for how teachers can use these sequences of questions to make assumed knowledge publicly available for subsequent work, offer opportunities to use technical vocabulary, and perceive regularity in mathematical processes. Each of these functions is an important part of the teaching and learning of mathematics. Whilst in each of the examples offered it is the teacher who is controlling the content, it is possible to imagine situations where the teacher is using a similar sequence of closed questions about a student's idea. The funneling pattern can and does have a role in the teaching and learning of mathematics but it is how it is used, rather than the structure of the pattern itself, that can offer or constrain opportunities for students to engage in mathematical thinking and communicating.

# Constructing mathematical meaning of the cosine function using covariation between variables in a modeling situation in Cabri

Faten Khalloufi-Mouha

Faculté des Sciences de Bizerte, Université de Carthage, Tunisia; [fkhalloufi@yahoo.fr](mailto:fkhalloufi@yahoo.fr)

*Many studies argue that dynamic features of the technological artifact Cabri may function as instruments of semiotic mediation. Our study is situated in this perspective and aims to analyze the impact of the artifact Cabri on the construction of the mathematical meaning. Using the theoretical approach of the semiotic mediation, a teaching experiment was designed with the aim of introducing the notion of trigonometric function as a covariation. Assuming that the use of a semiotic system in social interaction as the natural language contribute to the emergence of internal process (such as concept formation), this paper analyses the verbal signs elaborated and used by the students and the teacher in order to describe the evolution from students' personal meanings to mathematically shared meanings of the trigonometric function cosine.*

**Keywords:** Verbal signs, semiotic mediation, covariation, collective discussion, Cabri.

## Introduction and research problem

The notion of trigonometric function is related to three mathematical domains: trigonometry, algebra and function. Understanding the idea of a trigonometric function requires students to realise the relationship between the length of an arc and the measure of the angle that is subtended by the arc, the relationship between the real line and the unit circle, the covariation between a point moving on the unit circle and its projection on one of the axes, and the idea of the graph of a function (Khalloufi-Mouha, 2009, Khalloufi-Mouha & Smida, 2012).

From a historical perspective, the idea of the functional relationship between the real line and the unit circle is related to the notion of motion as a variation in the space and time. (Falcade, Laborde & Mariotti, 2007) So, this idea could be understood from a dynamic perspective, referring to the wrapping of a line around the unit circle and to the variation of a moving point. Many studies (e.g., Laborde, 1999; Laborde & Mariotti, 2002) claim that the key to understand the dynamic aspect of function is the notion of trajectory. According to Laborde (1999) the graph of a function could be considered as the trajectory of a moving point, representing the dependent variable according to the variation of a variable point on the axis of abscissas, so, the covariation of these two points becomes a relationship between two variations depending on time. Adopting a teaching approach based on the idea of covariation in the semantic field of space and time, Laborde et al. (2002) and Falcade (2006) assume that the teaching and learning of the notion of function should start in a dynamic environment. They claim that the use of Cabri allows access to the ideas of variation, functional relationship and covariation through the movement of a point on the screen. According to the Vygotskian (1978) perspective of semiotic mediation, Laborde et al. (2002) and Bartolini Bussi and Mariotti (2008) argue that some of Cabri's features can be viewed as potential tools of semiotic mediation carrying mathematical meanings. Cabri's tools can be thought as external signs referring to a specific mathematical meaning, and may become tools of semiotic mediation Laborde et al. (2002).

Following these studies, we propose a teaching experiment integrating the technological artifact Cabri, aiming to introduce the trigonometric function cosine as covariation.

## Theoretical framework

According to Vygotsky (1978), human intelligence is defined by the ability to use various types of tools with signs playing the role of mediators. Vygotsky distinguishes between tools (technical tools) and signs (psychological tools). Tools are externally oriented and aimed at controlling the process of nature. Signs are internally oriented and aimed at mastering the individual's behavior and cognitive processes. Vygotsky claims that, through the process of internalization, a tool may be transformed in a sign, and then may function as a tool of semiotic mediation. Vygotskian theory supposes that the development of behavior and cognitive processes is the product of activities practiced in the social institutions of the culture in which the individual grows up. For Vygotsky, language is the most important semiotic mediator allowing the passage from the interpsychological level to the intrapsychological level. The theory of semiotic mediation (TSM), developed by Bartolini Bussi and Mariotti (see, for instance, Bartolini Bussi & Mariotti, 2008), is situated in the Vygotskian perspective. Two key notions support this theory, the *zone of proximal development* and the *internalization*. Vygotsky introduces the concept of the zone of proximal development as “*the distance between the actual developmental level as determined by independent problem solving and the level of potential development as determined through problem solving under adult guidance or in collaboration with more capable peers*” (Vygotsky, 1978, p.86). This concept models the learning process through social interaction. In fact, the collaboration between one individual, whose cognitive attitude has the potential to facilitate change, and another individual (or group) who intentionally cooperate to accomplish a task or to pursue a common aim may generate a possible development (Bartolini Bussi & Mariotti, 2008). The transposition of this concept in the school context is possible thanks to the intrinsic asymmetry of the relationship between students and teacher in terms of knowledge. Therefore, the teacher's actions should be within this zone for achieving a didactic objective through the use of the signs and tools as semiotic mediators. In this zone of proximal development, cognitive development is modelled by the process of internalisation.

According to the TSM, the social use of an artifact in the accomplishment of a task leads to the emergence of signs expressing students' personal meanings, i.e. “*the conscious sense created by each individual to express the direction of his or her action*” (Bartolini Bussi, 1998, p.69). The evolution from personal meanings towards mathematical meaning, i.e, what describes the properties of the concepts under scrutiny inside a system of theoretical knowledge (Bartolini Bussi, 1998, p. 81), is an educational aim that can be realized promoting the evolution of signs, expressing the relationship between artifact and tasks, into signs expressing the relationship between artifact and knowledge (Bartolini & Mariotti, 2008). The teacher can guide this evolution through collective discussions.

## Rationale for the teaching experiment

Our teaching experiment aims at constructing the meaning of the cosine function and of its graph using the notion of covariation (Khalloufi-Mouha & Smida, 2012.) The experiment has four parts. The first two parts use the situation *A rope on a wheel* (Genevès, Laborde & Soury-Lavegne, 2005), which is a modelling situation in Cabri: a thread that can be wound around a wheel through the Dragging tool. The experiment involves description and prediction tasks intended to provide students with opportunities to realise that in the unit circle the length of an arc is equal to the measure (in radian) of the angle that it subtends. In addition, wrapping the thread on to the wheel aims to make students construct, for a given real  $x$ , the point M on the unit circle with the arc  $\widehat{IM} = x$ . Thus, they

could realise the functional relationship between the real line and the unit circle. Mathematically, this relation is interpreted by the existence of a surjective group homomorphism between the set of real numbers and the unit circle. Throughout these activities the role of the teacher is crucial. He has to establish strategies fostering the development of meanings of functional relationships and variation. The third and fourth parts of the experiment aim to analyse how the Dragging tool, the Measurement tool, and the Trace tool function as semiotic mediators for the ideas of variation, the functional relationship and covariation. The cosine function is introduced as a relationship between two variations depending on time, and its graph as the trajectory of a moving point.

The teaching experiment involves different typology of activities aimed to develop different components of the complex semiotic process: working in pairs and collective discussions generally initiated and guided by the teacher. When working in pairs, students use the artifact to accomplish the given tasks. This type of activities promotes social exchange through the use of verbal signs (both oral and written), gestures, drawing... Consequently, this provides students with opportunities to construct personal meanings linked to the mathematical target concepts. Students' personal meanings may evolve to the shared mathematical meanings through collective discussions. These discussions involve all students and allow the confrontation between their personal meanings and the mathematical meanings. These collective discussions may reach the status of mathematical discussions, in the sense of Bartolini Bussi (1996), and can also involve phases of institutionalization (Brousseau, 1998) and the introduction of new formal notations. The analysis of the verbal signs used by the students and the manner in which the teacher exploits them can highlight the evolution process from the students' meanings towards mathematical meanings. According to the TSM, the status of the signs belonging to the different categories vary in the evolution process, they can be used as an index of the move from personal sense to mathematical meaning. (Bartolini Bussi & Mariotti, 2008).

## Methodology

The sample of this study consisted of 16 students from a class of 2<sup>nd</sup> year (16-17 years) in a high school in Bizerte, Tunisia. The students were familiar with analytic trigonometry and they regularly used computer software in class. The teaching session was carried out in the computer laboratory. Students were grouped in pairs and asked to produce a shared written answer on a worksheet. The discussions within pairs and the collective discussions have been audio-recorded.

The analysis is based on several kinds of data that were collected: protocols produced from the student working in pairs (audio-recording, texts, and drawings), audio-recordings of collective discussions and the teacher's and observer's notes.

The impact of the use of Cabri on the construction of mathematical knowledge was analysed by identifying the development of the students' and the teacher's verbal signs related to the target mathematical concepts. We distinguish the two types of signs identified by Falcade (2006): simple signs and complex signs. Simple signs are "*easily recognizable by representations of almost atomic type (words or specific formulations)*" (p.202). For example, the word "circle" is a simple sign. Amongst the simple signs Falcade (2006) distinguishes three types, i.e. artifact-signs (arising directly from the use of the artifact, their meanings are personal and commonly implicit. The artifact-signs are strictly related to the use of the artifact to accomplish the task), mathematical-signs (referring to the culture of mathematics and constitute the goal of the semiotic mediation process.), and pivot-signs which play a pivotal role between the semantic and mathematical fields. "The characteristic of these

signs is their shared polysemy, meaning that, in a classroom community, they may refer both to the activity with the artifact; in particular they may refer to specific instrumented actions, but also to natural language, and to the mathematical domain.” (Bartolini Bussi & Mariotti, 2008).

The complex signs refer to relationships between families of relatively ‘simpler’ signs. For example, the sentence “the set of points that are equidistant from a given point” is a complex sign that refers to the mathematical-sign circle. Complex signs are subdivided into four categories: characterisations, definitions, interpretations and instantiations. Characterizations tend to highlight some characteristics that could be interpreted in mathematical terms. Nevertheless, characterizations are not real definitions because in the mind of the speaker the statement is not precise. A definition for an object provides a "boundary in words" which was until then unknown or little known. They are not definitions in the mathematical sense, but can be considered as being part of the process towards a mathematical definition. The interpretations concern explicit links between two families of signs which belong to two different semantic fields. Instantiations are signs which concern the establishment of an interpretative link between artifact-signs and mathematical-signs. Falcade (2006) elaborates that “Instantiations are of the same nature as the interpretations. However, the latter concern universal, while instantiations refer directly to the specific activity in Cabri” (p.210).

In our analysis of the development of students’ and teacher’s verbal signs, all the relevant mathematical notions and all the different signs used were identified. The classification of Falcade allows us to analyse the development of students’ personal meanings. Every evolution from an artifact-sign to a pivot-sign will be interpreted as a step towards the construction of personal meanings. The use of complex signs of the type characterization or instantiation will be interpreted as an attachment to the artifact. The use of the complex sign interpretation will be interpreted as a step in the process of semiotic mediation. Finally, the complex sign definition will be interpreted as a step in the process of internalisation of a mathematical definition of the object.

## Findings and discussions

The first two parts of the teaching experiment focus on the situation "a rope on the wheel".

**Figure 1: The situation *A rope on the wheel***

From the first task, when working in pairs, students used a large number of artifact-signs related to the ideas of motion and numerical domain, such as "to unwind", "to turn", "to move", "to increase",

and "to decrease". For some students, we identified initial pivot-signs related to variation such as "to change" and "to vary", and related to the meaning of functional relationship such as "depends on" and "being a function of". The pair discussions indicate that the use of the artifact facilitated students' use of complex signs of the instantiation type: "If the length of the arc changes, the point N will change", and of the interpretation type: "Then the length of the arc varies as a function of the angle". These complex signs show the construction of personal meanings of the relationship between the length of an arc, the measure of the angle and the radius of the wheel. The collective discussions initiated by the teacher led to the use of these signs in the process of constructing mathematical meanings. The role of the teacher was crucial in the collective discussion. Taking into account individual contributions, the teacher engaged students through juxtaposing their personal meanings, and encouraged them to disregard the artifact and then to focus on the mathematical concepts.

The second part of the experiment aimed at exploring the metaphor of the winding of the real line around the unit circle. During the working in pairs, we observed artifact-signs such as "put the point", "move the point", and pivot-signs as "length of the arc". This characterizes a first step related to the recognition of the numerical and geometric variation. Students used also mathematical-signs "For every  $x$ , we can construct a point" and interpretations of the functional relationship between the real line and the unit circle. This can be interpreted as a second step: the identification of the covariational relation at a perceptual level. During the collective discussion, the teacher used the rope as a semiotic mediator to introduce the idea of the functional relationship between the set of real numbers and the points of the unit circle. The collective discussion highlights the use of mathematical-signs such as "for every real  $x$  in ..", "symmetry", "absolute value" and "a function of". In addition, we also observe an interpretation of the idea of the functional relationship: "For every positive real  $x$  we can construct a point on the unit circle". It seems that students found themselves in a familiar mathematical environment and had no difficulties in generalising the use of the artifact. They were engaged spontaneously in the intended process of mathematical meaning construction.

### **A definition of the cosine function**

The third part of the teaching experiment focused on the ways the Cabri-tools Dragging, Measurement and Trace function as semiotic mediators for the development of the definition of the cosine function as a covariation, (i.e. the relationship between two variations depending on time), and the construction of its graph as a trajectory of a moving point.

Students were asked to construct a point  $N$  on the  $x$ -axis  $(1,0)$  with abscissa  $x$ . Using the Measurement tool, they should then construct the point  $M$  of the unit circle such that  $\widehat{IM} = x$ . Finally they should construct the point  $K$  on the  $x$ -axis  $(1,0)$  with the same abscissa as  $M$ , and the point  $H$  on the  $y$ -axis  $(0,1)$  with the same ordinate as  $M$ . Using Dragging tool, students were asked (a) to describe the relationship between the points  $N$ ,  $M$ ,  $H$  and  $K$  when  $N$  is moving, (b) to determine the values taken by the abscissa of  $M$  when the point  $M$  is moving on the unit circle and (c) to identify the relationship between  $x$  and the abscissa of  $M$ .

**Figure 2: The figure related to the third part of the teaching experiment.**

The evolution of the verbal signs elaborated and used by the students and the teacher attest the existence of four steps towards the definition of the trigonometric function cosine.

### **1<sup>st</sup> Step: Recognition of numerical and geometric variation**

The use of the artifact to accomplish the task promoted the emergence of verbal signs related to the idea of motion. The first step is characterised by an important use of artifact-signs stressing the attachment to the activity with the artifact. In fact, students used verbs of action as “to move”, “to vary”, “to turn”, “to change”.... and used expressions as “we draw the point  $M$  on the unit circle and we move it” or “we can choose different values for  $x$ ...”

### **2<sup>nd</sup> Step: Identification and recognition of covariation at a contextual level**

This step is characterized by the emergence of complex signs “interpretation” linking two variations. In these signs the reference to space and time was eliminated and we noticed the use of expressions related to the indirect variation and to the simultaneity of variations such as “When  $X$  varies then  $Y$  varies” or “If  $X$  varies then  $Y$  varies”

### **3<sup>rd</sup> Step: Interpretation of covariation as a functional relationship.**

This step is characterized by the use of pivot-signs “depend on”, “a function of” and “relation between” to replace the expressions “When  $X$  varies then  $Y$  varies”. Students identify the functional relationship as a relation between two variations. This was interpreted as an evolution of students’ personal meanings related to the notion of function.

In the collective discussion the teacher used the artifact to promote the emergence of the students’ simple and complex signs related to the ideas of functional relationship and covariation “ $T$ : Well. Now what is going to change if you move  $N$ ?” The artifact is used as a semiotic mediator supporting the transition of signs expressing the artifact-tasks relationship into signs expressing the artifact-knowledge relationship. As a result of the guidance of the teacher, students expressed mathematical-signs such as “the function which associates  $M$  to  $N$ ”, and others related to the idea of covariation.

### **4<sup>th</sup> Step: The mathematical definition of the notion of cosine function**

When exploring the relationship between  $x$  and the abscissa of  $M$  through the use of *Dragging*, we observed students’ interpretation of the movement of point  $K$  as a variation of the abscissa of  $M$  and the description of the functional relationship between  $M$  and its abscissa.

The use of mathematical-signs related to the meaning of the cosine function illustrates the development of personal meanings related to the mathematical meaning of the cosine function as covariation. The collective discussions, guided by the teacher, allowed for the construction of the accepted mathematical meaning, i.e. the mathematical definition of the cosine function. (Khalloufi-Mouha, 2012) The main goal of the teacher’s actions in the collective discussion is managing the

students' discourse, in order to support them to move from the artifact and place them in a mathematical environment which allows the recognition of the cosine function. The discussion shows a large commitment of students to the process of meaning construction. By using many mathematical-signs, they succeeded in linking their mathematical and physical knowledge. In this case, we can say that the artifact was a powerful resource for the construction of the mathematical meaning based on the activity with the artifact.

## Conclusion

The epistemological importance of introducing the notion of trigonometric function as covariation to make the link between trigonometry and trigonometric functions led us to design and experiment a teaching sequence integrating the artifact Cabri. The analysis of the process of constructing the mathematical meaning of the cosine function, through the analysis of the verbal signs, allowed us to identify that this process begin by a first step related to the recognition of the numerical and geometric variation. This step is characterized by an important use of the artifact-signs and an attachment to the task with the artifact. The second step is the identification of the covariational relation at a perceptual level. The third step marks a mathematical interpretation of the activity with the artifact following the collective discussions orchestrated by the teacher. The process is carried out following the interventions of the teacher, by the mathematical definition of the notion of cosine function.

The teacher's role is very important in the process of constructing mathematical meaning among students using a technological artifact. The teacher has to use the semiotic potentialities of Cabri and orchestrate the discussions in order to guide this process towards the construction of mathematical meaning. For this reason, further investigations into the role played by the teacher are required for a better description of the process of construction of mathematical meaning among students using a technological artifact.

# DeafMath: Exploring the influence of sign language on mathematical conceptualization

Christina M. Krause

University of Duisburg-Essen, Germany; [christina.krause@uni-due.de](mailto:christina.krause@uni-due.de)

*Sign languages are performed in a modality other than spoken languages, using the entire body in a spatial-visual-somatic way. With reference to spoken language, performance of the language in terms of articulation, but also perception and interpretation, changes in the medium of sign language as a visual means of expression. Considering mathematical discourse and social interaction as an important factor in the learning of mathematics, this paper discusses theoretical approaches of a research program, currently underway, that aims at getting a better understanding of how the use of sign language may influence the learning of mathematics. From this a more profound basis shall be derived for developing didactical strategies responding to the special needs of deaf learners and understanding the role of bodily language in mathematical conceptualization.*

*Keywords: Sign language, deaf learners, gestures, mathematical discourse and social interaction.*

## Introduction

Research in the area of Deaf studies and Deaf education points at the special challenges deaf students face when learning mathematics. Their lack of basic mathematical skills—deaf children lack several years on average behind hearing peers (Nunes, 2004; Traxler, 2000)—is considered to be mainly caused by social and linguistic aspects.

Deaf children do not ‘pick up’ informal knowledge (Ginsberg, Klein, & Starkey, 1998) about mathematical concepts in early childhood as easily as hearing children do, due to growing up in an environment that is primarily aligned to auditive social experience (Nunes & Moreno, 1998). For example, everyday phrases of “mathematical conversation” (Gregory, 1998) just as ‘It is five to twelve’ or ‘Turn right in three quarters of a mile’ can provide a first contact to numbers that is not accessed ‘en passant’ by deaf children. Not necessarily growing up in a deaf community, they may also lack everyday interaction with peers that may initiate first instances of problem solving in playful situations, e.g. dividing a quantity in equal parts. Furthermore, deaf learners struggle with reading, understanding and processing written word problems (Hyde, Zevenbergen, & Power, 2003). Their challenges are partly explained by a decreased short term memory in serial recall of linguistic material, by a problematic comprehension of certain language structures like conditionals, comparatives, inferentials and lengthy passages (Rudner, 1978), and by the semantic understanding of the written language as a second language (Barham & Bishop, 1991; Traxler, 2000).

Hence, and probably as no surprise, language is considered a main factor influencing the learning of mathematics for deaf learners. However, language has mostly been considered a problematic condition that impedes deaf students’ learning rather than investigated as an integral part of the learning process itself. As a spatial-visual-somatic language, the sign language used by the Deaf provides access to mathematical ideas different than that of spoken language. But what exactly does this mean for the learning of mathematics? And what can we learn from looking at how learning under these special conditions takes place?

The approach presented takes into account the specificity of sign language to encounter the peculiar characteristics of mathematical discourse and social learning processes in the deaf classroom. Furthermore, I support the claim that the modality of language not only affects how mathematics is learned, but that it also influences how mathematical ideas become conceptualized by impacting the structure and process of thinking (Healy, 2015). This contribution therefore outlines theoretical approaches and possible implications of a new research program that aims at developing a better understanding of how mathematics is learned using the medium of sign language.

## **Sign language(s) and gestures**

Sign languages are visual languages that are formed by several components such as the configuration, movement and orientation of the hands and their location in space, body posture, facial expression and the viseme (or ‘mouthing’: the movement of the mouth). These aspects shape what is considered the utterance in sign language and are, just as spoken language, more or less conventionalized. These conventions distinguish the manual expression from the gestures defined in the style of McNeill. While he defines *co-speech* gestures as “idiosyncratic spontaneous movements of the hands and arms accompanying speech” (McNeill, 1992, p. 37), I adapt this definition for an understanding of co-sign gestures as being ‘idiosyncratic spontaneous movements of the hands and arms’ *accompanying the signed discourse*. Signers use non-conventionalized gestures in addition to the signs and both types of gestural expression can hardly be distinguished (see also Healy, Ramos, Fernandes & Botelho Peixoto, 2016). Being performed in the same visual-gestural modality, signs and gestures are deeply intertwined in their use and in their interpretation, probably even more intertwined than in the case of spoken language.<sup>1</sup>

## **Cognitive aspects of the influence of sign language on the learning of mathematics**

### **Embodied cognition**

Following the theory of *embodied cognition*, our (mathematical) thinking is deeply influenced by how we experience the world as physical beings (Lakoff & Núñez, 2000). How we act in and perceive the world structures our thinking and shapes to large extent our conceptual understanding:

Human concepts and human language are not random or arbitrary; they are highly structured and limited, because of the limits and structure of the brain, the body, and the world. (Lakoff & Núñez, 2000, p. 1)

A slightly more cautious claim is stated by Wilson and Foglia in the *embodiment thesis*:

Many features of cognition are embodied in that they are deeply dependent upon characteristics of the physical body of an agent, such that the agent's beyond-the-brain body plays a significant

---

<sup>1</sup> This also becomes a methodological issue. It is almost impossible to translate from sign language to written language, even if using lexemes for the notation. Gestures contribute naturally to the interpretation of the utterance such that the analytical distinction between which aspects are signed and which are gestured cannot be made as clear as analytical distinctions between the spoken and the gestured. Neither can be considered separately.

causal role, or a physically constitutive role, in that agent's cognitive processing. (Wilson & Foglia, 2011, paragraph 3)

More precisely, Wilson and Foglia distinguish three roles the body can play in cognition: It can constrain cognition, distribute cognitive processing and regulate cognitive activity (Wilson & Foglia, 2016, paragraph 3). In sum, “such determinate forms of the Embodiment Thesis can ascribe the body either a significant causal role, or a physically constitutive role, in cognition” (Wilson & Foglia, 2016, paragraph 3).

However, the “body as constraint” is not to be understood with a merely negative connotation as one may get at first sight, taking into account two further implications provided by Wilson and Foglia (2016):

- Some forms of cognition will be easier, and will come more naturally, because of an agent's bodily characteristics; likewise, some kinds of cognition will be difficult or even impossible because of the body that a cognitive agent has.
- Cognitive variation is sometimes explained by an appeal to bodily variation. (paragraph 3)

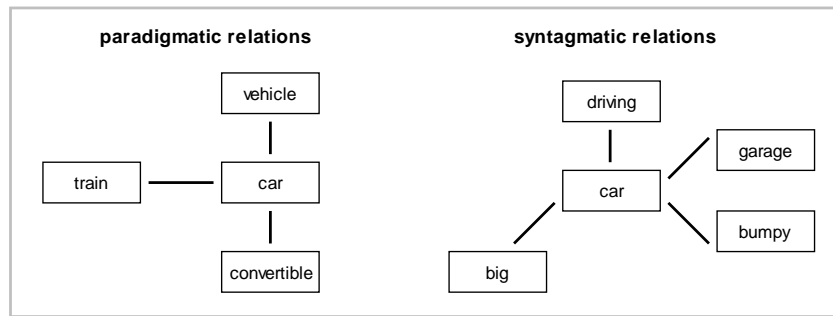

This view on embodied cognition is coherent with the approach taken by Healy and colleagues who understand bodily organs as tools in the sense of Vygotsky, influencing structure and process of thinking (Healy, 2015). As instrumental tools, the sensory organs can be substituted among each other, which “is expected to cause a profound restructuration of the intellect” (p. 299).

Such a substitution comes into play for deaf learners, where the lack of auditive perception becomes substituted by other sensory experiences. In the hearing classroom, information and ideas are shared to a large extent verbally while deaf students acquire information and interact by means of visual modes of expression, just as sign language. Following the theoretical approaches laid out, such a variation concerning the process of learning mathematics should alter cognitive structures and thinking processes, perhaps also leading to differences in conceptualization of mathematical ideas.

### **Features of sign language**

Research in the field of Deaf Studies in fact indicates that deaf people ‘think differently’ (Grote, 2010, 2013). Grote emphasizes that the modality of language—whether it is communicated in vocal language or in sign language—influences processes of conceptualization. She identifies two features of language modalities with such influences: *Articulation* and *iconicity*.

While information is strung together sequentially and linearly in vocal language, sign language offers the possibility to represent different aspects of the utterance simultaneously. This can compensate for the greater time required by spatial articulation in sign language over that of verbal articulation (Bellugi & Fischer, 1972; Grote, 2013). However, sign language can represent only those concepts simultaneously that stand in a *syntagmatic relationship*, that is, concepts that consist of several aspects connected through linguistic contiguity. Signs that bundle these aspects by using a particular handshape to express additional information are sometimes called *polycomponential signs* (Grote, 2013), *classifier predicates*, or *depicting verbs* (Liddell, 2003). In contrast to this stand the representation of concepts from the same paradigm, e.g. concepts that are connected in hierarchy (see Fig. 1).

**Fig. 1: Example for paradigmatic and syntagmatic relationships (following Grote 2013, p. 313)**

These *paradigmatic* (or ‘associative’ (Saussure, 1983)) relationships need to be articulated linearly, just as in verbal language (Grote, 2010, 2013). Grote (2010) claims that this may lead to a preference for communicating those ideas that stand in a syntagmatic relationship and gives empirical evidence that this preference may engender the establishment of a stronger link between these relations over paradigmatic ones.

Furthermore, gestures often show a certain resemblance with what they signify; they evoke an iconic relation to its referential object. This relationship, however, needs to be established since it is not self-evident. Related to the process of conceptualisation, Grote claims that

assuming that epistemic processes are processes inherently mediated by signs, the similarity that forms the relationship between icon and referential object is constituted actively. This means that in the process of iconisation, there is a focus on specific features of the semantic concept which probably become stronger linked and get an exposed position in the semantic net. (Grote, 2010, p. 312, translated by the author)

When conducting verification tests, she found remarkably shorter reaction times for those pictures that showed the feature that was iconically reflected in the sign. This pointed to a stronger semantic link between this feature and the signed concept and provided evidence that “those features that are reflected in the iconic moment of sign language get a specific relevance for the whole semantic concept” (Grote, 2010, p. 316, translated by the author).

### **So what might this mean for the learning of mathematics?**

Learning mathematics is not perceived as a purely cognitive phenomenon but can be understood as a social process in which individuals co-construct mathematical meaning and knowledge within the social interaction that is constituted by the use of signs. These signs can be of written, spoken, or gestural form or anything else that can be considered a semiotic sign, performed in any modality. In this sense—and taking into account the embodied approach outlined earlier—learning is understood “as a multimodal process” (Arzarello, 2006, p. 1), influenced by production and perception of signs within social interaction. The use of sign language plays part in both, production and perception.

Based on this, possible issues that can arise are the following:

- A preference of communicating syntagmatic relationships may lead to place special emphasis on these when carrying out social epistemic processes in social interaction and therefore, may lead to make syntagmatic relations conceived as being more important for the related mathematical concept.

- Knowledge about which relations are ‘linked’ linearly and which simultaneously can influence teaching methods. While in the learning of deaf students there needs to be emphasis on developing paradigmatic inner-mathematical relations, the use of co-speech gestures may support strengthening syntagmatic links also in the regular classroom. Theoretical foundations for such an approach are provided by the results on gestural specification of the verbal utterance in processes of constructing mathematical knowledge in social interaction, as described in Krause (2016).
- Providing ‘mathematical signs’ as nonverbal terms to students, it needs to be noted that the iconicity of the sign may lead to an exposed position of the aspects that become visually reflected in it. Oftentimes, official and conventionalized ‘mathematical signs’ do not exist or are not known so that a ‘suitable’ mathematical sign may develop hand in hand with the knowledge during the learning process in the mathematical classroom (see also Fernandes & Healy, 2014; Krause (2018)). To support the conceptualization of mathematical ideas, it is therefore important to take a closer look at which aspects of a mathematical idea are reflected iconically in a mathematical sign, and how meaning develops in the respective signs in a process of iconization while the ideas become encountered. Within this process, the iconicity of the gesture may inform about the signer’s current conceptionalization of the mathematical idea. This may be used for the purpose of assessment and fits the development of the ‘associated gestures’ found in hearing learners’ social processes of constructing mathematical processes (Krause, 2016).
- Many mathematical concepts are shaped metaphorically so that the mathematical concepts are understood through something familiar or more illustrative (Lakoff & Núñez, 2000). These metaphors cannot be represented iconically in a direct way, the developing sign/gesture rather refers to an ‘underlying’ meaning (see again Fernandes & Healy, 2014). Gestures developed by deaf students while constructing mathematical knowledge in social interaction may therefore indicate possible approaches to these ideas and concepts. Knowledge about these approaches can also help in cases of learning mathematics in a second language since linguistic approaches to metaphors may not be accessible.

### **The research program “DeafMath”**

These considerations motivate my research program in which I investigate the influence of sign language on the conceptualization of mathematical ideas, focusing on two main aims:

- Contributing to the development and further elaboration of a theory on the role of the body in the conceptualization of mathematical ideas,
- Providing theoretical foundations for developing didactical methods and strategies that involve the body in processes of teaching and learning.

Furthermore, another goal lies in the development and evaluation of methodological approaches that take into account the specificity of the research setting when working with deaf children. The crucially different characteristics of sign language as a visual-gestural language, as well as the students’ difficulties with written language, demand an adaption of methods for collecting, preparing, and analysing data. This becomes especially important with respect to qualitative studies that follow interpretative and reconstructive methods since the holistic representation in sign

language cannot be captured merely in written form that can only reflect linear and segmented language. A (more) suitable methodological approach might place a greater emphasis on the coordination of written transcripts, pictures, and videos for means of analysis, but also for the documentation of the results.

Potential long-term goals with respect to implications on teaching methods and strategies concern the following aspects:

- The identification of challenges that are specific to deaf students and countering them in their core: Is one challenge grounded in their understanding of (some) mathematical concepts as deviating due to the deviating modality of their language?
- Understanding the inclusion of deaf learners and their way of communicating as actual surplus in the inclusive classroom. Results gained from these studies can point out how an actual inclusion of hearing-impaired students can enrich the entire classroom.
- Using representational gestures in a goal-directed way as didactic means. In Krause (2016) I describe how the use of representational gestures can influence the collective formation of mathematical concepts in a beneficial way by its various representational functions. Results derived from the here described study may give insights in how these representational gestures may look like.

This program therefore considers ‘barriers and chances’: While the different kind of communication may lead to specific challenges when learning mathematics, taking into account these differences entailed by the spatial-visual-somatic and embodied medium of sign language might help to “become better able to respond to their particular needs, but also build more robust understandings of the relationships between experience and cognition more generally” (Healy, 2015, p. 289).

# Fostering of interdisciplinary learning through basic education in computer science in mathematics in primary education

Peter Ludes and Marcus Schütte

Technical University Dresden, Germany; [peter.ludes@tu-dresden.de](mailto:peter.ludes@tu-dresden.de)

*Digitalization is a topic that is ubiquitous in everyday life. The technological revolution progresses with high pace. Technology/web/mobile companies all over the world are flourishing but primary schools (in Germany) do not follow the economy's development and has not made computer science part of its curriculum yet. This is either due to technical equipment limitations or to the inability or insecurity of teachers to include technology and the underlying principles in their classroom. Furthermore, it is not officially integrated into the core curriculum which prohibits the implementation of a universal standard for computer science competences that have to be taught in primary schools. The paper will present the underlying project and the development of specific learning environments that are designed to nurture cooperation and interaction between participants to have a closer look at the in-between, where learning occurs. This will help to solidify the claim that computer science in primary school has a right to exist.*

*Keywords: Computer science, interaction, mathematical competences, digitalization.*

## Introduction

Computer Science, digitalization or technology are only three out of many other terms concerning the digital age that ubiquitous in today's society. Nearly every professional branch has to deal with technology and digitalization at some point. Employees have to learn how to deal with these digital structures mainly on their own, because they never experienced a fundamental education in computer science. Many schools in Germany offer Computer Science only as a subject in secondary school although coding is seen as the language of the 21<sup>st</sup> century. Whoever is able to "speak" a programming language will be understood all over the world. Many IT unicorn businesses have their roots in a teenager's room or the parents' garage. Often, these businesses came to be because exceptional skill and auto didactical training come together. The masses only seem to use the technology that emerges from these businesses without understanding the basic underlying structures that enable the creation of a product. No matter which idea came to be, it has almost certainly been realized through programming. The choice of programming language is rather secondary as they all follow the same basic rules. Children, from first grade onwards, know about digital technology and computers in different shapes and formats, but when they enter school, these digital tools often cease to exist. Therefore, a responsible use of these technologies and learning in computer science is not fostered in primary schools. Tablets, laptops, smartphones and gaming consoles are at least present once in every household. According to the KIM study, most families own more than one of these devices and use them more than once a week (e.g. the percentage of smartphone/laptop ownership is 97%). In fact, 41% of children from 6-10 own a smartphone themselves. Children learn from an early age how to use e.g. tablets. The functions of these devices are often self-explanatory. The underlying structures, e.g. how is software developed, what rules does a computer follow or how to troubleshoot problems, are not that clear to most children although these structures are relatively similar across all digital devices, this also is true for most teachers, who did not grow up with technology and are now supposed use it in the classroom and teach its responsible use. Compared to mathematics this would

be similar to learning specific calculations with specific numbers or materials but not understanding how to transfer and apply e.g. long division to other tasks. The paper does not aim to defy media competences and how they can be accomplished, it is rather a claim to go further and to embrace computer science itself into primary education and see where and when interaction and negotiation of meaning between children occurs and how it fosters the learning of computer science and mathematics competences. This would empower children to accomplish much more with their knowledge about media and their use (knowledge, they undoubtedly gained while growing up in a digital world).

### **Status Quo: Media competences, a watered-down term**

Computer Science is a topic that is present in almost every secondary school, either as a mandatory or a facultative subject. Either way, the subject is taught by teachers, who have a higher education degree in computer science. To become a primary school teacher in Germany, as in many other countries, the selection of specific subjects is not necessary, as the primary teacher is trained to teach all subjects that are part of the primary school curriculum (although many universities offer the opportunity to choose a core subject (e.g. mathematics) that will give the student the ability to enjoy an even more focused education in this specific area. Computer Science as a subject is not present in either primary school or primary school teacher education. Future teachers rather can achieve something that is often called media certificate or media training. Mostly, this is integrated into the courses that are already taken at university. E.g. one course would include a topic like “use of digital media in geometry in primary school”. This is neither standardised, nor does it aim at specific competences. It is rather a subject specific realization of the use of technology for a certain topic. Today, most schools decide themselves how and when to use digital media and often one feels that it is mostly aimed at helping teachers to keep up with what children already know. If they decide to do so it is often done under the term of media competency. Krauthausen (2012) mentions that the term “media competences” is colorful and can be interpreted very differently according to specific interests. For some schools media competency means that the teacher uses e.g. an iPad, for others that the children learn how to use word processing software. Other projects try to foster the use of specific types of media such as podcasts to facilitate learning process for mathematics (cf. Schreiber, 2012). This is far away from being similar to what computer science would request children to learn. Computer science is considerably more than just knowing about the functions of a computer. It is learning about logic, about algorithms, about programming & robotics and (late-breaking) cryptography. Questions like: *What is an algorithm? What is logic? What technology can I use to facilitate my work?* can be answered by young children to improve their learning. But not only will the acquisition of such skills foster the expert knowledge, it will also nurture competences that can be interdisciplinary used. This is important, as we have to ask whether our traditional cultural competences are still sufficient in a more and more digitalized world or whether we need to teach computer science as well. Some projects try to accomplish this, e.g. Herper and Hinz (2009) through computer science education in primary school and Weigand (2009) with his project: “Algorithms in primary school” (title translated by the author). Weigand especially shows that to work on basic principles of computer science (in this case algorithms) a computer itself does not necessarily have to be available, as he uses pen and paper to work on algorithmic processes. Primary schools do not offer the subject of computer science and it will not be easy to implement it into the curriculum as an independent subject. To achieve this goal, a back door has to be found to sneak computer science into

primary school. Then, once its benefits have become obvious the step from being part of another subject to being an independent subject is only a small one. The answer to the question what subject should be used to include computer science in its contents could not be answered more easily. Mathematics seems to be the ideal candidate, as competences in both subjects are similar right up to identical. We will now focus on these similarities in more detail.

## Competences in Mathematics and Computer Science

The German core curriculum provides two types of competences for the subject of mathematics: the general mathematical competences and the content-related mathematical competences (KMK Bildungsstandards, 2005). General mathematical competences include arguing, problem solving, communicating, modelling and the presentation of mathematics. Although these competences will equally be taken into account, the main focus here will be placed onto the content-related mathematical competences, which are numbers and operations, space and shape, pattern and structures, sizes and measurement and data, frequency and probability. These content-related mathematical competences provide the framework for the contents of the learning environments. To justify these contents, a side by side comparisons of some chosen content-related mathematical competences and where to find them in computer science will be done. The mathematical competences will be presented as written down in the German core curriculum, then computer science content that also matches these competences will be provided.

Mathematics	Computer Science
Understand the relationship between and the representation of numbers, Understand and master calculations	Algorithms use calculations, Loops have to be counted, Sorting algorithms, Types of variables integer, float, double

**Table 1: Competences in Mathematics and CS: Numbers and Operations**

Mathematics	Computer Science
Spatial orientation	Program robots, Define an area of movements, Plan with obstacles and predict motion sequences

**Table 2: Competences in Mathematics and CS: Space and Shape**

Mathematics	Computer Science
Recognize and characterize regularities	Structure and plan algorithms, Plan processes and translate them into a programming language, logic, Sorting algorithms

**Table 3: Competences in Mathematics and CS: Pattern and structures**

<b>Mathematics</b>	<b>Computer Science</b>
Have the ability to imagine sizes, Have the ability to use sizes in specific situations	Determine the step range of a robot, Determine run time

**Table 4: Competences in Mathematics and CS: Size and Measurement**

<b>Mathematics</b>	<b>Computer Science</b>
Understand the relationship between and the representation of numbers, Understand and master calculations	Algorithms use calculations, Loops have to be counted, Sorting algorithms, Types of variables integer, float, double

**Table 5: Competences in Mathematics and CS: Data, Frequency and Probability**

(KMK Bildungsstandards, 2005)

This selection of competences from the core curriculum shows that to each content related mathematical competence a related topic in computer science can easily be found. This is highly interesting, as it suggests that mathematical competences are similar to those that are required to perform tasks in computer science. Thus, mathematics can fulfil the requirements to integrate elements of computer science into its curriculum. To prove this claim, it would hardly be possible to modify the existing mathematical lessons to include this content. Rather, specific learning environments have been developed to show that learning computer science topics nurtures the competences that are necessary for both mathematics and computer science.

## **The pilot project**

### **Partner school**

The search for partner schools was far from easy. Many schools were not interested. One school on the other hand was immediately willing to participate and upon further information managed to interest 19 children from grade four to take part in the project. As we did not expect such an overwhelmingly large number of participants from one single school, we cancelled all further efforts to acquire more schools and decided to work exclusively with the just one partner school. The school was very open to our project and supported us from day one. The first feedback suggests that all children are highly enthusiastic and motivated. A claim that we can only support after our first three weeks. In agreement with the school, we chose two time slots of 90 minutes in the afternoon twice a week (Tuesday and Thursday) over the course of six weeks. During the time slots the children worked on the learning environments in pairs (some tasks required two groups to come together to discuss) supervised by a student from the seminar or Peter Ludes.

### **Learning environments**

To examine whether certain competences are used during working with tasks, specific learning environments have been developed that have a computer science topic as a core topic. The learning

environments have been developed during one of Peter Ludes' empirical seminars for future elementary school teachers. The students developed the first draft of the learning environments on their own and after a review process finalized them collectively during the seminar. The main topics are: logic (general and propositional), algorithms, cryptography and programming/robotics. The main challenge for the students was to develop learning environments with core topics that are not (yet) part of their actual studies, as computer science is not a topic that is taught in elementary school. Therefore, an extensive introduction into the field of computer science has been necessary.

A second demand that had to be kept in mind during the development has been a focus on interaction. The tasks should be designed in a way that -at least partially- fosters interactional processes between the participants as we focus on learning through collective argumentation and participation (Krummheuer, 2011). The first learning environment focused on the topic of logic. The primary task always aims to get a first impression of what the participants already know (or think to know) about the concept. This very open question (e.g. *What does logic mean?* or *When does a person have to think logically?*) provides a wide variety of possible answers without any pressure for right or wrong. The supervising students are always advised to let the children speak freely as much as possible, unless a lively discussion does not occur, general questions or guidance is to be avoided. Although the content is important, the actual focus for this pilot project is not to survey content learning, but rather the learning that occurs between individuals whilst discussing and arguing about the specific topic. Learning in primary school is initially dialogical learning. That is, learning is seen as a dialogical process in contrast to learning as a monological process, which would be rooted in the individual (cf. Miller, 1986). The learning of mathematics can be seen as an increasing autonomous participation in collective argumentations that are produced and nurtured collectively by the group itself (Krummheuer, 1992; Voigt, 1995). This idea of learning can be transferred to the learning of basic competences in computer science. To build upon this concept, all ways of communication and interaction between the children has to be supported as much as possible. To ensure an efficient way to videotape the children working on the learning environments, we designed the environments to be worked on in pairs or groups of three, sometimes with a closing task, that included a larger group discussion in groups of up to six children. Working in smaller groups for us provides the advantage, that single children are not able to extract themselves from group tasks or discussions but rather encourage them to participate. Every learning environment is designed to cover three timeslots of 90 minutes. Here, two sessions of 90 minutes are planned for the actual content-related activities and one session of 90 minutes reserved for documentation and evaluation of learning processes through tools like learning diaries, wikis and storyboards. Learning diaries can e.g. be used to recapitulate the learning process, correct misconceptions and enables the child to visualize what learning progress it has made. We chose the storyboard as an adequate tool for the programming/robotics learning environment. This environment will be realized with LEGO Mindstorms EV3 Education sets. The main goal after developing and building the robot itself will be to program its specific actions. These actions should be planned beforehand because the children can choose from a variety of actions and sensors with endless combinations. For this task, a storyboard is the ideal candidate as it enables the children to structure their thoughts and plan the movements and sequences that the robot has to fulfil. It also makes trouble-shooting rather easy as the children can always compare their plan to the robot's actual movements and actions.

## Analysis

The analysis of the results of the work on the learning environments is based on methods of interpretive classroom research, such as interaction analysis. As we place much importance onto interaction, cooperation and discussions this method seems most appropriate to us. It helps to find more suitable tasks that help children to collaborate in a productive way. The negotiation of meaning is a key element that has to be focused (cf. Krummheuer, 1992). How does the negotiation of meaning in collective processes of argumentation occur and how can it be supported through the task itself? According to our perception, learning does not occur inside the individual but during the interaction between individuals, whilst discussing, talking, arguing and also justifying the own answers and the answers of others (cf. Krummheuer, 1992). The underlying concept is founded on the ideas of the symbolic interactionism (cf. Blumer, 1969) that will allow us to examine learning as the increasing autonomous participation in collective argumentation in computer science discourse. Possibly this could lead to the definition of participation profiles (cf. Brandt, 2004) for different students, specifically tailored to the computer science classroom. This could not only benefit primary education, but also computer science classrooms in secondary schools. If a specialized and standardized computer science education in primary school was mandatory, secondary schools would have a contact point and a profound basis on which they could build and focus their curriculum.

## First impressions

The first impressions of the pilot project are consistently positive. One major question during the development process was whether children could be unchallenged or overwhelmed with the tasks as they work with topics that are not being taught in primary school and are therefore unfamiliar. The individual knowledge of the children concerning this specific topic could therefore be developed very differently. The children engaged immediately with the tasks and lively discussions occurred. In the very beginning, a certain insecurity was noticeable. This was expected as the children naturally try to give correct answers. This was not possible as most questions are designed in a way that multiple answers and also very individual answers are possible. After the first sessions, the children got more and more used to the types of tasks and felt more comfortable when joining the discussions.

Interestingly, mathematical discussions occurred very often, whether they were planned or not. One example where a rather simple question led to a lively discussion occurred during the learning environment: logic. The children had to decide whether a statement is right or wrong. One of the statements claimed: If something is round it is not pointy. Right or wrong? The children then engage into a discussion, where they have to decide what qualifies as being round:

- S1: If something is round it is not pointy\ [reads]  
That does not have to be true\  
S2: (It is not\ ) [laughs].  
S1: That does not have to be true maybe it is so to say a pointy circle\  
I: How does a pointy circle work?\  
S1: So . wait (4) [draws into his folder]  
S2: [looks into S1's folder]

- S1: Like this and so on and on \ [points at the drawing in his folder]
- S2 Yes, but if something is round [draws a circle into the air with his pen] so this here [points at S1's drawing] that is not round\ that is pointy\
- S1: Yes, it is **roundly** but fi it is round then you are right\

First, S1 states that he is not convinced that this statement is true and he tries to find a shape that is pointy and round. He therefore draws a shape that has corners but is not just one straight line, similar to a part of a polygon. S2 then looks at the drawing and defines the shape as pointy because it has corners. S1 then again discusses the word round and seeks for a better word to describe his drawing and proposes the word roundly for something that is not a straight line but follows the form of a circle part although it has corners. S1 and S2 clearly have a dissent in what qualifies as being round and then shift this disagreement into a consensus through the introduction of a new vocabulary. It is rather interesting that the S1 and S2 discuss to find a consensus and the questions remains, what would happen if they could not find one. Here, the material itself proposes a research question: How do consensus and dissent influence cooperative learning. Is learning through collective argumentations also possible on the basis of a dissent or does a consensus have to be reached in order to complete/move on with the task itself? The structures in cooperative learning opportunities could be fundamentally different if the necessity of reaching an agreement would not be mandatory. This question will be focused during further analysis as the concept of computer science learning environments provides a perfect frame: It has clear and visible connections to mathematics but is fundamentally new and different, so that children can learn a new topic in which they do not have prior knowledge to build on.

### Prospects

The learning environments with the topics cryptography, algorithms, programming/robotics are also completed by now. The videos and writings of the children are being extensively analysed using methods of interpretive classroom analysis. The analysis will enable us to look at the negotiation processes in more detail and determine, where the learning of individual computer science concepts and understandings occurs and how meaning is negotiated during the task itself also in regard to cooperative learning and the underlying structures. Through this, it will be possible to rework the learning environments to tailor them even more specifically to their purpose. The reworked learning environments will then be used in a more extensive main study to examine our claims and to strengthen the position of computer science as a key part of a profound and forward-thinking education that will not only benefit children's abilities in this specific subject but also strengthen their mathematical competences

# On the nature of spatial metaphors: Dimensions of spatial metaphors and their use among fifth graders

Angel Mizzi

University of Duisburg-Essen, Faculty of Mathematics, Essen, Germany; [angel.mizzi@uni-due.de](mailto:angel.mizzi@uni-due.de)

*This paper reports on a study about the use of spatial metaphors among students solving spatial tasks. The aim is to describe the nature of spatial metaphors and analyze the use of spatial metaphors under consideration of other factors, such as students' language proficiency and spatial ability. Sixteen fifth grade students, chosen according to a theoretical sampling, were required to describe to other students how to build a pre-designed spatial object made up of building cubes. The data was analyzed and different dimensions of spatial metaphors were identified and described. Whereas the overall frequency of use of metaphors in spatial discourse does not differ substantially among different groups of students, findings show that the use of spatial metaphors might differ if one analyzes the functions and the conceptions of the underlying metaphors.*

**Keywords:** Language, metaphors, spatial ability, geometry.

## Introduction

Metaphors and their role in shaping the teaching of mathematics has been an area of research in the domain of language and mathematics education for a long time (e.g. Lakoff & Núñez, 2000). Further research is required to show the individual use of metaphors among students learning mathematics. The aim of this paper is to show the nature and diversity of spatial metaphors by describing and illustrating the different dimensions involved when students use spatial metaphors to verbalize their spatial thinking. The use of the spatial metaphors among different students chosen according to background factors (language proficiency and spatial ability) will also be an object of discussion in this paper. Hence, the research questions of this paper are as follow:

1. What are the different dimensions of metaphors used by students in their spatial discourse?
2. Does the use of spatial metaphors differ significantly among students with different background factors (language proficiency and spatial ability)?

## Theoretical considerations

### Language in mathematics classroom

Several researchers of language in mathematics education have pointed out the different planes of language which co-occur in the learning and teaching of mathematics. A bi-planar model about the use of language has been developed by Cummins (2000), who differs between Basic Interpersonal Communication Skills (BICS) and Cognitive Academic Language Proficiency (CALP). BICS describes the use of language in everyday-life context, for instance, in order to communicate with friends or family. In contrast, CALP refers to the language used for academic purposes, which includes a more complex syntax and specific vocabulary, used to describe abstract ideas, such as mathematical concepts. There are no clear-cut boundaries between BICS and CALP, since both can

influence each other. Hence, both planes should be visualized as a continuum of language in the mathematics classroom, rather than as separate entities.

### **Metaphors**

Metaphors play an important role in constructing mathematical discourse and are present in the language of mathematics. Lakoff and Núñez (2000) use the term conceptual metaphors, which are metaphors used to understand abstract ideas by referring to concrete objects or experiences. In their notion of metaphors, properties are transferred from the source object to a target object. If one considers the metaphor “container”, which is an object of everyday use, it can also be used to describe the notion of class in mathematical language. Therefore, certain characteristics are transferred from the source (“container”) to the target domain (“class”) (Lakoff & Núñez, 2000).

### **Spatial ability and spatial language**

Along with language proficiency, spatial ability is another factor which plays an important role in mathematics performance (Büchter, 2011). From a psychological perspective, spatial ability or knowledge is considered to include all abilities needed to navigate through space, visualize objects from different angles, and recognize space and spatial characteristics and other abilities needed to solve spatial tasks (Gardner, 2006). The solving of spatial tasks requires several cognitive processes, such as perception of figure and ground, which is the ability to identify a figure in space, spatial relations, which is the ability of identifying the spatial relation between two spatial objects, and position in space, which deals with the identification of the object’s position in space under consideration of one’s own body (Maier, 1999).

From a mathematics education perspective, spatial ability is incorporated in geometry teaching and is considered an important domain for successful acquisition of geometrical understanding. This is the case in Pinkernell’s (2003) spatial ability model, which consists of three main categories of abilities which play a major role in solving spatial tasks: *spatial-visual operations*, which concerns mental and real actions performed on spatial objects, geometrical thinking, which refers to the abilities of recognizing and describing spatial objects by referring to their geometrical properties, and *visual abilities*, which includes the abilities of constructing different forms of representations of spatial objects and being able to interpret them in space.

When analyzing the notion of spatial language and the different ways of representing spatial objects, Mizzi (2016) states that spatial metaphors play an important role in shaping students’ language when describing the construction of spatial objects. Spatial language can be described as the language required for talking about spatial objects and their underlying spatial characteristics. An analysis of spatial language can reveal more about the students’ spatial thinking and their spatial concept images (Landau & Jackendoff, 1993).

### **Conceptions of mathematical notions**

Sfard (1991) states that mathematical concepts have a dual nature – the structural and the operational conceptions. In the former, a mathematical concept is treated as an abstract object and is mostly likely to be conceived as a static entity. In the operational conception, the individual “speaks about *processes, algorithms, and actions* rather than about the objects” (Sfard, 1991, p. 4). Hence, mathematical objects can be perceived as objects with static properties, which should be denoted as

static conception, or as a sequence of actions on the mathematical object, denoted as dynamic conception. An integration of both conceptions is considered to be important for concept formation in learning and teaching of mathematics.

## Methodology

### Task design

In order to analyze spatial metaphors, a method is needed to investigate the interplay between language and spatial abilities, and to allow the verbalization of students' spatial thinking. The reconstruction method, a data collection method in which two or more learners seated in a back-to-back position communicate with each other to solve a task using learning manipulatives, was chosen. In this data collection method, one learner (the describer) is given a spatial object, designed by the researcher and he/she must describe to the second learner (the builder) how to build the same object, as in the following student instructions given by the researcher:

In this experiment you [the describer] will be given an object made up of these building blocks, which can be put together. You must give him/her [the builder] instructions on how to build this object, so that he/she [the builder] can reconstruct the same object. The colour of the building blocks is not important and whilst you [the describer] are describing you can also touch and move the object as you like, but the object structure needs to remain unchanged. At the end, the objects' structure must be identical.

The above spatial task and instruction required an appropriate spatial object which should be described by the describer. In order to possibly obtain as many metaphors as possible, two spatial objects were used in the study.

**Figure 1: Spatial object I**

**Figure 2: Spatial object II**

The criteria for spatial object design included *three-dimensionality* (a requirement to describe along three dimensions), *breakdown* (different possibilities of breaking down the object) and specific *spatial relations* between parts of the object. Both objects consisted of building cubes (see Figure 1 and Figure 2), which were provided for the builder to build the described object.

### Data collection and analysis

Thirty-two students attending the fifth grade were chosen to participate in this study. In order to consider different factors which might play a role in solving the task, a theoretical sampling was used for choosing the describing students based on two dichotomies (since the describers are considered to be the ones mostly contributing to the spatial discourse in the underlying spatial task): high vs. low language proficiency (LP+/LP-) and high vs. low spatial knowledge (SK+/SK-). The students' language proficiency and their spatial knowledge were assessed using C-Tests and Pencil-and-Paper tests (Büchter, 2011), respectively. These dichotomies were established after considering which factors could possibly influence the solving of spatial tasks, which created four sample groups, each consisting of four describers, as illustrated in Table 1.

	LP+	LP-
SK+	Group 1 (four students)	Group 3 (four students)
SK-	Group 2 (four students)	Group 4 (four students)

**Table 1: Theoretical sampling under consideration of two student's background factors**

Sixteen other students were chosen to act as builders for the sixteen descriptors chosen according to the theoretical sampling. The descriptors were given the first spatial object (Figure 1) and the instructions were given by the researcher. The task was repeated by using the second spatial object (Figure 2). The students were video recorded and their discourses were transcribed for the data analysis. Based on an interpretative qualitative approach, the collected data was analyzed to establish categories for metaphors based on the theoretical considerations about language and spatial abilities. The frequency of the metaphors identified in the spatial description of both spatial objects was analyzed in terms of the students' language proficiency and spatial knowledge.

## Results and discussion

### About the nature of spatial metaphors

Spatial metaphors can be described as metaphors in terms of Lakoff and Núñez (2000), whereby target objects are spatial objects. The spatial metaphors used among students to describe the spatial objects in the reconstruction method can be characterized by three dimensions: the linguistic, the spatial and the conceptual. In the linguistic dimension, spatial metaphors are characterized by the use of everyday (E), letter-based (L) or mathematical (M) language. Everyday language denotes the use of language from everyday situations (based on BICS). Letter-based language is the use of symbols or letters from written language in spatial discourse. Mathematical language denotes the use of mathematical terms or concepts in spatial discourse, which are more likely to be acquired in mathematics classroom (based on CALP). Again, these three categories should not be considered as entirely separate, but rather as a movement along a continuum with two poles from "concrete" to "abstract" (E – L – M respectively) and vice versa (M – L – E).

The spatial dimension of spatial metaphors involves the function which the metaphors serves from a spatial content perspective. The functions are: structure (ST), spatial position (SP) and spatial relations (SR). In the third dimension, conceptual, the spatial metaphors can either be of a static (S) or of a dynamic (D) nature regarding the conception of spatial objects. In Figure 3 spatial metaphors and their dimensions are represented in a three-dimensional coordinate system.

**Figure 3: Representation of spatial metaphors and their three dimensions**

In the following, I will give some examples of spatial metaphors which can be represented as different points in the coordinate system visualized in Figure 3. Consider the following transcript of a student during his/her description of spatial object I:

Student A: “Do an L only with one, two, three, four, (...), six pieces. (...) And then do again one, two, (...), five, do five again, so that it looks like an L”.

The spatial metaphor ‘L’ used by student A can be categorized as letter-based on the linguistic dimension of spatial metaphors, because the properties of a capital letter in the Latin alphabet (source domain) are transferred to the spatial object (target domain) (however, Student A does not mention “capital” in the reconstruction method). If one thinks of the distinction between everyday language and mathematical language as a continuum in terms of abstraction and of specific knowledge acquisition, the use of symbols from written language could conceivably be located in between, because symbols represent abstract thinking in terms of lines and distances between them, which are, nevertheless, used in everyday life. From a spatial meaning perspective, Student A uses the spatial metaphor to describe the structure of internal parts of the spatial object and can therefore be assigned to the rather static conception of the object in terms of the conceptional dimension. Therefore, Student A’s spatial metaphor ‘L’ can be assigned to the vertex (L, ST, S) in Figure 3. A more explicit trigger of use of letter-based spatial metaphor (‘H’) is given by the structure of spatial object II, which has proven students’ strong emphasis on spatial metaphors for describing spatial objects rather than on other spatial-geometrical characteristics, such as dimensions etc.

The following transcript excerpt shows another example of the use of spatial metaphors when describing spatial object I:

Student B: “And now do three steps at the other staircase which you have done. Place it in a way in front of you as if you would walk up (...) and then (...) and now take the other stairs which you have done now, and set it in the most front (...) in a way as if you would walk up at the front and then go down again the other staircase”.

The first spatial metaphor used by Student B is ‘staircase’ and can be assigned to the everyday language to describe the structure of the spatial object and to the static conceptional dimension (E, ST, S). The next spatial metaphor used by Student B is ‘walking up or down on the stairs’, which is used to rather describe the spatial position of the object, so in which position the ‘staircase’ is in space under consideration of the subject’s own body. In contrast to spatial metaphor ‘staircase’, the student includes his body in the description to perform an imaginary action on the spatial object. Since the spatial metaphor of ‘walking up and down on the object’ consists of actions and processes, this metaphor can be described as having a dynamic conception, hence it can be assigned to the vertex (E, SP, D) in Figure 3.

Another example of a spatial metaphor coded from the mathematical language in the linguistic dimension can be observed in the following transcript excerpt:

Student C: “At the right. And then make this one to the foursome like a triangle to it (...)”.

In the above utterances, Student C uses the spatial metaphor ‘triangle’, which conceivably originates from mathematical language, to describe spatial object I. Student C states that an internal part of the spatial object should be linked to another (the foursome) like a triangle, which indicates

that the spatial metaphor ‘triangle’ primarily describes the spatial relation between both parts. The student seems to refer to a type of triangle (right-angled triangle), using its properties to describe the spatial relation between the two internal parts of spatial object I. Since the spatial relation of the two objects is rather fixed in this context, this particular spatial metaphor ‘triangle’ can be assigned to the vertex (M, SR, S). More examples of spatial metaphors can be found in Mizzi (2016).

### Use of spatial metaphors in spatial discourse

Spatial metaphors are characteristic elements of spatial language and they are used very frequently among students in description of spatial objects, as can be observed in Figure 4.

**Figure 4: Frequency of use of spatial metaphors in students’ spatial discourse among the four groups**

At a first glance on Figure 4, one can see that the use of spatial metaphors in the students’ discourse has the largest variation among the four students in Group 4. However, on average (represented by the squared light grey dots in Figure 4), spatial metaphors tend to be used on average in approximately 36 % to 40 % of the total phrases of the spatial discourse by the students regardless of their assigned group. So the general use of spatial metaphors among the students do not differ significantly among the different four groups.

### Use of language and spatial metaphors in students’ spatial discourse

The type of language used in spatial metaphors by students is worth looking at. The underlying hypothesis is that the use of the linguistic dimension of spatial metaphors differs among students with different language proficiency. Students with high language proficiency may use more spatial metaphors, since they may have more vocabulary (in mathematical language) at their disposal.

**Figure 5: Use of language and spatial metaphors by students’ language proficiency**

Figure 5 presents the different uses of language in spatial metaphors among students with low and high language proficiency. It shows that students with high language proficiency use slightly more spatial metaphors from everyday and mathematical language, and slightly less letter-based spatial metaphors than students with low language proficiency.

## Functions of spatial metaphors in students' spatial discourse

The next step is to analyze the functions of the used spatial metaphors among the different students. Figure 6 shows the number of spatial metaphors used in relation to the average students' total number of phrases by their spatial functions: ST, SP, and SR.

**Figure 6: Frequency of the used spatial metaphors classified according to their function**

According to Figure 6, most of the spatial metaphors were commonly used to describe the structure of the spatial objects. On average, every metaphor with ST-function occurs in at least every third phrase of the student's discourse. Students in Group 4 relatively used relatively less spatial metaphors to describe the spatial position of spatial objects. Moreover, one can notice the relatively higher use of spatial metaphors with SP function in comparison to SR, especially among students with high spatial knowledge (students in Groups 1 and 3). In contrast, spatial metaphors with SR function were very rare and if used they tend only to describe the spatial relations between two object parts after breaking down the spatial object in the description.

## Conceptions of spatial metaphors in students' spatial discourse

Consider the conceptions of the spatial metaphors used by the students, which were based on the theoretical framework of Sfard (1999). It is worth mentioning that although most utterances were action-based and therefore of a dynamic nature, spatial metaphors were analyzed as distinctive elements conveying an idea which is either of static or dynamic nature. The former tends to be more property defining or transferring, whereas the latter entails a movement in the spatial metaphor itself. Considering the conceptional nature of spatial metaphors used by the participants, one can conclude that most of the spatial metaphors used are predominantly static in nature, regardless of the two dichotomies in the theoretical sampling. The high occurrences of static and the low occurrences of dynamic spatial metaphors seem to be linked to the function of the underlying metaphors. Since most of the students used spatial metaphors to describe the structure of the spatial object (see Figure 6), the corresponding nature was static. Whereas, if more spatial metaphors were used to describe the spatial position of the spatial object, then there is a higher tendency of the spatial metaphor being dynamic. However, this does not imply that all the spatial metaphors of S and SP function are static or dynamic respectively, as the following transcript excerpt of Student D describing object I shows.

Student D: "At first it not much far, and then forth and forth. And at the other edge as well, and then they meet each other at the top. It is almost four cubes to the top and four steps".

Student D uses the spatial metaphor of 'meeting' to describe the structure of the spatial object, which she has broken down in two parts (two 'edges'). The metaphor 'meeting' is used to convey the convergence to one point of the structure of the object created by the two parts or 'staircases'. Hence, this metaphor is of a dynamic nature and an example for the vertex (E, ST, D) in Figure 3.

## Conclusion

This paper has offered an insight into the nature of spatial metaphors which fifth grade students use when describing particular spatial objects. The different dimensions of spatial metaphors reflect the integrated language and spatial content learning which is important in mathematics education research. The analysis of groups of students according to theoretical sampling shows that spatial metaphors are common features of spatial language. Regarding the function of spatial metaphors used, spatial metaphors were prevalently used to describe the structure of the spatial object. However, on average, students with high spatial knowledge tended to use more spatial metaphors to describe the spatial position of an object or its parts. In terms of conceptual dimension, most spatial metaphors used by the participants were of static nature, which is consistent with the finding that most spatial metaphors were used to describe the structure of the object. These findings about spatial metaphors reveal some characteristics about fifth grade students' spatial thinking, i.e. the predominant role of associations from everyday-life and the preference of static conception of spatial concepts to master spatial tasks which require verbalization. These results provide an initial step toward understanding the under-researched relationship between spatial thinking and language.

*Given the nature of investigating bilingual mathematics learners and learning environments, a key concern is how we can ensure that the rigor of our research is matched by the rigor of methodological frameworks and approaches employed. Our goal is to develop a theoretical framework and associated methodology and methods, in practice, in order to ascertain their suitability for investigating bilingual mathematics learners in an educational context. Moschkovich (2016) identified four key recommendations for conducting research on language: utilising interdisciplinary approaches, defining central constructs, building on existing methodologies, and recognizing central distinctions. Utilising Moschkovich's framework, this paper provides an appraisal of the methodology and methods to be employed in a research project examining bilingual mathematics learners.*

*Keywords: Methodology, methods, bilingualism, discourse, framework.*

## Introduction

Investigating mathematics and languages is a complex process. Therefore, the authors argue that there is a need to develop appropriate research methods in order to investigate language use and its impact on mathematics learning. In particular, we believe that the role of language(s) should be examined within mathematical activity and in situ (Barwell, 2016). This paper draws from the researchers' current study, which explores the potential for developing a coherent and integrated interpretive theoretical framework to examine whether differences in languages, and their use, by bilingual mathematical learners have a differential impact upon cognitive mathematical processing, while recognizing the social aspects of learning. The project, entitled 'M<sup>2</sup>EID: Mathematical Meta-level developments in English and Irish language Discourses', is a mixed-methods study, comprising video-recorded observations, questionnaires and cognitive interviews. The research project is being undertaken with first year, undergraduate students, who choose to study Mathematics through a bilingual approach (English and Irish) during their first year of undergraduate education at the National University of Ireland, Galway (NUI Galway). This option runs parallel to its English-medium counterpart, which typically receives a large intake (at least 150) of students. Four weekly lectures are provided in the Irish language with all terminology given bilingually. In addition, lecturers may opt to describe more complex concepts (such as limit of a function) bilingually. The lectures are supplemented by the provision of a weekly workshop in English in addition to an Irish-medium workshop.

Given the nature of investigating bilingual mathematics learners and learning environments, a key concern of this paper is to describe and discuss how we can ensure that the rigor of our research is

matched by the rigor of methodological frameworks and approaches employed. It is imperative to review epistemology and associated underlying assumptions in order to make meaningful the methodology and methods of the research being undertaken in a bilingual mathematics education context. Grix's (2004) definitions of 'method' and 'methodology' are valuable for interpreting these constructs. A 'method' refers to the procedures or processes by which data is gathered; whereas, a 'methodology' refers to both the theory applied to inform the research and the data analysis strategies employed as appropriate to the data collected (via the specific methods). While Grix's definitions regulate our M<sup>2</sup>EID research study, this paper focuses on possible methodological constructs that can frame such practice-based and context-driven bilingual classroom research. Consequently, the purpose of our paper is to describe and discuss the M<sup>2</sup>EID research methodology and methods utilising Moschkovich's (2016, p.1) recommended constructs for conducting research on language use and learning in mathematics. These are: (1) using interdisciplinary approaches, (2) defining central constructs, (3) building on existing methodologies, and (4) recognising central distinctions while avoiding dichotomies. The paper is structured in accordance with these four recommendations and outlines their application to the main research study (M<sup>2</sup>EID).

## Using interdisciplinary approaches

Research on language and mathematics needs to consider interdisciplinary approaches in the development of methodology and methods and should be grounded in classroom discourse as well as language and bilingualism (Moschkovich, 2016). Therefore, this necessitates the development of integrative frameworks for examining, in situ, both the cognitive and social constructs of mathematics learning through and with languages.

In terms of the mathematics as a composite register comprising content, languages (e.g. English and Irish) and shifts between everyday and subject-specific registers, the authors emphasise the social and interpersonal aspects of language use and bilingualism in mathematics. Such aspects include the use of modes and gestures for communicating understanding and in particular, engagement in the situated and sociocultural practices of mathematical Discourses (Gee, 1996; Moschkovich, 2002). Further, the M<sup>2</sup>EID study is aligned with the perspective that learning mathematics is essentially a discursive activity in which learners form and actively participate in a community of practice (Lave & Wenger, 1991; Lemke, 1990). Therefore, learners develop unique sets of mathematical practices and modes of communicating with each other using all of the social, cultural and cognitive resources available to them. Consequently, a democratic process of learning emerges through a continuous cycle of negotiations in relation to views, beliefs, knowledge and meaning making (Moschkovich, 2002). So, by adopting this comprehensive sociocultural perspective of learning and language use in mathematics, this study requires an interdisciplinary approach to research within this educational field. Based on the sociocultural nature of mathematical concepts and how we understand and communicate this nature, it is vital to consider how various disciplines contribute to mathematics education. In order to address the aims of this study we will draw on the principles of Discursive Psychology, Cognitive Psychology, Semiotics, Pedagogy and Anthropology to progress a unified approach to researching learning and language use within mathematics. Due to the multi-ontological nature of this grounding framework for the M<sup>2</sup>EID research project, it is essential to develop a dynamic and multifaceted methodological approach to the research, data collection and analysis strategies, which this paper focuses upon. Drawing on the body of relevant literature in this

regard, the authors designed a methodology for investigating bilingual mathematics learners that is underpinned by Sfard's (2008) commognitive framework for examining learning. This framework, described later in this paper, is founded on the premise that thinking is a form of (interpersonal) communication, and that learning mathematics entails extending one's discourse.

## Defining central constructs

Moschkovich (2016) emphasises that research studies need to be clear and explicit in relation to the key constructs utilised. Considering the centrality of discourse to the commognitive approach, it is important therefore, that our perspective of discourse is outlined first. Discourses encompass more than verbal and written language and the use of technical language; discourses also involve communities, points of view, beliefs, values, and pieces of work (Gee, 1996). Accordingly, we perceive mathematics as a discourse and a complex form of communication (Sfard, 2012). Gee's concept of Discourse will inform the examination of conceptual mathematical development of bilingual learners, linking both the cognitive and social aspects of language use.

Equally difficult and demanding is the task of defining bilingualism and in particular defining whether a person is bilingual or not. To illustrate these concepts further we employ Grosjean's (1999) model of a continuum of modes with monolingual and bilingual occupying opposite endpoints; this continuum reinforces an understanding of bilinguals using their languages independently and jointly depending on the context/purpose in which the language(s) is being employed. Appropriately then, we support a non-deficit view of bilingual learners, combining everyday and mathematical registers and view language(s) as a resource and a support for learning. Our research is particularly concerned with the role of bilingual students' languages in mathematics teaching and learning. We consider mathematical language as a distinct 'register' within a natural language and each language will have its own distinct mathematics register, encompassing ways in which mathematical meaning is expressed in that language. Specifically, we are concerned with conceptual mathematical activity. This encompasses a knowledge of what it means to understand a concept and an appreciation of how such an understanding can be constructed by a student, thus providing a model of cognition for the concept (Asiala et al., 1996). Given that language influences thought and thinking and that each language will have its unique manner of constructing the concept, it is critical to develop an insight into the role and effect of bilingualism/languages on conceptual mathematical learning. In addition, language(s) facilitate the development of a student's mathematics register and participation in discourse. Consequently, it is an essential instrument of thought and it is vital for understanding and combining experiences and for organising concepts (Vygotsky, 1962). We propose that there are differences 'between linguistically distinct versions of "the same discourse"' (Kim, Ferrini-Mundy & Sfard, 2012, p. 2) which correspondingly impact on mathematical learning. Therefore, it is the use of language as an instrument of thinking that is of importance, as well as its effect on cognitive processing.

When examining bilingual mathematics learners, it is important to address the social use of language within the learning context, not just its role in cognition. As previously noted, Moschkovich (2012) emphasises the importance of learning being illustrated within the sociocultural practices of a certain setting. These practices involve a process of describing learners and communities and considering culture as a set of practices, which actively involve participants

(Gutiérrez & Rogoff, 2003). Hence, bilingualism is described in terms of learners' participation in and use of language(s) for different purposes and particularly in the context of mathematical discourse. Similarly, Moschkovich (2012) emphasises the importance of discerning between the *conditions of learning* and the *processes for learning*, and the importance of describing the curriculum, courses/programmes and teaching and learning approaches utilised that yield successful outcomes for different groups of learners.

Due to the multifaceted process of investigating bilingual learners' use of language in mathematics education, it is vital that an extensive research methodology is developed to facilitate examination of central constructs such as discourse, bilingualism, and language use.

## **Building on existing methodologies**

Research examining the development of mathematical learning and its relation to language draws on multiple theoretical frameworks to support investigations and accordingly methodological approaches (Moschkovich, 2016). Adopting Sfard's (2012) commognitive approach, data collection and analysis must adhere to its five methodological principles. These principles have been expounded upon to reflect our investigative framework and are 1) Operationality, 2) Completeness, 3) Contextuality, 4) Alternating Perspectives and 5) Directness. First, Operationality refers to the provision of a balanced account of the process through the sharing of practical, unambiguous stories that emerge from the study. Second, Completeness of the research emphasizes that the unit of analysis must comprise the entire discourse related to the topic. The researchers extended this principle for M<sup>2</sup>EID to include the documentation of such discourses (plausible developmental trajectories) in both the English and Irish languages. Third is Contextuality, which encompasses the premise that all interaction can be characterized as a learning event. We extend this, in the given context, to the need to examine when and how bilingual students/researchers use their language(s) in interactions. The fourth principle is that of Alternating Perspectives and explains the interchangeability of the researcher's insider/outsider methods of using words. This is intensified within a bilingual context because consideration must be given to both languages, their use within the given context as well as the possibility of significant differences between researcher and participant discourses. Fifth, the principle of Directness affirms that all descriptions of the study should commence with the specific raw data from the participants rather than the researcher's interpretation of that data. The application of these distinctive methodological standards will provide unique insights into the processes of bilingual mathematics learning and potentially contribute to the development of an empirical research base to ensure rigor in examining whether differences in languages, and their use, by bilingual mathematical learners have a differential impact upon cognitive mathematical processing.

Further to adopting Sfard's approach, it is vital to consider that epistemological assumptions inform methodology, which subsequently engender the methods employed to collect data. Therefore, aligned with the interdisciplinary foundations of the M<sup>2</sup>EID research project, the following are the proposed methods to be utilised in the study in order to ensure that a robust methodological framework and approaches support our inquiry.

1. *Discourse models*: This study will map the plausible developmental trajectories in both the English and Irish languages with respect to students' learning in various mathematical topics

- e.g. functions– as consistent with the NUI Galway undergraduate module. The purpose of discourse models is to examine how language nuances and use affect learning (Kim et al., 2012).
2. *Videographic evidence*: This study will identify and explore when and how bilingual learners at NUI Galway employ each language (English and Irish) when engaged in mathematical learning. Specifically, the research will examine the cognitive functions of code switching and language use within a natural educational context, while also providing for the social aspects of learning. Videography is an effective method of examining teaching and learning experiences in naturalistic contexts and the affordances of modern technologies provide opportunity to document, share and analyse cases of particular practice (Derry et al., 2010). All lectures and tutorials relating to the bilingual mathematics module in NUI Galway will be recorded and analysed as appropriate.
  3. *Questionnaire*: The purpose of the first part of the questionnaire is to gather participants' background data. The second part of the questionnaire will engage participants in discourses related to particular mathematical topics (linked to the developed discourse models) with the option of utilising English or Irish or both languages. The Cognitive Aspects of Survey Methodology (CASM) model will guide participants in an activity series involving thinking-aloud their thought processes as they recall prior knowledge and experiences of mathematical discourses while answering the questions (Desimone & Carlson Le Floch, 2004). The focus will rest on conceptual mathematical activity based upon a variety of constructs, both familiar (such as functions and their analysis) and new (such as logical form, equivalence relations and classes, and related number theoretic constructs). A primary mathematical objective of the first year module in NUI Galway is to facilitate and develop advanced mathematical thinking.
  4. *Video-recorded Cognitive Interviews*: Cognitive interview methods will be employed to explore respondents' explanations of the answers in order to acquire comprehensive knowledge about how well respondents comprehend, appreciate or even misinterpret the specific mathematics concepts central to the study (Desimone & Carlson Le Floch, 2004). Participants will engage in paired discussion of mathematical tasks (the same as in the questionnaire) and justify their answers where appropriate.

It is proposed that the combination of the above methods facilitates a progressive and incorporative investigation into the cognitive aspects of bilingual mathematics learning and to evaluate the impact of languages on mathematics learning in practice.

### **Recognizing central distinctions while avoiding dichotomies**

With Sfard's (2008) commognitive framework undergirding the approach, the following are key aspects of the methodological framework under investigation (Ní Ríordáin & McCluskey, 2015):

- **Discourse changes**: If assuming the premise that mathematical learning involves initiation into the discourses of mathematics, then learning mathematics involves substantive discursive changes for learner. Sfard (2012, p. 3) distinguishes between two types of mathematical learning (change in discourse) as follows: *object-level learning* (expansion of

what is known already and is mainly accumulative) and *meta-level learning* (change of meta-discursive rules and is a more radical and complex change). Within the proposed framework, development refers to a change in discourses. Accordingly, we refer to the development of students' mathematical discourses as opposed to the development of the students themselves.

- **Sociocultural perspectives:** Discourse is more than just language. We utilize Gee's (1996, p. 131) work which refers to Discourse as incorporating both talk and non-talk modes of participation such as gestures and artifacts, as well as participation in a social group. The employment of this definition synchronises with the concepts of discourses inherent within the sociocultural and Community of Practice perspectives.
- **Community of practice:** Within the framework, thinking can be defined as the activity of communicating with oneself. Accordingly, mathematical thinking can be viewed as a discourse, which in turn is a form of communication and involves being part of a mathematical community. Taking this view, the language or languages in which mathematics is being learned becomes an important issue for consideration.
- **Conceptual learning:** Given that language influences thought and thinking (Vygotsky, 1962) and that each language will have its own way of constructing the concept, insight into the role and effect of bilingualism/languages on conceptual mathematical learning is critical. We consider languages and registers as vital resources and skills for learning and language use in mathematics. Grosjean's (1999) concept of a continuum of modes will be employed to trace bilinguals' use of languages in situ.
- **Linguistic relativity hypothesis:** It is the use of language as an instrument of thinking that is of importance, as well as its effect on cognitive processing. The linguistic relativity hypothesis proposes that the vocabulary and phraseology of a particular language influences the perceptions and thinking of speakers of that language (Whorf, 1956). Accordingly, each language (e.g. English or Irish) has a different cognitive system that influences concept formation and development. The study adopts the premise that a language influences, rather than determines, our mathematical thinking, and is cognisant of the impact of linguistic distinctions in a particular discourse on mathematics learning (Kim et al., 2012).
- **Meta-discourses:** The proposed framework is primarily concerned with meta-level developments in mathematical discourses. Since our focus is on bilingual mathematics learners, it is important that an analysis of the language(s) in which the discourse is taking place is conducted. In particular, the successive meta-discourses relating to mathematical topics of interest will be documented and compared between languages.
- **In situ research:** Since the development of discourses is essentially a product of collective human actions, the specific contexts must be acknowledged. Hence, learning and language use in mathematics will be analyzed within the social, cultural and cognitive practices of the particular learning context (Moschkovich, 2012).

## Conclusion

Utilising Moschkovich's framework, this paper has provided an appraisal of the methodology and methods to be employed in the M<sup>2</sup>EID project, which is concerned with examining bilingual mathematics learners in situ. We assume that methodology is inclusive of both theory and methods. Accordingly, it is of importance to outline the underlying theoretical assumptions relating to the M<sup>2</sup>EID project, as well as how we plan on documenting, describing and explaining these phenomena. Hence, a core consideration for our project is what data to collect and how to collect such data. Therefore, a key aim of the M<sup>2</sup>EID research project is to evaluate the proposed methodology and methods in practice in order to ascertain their suitability for investigating bilingual mathematical learners in an educational context. In particular, the project will evaluate whether differences in languages, and their use, by bilingual mathematical learners have a differential impact upon cognitive mathematical processing, when engaged in conceptual mathematical activity.

## Acknowledgment

The M<sup>2</sup>EID research project is funded by the Irish Research Council - New Horizon's Research Grant (REPRO/2015/53).

# Entering the mathematical register through evolution of the material milieu for classification of polygons

Frode Rønning and Heidi Strømskag

Norwegian University of Science and Technology, Department of Mathematical Sciences,  
Trondheim, Norway

[frode.ronning@math.ntnu.no](mailto:frode.ronning@math.ntnu.no) [heidi.stromskag@math.ntnu.no](mailto:heidi.stromskag@math.ntnu.no)

*This paper is based on classroom observations from Norway with 7-8 years old children working on geometrical shapes. The intention is that the children shall classify different polygons according to their number of edges. The observations are part of a teaching sequence that is designed using principles from Brousseau's Theory of Didactical Situations (TDS). From the teaching sequence we identify certain challenges in the children's development of scientific terms and the observations allow us to conclude that these challenges to some extent are connected to specific semantic features of the Norwegian language. The use of TDS is instrumental in revealing the challenges that occurred and explaining what was changed to overcome them.*

*Keywords: Register, language of nearness and distance, polygons, didactical situation, milieu.*

## Introduction

This paper reports on a teaching sequence within the project Language Use and Development in the Mathematics Classroom (LaUDiM)—an intervention study carried out in collaboration between researchers at the Norwegian University of Science and Technology and two local primary schools in the period 2014-2018. The main objective of the project is to study pupils' development and use of mathematical language in order to gain knowledge that will help the teachers to develop their teaching—aimed at pupils' increased proficiency in expressing mathematical ideas, mathematical reasoning, arguing and justification. Teaching sequences are designed in collaboration between researchers and teachers, where the design is guided by principles from the theory of didactical situations (Brousseau, 1997).

In this paper we study a teaching sequence at one of the project schools including pupils from Grade 2 (7-8 years old) and their teacher. The main aim of the teaching sequence—consisting of three sessions—is that the pupils shall develop their language use about polygons, with the specific aim that they shall be able to classify polygons based on seeing visual images and that they can discern different parts of a polygon (vertices and edges). The classroom observations (recorded on video) give insights into pupils' evoked concept images (Tall & Vinner, 1981) of vertex and edge, and how discrepancy between these and the scientific definitions of them constrains the teacher's goal of the first session. Further, we show how this is resolved by the teacher in the subsequent sessions.

## Theoretical framework

According to Halliday a register is “a configuration of meanings that are typically associated with a particular configuration of field, mode and tenor” (1985, pp. 38-39). Halliday compares *register* to *dialect* and states that “dialects are saying the same thing in different ways, whereas registers are saying different things” (Halliday, p. 41). So changing between registers can mean that the same

word gets a different meaning. The mathematical register is characterised by the property that words have very precise meanings and sometimes the same word may be used in the mathematical register and in the register of everyday language but with different meaning. This feature is language specific in the sense that for a given word it can be present in one language but when this word is translated to another language it may lead to one word in the everyday register and another word in the mathematical register.

Koch and Oesterreicher (1985) make a distinction between language being *conceptually oral* or *conceptually written*. They refer to the first category as *a language of nearness*, where the interlocutors are in direct contact and can comment on each other's utterances and directly refer to the given situation, for instance by using gestures. The second category they refer to as *a language of distance*, where the sender and the receiver are not necessarily in contact and the language therefore has to be more precise. The mathematical language is in its nature conceptually written because of the way it strives for precision and unambiguity. However, much of the communication in the mathematics classroom has many of the features characterising a conceptually oral language, a language of nearness. In particular, when working with young children the communication is characterised by dialogue, face-to-face interaction and a desire to avoid complexity, features characterising a language of nearness. However, one of the aims of schooling is to develop the mathematical language into a language characterised by greater precision, compactness, density of information, features characterising a language of distance Koch et al., 1985, p. 23.

The theory of didactical situations in mathematics, TDS (Brousseau, 1997) is a scientific approach to the problems related to teaching and learning of mathematics, where the particularity of the knowledge taught plays a significant role. Its methodology—for a targeted piece of mathematical knowledge—is based on creating a *situation* with a problem to be solved, where the knowledge aimed at is the optimal solution to the given problem. In the following, based on Brousseau (1997), we explain some concepts of TDS that are relevant for our analysis.

An *adidactical situation* is a situation in which the student takes a mathematical problem as his own and tries to solve it without the teacher's guidance and without didactical reasoning (i.e., not trying to interpret the teacher's intention with it). The *milieu* models the elements of the material and intellectual reality on which the students act when solving a problem—these elements are conditions for the students' actions and reasoning. The milieu may comprise: the problem to be solved; material or symbolic tools provided (artefacts, informative texts, data, etc.); students' prior knowledge; other students; and, arrangement of the classroom and rules for operating in the situation (determinative of who is supposed to interact with whom). The milieu of an adidactical situation is called an *adidactical milieu*. An appropriate adidactical milieu provides feedback to the students, whether their responses are adequate with respect to the knowledge at stake.

After *devolution*, a phase where the teacher has (temporarily) transferred responsibility for solving the problem to the students, four situations (or phases) follow: Situations of action, formulation, and validation are (intentionally) adidactical situations, whereas the situation of institutionalisation is a didactical phase. The situation of *action* is where the students engage with the given problem on the basis of its inner logic, without the teacher's intervention. The students construct a representation of the situation that serves as a “model” that guides them in their decisions. This model is an example of relationships between certain objects or rules that they have perceived as relevant in the situation.

The situation of *formulation* is where the students' formulations are useful in order to act indirectly on the (material) milieu—that is, to formulate a strategy enabling somebody else to operate on the milieu. In this situation the teacher's role is to make different formulations “visible” in the classroom. The situation of *validation* is where the students attempt to explain some phenomenon or verify a conjecture. In this situation the teacher's role is to act as a chair of a scientific debate and (ideally) intervene only to structure the debate and try to make the students use more precise mathematical notions. The situation of *institutionalisation* is where the teacher connects the knowledge built by the students—through didactical interaction with the milieu—to the scholarly and decontextualised forms of knowledge aimed at by the institution.

## Methodical approach

Each teaching sequence in the project starts with a planning session where teachers and researchers work together to plan the activities for two classroom sessions, and in particular set the learning goals for the classroom sessions. Activities and actions are planned according to the phases of TDS, devolution, action, formulation, validation, and institutionalisation (Brousseau, 1997). Some days later, the first classroom session takes place, immediately followed by a reflection session, where experiences from the first classroom session are discussed and adjustments are made for the second session, taking place yet a couple of days later. Researchers are also present in the classroom. Observations from all sessions (planning, classroom implementation and reflection) are recorded on video, and additional audio recording is used to secure the quality of the sound. In the classroom sessions selected pupils working in groups (2-3) are video recorded, as is the teacher in whole-class sessions. Tasks given to the pupils in the observed sessions and written material produced by the pupils are also data sources. After completing a cycle of planning, reflection and classroom sessions, teachers and researchers meet to watch parts of the video recordings from the classroom. This represents the first step in analysing data, where interesting sequences from the classroom are identified. In the planning session and the video session, teachers from both schools are present.

This paper is based on a teaching sequence on geometrical shapes, consisting of three classroom sessions<sup>1</sup>. Data from the teaching sequence form the basis for answering the following research question: *What conditions enable or hinder pupils' opportunities to categorise polygons according to their number of edges?*

The utterances reproduced are excerpts from a transcript of the video recorded whole-class discussion in the second session. The camera faces the teacher at the board and it captures the dialogue between the teacher and the 14 pupils who are sitting in a semi-circle close to the board. Parts of the dialogue between teacher and pupils have been transcribed and translated from Norwegian into English. In cases where it is important for the analysis to emphasise the meaning of a particular word in Norwegian, the Norwegian word is included in square brackets in the transcript.

Our analysis is based on ethnomethodological conversation analysis, focusing on the thematic development of an interaction rather than on its structural development (Holstein & Gubrium, 2005). This gives the possibility to analyse the relationship between language and the figures with

---

<sup>1</sup> The analysed teaching sequence consists of three sessions (instead of two which is common in the project). The third session involves pupils' interaction with a milieu designed so as to give feedback in the devolved didactical situation.

their components while teachers and students negotiate mathematical meaning (Fetzer & Tiedemann, 2015).

The teaching sequence analysed here is chosen because: (1) it illustrates how the phenomenon of words having different meanings in the mathematical and everyday registers constrains pupils' conceptual development; and (2) it illustrates how an evolution of the milieu gives a rationale for *using* the target knowledge.

## Analysis of the teaching sequence

### *First session—classification*

In the first session of the teaching sequence, pupils work in pairs on sheets of paper showing 12 shapes, as presented in Figure 1 (one pupil has blue, the other has red figures). The task they get is that each pupil shall (individually) sort the figures into groups (cutting the individual figures from the sheet) and give a name to each group (ACTION). Then they are supposed to compare (in the pairs) how they have sorted the figures and agree on a way to sort them and also agree on a name for each group (FORMULATION). The final result from each group is a sheet of paper on which the pupils have glued on figures from the same group and with the text “These are <\_\_> because <\_\_>” and the pupils have filled in the blanks (VALIDATION). After the session the teacher collects the worksheets and she uses them as background for a whole-class discussion in the second session (INSTITUTIONALISATION).

In Norwegian, polygons are named literally after the number of edges, using the standard Norwegian number words, so that a triangle is called a “three edge” (trekant), a quadrilateral is called a “four edge” (firkant), and similarly for the others. An accepted name for the generic concept *polygon* is ‘mangekant’ which literally means “many edge”. Learning names of polygons, and understanding the reason for the names, is therefore not considered to be a challenge for Norwegian students.

**Figure 1: Shapes to be classified**

This is in contrast to the situation in English where it is not obvious from the everyday language that for instance a pentagon is a shape with five edges. The teacher has seen from the collected worksheets that all groups have given names to the shapes based on the number of edges and they have written for instance “these are ‘five edges’ because they have five edges”. However, from the discussion in pairs she has observed that even if all the pupils talk about *edges* (kanter), the way they point at the figures indicates that some counts the edges but others count the vertices. The Norwegian language has no precise scientific word for *vertex*, the word which is used is ‘hjørne’, which (also) means *corner*.

### *Second session—the meanings of edge and corner*

In the institutionalisation phase the teacher asks pupils to come to the board and explain their reasoning. She has observed Oliver and Amelia counting the vertices and Thomas, Daniel and Sophie counting the edges. Among the figures is a quadrilateral with three acute angles and one reflex angle (Figure 2), where we have inserted the letter A for reference in the dialogue. Although Oliver and Amelia have grouped this among the quadrilaterals,

**Figure 2: Non-convex quadrilateral**

Oliver expresses some doubt when he is called to the board to explain how he and Amelia have thought.

- Oliver: If we had pulled this out a little (pointing to vertex A with the reflex angle) it would have been a “four edge” [firkant].
- Teacher: OK, but still you have grouped this among the “four edges”.
- Oliver: One, two three, four (pointing to the vertices).
- Teacher: So what is an edge?
- Oliver: That is the pointed parts [spissene].

When Thomas is called to the board he uses a rectangle as his example and clearly points to the edges, counting “one-two-three-four”.

- Teacher: What is the difference between what Oliver did and what Thomas did?
- Megan: Thomas counted the lines [strekene] and Oliver counted the pointed parts [spissene].
- Teacher: So actually we did not quite agree on what an edge really is.

The dialogue above reveals that there are different opinions among the pupils as to what the word ‘kant’ means. All the pupils claim that they are counting the edges but when asked to explain what they have counted, Oliver points to the vertices and Thomas points to the edges. Megan makes the observation that the two boys have actually counted different parts of the polygon.

The teacher has in many sessions talked about “what mathematicians do” and that they for instance decide and agree on what names to give to mathematical objects. At this stage the teacher says that now we have to agree on something—as the mathematicians do—so that we have a common understanding of what an edge is. The teacher has also observed that some pupils use the word ‘hjørne’ and she draws their attention to this. One pupil, Jessica, says that they had talked about ‘hjørne’ but they did not know what it was, so they had written ‘kanter’. The teacher asks the pupils to explain what a ‘hjørne’ is and encourages William to come to the board.

- William: That inside is a corner and those outside are edges.
- Teacher: Can you show us?
- William: This is a corner (points to vertex A with the reflex angle in Figure 2) and that is an edge (points to one of the acute angles).
- Teacher: But what about this (points to the rectangle)?
- Oliver: Edge, edge, edge, edge (points to each of the four vertices).

Then the pupils continue to discuss the inner and the outer angle at a vertex, and that one is a ‘hjørne’ and the other is a ‘kant’. Thomas says that “the corners are inside and the edges are outside” and Chloe agrees that the corner is inside but she refers to the outside as the “pointed parts” (spissene). William is making a distinction between the vertex at the reflex angle of the non-convex quadrilateral (Figure 2), which he refers to as a ‘hjørne’, and the vertices at the acute angles, which he denotes by the word ‘kant’. Oliver, using the rectangle as his reference context, refers to all the vertices by the word ‘kant’.

To get the pupils to agree on *one* name for the same object the teacher brings in a reference context from their everyday life, a mini-pitch. The picture in Figure 3 is shown on the whiteboard. Using this picture as the reference context, the teacher asks questions like “If I say that you should place yourself on the edge of the mini-pitch, where would you be standing?” or “...place yourself at the corner, where would you go?”

**Figure 3: The mini-pitch**

There is still some confusion among the pupils, so the teacher says that she will tell them “what the mathematicians have decided”. She holds up a rectangular sheet of paper (A4) and says:

Teacher: Corner (vertex), that is where two sides meet. When we talk about edge, we can also call this the side-edge [sidekant], and where two edges meet, that is a corner (vertex). There is the corner (points to a vertex of the sheet).

The last part of the session was completed at the mini-pitch in the schoolyard, where they played the game of the teacher telling where to go—by using the concepts of edge and corner—and the pupils went to a place which (supposedly) fulfilled the teacher’s command.

The teacher’s reference to “work like mathematicians” and that this entails giving precise definitions indicates that she intends to introduce her pupils to the mathematical register. However, the communication is hindered by the fact that some of the words have different meanings in the mathematical register and the everyday register. In particular this is the case for the word ‘hjørne’ which can mean vertex (mathematical register) as well as corner (everyday register). In everyday language the corner is a spacious area, somewhere you can stand, but in mathematics it is a point, the intersection between two lines. The word ‘kant’ has the same connotation as English edge, and in everyday language this is used as something that is sharp. This may explain why ‘kant’ is used to denote both the side, or edge, and the vertex when it is approached from the outside.

*Third session—a milieu that affords feedback*

As a follow up, a game with 12 tiles was developed. On one side of the tile was depicted a polygon where the edges had one colour and the vertices were marked with another colour. On the reverse side was written “<name of shape> with <colour> edges” or “<name of shape> with <colour> vertices”. An example is shown in Figure 4. On the back of this was written “Pentagon (femkant) with blue edges”.

**Figure 4: Pentagon with blue edges**

This game was played in pairs of pupils both having the full set of tiles. One pupil reads the text and the other one is supposed to pick the correct shape. After picking he/she can turn the tile and read the text to see if the correct shape has been picked.

## Discussion

The target knowledge of the teaching sequence was that the pupils should develop the scientific language for naming 2D shapes and become aware that these names are based on the number of edges in the shape. To know the difference between edges and corners (vertices) will then also be

part of the target knowledge. A condition that hinders pupils' opportunity to categorise polygons according to their number of edges, is the ambiguous use of the concept of edge. Many of the pupils thought that edge ('kant') referred to corner/vertex, and since the number of edges equals the number of vertices it gave meaning to classify polygons according to the number of corners.

The material milieu in Session 1 did not have an adidactical potential for categorisation according to the number of edges, since it was possible to solve the task apparently correct, without the pupils having a common understanding of what is an edge and what is a corner/vertex. There was no feedback from the milieu that could have told them whether they used the desired concept to classify: In action they counted either edges or corners (which gave the same answer); in formulation they compared their categorisations (and if they had a figure that was categorised differently, they used either edges or corners as a basis for categorising jointly and agreeing); in validation, if they reasoned on the basis of different attributes (edges or corners), they concluded that it did not matter which attribute to use.

During Session 1, the teacher realised that the pupils had other connotations of edge and corner/vertex than the scientific ones. In institutionalisation (Session 2), the teacher let the different connotations be displayed, and—with reference to mathematicians—she introduced the scholarly meaning of the concepts, in the mathematical register. Further, she connected them to the pupils' everyday register, through the mini-pitch context.

Based on results from Sessions 1 and 2, the teacher designed a new material milieu (tiles) that has an adidactical potential (see Figure 4). The game will produce a win if the pupil uses the scholarly meaning of edge and corner, and a loss if not. Hence, the pupil will *need* the target knowledge to act on the milieu—a principle at the core of TDS' instructional design. The evolution of the milieu described here is a condition that *enables* the pupils' opportunity to categorise polygons according to their number of edges.

The teacher's desire to introduce precise mathematical terms also points to introducing a language of distance. However, the situation is such that the pupils are able to express themselves clearly using gestures together with oral language, thereby using a language of nearness. However, in the game with the tiles it is necessary to use a language of distance in order to pick the correct tile. Hence, the intended language development is stimulated by the activity's adidactical potential.

It has been observed earlier that Norwegian children focus on the vertices when naming polygons (Rønning, 2004) but the observations made in this paper show that they may use different words depending on whether they approach the vertex from the inside or from the outside. We have also seen that they may use different words within the same shape, as with the non-convex quadrilateral in Figure 2. This shape is also interesting in the sense that it is not really accepted by Oliver as a quadrilateral but it would have been if "we had pulled this [the vertex with the reflex angle] out a little". We interpret this as Oliver's inclination to distinguish between convex and non-convex polygons. In future learning of geometry, the concept of a convex polygon will be introduced and this example indicates that early exposition to non-convex shapes can be important for making pupils familiar with these shapes.

Distinguishing between edges and vertices can also be seen to be important for future learning. For polygons, the number of edges is equal to the number of vertices so to name a polygon one may just

as well count the number of vertices instead of the number of edges. However, for polyhedra the number of vertices, edges and faces are not the same, and the naming is based on the number of faces.

The results presented here are relevant for mathematics teachers and teacher educators: They present challenges and affordances related to teaching of properties of polygons—with emphasis on language and characteristics of the milieu with which the pupils interact when solving a problem.

*This article presents the analysis of the discourse of a novice teacher when he tries to clarify what the sign of a vector quantity is. The elements considered for the analysis are language (speech and gesturing) and reference system concept as mediators within the process of meaning-making. Our analysis shows the novice teacher has difficulties promoting the understanding of the (negative) sign of a vector quantity and its relationship with the convention used to solve problems of motion of objects. The results shown here are part of a wider ongoing research concerning discourse analysis and teaching practice in grade 11 of two teachers with different profiles, expert and novice, from the theoretical approach of semiotics—the theory of objectification.*

*Keywords: Novice teacher, classroom communication, objectification theory, sign of a vector quantity, semiotic approach.*

## Introduction

From the discussion on the state of research in mathematics education which arose during the 10<sup>th</sup> *International Congress on Mathematical Education* (ICME-10), and as different works indicate (e.g., da Ponte & Chapman, 2006; Adler, 2000), there is growing attention to the teaching practices compared to what occurred in the past, when such practice was not a primary concern. Sfard (2005) states that it was particularly during the first decade of the 21<sup>st</sup> century when there was a decisive change towards the study of teachers' practices. From the works presented in the work group of mathematics and language in the past CERME9, and related with the interests of this research, it is of great importance to point out the interest on communication and interaction in the mathematics teaching and learning processes. In these processes, the use of gestures is included both in a communicative role and as a resource during teaching practice. Thus, we must highlight the works by Nachlieli and Tabach (2015), who show the elements of teaching practice that promote learning, and the work by Farsani (2015) on the role that deictic gestures play as a communicative tool. There are the works regarding the way in which meanings are produced in the classroom and the role of gestures as mediators of such process (e.g. Miranda, Radford & Guzmán, 2013). In this way we seek to contribute to the discussion on the relevance of interaction and communication on teaching and learning processes from an analysis perspective of semiotic orientation.

## Research problem

Da Ponte and Chapman (2006) agree that, in the 90s, Vygotsky's work came to prominence and evolved in a number of research lines with respect to teaching practices. Considering Vygotsky's concept of semiotic mediation —defined as usage of means [artifacts and signs] by which the individual receives the action of social, cultural and historical factors, and acts upon them (Vygotsky, 2009)—, Mariotti (2009) conducted a research with the aim of observing the teacher's role and the use

the teacher gives to artifacts in order to develop mathematical signs in the students during the teaching-learning processes. Mariotti considers that the teacher, playing the role of cultural mediator, is responsible for introducing specific terms and using his or her judgment to recognize what may be referred to as mathematical concepts. Morgan (2006) considers that: “An important starting point for a social semiotic perspective is the recognition that meaning making occurs in social context and language use is functional within those context.” (p. 220). In the same work, the author emphasizes the multimodal characteristic of communication in which, besides language, gestures and the use of other resources are found. In this sense, Arzarello, Paola, Robutti and Sabena (2009) highlight the dynamic process that takes place during the multimodal semiotic activity of the subjects.

Then, the research firstly goes back to the interest on teacher’s practice (a novice teacher data are reported here), and additionally it considers the use of a sociocultural approach of semiotic orientation to observe teachers’ practices. Our objective is to analyze the teacher’s discourse at the moment when he talks about the sign of a vector quantity in a physics class, in which the use of language and gestures is essential during the process of meaning making and awareness. Therefore, we pay close attention to the semiotic means of objectification [language, gestures and signs] that the teacher uses and encourages in the interaction with the students.

### **Conceptual framework**

The research is supported by the theory of objectification (Radford, 2014; 2008) that includes Vygotsky’s notion of semiotic mediation as well as the importance of the use of artifacts and gestures in the processes of knowledge production. Radford (2014) considers that the main objective of the theory of objectification (TO) is that of mathematics education as: “[A]s a political, social, historic and cultural effort with the aim of creating ethical and reflective individuals who take a critical position in mathematics practices historically and culturally constituted.” (Radford, 2014, p. 135–136, free translation). Thus, this formation of the individual involves an analysis between being and knowing in which both of them are closely interrelated. The principle of *labor* or activity represents the fundamental principle of the TO (Radford, 2014). It is through *labor* that the individuals are developed and continuously transformed and that we find the Other and the world in its conceptual and material dimensions. Through labor we find the systems of ideas of culture (systems of scientific, legal, and artistic ideas, etc.) and cultural forms of being as well. Radford and Roth (2011) introduce the concept of joint action, which implies more than a spatial notion where the interaction takes place. It represents the place in which the students and the teacher think and act together in pursuit of a common goal. It is important to emphasize that from TO approach, what mediates is the activity. Where both students and teacher are immersed. However, artifacts and signs continue play a relevant role. They are also part of the activity and are defined as semiotic means of objectification; which are: “These objects, tools, linguistic devices, and signs that individuals intentionally use in social meaning-making process to achieve a stable form of awareness, to make apparent their intentions, and to carry out their actions to attain the goal of their activities” (Radford, 2003, p. 41).

This approach also revisits the notion of consciousness as something concrete; it is a subjective reflection of the world. Then, any consideration regarding learning must also comprehend the field of consciousness in which the students’ thought and emotional orientations are included. Consciousness can be captured through its manifestations: discourse, gestures and all the other sensual actions. In order to recognize the forms of expression, action, and reflection, that are the

mathematical objects, the student goes through a social and physical process of awareness, which is mediated, in turn, by the activity; and where the artifacts and signs both physical and psychological belong to this activity (Radford, 2014; 2008). Therefore, gestures and artifacts act as important elements of the activity and are essential to the reflection processes. In this way, in TO, knowing and individuals are produced in the classroom through labor or activity. One way of identifying how meanings of mathematical objects are produced is through language and gestures.

Within the aim of this work, we include the teacher's practice to seek to characterize how the novice teacher promotes the objectification of the sign of vector quantities. In other research works, the role of gestures and the character of artifacts and signs as mediators has been developed; Roth (2000) particularly points out the importance the use of gestures has in the relationship with speech and in the road towards the scientific language. Roth indicates that, in the absence of an appropriate scientific discourse, gestures help to explain and describe the phenomena among the students. Additionally, he stresses that, during the emergence of the [scientific] discourse, both the iconic and the deictic gestures precede the spoken words associated with them. For their part, Moreno-Armella and Sriraman (2010), consider that the access to [mathematical] objects is not direct, but through mediation. The way in which we interact with our environment and the rest of the people—for instance, through language—is part of our symbolic nature. They state that: “Only humans possess, (...) what can be termed *explicit cognition* that allows us to go from learning to knowledge. Explicit cognition is symbolic cognition. The symbol refers to something that, although arbitrary, *is shared and agreed by a community*.” (Moreno-Armella & Sriraman, 2010, p. 216).

## Method

This is a qualitative research performed through a case study. The pilot study was carried out in a high-school (grade 11) from Mexico City. The participants were two teachers (expert and novice) who teach physics and who have over 20 years and 2 years of experience, respectively. This article reports the data collected from the novice teacher. The instrument to collect the data was non-participant observation of the *Physics I* classes. In the classes, the teacher addressed mechanics topics, specifically, Newtonian dynamics. The teacher considered the concepts of force, displacement, and interpretation of Cartesian graphs. The classes lasted two hours (twice per week) and one hour (once per week). We observed 12 sessions and obtained 20 hours of recording. We used two cameras controlled by the researcher. One camera remained fixed and was directed to the board while the other was moved to focus on the interactions during the students' participations. In addition, we used a voice recorder placed on the teacher to obtain audio recordings of the classes. After the data were collected, we watched the videos from the classes to identify moments when key concepts had been addressed. Once the moments (class segments-excerpts) were identified, we transcribed what occurred in those segments. Our analysis is based on those transcriptions.

## Analysis and discussion of results

Below we present excerpts that show the discourse of a novice teacher who tries to clarify the purpose of using the sign in a vector quantity on a free fall problem. In its entirety, the teacher's discourse lasts around 10 minutes. To carry out the analysis, we identified three main excerpts that deal with the teacher's discourse regarding the concept of a vector quantity. The excerpt starts after a student [who does not take part in the dialog] goes to the board to write a response and uses the value of

acceleration of gravity (“ $g$ ”) with a positive sign (see Figure 1-Photo 2). It is two students (S1 and S2) have a question about the sign that the teacher’s explanation starts. The excerpts correspond to a class in Spanish, in such a way that a translation in English is presented, trying to maintain dialogues fidelity.

### Excerpt 1- Is gravity negative?

S1: Teacher, is gravity negative?

Teacher: It is negative.

S2: Is it?

Teacher: Gravity will always be negative, right? But in this case (...) I’d told you that acceleration was a vector, right? Then, for example, if you want to speak in, let’s say, a vector manner, you must express gravity with its negative. Because it will always point down [*makes a gesture; see Figure 1-Photo 1*], right? But in this case, if you place it like this, in a scalar manner (...) we’re only looking at the magnitude of the gravity. Which would be 9.8. I mean, gravity will always go down [*A student says: “but not now”*] on the axis and down. Let’s leave it at that for now [*with the positive sign*].

**Figure 1: Photos of gestures used by the teacher to represent the sign of gravity in two moments (Photo 1-left; Photo 2-right).**

The intention of the teacher is that the students understand the sign of  $g$ ; that is to say, the students have to be aware of the meaning of the sign of gravity. The teacher seeks to encourage this awareness through a speech in which he includes gestures. However, from this point it is evident there is no articulation between the teacher’s verbal arguments and his gestures. The teacher stressed that  $g$  “will always be negative.” However, the argument the teacher uses gesturally links  $g$  with the type of motion (free fall) and not with the mathematical relationships of the function of motion (position with respect to time). When he says “Because it will always point down”, the teacher does not explain that “down” —or “up”, given the case—depends on a frame of reference involving a starting point (origin) from which measurements and directions (orientations) are taken to obtain numerical values. That is, the set of conventions used is arbitrary.

### Excerpt 2- The system of reference

S3: And if I did it using the minus nine point eight? [*referring to  $g = -9.8\text{m/s}^2$* ].

Teacher: If you did it with the minus, that means that, what does it mean? That when you were talking about this problem... [*He is interrupted by another student*].

S1: But you said that it was if it was falling, then...

Teacher: I'm telling you " $g$ " will always be negative, right? [See Figure 2-Photo 1] Now, you will take a point of reference (...) [the teacher draws a system of coordinated axes; see Figure 2-Photo 2]. If you take a point of reference here. Here, it would be  $y$  [vertical],  $x$  [horizontal], right? Then, if you take the point of reference there, what is the value of this point? [pointing at the origin of the Cartesian system he drew] It is the origin, what is its value? [S1 answers: "zero, comma zero"] Right now, we are only acting on  $y$ , then the value will always be zero at  $x$ . Then, if this [the stone] is falling towards here [simulates the fall of the object with respect to the diagram; see Figure 2-Photo 3], that is why we have a negative value in  $y$ . Because  $y$  that goes down is negative. (...) Because the point of reference, we are up here [points at the origin of the Cartesian system] and we are measuring how the little ball falls down, but from my point of reference [makes a gesture using both hands; see Figure 2-Photo 4]. Which would be from the bridge. I won't be measuring this in the water, right? Then, that's why it is negative in this case [the distance (height)] and that's why I'm telling you that this [acceleration of gravity] is negative.

**Figure 2: From left to right, photos of gestures used by the teacher to represent: the phenomenon (Photo 1), the system of reference (Photo 2), the motion of the object with respect to the system of reference (Photo 3), and the measurement of the distance (Photo 4).**

S1 goes back to the notion that the sign and the values obtained depend on the direction of the motion observed. Later, the teacher incorporates a conceptual resource he considers necessary to understand the sign of  $g$ , that is, the concept of system of reference. It is observed that the teacher determines it [system of reference] from the system of coordinated axes (Cartesian graph) and its usual directions (positive: up and to the right; and negative: down and to the left). At this point of his speech, the teacher mainly uses the mathematical concept of system of reference. His use of the language makes him focus on conveying the mathematical meaning of the problem while he uses gestures only when addressing the physics phenomenon. What is observed is that it considers mathematical thinking and physics separately. For instance, the teacher seems to use gestures to exemplify frames of reference oriented negatively down only. The meaning of his gestures only depends on the particular motion of the object (Photos 3 and 4). Thus, the teacher is explicit when he says: "That is why we have a negative value in  $y$ . Because  $y$  that goes down is negative." Therefore, with respect to the language used by the teacher in this excerpt, it is unclear how students can be aware of the sign of  $g$  from the use of reference systems when the teacher includes the system of reference in his speech.

### **Excerpt 3- Two signs for the same problem**

S3: But I still don't understand the thing about gravity.

Teacher: I'm telling you that, in this case, the acceleration is a vector. And if the acceleration is a vector, the acceleration of the gravity will also be a vector, ok? Then, this here [*points out at the sign in Figure 2- Photo 1*], the negative of the gravity is indicating where gravity is always directing to. Then, it would be something like this [*draws an arrow pointing down on the board*]. It will always be directed downwards. Now, this will always be [*writes: " $g = -9.8\text{m/s}^2$ "*], this will never change. Now, if you do not want to express this to me [*referring to the acceleration of gravity*], then give me the scalar, I mean, give me the magnitude of your gravity. Then, if you give me the magnitude, it would only be this here [*see Figure 3-Photo 1*], yes? I mean, without the negative, 9.8. If you tell me where it is headed to, you're giving me the direction [*see Figure 3-Photo 2*], which is downwards, really. And in that same way, to get the distance covered. If you tell me, are you going to say it in distance? Or are you going to say it in displacement? Displacement is supposed to be a vector, too. (...) Then, when you get the magnitude, it will always be a magnitude like this [*covers the negative sign of the acceleration of gravity again*], positive.

**Figure 3: Photos of gestures used by the teacher to represent: the magnitude of a vector (Photo1-left) and the direction of a vector (Photo2-center); additionally, a photo of the board (Photo 3-right)**

What S3 says at the beginning of the excerpt indicates that, so far, the “relativity of the sign” has not been understood and that it depends on the frame of reference used to analyze the physics phenomenon. The teacher goes on with the discourse, explaining that knowing the sign of a quantity means knowing the direction of the motion, and says: “the negative of the gravity is telling [us] where gravity is always directed to.” However, gravity does not go “upwards” or “downwards”, but to the core of Earth, which to our perception is “falling down”. The difficulties arise when trying to explain why. Then, the teacher focuses his attention on the magnitude of a vector (see Figure 3-Photo 1). Again, using a gesture, he hides the negative sign of  $g$  to refer to a probable positive value, yet he relates such value to a scalar quantity and not to the direction of the vector in a system of reference. The teacher implies that one can make reference to the two signs in one quantity in the same problem, which results in an ambiguity to the student.

In teacher discourse, it is important to realize the use he makes of the board, it is noteworthy saying the teacher only writes numbers, symbols (Cartesian graph, vectors) and formulas, but fails to write a single word; and that creates a gap between his discourse (spoken language and gestures) and symbolic language. The students are used to writing down what information is on the board, without adding elements from the spoken language. Therefore, when they go back to check their notes, they can hardly remember the exact words the teacher used, instead, they only see abstract symbols. Thus, reconstructing both the discourse and the discussion that unfolded can be difficult for them. Thus, it would be convenient to carry out research aimed at an analysis of the use of resources by the teacher.

## Conclusions

In this work, we observe the roles language and gestures play in a novice teacher's discourse and the difficulties he faced when trying to stabilize awareness on the meaning of the sign of  $g$ . Then, the way in which the meanings of the mathematical concepts are displayed and understood involves the mobilization of gestures and signs. This is because gestures, artifacts, signs, and the process of meaning making in the classroom, have a semiotic nature. We observed the complexity and the importance of articulating language and other semiotic resources as gestures and concepts—system of reference—in the processes of meaning making. Particularly, we observed there was no satisfactory coordination between the teacher's gestures and language. While the teacher consistently used gestures to point out the negative sign of the gravity when the object “falls down”, he was vague when trying to explain why the sign was negative from its vector character. Then, the teacher focused his language only on the mathematical characteristic of the problem, but he focused his gestures on the physics description of the problem. We observed, however, an attempt to coordinate language and gestures in the excerpt in which he includes the use of the concept of system of reference. It follows that determining the system of reference to solve a given problem in advance is essential. Therefore, the system of reference used as a semiotic resource may allow this articulation between the mathematical meaning and the physics motion of objects to be understood. And this motivates us to conduct further research on this line.

*In Germany, as in other countries, language proficiency impacts the achievement in mathematics. Linguistic features may constitute possible obstacles for students solving word problems. This study explores the interplay of language proficiency and achievement in mathematics with tasks in which linguistic characteristics were varied experimentally. 640 10<sup>th</sup> grade students solved the tasks. An analysis of the shift in difficulty of linguistically varied tasks indicates an irregular scheme: Only tasks with extreme variation of linguistic aspects, for example many nominalizations, show a significant shift. Data collected from student interviews using the think-aloud method show that linguistic aspects can be obstacles and therefore have an impact on the solution process, even if these linguistic aspects may not have an impact on the results in the quantitative part of the study.*

*Keywords: Language proficiency, difficulty level, item analysis, language obstacles, mathematics achievement.*

## Language and mathematics

### Impact of language proficiency on mathematics achievement

Research on the relationship between language and mathematics has a long tradition in Germany and internationally (Barwell et al., 2016; Maier & Schweiger, 1999). In Germany, research on differences in achievement in mathematics due to background factors is relatively new when compared to research in Anglophone countries. Internationally, the strong influence of language proficiency on mathematics achievement, especially for word-problems and tests that follow the literacy approach, has been an issue for decades (Abedi, 2006). International surveys, such as PISA, show that there is a strong connection between mathematics achievement and family background in Germany, especially regarding the socio-economic status and the first language (Gebhardt, Rauch, Mang, Sälzer, & Stanat, 2013). In a recent German study, Prediger and colleagues have identified that “language proficiency is the background factor with the strongest connection to mathematics achievement, among all social and linguistic background factors” (Prediger, Wilhelm, Büchter, Gürsoy, & Benholz, 2015, p. 77; see also Prediger, Wilhelm, Büchter, Gürsoy, & Benholz, 2013).

### Linguistic aspects causing difficulty in mathematics

For English, Abedi and Lord (2001) showed that word problems with low linguistic complexity can reduce the achievement gap evoked by differences in students’ language proficiency. However, Martiniello (2008) reports that research about effects of linguistic features is inconsistent. For example, items with many polysemous words, pronouns or prepositions are difficult only in some grades and the number of subordinate clauses and passive-voice sentences had no significant effects. In her own study, she highlights complex sentence structures with embedded adverbial and relative clauses, long noun phrases and limited syntactic transparency on the syntactic level and

unknown or polysemous words on a vocabulary level as linguistic features creating difficulties (Martiniello, 2008).

For the German language context, there are only a few studies about linguistic obstacles. For example, noun phrases and the number of academic language words seem to be difficult. The identified obstacles of word problems in the study by Prediger et al. (2015) included prepositions, complex syntax and nominalizations. The obstacles did not only occur in the context of reading, but more often they were related to conceptual understanding. In this study the specific linguistic features which made the text complicated could not be isolated as they interacted with each other as well as with the mathematical content. With the experimental approach in our study, we strived to address this issue. For the specific context of the German language, we wanted to specify to what extent linguistic aspects could explain the achievement gap between students of higher and lower language proficiency by investigating the questions:

Q1. What impact do different linguistic aspects have on the achievement in literacy-based tests?

Q2. Which linguistic aspects are difficult for (lower language proficient) students?

## **Research design and methods for the mixed-methods study**

### **Context of the study**

The mathematical tasks of the study were oriented towards the literacy-based high stakes exam “Zentrale Prüfungen am Ende der Klasse 10 (ZP10)” [central examinations at the end of 10<sup>th</sup> grade] of North-Rhine-Westphalia (NRW), the most populous federal state of Germany. The ZP10-exam is designed by QUA-LiS NRW, the “Qualitäts- und UnterstützungsAgentur – Landesinstitut für Schule NRW” [Quality and support agency – Institute for school NRW] that supports the Ministry of Education and lifelong learning in NRW. The exam does not only assess mathematical competencies acquired in 10<sup>th</sup> grade, but also the competencies acquired during grade 5 to 10. For that reason, our tasks are required to illustrate different mathematical levels.

### **Design for the quantitative part of the study**

The sample consists of 640 students from ten different comprehensive schools in the metropolitan area of Rhine-Ruhr. As independent variables, we collected information about students’ language proficiency, cognitive capabilities and family background (cf. Table 1). Another important variable was the linguistic variation in the tasks. The dependent variable was mathematics achievement.

Language proficiency was measured using a standardized C-Test. Cognitive capabilities were measured by the extended standardized German adaption CFT-20R of culture fair intelligence tests. Information about family background (socio-economic status, immigrant status, languages spoken at home) was collected by questionnaire.

The mathematics test was designed referring to the ZP10-tests. Members of QUA-LiS NRW assured that our test would be acceptable for the high-stakes exam. The 90 minutes long test contained the typical topics of ZP10 – functions, descriptive statistics and percentage calculation – which appear in the exam every year. These tasks were also chosen since the study of Prediger et al. (2015) revealed many language obstacles in tasks about these topics. These observations are supported by results of Martiniello (2008) who identified data analysis, statistics and probability as topics that were difficult for English learners with Spanish as native language in the US.

The test was presented in three versions (A, B and C) with six identical anchor tasks (21 items) and six tasks with linguistic variation (13 items). The tasks with variation always existed in three different versions; the context and mathematical content remained unchanged at all times. In the initial version, we avoided difficult linguistic structures in the tasks, especially those structures that were varied in the other versions. Besides this initial version, the tasks were varied using two of the four linguistic features context vocabulary, verbs followed by prepositions or separable verbs, nominalization and density of the text, and reference structure, which were chosen out of possible linguistic obstacles in word problems reported in Prediger et al.'s study (2015).

On the word level, we chose the criterion “context vocabulary”, which often causes problems but – in contrast to technical terms – can be changed without having influence on the mathematical content. Concerning the syntactical level, interviews in the study of Prediger et al. (2015) confirmed the linguistic supposition that it is difficult for students to connect information given in sentences with separated separable verbs or between a verb and its preposition. Since Uessler, Runge and Redder (2013) also state that separable verbs influence the understanding negatively, we selected these two features as a variation-category. As mathematical texts are often very dense and their length and density play an important role in student's understanding, the feature “density of the text” was chosen. This goes hand in hand with the feature “nominalization”, because a dense text implies (in German) the use of many nominalizations which have a negative effect on the understanding (Uessler et al., 2013). Therefore, these two features form one variation-category on the text-level. As mathematical texts try to avoid repetitions, the reference structure is often unclear. This led to consideration of “reference structure” as another category on the text-level. An example of a varied task will be presented later.

The groups of students sitting for the tests A, B or C were systematically formed based on the results from the C-Test and the CFT-20R. The variations were dispersed equally to the three versions of the test. There were no statistically significant differences between the groups concerning language proficiency, cognitive capabilities and mathematics achievement.

For data analysis, different statistical analysis procedures were applied. We split the group in half depending on students' results on the C-Test into groups of students with lower (C0) and higher (C1) language proficiency. The mathematical items were scaled using a Rasch model. An analysis of variance (univariate ANOVA) and a regression analysis were used to identify the background factors with the highest impact on mathematics achievement and to determine the explained variance. The shift in difficulty from the initial version of a word problem to its linguistic variation was determined by an analysis of the change of the WLE for these items on the Rasch scale.

### **Design for the qualitative part of the study**

The purpose of this part of the study was to gain a deeper understanding of the quantitative results through a qualitative approach. For this reason, four tasks were presented to N=32 students with different levels of language proficiency from different comprehensive schools. The students were required to solve the designed tasks independently using the think-aloud method. Once the students solved the task, there was a discussion about the task between interviewer and student. All processes and discussions were videotaped, transcribed, and analyzed interpretatively with respect to whether the linguistic variations created difficulties for the students.

## Examples of linguistic variation of tasks

An example of the linguistic variation of a particular task is represented in the translated initial version (1) and its variation “nominalization/dense structure” (2) of the task “Bathtub”.

(1) A bathtub has one cold water tap and one hot water tap. The bathtub can be filled with 135 liters of water. If both water taps are open, it takes 9 minutes until the bathtub is filled completely. If only the cold water tap is open, it takes 7.5 minutes more than with both water taps open. How much water runs out of the opened cold water tap per minute? Note your calculations.

(2) A bathtub **with one cold and one hot** water tap can be filled with 135 liters of water. **Opening** both water taps, the **filling** of the bathtub takes 9 minutes; **exclusively opening the** cold water tap, it takes 7.5 minutes more than **by opening** both water taps. Which **amount of water** runs out of the opened cold water tap per minute? Note your calculations.

The bolded words or phrases show the variations in the task for this article. The translation of the tasks can only give an idea of the linguistic aspects that have been changed during variation, because most characteristics are inherent to the German language and sentence structure. For example, if you try to nominalize “the cold water tap is open [der Kaltwasserhahn ist geöffnet]” into “**opening the** cold water tap [Öffnung des Kaltwasserhahns]”, in German, it implies the genitive case of “the cold water tap” tagged by an additive “s” at the end of the word [“Kaltwasserhahns”].

The variation of the items was not possible in every case, because of the structure of the German language. Sometimes it was impossible to use alternative formulations using the defined categories and employing them at positions in the text that are significant for the mathematical solution. The variations were limited due to the common use of language, the context and the linguistic realization of mathematical concepts. In addition, we had to accept the fact that variation of isolated linguistic aspects is almost impossible. In the German version of “If only the cold water tap is open [Wenn nur der Kaltwasserhahn geöffnet ist]”, we find the participle II of the verb “open [geöffnet]” (in the English sentence it has the function as an adjective) because of the use of passive voice “is open [ist geöffnet]”. This has to be nominalized. In the nominalized version, it is linguistically not possible to continue to use the familiar adverb “only [nur]” but necessary to use the less frequently used adjective “exclusively [ausschließlich]”, which imposes another possible lexical obstacle.

## Selected results

### Impact of background factors

To check if linguistic features can explain the achievement gap due to different levels of language proficiency, we first analyzed the impact of background factors in our study. The results provide additional support for evidence of the impact of language proficiency on mathematics achievement. Students with higher intelligence or higher language proficiency, without immigrant status, and students who only speak German at home had statistically significant better results in the mathematics test (see Table 1, the number of the test persons varies because not all students gave the questioned information).

Regression analysis shows that language proficiency and cognitive capabilities as isolated background factors have the highest impact on mathematics achievement. They both explain about

15 % of the variance. The other background factors explain much less: Univariate variance analysis showed only low explanation potential of immigrant status (12 %), languages spoken at home (8 %) and socio-economic status (1 %). As language proficiency has such a high impact in our study, we investigated if it is possible to explain the achievement gap by the introduced linguistic obstacles.

Background factor	Specification of groups	Distribution of groups	Mean score (WLE), m(SD)	Significant differences
<b>Students</b>	10 schools	n=640	-1.37 (1,16)	-
<b>Version of mathematics test</b>	version A version B version C	219 (34.2 %) 214 (33.4 %) 207 (32.3 %)	-1.28 (1,16) -1.49 (1,14) -1.34 (1,16)	-

**Table 1: Distribution and differences among groups**

### Shifts in difficulty due to linguistic variation

All results for the different variations have been scaled in a Rasch model. Shifts in difficulty due to the linguistic variation were identified especially in Item 6 “Bathtub”. In the initial version, 69 % of the C1-students and 48 % of the C0-students solved the item correctly. This shows that the initial version was easy for C1-students and common for C0-students. In the nominalized version with dense structure, half of the C1-students solved the item correctly compared to only 37 % of the C0-students. The varied version was common for C1-students and difficult for C0-students.

Figure 1 depicts the shift in difficulty for the variations in comparison to the initial version. In comparison to the initial version, the denser text containing nominalizations became 0.6 WLE more difficult on the Rasch scale, comparable to three out of 34 correctly solved items in our study. Other items of this variation had no significant shift in difficulty (see Figure 1, left side). Students who only did tasks formulated like Item 2b would solve one item less correctly (0.2 WLE = 1 item); students who only had tasks formulated like Item 2a or 8a would solve the test basically the same. One explanation for the increasing difficulty of “Bathtub” is that this item is linguistically more difficult than others with the same linguistic variation, as the Flesch-Reading-Ease index shows.

The variation “reference structure” equally evoked a shift of 0.6 WLE for Item 6 “Bathtub”. Other items with variation showed inconsistent shifts. Some items became more difficult, other items less

difficult. A possible explanation is the higher relevance of mathematical content in contrast to language in particular items. For example, language has less effect in Item 8a, “What is the median?”. In this case it is more important that the concept of median has been taught in mathematics classroom. Similar irregular shifts are visible for the other variations.

**Figure 1: Shift in difficulty compared to initial version (in WLE)**

In summary, linguistic variations make word problems more difficult, when applied often and when the general difficulty for understanding the word problem (cf. Flesch-index) increases greatly because of the application of these variations. In these cases, we talk about “extreme variations”. Slight variations with only few modifications, which do not increase the difficulty for understanding, do not have statistically significant shifts. As the effect fluctuates substantially between different items, we can presume that the topic of a task is very important.

### **Linguistic variations as source for mathematical difficulty**

The fact that the difficulty does not increase significantly for all items (with linguistic variation) does not imply that linguistic variation does not evoke obstacles for students, as our qualitative analysis highlights. Furthermore, we have observed that linguistic aspects do not create difficulty on their own, but in combination with other characteristics of the task as illustrated below.

In addition to the quantitative data, 16 tenth grade students solved the item “Bathtub” in the version “nominalization/dense structure” during the interviews. In particular, students with lower language proficiency had difficulties in understanding the word “exclusively [ausschließlich]”, which had to be used due to the nominalization. While reading the text aloud, several students were puzzled by this word and explained they would never use it. This problem has already caused wrong solutions in the tests. One student wrote: “I do not understand the question. Does ‘exclusively opening the cold water tap’ mean that only the cold water tap is used?” He knew the correct meaning of “exclusively” but he was not sure about it. Probably, this was the reason he did not solve this item. The nominalization “Opening [Öffnung]” of “to open [öffnen]” and the following genitive case of “the cold water tap [der Kaltwasserhahn]” also caused understanding problems, as the genitive case of “cold water tap [Kaltwasserhahn]” finishes with an ‘s’ “[Kaltwasserhahns]” which in German is sometimes also a cue for plural of a word. In this case, the plural would be [Kaltwasserhähne].

Student: I was confused by the word “Kaltwasserhahns”. Does it mean two water taps or only one?

Apart from the linguistic variation, we identified other difficulties in our interviews. In particular, students with lower language proficiency had problems in understanding the relation “more than” and made wrong calculations. One student thinking aloud said (after three minutes of task solving):

Student: Ah, now I made a wrong calculation [...] I thought that ... the filling takes 7.5 minutes, but it takes 7.5 minutes MORE. I have to do a new calculation.

In the final discussion, many students could identify the relevant information “more than” and “exclusively opening the cold water tap” on their own or after a question from the interviewer. This shows that, even if there are difficulties in understanding the text, most of the students could solve the task if they had enough time and could verbalize their thoughts aloud. In contrast, in the tests, students often stopped solving a task because of uncertainty concerning their understanding.

## Conclusion and consequences

Our outcome concerning Q1 is that linguistic variations had significant impact when the task varied in an extreme way. The fact that in German isolated variations have no overall significant impact evokes the hypothesis that they create difficulty in combination with each other or with other characteristics of the tasks. This hypothesis is supported by the qualitative results showing that not only the linguistic feature itself, such as nominalizations, but also the linguistic structures evoked by this feature, such as genitive cases, create difficulty. However, this has to be analyzed further.

In the context of Q2, in German, nominalization/dense structure, academic words such as “exclusively [ausschließlich]” or genitive cases are obstacles for several students, especially those of lower language proficiency. This was, for example, prominent in the results of lower language proficient students for the item “Bathtub”. Students struggled in understanding these structures, which sometimes lead to not solving the task. When students had a lot of time and could speak out their thoughts, they reflected on these difficulties.

Consequences of this study for test construction are that high stakes tests should try to avoid extremely difficult linguistic structures, e.g. due to the frequent use of nominalizations, to reduce the achievement gap. Our study also showed that linguistic difficulties cannot always be avoided because there are constraints in the language. A consequence for mathematics classrooms that has emerged from students’ ability to overcome linguistic difficulties by talking about them in our interviews, would be to explicitly address language issues and not to avoid linguistic difficulties.

The fact that our results pertaining to the effects of linguistic variations cannot explain the achievement gap, entails further and deeper research on the interplay between language proficiency and mathematics achievement in order to determine the nature of this correlation. A hypothesis that came up in our study and will be investigated is that the selection of strategies by students and their processes of solving tasks differ according to their language proficiency.

## Acknowledgment

We would like to thank Claudia Benholz, who was part of the project team as a linguistic expert, Susanne Prediger for the discussion and advice, and QUA-LiS NRW for funding this study.

# Multilingual learners' opportunities for productive engagement in a bilingual German-Turkish teaching intervention on fractions

Alexander Schüler-Meyer

TU Dortmund University, Germany; [Alexander.Schueler-Meyer@math.tu-dortmund.de](mailto:Alexander.Schueler-Meyer@math.tu-dortmund.de)

*A teaching intervention should provide learners with opportunities for productive engagement with mathematics. Teaching learning situations are organized in patterned ways along culturally shared expectations of how these situations unfold. However, in multilingual classrooms, expectations of language learning can compete with mathematical expectations. Drawing on positioning theory, I will reconstruct these expectations – storylines – in a bilingual Turkish-German teaching intervention, specifically for the case of two learners, Akasya and Ilknur. I will show how the teacher establishes two expectations, one of “deciding who has downloaded more gigabyte” and one of “giving a Turkish explanation”. After some effort on forming an explanation, Ilknur’s and Akasya’s shift their activities towards fulfilling the second expectation, which results in them being less agentic for the mathematics at hand. Instead, Ilknur and Akasya focus on the form of their explanation.*

*Keywords: Mathematics education, multilingualism, positioning theory, agency.*

## Introduction

As learners construct mathematical knowledge by participating in social practices, they need to engage in interpretations and reflections on the meaning of mathematics, rather than being mere “receivers of predetermined knowledge” (Boaler & Greeno, 2000, p. 179). Productive engagement is an engagement in the classroom where learners are making each other understandable and where the students are responsible for the mathematics at hand, in ways that allow the learners to actively develop their interpretations of knowledge involved in a teaching-learning environment (Turner et al., 2013).

Multilingual mathematics learners are especially at risk to not engage productively. For example, it has been documented that many multilinguals do not actively engage in classroom discussions because of the demand to speak in the language of instruction (Planas & Setati, 2009) or that a focus on correctness in the language of instruction excludes multilingual learners and interrupts the engagement with mathematics (Planas & Civil, 2015, p. 47). Such mechanisms of inclusion and exclusion from productive engagement can be understood with positioning theory, where individuals in a conversation dynamically take up specific roles – positionings – and act according to the duties and rights that come with these positionings. To make sense of their positionings and their rights and duties, learners relate to storylines, where storylines stem from culturally shared patterned ways in which conversations are organized (Wagner & Herbel-Eisenmann, 2009). For example, in a storyline where the teacher asks questions and evaluates students’ answers, the teacher is positioned to evaluate these answers. The learners are positioned with the duty to give answers, but also with the right to not contribute for a certain time. When the learners perceive this storyline as “I may be negatively evaluated”, they may refuse to contribute, and might be less productively engaged with mathematics.

This study addresses two questions: How does the use of two languages in a bilingual teaching intervention influence the learners’ positionings, and how does this affect their productive engagement with mathematics? Accordingly, the paper presents the here employed theoretical

framework of positioning theory; analyzes data from a bilingual Turkish-German teaching intervention on fractions, specifically the case of Ilknur and Akasya; and shows that by switching the understanding of the storyline of the intervention “giving a Turkish explanation” towards “giving an answer with the form of an explanation”, the learners are less agentic for the mathematics at hand.

## **Positioning theory for investigating productive engagement in multilingual settings**

In a teaching-learning situation, teacher and students fluidly take up certain roles, similar to the roles actors take up in a stage play, where these fluid roles are called positionings. “Positioning [...] is the discursive process whereby selves are located in conversations as observably and subjectively coherent participants in jointly produced storylines” (Davies & Harré, 1990, p. 48) The individual in a conversation will take up, resist or reframe positionings as it tries to be subjectively coherent in his or her actions. At the same time, the actions of the individuals become intelligible to the others as they assume that the individual’s actions are coherent with his or her position (Langenhove & Harré, 1994, p. 362). The theoretical construct of positioning resonates with classical interactionist perspectives on classroom interaction in its assumption that learning, identities and even competence are a result of social interactions (e.g. Cobb & Bauersfeld, 1995). Positioning theory has been used in mathematics education to investigate classrooms in regard to issues of opportunities to participate.

Storylines are jointly produced, they “stem from culturally shared repertoires” (nurse/patient; coach/athlete) (Wagner & Herbel-Eisenmann, 2009) and the culturally shared patterned ways in which conversations are organized. Different storylines provide learners with different means for productive engagement (Herbel-Eisenmann & Wagner, 2015). The use of more than one language reinforces these issues, because it brings more diverse storylines to the classroom – for example of the political value of languages or storylines of language learning – that might affect mathematics learning. Studies on multilingual mathematics learning from the perspective of positioning theory suggest which storylines might lead to productive engagement, and which not: in his research with Latino learners in the US, Domínguez (2011, p. 325) shows that students’ home language “figures as a language to discuss, argue, take risks, and learn with others, whereas English tends to be reserved for enacting more traditional schoolwork”. Storylines that allow learners to position themselves as mathematically competent while relating to everyday experiences tend to lead multilinguals to productive engagement (Moschkovich, 2002). Norén (2015) gives an example where multilingual students are productively engaged because the teacher establishes a storyline that allows for talking in non-formal ways and making use of out-of-school-experiences. On the other hand, multilingual students may position themselves and others based on storylines from previous classrooms where they have been positioned as less proficient language learners (cf. Civil & Planas, 2004).

As storylines are a product of the individuals’ interpretations in a conversation, more than one storyline can coexist in a given situation. These different storylines mirror themselves in the different positionings that are on the one hand assigned, and on the other taken up by the individuals: while in a teaching learning situation the storyline of teacher/learner is jointly produced, the individuals in the conversation might have different notions of what this storyline is and how they are positioned in it. In this paper, I will analyze the storylines that are jointly produced and the notions the students have of this storyline. I investigate the question: *How does a jointly produced storyline in a multilingual teaching intervention influence the students’ productive engagement, and hence, their agency?*

## A bilingual teaching intervention on fractions

The here presented case study is part of the research project MuM-Multi which investigates how to foster multilingual learners in the mathematics classroom. A multilingual Turkish-German teaching intervention on fractions was conceived. The teaching intervention builds on a previous project (Prediger & Wessel, 2013) in that it combines a conceptual learning trajectory with a language learning trajectory. Furthermore, it builds on the relating registers approach (Prediger, Clarkson & Bose, 2016). In this approach, the mathematical-technical-register, the academic-school-register and the everyday register are continually interlinked. For example, the multilingual students are asked to reflect on the Turkish way to express fractions as ‘5 de 3’ (‘5 therein 3’) (Turkish mathematical-technical register) for which they are asked to employ the graphical representation of a fraction bar and the activated everyday contexts (sharing a bar of Baklava-cake). The relating registers approach serves as a heuristic tool for designing activities and learning opportunities in which the multilingual learners can access their multilingual resources for developing conceptual understanding of fractions.

Each session of the teaching intervention starts with an everyday, out of school contexts that connect in culturally sensitive ways to the multilingual experiences of the learners. For example, the first task starts with a short story about a traditional Turkish figure, the “Nasrettin Hoca” and children sharing a Baklava with him in an unfair way. The following tasks in a teaching intervention are then anchored in the culturally sensitive out-of-school context, so that the students can relate to their everyday experiences while working on the mathematical tasks. During all sessions, the fraction bar is implemented as a central graphical representation. All worksheets are given in both Turkish and German, assigned by the teacher.

41 multilingual students in grade 7 with low mathematics achievement and heterogeneous German and Turkish language proficiency participated in eleven small groups in the bilingual teaching intervention lasting five sessions of 90 minutes each. The intervention was conducted by four specifically trained bilingual Turkish-German teachers who were sensitized for specific affordances of teaching in multilingual settings, for example strategies of revoicing. However, the teachers were not aware of the specifics of positioning students in conversations.

The eleven groups of the bilingual intervention were videotaped over the course of the intervention, and specific groups and sessions were selected for transcription based on considerations of key points in the learning trajectory that occur after the students got familiar with speaking Turkish (Sessions 2 - 4). The video material was transcribed and, where necessary, translated into German. The data is analyzed qualitatively in a turn-by turn analysis of the learners reflective positionings and the teachers interactive positioning, that is, the positioning of learners themselves within a conversation (reflective) and the positioning of the learners by the teacher in the conversation (interactive) that affects how the learners position themselves (reflective).

I illustrate the case of Akasya and Ilknur, as examples of students who successfully engage with mathematics in Turkish language in the last intervention session. I employ a positioning analysis that focuses on the students’ reflective positioning in reaction to the teachers’ interactive positioning in the unfolding mathematical conversation. By investigating the positionings the storylines of learners and teacher can be reconstructed. Productive engagement is analyzed with the construct of agency, according to which students are coded as productively engaged in moments when they are

- influencing the direction of the discourse
- asking for clarifications or clarifying
- taking charge of ideas
- establishing competence

This analysis allows investigating in which storyline the students are highly productively engaged, and when less. The analyzed transcript belongs to the first task of the second teaching intervention (Figure 1), in which ordering fractions for different referent wholes is approached by the everyday context of downloading movies.

<p><b>1 Film indirmek</b></p> <p> Selin ve Bleda internet'den bilgisayara farklı büyüklükte olan iki film indiriyor.</p> <div data-bbox="172 719 770 801"> <p>Canavar.mp4'ü „filmlere” kopyalıyor</p>  <p>0 GB 7 GB 10 GB</p> </div> <div data-bbox="172 853 770 936"> <p>At rüyası.mp4'ü „filmlere” kopyalıyor</p>  <p>0 GB 4 GB 5 GB</p> </div> <p>a) Hangi filmde şimdiye kadar daha fazla GB (Gigabyte) indirilmiş?</p> <p>b) Selin'in indirilmiş GB daha az olmasına rağmen download çubuğu neden daha ileride?</p>	<p><b>Downloading movies</b></p> <p>Selin and Bleda are downloading two movies in the internet, with different sizes.</p> <ul style="list-style-type: none"> <li>– copying monster.mp4 to “movies” –</li> <li>– copying horsedream.mp4 to “movies” –</li> </ul> <p>a) Where has more GB (gigabyte) been downloaded</p> <p>b) Why is Selin's fraction bar longer even though she has downloaded fewer GB?</p>
---	--

**Figure 1: First task of Session 2 of teaching intervention**

## Analysis: Storyline of Turkish speaking and less productive engagement

Two girls, Akasya and Ilknur, work on the first task in Session 2 of the intervention. Briefly, I will refer to another group of two students who work separately at another table on the same task. I will show here how the teacher changes and refines the storyline that guides his actions over the course of the task. As storylines are jointly produced, the students have to actualize their storylines in line with how they perceive this changed storyline. While Ilknur adapts her notion of the storyline to the newly established storyline of the teacher, Akasya seems to subsume this change under her notion of the storyline as “the teacher guides the discourse and will give the resolution of the task in the end”.

### Episode 1: The teacher changes the storyline

The teacher introduces the subtask b) to the students, and with it, also changes the previous storyline of “deciding who has downloaded more”. The students have signaled, by hand signal, that they have a solution to subtask a). The teacher now establishes a storyline which is not centered on finding a solution anymore, but one where explanations in Turkish are valued.

In the following transcript, the teacher comes to Ilknur and Akasya, after he talked to the other two students at another desk. His utterance marks the first change of the storyline:

- |    |         |   |   |
|----|---------|---|---|
| 75 | Teacher | [coming back to Akasya] Ben size ehm yanlış, hayır hayır yanlış var mı diye hiç korkmana gerek yok. | I have you, ehm, something wrong, no, no, you don't have to be afraid if it is wrong. You just have to write down |
|----|---------|---|---|

Sen sadece düşünceni yazacaksın.  
 Tamam? Yani siz Bleda kazandı  
 diyorsanız Bleda kazandı yaz ve  
 neden kazandığını düşündüğünü  
 yaz. Tamam?

your idea.  
 Okay? So, when you say that Bleda  
 has won, then write down that Bleda  
 has won and justify why he has won.  
 Okay?

The teacher metadiscursively addresses the rules of the conversation. In this way, he positions Akasya, and implicitly Ilknur, as competent regardless of the correctness of their solution, as long as she writes down her ideas, and justifies “who has won“. The students are explicitly positioned as explainer of their mathematical thinking in line with a storyline of “formulating a written explanation of your decision“. This is in contrast to the previous storyline of the teacher, where the students were asked to cooperatively decide whether Bleda or Selin has downloaded more.

In the following utterance, sometime after the previous transcript but still in the beginning of the work on subtask b), the teacher gives a reason why the students need to explain their thinking:

83	Teacher	Aber das ist gut, weil dann lernt ihr auch. Dann könnt ihr euch auch überlegen, wie ihr das auf Türkisch schreibt. Das ist eine gute Sache.	But that is good, because then you also learn. Then you also could think about how to write that in Turkish. That is a good thing.
----	---------	---	--

The teacher asks the students to think about how to “write [their explanation] in Turkish“. Again, he makes the rules of the mathematical discourse explicit by valuing the Turkish language and adding “That [Turkish] is a good thing“, which he repeats in the next turns. Valuing the Turkish language is a recurring theme in this storyline (turns 69, 83, 85) and is tightly interlinked with working on subtask b). In summary, by explicitly positioning the students in these ways, the teacher establishes a storyline where students are required to explain their thinking in (written) Turkish, perhaps best described as “Solving subtask b means giving a Turkish explanation of your solution“. This is a refinement of the new storyline.

## Episode 2: Ilknur takes over the teacher’s storyline

Ilknur seems to adopt the storyline established by the teacher. She makes several attempts to explain why, from her standpoint, Bleda has downloaded more. Her choice of language, her pauses and by “ehm“, suggest that she specifically tries to explain her thinking in Turkish:

86	Ilknur	Çünkü o .. on gigabyte [...]	Because he ... ten gigabyte
88	Ilknur	ehm yapti	um, he did

Ilknur attempts an explanation in Turkish, positioning herself in a way that acknowledges the position offered by the teacher (see turn 75). At first, she seems to be uncomfortable with explicitly using only Turkish – previously she only spoke Turkish in a mixed German-Turkish mode with focus on German – which is indicated by the hesitant way in which she forms her explanation. All her following task-related utterances after this turn are in Turkish (105, 108, 110), which suggests that she positions herself as Turkish speaker and that the storyline “giving a Turkish explanation” guides her actions.

## Episode 3: Students agency and potential for productive engagement

In engaging in Turkish, the students Akasya and Ilknur do not appear as agents for the content of their explanation. Ilknur explicitly positions herself as less competent with the Turkish language: When discussing which language their worksheets should have, Ilknur explicitly wants German worksheets, and she positions herself as being more proficient in French than in Turkish (94). This is reinforced by Ilknur and Akasya’s expressing the amount of effort it takes them to form a Turkish explanation

(see turns 86-88 and linguistic markers “Üfff“ (Boah), “Heh?“ in turns 106, 110). Above that, Ilknur and Akasya’s struggles also make them less competent in the eyes of the teacher. On the one hand, the teacher addresses those students who have already generated a Turkish explanation and positions them as competent by praising their solutions. Ilknur and Akasya, on the other hand, are addressed with “He şimdi kızlar (So, now, gals)” (turn 107) as a result of them not yet having generated a written explanation, this way positioning the students as being behind in the group.

In the following episode, Ilknur and Akasya seem to explicitly give up on their position as Turkish mathematics learners, and take up a position where they are responsible for the form of their solution. It seems that they give up their position because of mathematical difficulties, not language difficulties.

- |     |        |  |   |
|-----|--------|--|---|
| 113 | Akasya | Aber zehn ist doch mehr.               | But ten is still more.                  |
| 114 | Ilknur | Ist so. Ich weiß überhaupt nicht, baah | Its like that. I don’t know at all, wah |
| 115 | Akasya | Ich schreib einfach was.               | I will just write something.            |

When Ilknur and Akasya do not make progress in generating a Turkish explanation, they explicitly position themselves as learners who struggle with their task. This goes hand in hand with Ilknur switching back to German (turn 114). Akasya, in line with her storyline where the teacher guides the discourse, assumes that the teacher is likely to correct them in the end, so that only the form of their explanation matters, but not the content. It might be that in accordance with this storyline, Akasya and Ilknur will take up positionings where they exercise less agency for the mathematics at hand.

In summary, over the course of working on subtask b), the students have less capacities to engage with the mathematical content of the task within the storyline “giving a Turkish explanation”. They position themselves as insecure and less Turkish proficient, while they receive no help from the teacher or their peers, but are instead positioned as being behind the group. As Ilknur and Akasya have not yet written down their explanations, and as the teacher was not present, their efforts are not valued. In this sense, turns 114 and 115 can be read as a way to reclaim their agency: Within the teacher’s storyline of generating a Turkish explanation, the students change their activities towards writing “something” that conforms with the form of an explanation, but give up improving the content of the explanation. This is consistent with Akasya’s take on the storyline - in which the teacher is the guide of the conversation and responsible for the content of the explanations - seems to be taken up. The potential for productive engagement, that is, the potential for becoming responsible for the mathematical content, diminished in subtask b) as Ilknur and Akasya did not engage with finding a mathematical explanation in the task, but instead reclaim their agency with producing a Turkish sentence that complies with the form of an explanation. The storyline of the teacher allows for this, as the teacher gave a loophole with saying that “you don’t have to be afraid if it is wrong” (turn 75).

## Discussion

In order to be coherent with the teacher’s expectations of giving an explanation in Turkish, the students in the episodes try to form a Turkish explanation. This leads the students to focus solely on forming a correct Turkish sentence with adequate formal words, while the mathematics behind the explanation is not in focus anymore. As the students are not successful in forming a Turkish explanation, the students might take up a position of being less agentic for the content, resulting in less productive engagement with mathematics. It seems that the teacher, by asking for a Turkish explanation and by valuing the Turkish language, and the students, by taking over these positionings,

jointly produce two foci: one on the mathematical content in Turkish and one on the form of a Turkish explanation. In shifting to the second focus, the students lose their focus on the content of the explanation – which interestingly goes hand in hand with a code-switch back to German. It may be that the two foci are a product of valuing Turkish without giving the students the support they seem to need for talking about the content of the task.

Positioning theory and storyline analysis here proved to be a useful tool to reconstruct the participation of multilinguals and the opportunities for productive engagement and mathematics learning, especially in regard to the multilingual teaching-learning situation. However, it is an open question whether the students' multilinguality is a resource for the students in regard of what the storylines tell us in this research. Data suggest that difficulties with mathematics led Akasya and Ilknur to move the focus of their activity away from the content of the explanation. Previously, however, Ilknur struggles with the Turkish language. It is an open question whether Turkish might have added to Ilknur's mathematical difficulties in form of increasing cognitive-load, or if Ilknur is in a natural translanguaging mode where her choice of language is not relevant and where her difficulties would have remained if she had used German instead of Turkish.

### Acknowledgement

The project “MuM-Multi: Fostering Language in multilingual mathematics classrooms – effects and conditions of a content- and language integrated intervention” is funded by the German ministry BMBF (grant 01JM1403A, grant holder Susanne Prediger). I thank Susanne and my project partners T. Kuzu, L. Wessel, A. Redder, J. Rehbein, J. Wagner, and M. Celikkol for the cooperation.

## Authority structures in preservice teachers' talk

Konstantinos Tatsis and Bozena Maj-Tatsis

University of Ioannina, Greece; [ktatsis@uoi.gr](mailto:ktatsis@uoi.gr)

University of Rzeszow, Poland; [bmaj@ur.edu.pl](mailto:bmaj@ur.edu.pl)

*In the paper we draw on the authority structures that were observed in preservice teachers' talk while working with collaborating pairs of primary school pupils. We have found some interesting structures that emerged, especially when the preservice teachers had to consider the goals of their working sessions with the pupils, as conceived by them. Particularly, the preservice teachers switched to a more authoritative stance, usually when there was time pressure.*

*Keywords: Authority, preservice teachers, pair work.*

### Introduction

In any learning environment when there are more than one participants present, various interactions take place. Among these, the verbal ones have been the focus of numerous studies in the last decades. Most – if not all – of these studies originate from linguistics; in one the first papers that explicitly refer to the relationship between language and mathematics we read that “the processes of learning and communication are closely inter-related and both present the investigator with problems of bewildering complexity.” (Austin & Howson, 1979, p. 162). Today, almost 40 years since that statement was made, researchers in mathematics education are still struggling to interpret the complexities of learning and communication. However, the main interests of research remain on how students learn (at the same time, what constitutes learning may be by itself the topic of investigation) and what (can) teachers do to enhance their students' mathematical thinking. In our view, mathematical thinking relates to effectively participating in the mathematical classroom community (Yackel & Cobb, 1996). This in turn requires a particular distribution of authority in the classroom: the teacher is expected to “step back” from the official role and give room to the students to make conjectures, pose problems and generally think like mathematicians (Mason, Burton & Stacey, 2010).

Based on the above assumptions, we designed our study with preservice mathematics teachers. We engaged them in a research-type activity: they were asked to find a mathematical problem and use it as a tool to enhance pupils' creative thinking. Our main interest was in the ways these preservice teachers will manage the interactions and particularly their authority in order to achieve that aim. Our theoretical framework is presented in the next section, followed by our methodology.

### Theoretical framework

Language use in the mathematics classroom – or, more generally in mathematics learning contexts – can convey various aspects of the interactions or the mental processes that occur. There are at least two ways that we can view and analyse language use: at an object level, we may focus on the mathematical register and its use among the students and the teacher. From a teacher education point of view, this can be also related to mathematical knowledge (Rowland & Ruthven, 2011). Then, if we move to a meta-level, we realise that “sense-making in school mathematics is not solely a matter of private interpretation within some absolute, secure reality of ‘real’ objects (‘people’ and the like); it is also one of linguistic enculturation, of initiation to discursive practice”. (Walkerdine, 1988, p.

128, as cited in Rowland, 2000, p. 194). Mathematics learning is thus seen as a social process, regulated by rules and norms (Yackel & Cobb, 1996), in which the participants are continuously negotiating meaning by exercising their agency (Cobb et al., 2009). This requires a distribution of authority by the teacher. This is because verbal interactions between teachers and students are usually characterised by the teacher's authoritative stance: the teacher represents the mathematicians' community, thus s/he is *an* authority because of his/her content knowledge; at the same time, s/he is *in* authority, because of position (Wagner & Herbel-Eisenmann, 2014). Thus, depending on the didactical approach, the students may only have to follow the teacher's guidance, or they may be given space to actively participate in the learning process. For the purpose of the present paper we adopt the following definition for authority:

Authority concerns the degree to which students are given opportunities to be involved in decision making about the interpretation of tasks, the reasonableness of solution methods, and the legitimacy of solutions. Authority is therefore about "who's in charge" in terms of making mathematical contributions. (Cobb et al., 2009, p. 44)

The analysis of authority can be done by the use of positioning theory (van Langenhove & Harré, 1999) as implemented by Wagner & Herbel-Eisenmann (2014). According to this, there are some pervasive "lexical bundles" (i.e. speech patterns) in classroom talk, which are related to participants' positioning and authority. The main categories of these are: personal authority, discourse as authority, discursive inevitability, and personal latitude. Personal authority, which is the most common in the classrooms, relates to teacher's own authority; in other words, the students are expected to follow (the authority of) their teacher. A characteristic case of personal authority is when the teacher says, e.g., "I want you to solve this equation for me". Discourse as authority relates to the rules which must be followed in the interaction, "which come from outside personal relationships, [and] may be attributed to the discipline of mathematics (or perhaps school mathematics)." (Wagner & Herbel-Eisenmann, 2014, p. 873) An example of discourse as authority is the utterance "We need to follow the multiplication rules". Discursive inevitability relates to events or actions that are verbally presented as inevitable; as Wagner & Herbel-Eisenmann (2014) note: "there is no explicit reference to obligation, but rather a sense of predetermination" (p. 873) An example may be the utterance: "We are going to calculate the average of the given values". Finally, personal latitude relates to the students making their own decisions during the interactions, thus exercising their own authority; this is related to *conceptual agency* (Cobb et al., 2009) and mainly expressed by students' questions.

The above are usually accompanied by other verbal strategies; speakers sometimes feel the need to convey other messages related to power or solidarity. Politeness strategies (Brown & Levinson, 1987) have been the focus of a number of studies, either solely (Tatsis & Rowland, 2006) or juxtaposed with authority structures' analysis (Tatsis & Wagner, 2016); these studies stress the fact that students and teachers continuously interpret each other's actions, in order to perform their own actions.

Summing up, although various verbal patterns coexist in the mathematics classroom, there are situations in which particular patterns are prevalent – these patterns characterise the interactions and influence its outcome to a significant degree. Thus, in our study we were expecting to locate and identify such patterns in preservice teachers' discussions with pupils. Our methods of analysis are described in the next section.

## Context of the study and methodology

Our research was based on the work of six preservice teachers, at the third year of their studies in mathematics. They already had three weeks of practice in a primary school, during which they had taught for 18 hours per week. They had attended – among other courses in pedagogy, psychology, psychology of mathematical thinking, and didactics of mathematics – a course led by the second author of the paper in problem solving, during which they solved problems and analysed pupils' solutions and discussions; they had also watched and analysed a video with a study that involved a pair of young children (see Maj-Tatsis & Tatsis, 2015).

For the purpose of the present study, the preservice teachers were asked to find an interesting mathematical problem (the only clue given was it should offer the possibility for mathematical explorations) and give it to a pair of pupils from the class that they had already taught. The ages of the pupils varied from 10 to 12 years. There were no restrictions on how to choose the pair; this resulted in pupils from varying backgrounds and of various mathematical attainment. Other instructions provided to the preservice teachers were related to the distribution of their authority: they were asked to let the pupils talk and, generally to try not to impose their own way of thinking. The sessions lasted from 20 to 45 minutes and were videotaped. Then, the preservice teachers were asked to transcribe their sessions and analyse them, according to whether they had achieved their aim (as perceived by them) and the possible reasons or events that were responsible for that – including their own decisions and actions.

For the purpose of the present paper, we mainly focused on preservice teachers' transcribed discussions with the pupils; this data was complemented by their interviews given to the second author of the paper, after the completion of the sessions. Our analysis was a meta-level analysis (Rowland, 2000), since we focused on utterances related to the participants' interactions and we searched for manifestations of authority structures. Following Wagner & Herbel-Eisenmann's (2014) framework we located utterances or exchanges that accounted for personal authority, discourse as authority, discursive inevitability, and personal latitude. Particularly, personal authority "was identified by the presence of first- and second person pronouns together" (Wagner & Herbel-Eisenmann, 2014, p. 873). Discourse as authority was identified by the presence of modal verbs such as "need to" and "have to", which explicitly express a strong obligation; it was also identified by the use of "they", which refers "to a non-specified entity or group who have potentially made decisions about the mathematics students encounter" (Wagner & Herbel-Eisenmann, 2014, p. 873). Discursive inevitability was identified by utterances like 'you are going to' and 'it is going to'. Finally, personal latitude was mainly identified by the presence of questions by the pupils. These initial categories were then utilised in order to establish the various *authority structures*; these were not predetermined, but established during the course of the analysis.

Additionally, we looked into other verbal phenomena, such as the use of personal pronouns, such as "we" and "you" (Rowland, 2000). During our analysis, there were instances when we had to "make a step back" into an object level analysis, by looking into the mathematical concepts and processes that were discussed and established during the interactions; this was deemed necessary in order to fully comprehend the participants' actions and to study their effect on the authority distribution.

## Results

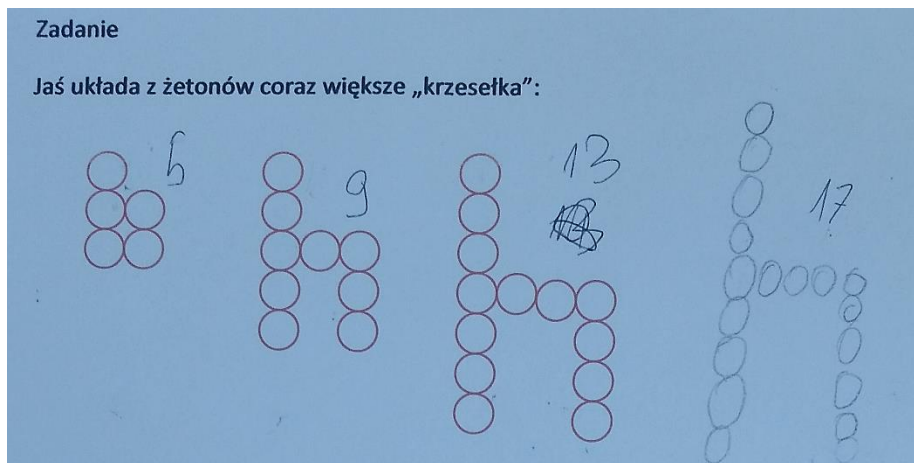

As we mentioned in the previous section, our analysis focused on the verbal interactions of the preservice teachers with the pupils. We will firstly present the analysis of the interactions between Tomek and two grade 6 boys (12 years old). We present this case because it demonstrates in a clear way the authority structure which was the most prevailing among the cases we analysed.

### The case of Tomek: Problem posing that leads to generalisation

The situation given to the pupils by Tomek included the following text:

John is creating “chairs” by using chips:

The text was followed by these drawings (Figure 1):

**Figure 1. The “chairs” made by chips.**

Below we read the initial discussion<sup>1</sup> between Tomek and Pupil 1:

- 1 Tomek: OK, the task is simple: firstly, read it. Have you ever seen something like this?
- 2 Pupil 1: Hmm, no, but I know how to do it.
- 3 Tomek: OK, so now think up of some questions. What questions would you ask? [small break] Usually, there are ready questions, and here...

Then, the pupils started working on making questions for the given situation. In turns 4-35, Tomek talked only four times, and among these only the next was related to the problem posing process:

- 10 Tomek: Just write your ideas.

In the next turn there is the following exchange:

- 35 Pupil 2: Do we have to answer every question? [which they have posed]
- 36 Tomek: Hmm, later we will choose two questions which we will answer.
- 37 Pupil 1: For example, what would be the sum of the second and the third figures? What would be the sum of the chips of the second and the third figures?
- 38 Pupil 2: [He writes Pupil 1's question to their worksheet]

<sup>1</sup> All the discussions were translated from Polish by the second author of the paper.

- 39 Tomek: You can always draw more figures.  
 40 Pupil 1 or 2: Aha.  
 41 Tomek: You are not limited to three [figures] only.

Then, until turn 59 the two pupils are working without any intervention by Tomek; they are making figures and discussing on the pattern. Then they draw the fourth chair shown in Figure 1.

- 60 Tomek: Are you sure about that chair?  
 61 Pupil 1: Why not?  
 62 Tomek: Calculate once again.

The preservice teacher started his research by asking pupils to put questions to the presented situation. By such way of guiding the process he gave them the possibility to engage in problem posing by formulating their own questions. Although his request is an expression of discursive inevitability, it resulted in the pupils being interested in the task and eventually the authority was passed to the pupils (personal latitude). Up to turn 59 Tomek did give space to the pupils, by letting them discuss. By his question in turn 60 he exercised personal authority, he used direct formulation “are you sure?”, and then asked them to correct it (62). We may claim that it was a good moment for an intervention, since the pupils had made a mistake and this would result in an improper rule and generalisation. However, that could be done in a less explicit way, e.g. “how did you know how many chips should be in the fourth chair?”. After the boys corrected the mistake, Tomek gave them again space to work, in other words, he let them exercise their personal latitude.

In turn 70 Tomek suggested: “So maybe let’s do the second question [which was formulated by the pupils and written at their worksheet: “How many chips will the next chair have?”] because I think it is the most interesting”. In this utterance we can find two different authority structures: personal latitude (inclusive imperative) and personal authority (“I think”). By that intervention Tomek directed the work of pupils into generalisation. But still the question was formulated by the pupils so it can be considered as an appraisal of their work.

The next intervention of Tomek took place when the pupils put a false hypothesis:

- 96 Pupil 1: So we can conclude from it [the number of chips in chairs 1, 2, 3 and 4 were calculated by the pupils as follows: 5, 9, 14, 17 – note that 14 is incorrect] that every figure increases by 4. So, the next figure will have 21. And so on.  
 97 Tomek: So, for example, how many will be in the tenth chair?  
 98 Pupil 1: 21 times 2 equals 42. Because it is times two. Because it is the fifth chair [number 21].  
 99 Tomek: Are you sure?  
 100 Pupil 1: Yes, for sure. Yes, right? [calculating] 21 times 2 is 42, the tenth chair is that. So, it’s like that.  
 101 Tomek: [movement by his head that it is wrong]  
 102 Pupil 1: No?! But how, if it is...  
 103 Tomek: Calculate precisely.

In the above transcript we see that Pupil 1 has formulated the assumption that the number of chips increases proportionally to chair’s number, thus the number of chips of the tenth chair is double the number of chips of the fifth chair. This incorrect assumption was formulated despite Pupil 1’s correct

observation that “every figure increases by 4 [chips]”. Tomek decided to resolve that situation by offering a counter-example, which falls into the discursive inevitability category:

111 Tomek: So, in that case, chairs 2 and 4 should... so, the fourth should be twice bigger than the second.

112 Pupil 1: Oh! That's right. Something went wrong (...)

It is obvious that Tomek's intervention helped the students realise their false assumption. Generally, the previous excerpts demonstrate the prevailing authority structure in Tomek's verbal actions: he mainly let the pupils exercise their personal latitude and he exercised his personal authority and discursive inevitability structures only at crucial moments (according to him, but also according to our interpretation). In other words, if he did not intervene at these moments, the pupils could have spent much time in explorations that would not lead to the desired generalisation. However, this authority structure changed significantly in the 16th minute of the session, when the person who was handling the video camera (who was Tomek's colleague) informed him that it is the 16th minute (turn 171). Tomek switched his behaviour to a more authoritative structure, by asking closed questions, prompting the pupils and generally drastically increasing his interventions. This is eloquently demonstrated in Tomek's own account of his actions:

Generally, making such a research was very tiring. Despite my earlier preparations I did not expect that it will go in such a way. I expected that they [pupils] will calculate chair x just by adding. And they started multiplying from the beginning. I made many mistakes, it could be conducted in a better way. Thankfully, the children liked it. Close to the end, more or less at the 14th minute, I started prompting them too much because I was afraid that I will not manage in time. Because of that [prompts] I limited their mental actions.

Tomek's case demonstrated how we performed our analysis over the six chosen cases. The following authority structures were identified:

- a) Structure 1: Personal latitude accompanied with mainly personal authority and discursive inevitability; followed by a blunt switch to personal authority, eventually accompanied with discursive inevitability.
- b) Structure 2: Personal latitude accompanied with mainly personal authority and less frequently with discursive inevitability.
- c) Structure 3: Personal authority.

The above structures are presented according to their frequency; the first one was found in four cases, while the other two appeared in one case each.

## Conclusions

Our study was inspired by studies on the authority structures that can be identified in the mathematics classroom (Wagner & Herbel-Eisenmann, 2014); we were interested to see whether similar structures would appear in preservice teachers' talk. Our results have shown that the preservice teachers of our study initially had been less authoritative, thus allowing the pupils to work collaboratively and exercise their personal latitude. However, during the interaction, and due to some events, they switched into more authoritative structures. One of the basic reasons for that switch was the time pressure together with the obligation to fulfil the request of their educators. The interesting thing was though that all of them were aware of this switch, as it was expressed during their interviews.

Following Cobb et al. (2009), we agree that the distribution of authority is closely linked to the ways that students exercise their agency in the mathematics classroom, including, as our study has shown, collaborative work. Thus, the teacher should be aware of that fact, in other words, s/he needs to know when it is time to exercise authority, and when s/he can deviate from the lesson plan; this is related to the notion of *contingency* as presented in Rowland, Huckstep and Thwaites's (2005) "knowledge quartet" framework. Particularly, the teachers' responses to students' ideas as well as their ability to deviate from their agenda affect the knowledge construction in a significant way. These considerations should be discussed and analysed in pre- and in-service teachers' training courses, preferably by involving teachers in self-monitoring with regards to the distribution of authority during their interactions with the students.

In our study, the preservice teachers' awareness of the nature and the effect of their own verbal actions was a clear result of their training courses. However, this did not stop them from exercising their personal authority at particular moments. Thus, there is still lots of work that needs to be done in the field of authority distribution by mathematics teachers in order to establish an active learning community in their classrooms.

# How do students develop lexical means for understanding the concept of relative frequency? Empirical insights on the basis of trace analyses

Lena Wessel

TU Dortmund University, Germany; [lena.wessel@math.tu-dortmund.de](mailto:lena.wessel@math.tu-dortmund.de)

*In order to enhance students' proficiency in the academic language, building up more formal language on the basis of individual and everyday language is claimed as a fruitful approach. However, there is little empirical research on how students adopt and develop lexical means of the academic language. This paper addresses this field of research for the case of concept-specific lexical means for relative frequencies by presenting the applied design principles for learning opportunities as well as empirical insights into initiated concept- and language development processes.*

**Keywords:** Academic language, relative frequency, scaffolding, design research, trace analysis.

## Introduction

Due to the cognitive and epistemic function of language, the academic language can be challenging for many students (Schleppegrell, 2004). These challenges are also relevant for mathematical learning, as shown in various empirical studies. Thus, studies in mathematics education concentrate on designing and researching learning environments that integrate mathematics and language learning (Prediger & Wessel, 2013; Prediger & Pöhler, 2015).

For the field of understanding relative frequencies, the presented study relies on analyses of design experiments in small group settings focusing on one lesson within the larger intervention study of the DFG project MUM-MESUT (Grant PR 662/14-1 to S. Prediger). Detailed analyses of students' conceptual development and language development against the background of intertwined conceptual and lexical-discursive learning opportunities serve to structure the relevant lexical means and give insights into how students become proficient in the academic language for relative frequency.

## Theoretical background: Design principles for learning opportunities

Academic language proficiency has repeatedly been shown to influence achievement in mathematics and this general finding also applies for the mathematical topic of understanding fractions (Wessel, 2015). As a consequence, some current design research studies focus on developing and investigating content- and language integrated instructional approaches for fostering students with low language proficiency (Prediger & Wessel, 2013). The following paragraphs deal with the major design principles that were implemented in the presented design research study.

*Design principle "Macro-scaffolding".* The general structure of intended lexical learning trajectories is well described in the principles of *macro-scaffolding*, namely from students' everyday resources to academic and formal technical registers (Gibbons, 2002). However, its topic-specific realization is still an urgent need of research, as well as explorations of students' individual learning pathways (Prediger & Wessel, 2013). Previous research shows the relevance of phrases and syntactical constructions needed to express the meanings of a mathematical concept in view, which is also relevant for understanding the concept of fraction (ibid). Wessel (2015, p. 327) shows the importance of understanding how macro-scaffolding and interactional moves on the micro level relate to each other for moving students beyond their zone of proximal development. Here, the principle of *macro-*

*scaffolding* by coordinating conceptual learning opportunities with well-structured language learning opportunities on the lexical level is applied.

*Design principle “Pushing students’ output by realizing discursive practices”.* Given the sociocultural perspective on the learning of mathematics as participating in mathematical practices, mathematical activity is to a great extent mediated by language and interaction. In the context of mathematics learning of English language learners (ELLs) and with a perspective on extending academic language proficiency, Moschkovich (2013) stresses the relation between the lexical and discursive level of language: “The question is not whether students who are ELLs should learn vocabulary, but rather how instruction can best support students to learn vocabulary as they actively engage in mathematical reasoning about important mathematical topics” (Moschkovich, 2013, p. 46). This theoretical assumption leads to an extension of the design principle so that we use the principle of *macro-scaffolding* by coordinating conceptual learning opportunities with well-structured language learning opportunities on the lexical level *in addition to rich demands and language initiation on the discursive level*.

*Design principle “Relating registers”.* Pushing the students’ output and applying scaffolding strategies can be supported by the *design principle of relating registers*, according to which the graphical, the symbolic and the different verbal registers (everyday, academic, and technical register) are related systematically to achieve conceptual understanding (Prediger, Clarkson & Bose, 2016). For the lessons of the presented intervention, activities of relating registers have been realized with the fraction bar and bar board as a prominent graphical representation. In order to activate students’ individual and everyday language resources, typical contexts of downloads, fair share and soccer competitions have been implemented (for detail see Prediger & Wessel, 2013).

In their combination, the formulated design principles allow to integrate theoretical aspects on developing learning opportunities on the conceptual, lexical and discursive level. However, while the integrated analysis of initiated learning processes on conceptual and discursive levels are well-established in mathematics education research, only rarely empirical studies reconstruct lexical learning processes (exceptions e.g. Prediger & Pöhler, 2015, for the field of percentages). That is why Schleppegrell (2010, p. 107) demands more respective research which goes beyond analyzing short interactional sequences: “More research is needed that takes a developmental approach (...). We need rich studies of how language and ways of talking about mathematics evolve over a unit of study, focusing on more than brief interactional episodes and fragments of dialogue”. The presented study aims at minimizing this research gap for the field of relative frequency.

## Research questions

On the basis of the theoretical background and the research gaps listed above, the developmental work and analyses of the learning processes are guided by the following two questions:

- 1) *On the level of design outcome:* How can conceptual and lexical-discursive learning opportunities for understanding relative frequency be intertwined and designed in a sequence of rich mathematical activities?
- 2) *On the level of initiated learning processes:* Which lexical means do students activate and how are those lexical means intertwined with individual conceptual development when working on the learning opportunities towards relative frequency?

## Methodological framework and research context

The research was conducted in the methodological framework of topic-specific didactical design research (Prediger & Zwetzschler, 2013) in which the analysis of teaching-learning processes takes place in carefully designed teaching experiments. The design outcome, namely the consolidated intertwining of conceptual and lexical-discursive learning opportunities, is next described.

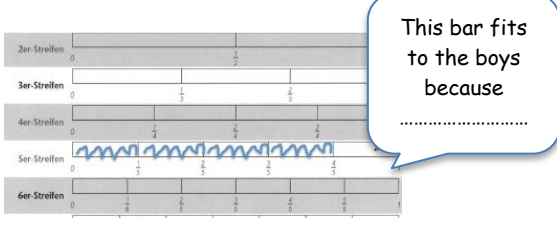

### Design outcome: Learning opportunities towards relative frequency (research question 1)

In order to combine conceptual, lexical and discursive learning opportunities according to the design principles described above, the larger intervention with five lessons for fostering conceptual understanding of students with diverse language proficiency in the language of instruction aiming at enhancing understanding of fractions was designed. For answering research question 1 the designed learning opportunities towards relative frequency as a design outcome are presented in the following section.

The intended *conceptual learning opportunities* were adapted from Prediger (2013). It starts with students' individual approaches and everyday experiences to compare three groups with different relative frequencies in the context of a soccer competition (see Table 1, Task 5). It then proceeds to constructing meaning of the given relative frequencies by introducing the bar board (Task 6). At this point, students' informal strategies for comparison are elaborated by focusing the need for normed referent wholes (here fraction bars of normed length) and the necessity of including every group's number of shots (not only number of strikes) to refine the concept of relative frequency which finally aims at the flexible use of relating number of shots and number of strikes.

The intended *lexical-discursive learning opportunities* focus on the vocabulary required for the conceptual learning process of thinking in relative frequency which is mainly the prepositional "of- or thereof construction" ("to score ... of ... shots", "... shots, thereof ...") (see Table 1), which can be conceptualized from the so-called 'basic meaning-related vocabulary' (Wessel, 2015). Students are asked to give reasons in the setting of discussing ways of fair or unfair strategies to rank the three groups. It starts from students' individual resources as well as with offering the relevant "of-construction" already in Task 5.

Conceptual learning opportunities	Tasks and mediator bar board	Lexical-discursive learning opportunities
Initiation of <i>individual</i> approaches for comparing relative frequency conceptualized as strike rates in soccer competition	<b>5. Who scored best?</b> In class 7c three groups took part in a soccer competition. <i>The group of boys scored 4 of 5 shots.</i> <i>The group of girls scored 8 of 10 shots.</i> <i>The group of teachers shot 20 times and didn't score 4 times.</i> a) Who won the competition? Write your answer on a card. b) Put your cards in the middle of the table. Do you agree? Give reasons for your answer.	Initiation of <i>discussing</i> individual approaches and <i>giving reasons</i>  Introduction of <i>lexical</i> means "to score / not score ... of ... shots"
Investigation of individual hypotheses in the bar board:  Comparing with fraction bars of normed length	<b>6. Who scored best?</b> Use the bar board in order to commonly find out whether one group scored better. The boys have already been marked. Add the results of the girls and the teachers as well as the speech bubbles.	<i>Reflecting and discussing</i> fitting of fraction bars and groups ("This bar fits to the boys because ...")

Necessity of including number of shots (not only number of strikes) to refine concept of relative frequency		Activating lexical means for marking strike rates in the bar board focusing number of shots as a referent whole, number of strikes and strike rate
Systematize and deepen understanding by giving reasons for all groups scoring equally well	<p><b>7. And the winner is...</b></p> <p>In the bar board you have found out how well the different teams scored.</p> <p>Which group won the competition?</p> <p>Give reasons for your answer.</p>	<p>Written reasoning on equivalence of relative frequency in the three groups</p> <p>Applying introduced lexical means</p>

**Table 1: Conceptual and lexical-discursive learning opportunities (not necessarily strictly sequenced)**

The tasks in Table 1 illustrate how conceptual and lexical-discursive aspects are intertwined. On the discursive level, students are encouraged to verbalize and discuss their own ideas and structures. The vocabulary for these discussions is bound to the bar board as well as the context of the scoring situation, which always allows students to relate the vocabulary to its meaning. In Task 7 the students are free to note their reasons either with reference to the bar board, to the context or to the formal level of expanding and reducing fractions.

### Methods for data gathering and selection: Design experiments

Design experiments were conducted and video-taped within the larger research project MuM-MESUT with  $N = 343$  mathematically low-achieving mono- and multilingual students in grade 7. For the detailed analyses in this paper, a group of three students was selected according to their German language proficiency (measured with a German C-test) and language background (mono- or multilingual, operationalized by “speaks at least one other language than German with a parent or grandparent”), with the aim to have a linguistically heterogeneous sub-sample for conducting case analyses (in total the below presented method of analysis was applied in detail to  $n=16$  students). Due to the larger study, we can also draw on fraction test scores of the students (Wessel, 2015).

### Methods of data analysis for reconstructing conceptual and lexical development

In order to qualitatively reconstruct the students’ lexical pathways and how their lexical means relate to the initiated discourse and individual concept development (research question 2), the following three steps were applied:

*Step 1. Conceptual analysis.* For reconstructing the students’ conceptual development, strategies for comparing the given three groups of girls, boys and teachers and steps on the pathway to understand the concept of relative frequency have been identified by analysing transcripts and video data.

*Step 2. Trace analysis.* Concept-specific lexical means (words and phrases) which the students activated were inventoried and coded whether the students used them in oral or written language and whether they self-initiated the use or whether they adopted them from the material, the teacher or another student (for detail of the method “trace analysis” see Prediger & Pöhler, 2015). In this paper the focus is on oral language.

*Step 3. Relating conceptual development and language.* On the basis of step 1 and 2, the results of conceptual and language analysis were related and contrasted to reconstruct prototypical learning pathways and critical steps on the pathway under the perspective of different language backgrounds.

### **Empirical insights into the initiated conceptual and language learning processes**

On the level of initiated learning processes, research question 2 asks for lexical means that students activate and how these lexical means are intertwined with individual conceptual development. By contrasting the inventory of lexical means of two students the first part of the research question is addressed in the next paragraph.

#### **Concept-specific language production: Qualitative overview and comparison**

Makbule and Kiran (working in a group of three together with Vehbiya) are multilingual learners in year 7 of a German secondary school. In a German C-test Makbule's score is at percentile rank 37 and Kiran's at 84. In the fraction test Makbule's score is at percentile rank 7 and Kiran's at 15 (percentile ranks for both tests for full sample of N=1124 seventh graders). While Kiran is the more language proficient student according to the C-test results, Kiran and Makbule started at comparable low levels of fraction proficiency.

In Table 2 the actual orally activated concept-specific lexical means in the analyzed transcript (23.46 minutes of video data) of Kiran and Makbule are contrasted. While Makbule activates 26 different concept-specific lexical means in the course of the process and 76 in total, Kiran activates 15 different concept-specific lexical means and 21 in total. As Makbule generally talks the most in this lesson, relating these numbers to each student's individual rate of participation will be a further step in the data analysis.

It becomes apparent that Kiran uses all lexical means correctly, which fits to his high percentile rank in the German C-test and which is not always the case for Makbule. Also, while Makbule uses many of the lexical means various times (which leads to the high number of lexical means in total), the list of Kiran can give a hint at the possibly *sufficient* language for working on the given tasks and developing the concept of relative frequency.

**Table 2: Variety of concept-specific lexical means in comparison**

However, the transcript analysis of Makbule's conceptual development indicates that the additional lexical means like "to divide in the middle", "normal big" and "separated in the middle" in Makbule's inventory are of great importance for her learning process towards understanding the idea of expanding fractions as refining the structure in the fraction bar. As a first conclusion, the comparison of the results from Makbule and Kiran shows that the question of the required language seems to vary between the students and demands further analyses of different cases.

### **Makbule's process of adopting concept-specific lexical means when relating registers**

As a conceptually relevant step in the learning process, it is important to move from the strategy of comparing the three groups' results (girls, boys and teachers) on the basis of the absolute number of strikes to experiencing the necessity of and applying the concept of relative frequency as a fair strategy for comparison (Prediger, 2013). How this pathway can be related to the activated and required lexical means becomes apparent in the following two excerpts taken from the corresponding learning process initiated by Task 6. The transcripts were translated from German and shortened to relevant utterances of Makbule which are needed for tracing those concept-related language means in focus (// indicates interruption).

When answering Task 5 (see Table 1), Makbule focuses on the three groups' absolute numbers of strikes and claims that the teachers won the competition. When working on Task 6, the following process was initiated by reflecting on why the chosen fraction bar of fifths fits to the boys group:

#### *Excerpt I: Kiran stresses the idea of relative thinking*

- 56 Teacher: So why does this fraction bar fit to the boys, the one that is marked?  
 58 Makbule: Because they, because they took yes, ehm, five shots **and** have only scored four times.  
 59 Teacher: And why does the fraction bar fit?  
 61 Makbule: Because it's **four fifths**.  
 66 Makbule: Because they//  
 67 Kiran: //took five shots and scored four **of them**.

On the lexical level, Makbule uses the coordination "and" to relate the number of shots and the number of strikes to each other (#58). As the teacher again asks why the fraction bar fits, Makbule focuses on the representation of rates as fractions, namely "four fifths" (#61). When starting an additional explanation ("Because they", #66) she is interrupted by Kiran, who finishes the sentence with "took five shots and scored four of them" (#67). This utterance in #67 is assumed to be a relevant trigger for the following discourse in the group, which becomes clear in the next excerpt.

#### *Excerpt II: Makbule adopts Kiran's "of them" construction*

- 70 Makbule: *reads her written answer:* because they took five shots and scored only four **of them**.  
 73 Teacher: So now the girls and the teachers. Where do we mark them?  
 74 Vehbiya: The girls in the bar of tens.  
 75 Kiran: Eight tens.  
 76 Makbule: so 8 of, **8 of 10**.  
 99 Makbule: Because they took ten shots **and** have scored eight times.

- 101 Makbule: So they have yes, ehm, they had 20 times to shoot, so could shoot 20 times. And they only, so they had, so they didn't score four of them.

In #70 Makbule reads out her written answer in the speech bubble next to the bar of fifths. She adopts Kiran's mathematically more adequate construction for the relation of shots and strikes by using the prepositional sentence structure ("take ... shots and score ... of them"). Further in the process, Makbule also adopts the "of-construction", which had been introduced by the material in Task 5, in order to reason the fitting of the bar of tens to the results of the girls (#76). Considering Kiran's utterance of the fraction in #75, it can be assumed that Makbule purposefully links the fraction with its meaning-related conceptualization "8 of 10". In #99 and #101, when reasoning the fitting of the bar of tens and bar of twentieths, she once again uses the coordination "and" as well as the prepositional "of-structure". However, in her written products she constantly applies the mathematically preferred "of-structure". Thus, it can be assumed that thinking relatively as well as having lexical constructions for expressing relative frequency meaningfully anchored in her mental lexicon was successfully achieved for Makbule. It is assumed that Kiran's introduction of the sentence structure "take ... shots and score ... of them" was supportive for Makbule's conceptual and lexical learning pathway.

## Conclusion

To summarize, the empirical insights show how rich and demanding discourse practices can be initiated in small group settings by means of the design principles of macro-scaffolding and relating registers. The dual focus of the applied macro-scaffolding on the conceptual learning opportunities intertwined with language learning opportunities on the lexical level has to be emphasized as this builds the basis for the analysis of the initiated lexical learning processes. On the developmental level the presented design outcome thus helps to answer the question of how instruction can support students to learn vocabulary as they engage in mathematical reasoning (Moschkovich, 2013), here with a focus on relative frequencies. Moreover, the case of Makbule implies that offering and relating various mathematically intended lexical constructions could be supportive for becoming more proficient in the formal language of schooling. This can be implemented more prominently in the material by activities of reflecting and discussing concept-specific lexical means, which again would be an intertwined conceptual and lexical-discursive learning opportunity.

So far, analyses of learning processes on the lexical level are quite rare in mathematics education research. Applying the method of trace analysis (Prediger & Pöhler, 2015) reveals details of students' language production and development on the lexical level. For Makbule and Kiran differences with respect to which and how concept-specific lexical means have been activated and adopted became apparent. However, further insights into the processes of the other groups are necessary to ensure the first empirical results and formulated hypotheses.

# Conceptions of the transition from the difference quotient to the derivative in imaginary dialogues written by preservice teachers

Annika M. Wille

Alpen-Adria-Universität Klagenfurt, Austria; [annika.wille@aau.at](mailto:annika.wille@aau.at)

*The transition from the difference quotient to the derivative is a step from the algebraic to the analytic concept formation. The aim of this article is to analyze the conceptions of this transition that can be traced in preservice teachers' imaginary dialogues, a form of mathematical writing.*

*Keywords: Elementary analysis, derivative, imaginary dialogues, preservice teacher education.*

## Introduction

An often formulated critique of the teaching of analysis in school is that syntactical calculus is used too early and there is a need for more content-related understanding of central concepts (cf. e.g. Hahn & Prediger, 2008). Therefore, there is a need to sensitize preservice teachers to this issue and strengthen their own understanding of analytical concepts.

The course “Didaktik der Analysis” at the Alpen-Adria-Universität Klagenfurt in 2015/2016 addressed this purpose. The preservice teachers often reflected on central concepts of elementary analysis, their relations and their meaning for classroom teaching. The reflections were written down as *imaginary dialogues*, a form of mathematical writing where a single student composes a written dialogue between two protagonists who discuss a mathematical task or question (Wille, 2008). This article focuses on one reflection task that addresses the transition from the difference quotient to the derivative. The preservice teachers' imaginary dialogues will be analyzed in order to determine their conceptions of this transition.

## Theoretical framework and research questions

Within Anna Sfard's *theory of commognition* (Sfard, 2008) *thinking* is seen as self-communication, an individualized version of (interpersonal) communication. The term *commognition* is used for both, the processes of thinking and communication, which are considered as two “manifestations of the same phenomenon” (p. 296). In commognitive research the *discourses* are precisely the main unit of analysis (cf. p. 276). Discourses are different types of commognition that “draw some individuals together while excluding some others” (p. 91). Sfard names as a precondition for learning the “recursivity of linguistic commognition” (Sfard, 2008, p. 116). An example of recursivity is *communicating-on-communicating*, such as “reports on what somebody else has said, remarks on her own thoughts, or reflects on other interlocutors and their communicative actions” (p. 103). The recursivity allows for a look from the outside in order to reflect, abstract and reason.

Conceptions of central concepts of elementary analysis have been described in various studies (e.g. Thompson & Thompson, 1994; Hahn & Prediger, 2008; Roh, 2008; Greefrath, Oldenburg, Siller, Ulm & Weigand, 2016). Danckwerts and Vogel (2006) list interpretations of the difference quotient and the derivative in overview tables (p. 57 and p. 85). Figure 1 shows an adapted and translated version of these tables.

difference quotient	→	derivative
$\frac{f(x) - f(x_0)}{x - x_0}$	→	$f'(x_0) = \lim_{x \rightarrow x_0} \frac{f(x) - f(x_0)}{x - x_0}$
secant slope	→	tangent slope
rate of change (or relative change) (e.g. average speed)	→	local rate of change (or momentary rate of change) (e.g. momentary speed)

**Figure 1: the transition from the difference quotient to the derivative**

Here, the vertical dashed line denotes the transition from the algebraic to the analytic concept formation, which is, according to Danckwerts and Vogel, particularly difficult to realize in the mathematics classroom (p. 85).

In the author's view, this is why it is particularly important for the preservice teachers to develop a profound understanding of this transition from various perspectives. Therefore, the focus of this paper is not on a single analytical concept, but on the whole figure, in particular on the arrows going from left to right in Figure 1. Thus, the focus is on the *conceptions of the transition from the difference quotient to the derivative* that can be traced in the preservice-teachers' imaginary dialogues. The main question is: *What are the aspects of the preservice teachers' conceptions of the transition from the algebraic to the analytic concept formation?*

In the light of the framework of commognition, in order to initiate preservice teachers' reflection processes and investigate their conceptions of elementary analytical concepts and relations, a form of communication seems appropriate that allows for a "look from the outside". Imaginary dialogues, where one person writes what two protagonists are discussing, is such a form of communicating-on-communicating. Furthermore, imaginary dialogues are *written* works of a single student (or preservice teacher), but they consist of written *oral* dialogues. Therefore, imaginary dialogues display characteristics of both, written and spoken language (cf. Wille, 2017). In particular, the *processuality of spoken language* comes into play and students tend to write *how* they understand something instead of only what. Therefore, imaginary dialogues are one appropriate method to approach research questions that concern a transition process. Another reason is practicability: by using imaginary dialogues it is possible to receive reflections of each student of a course several times within the semester, which – although they are written – contain attributes of oral language. Moreover, the lecturer can react to the reflections within the course.

## Method

Altogether 40 preservice teachers participated in two parallel courses "Didaktik der Analysis" at the Alpen-Adria-Universität Klagenfurt in Austria in the winter term 2015/2016. The content of the course was oriented on the book "Analysis verständlich unterrichten" (translation: teaching analysis comprehensibly) by Danckwerts and Vogel (2006). Five times within the course lectures, exercises, and reflections alternated. As reflection tasks the preservice teachers were given written initial dialogues that each of them had to continue in the form of an imaginary dialogue. In the following,

the second reflection task, the transition from the difference quotient to the derivative is in the focus. The initial dialogue given to the preservice teachers was the following:

Two preservice teachers S1 and S2 are talking with each other. Continue the dialogue.

- S1: Can you please explain to me one more time what was important during the last hour?
- S2: Do you have a specific question? We talked about three approaches to the concept of derivation: one geometrical, one application-oriented and at the end, in addition, local linearization.
- S1: In the application-oriented approach there was the local change rate?
- S2: Yes, exactly.
- S1: That seemed to be particularly important for analysis teaching at school. But why?
- S2: You go from the actual amount via the absolute change to the relative change and – schwupp – you have the local rate of change!
- S1: Schwupp???
- S2: Excuse me, the “schwupp” really is not that simple and, actually, it is the crux of the matter. I’ll explain it to you one more time precisely and after that why it is important for the teaching of analysis in school.
- S1: Thanks, because I cannot make any use of all these terms at the moment.

**Figure 2: Initial dialogue task (the original German text was translated by the author)<sup>1</sup>**

Of all participants, 30 preservice teachers wrote an imaginary dialogue by continuing the initial dialogue above. These written texts serve as the *data material* for the analysis. In the following the research questions that will be addressed are how the preservice teachers describe the transition from the algebraic to the analytic concept formation, and in particular, what the aspects of their conceptions of the transition are. The percentages named below are meant only as informative “mini-statistics”, because of the small number of participants. Within the *data analysis* categories of aspects were built inductively. In a second step these aspects were categorized into two perspectives. For a discussion regarding the depth of the preservice teachers’ reflections, see Wille (2016).

## Findings

Within the imaginary dialogues of the preservice teachers several aspects of the previously named transition can be detected. In what follows they will be explained and exemplified (all examples were originally written in German and translated by the author).

### A1: The calculus aspect – describing the calculation of concepts with formulas

Eleven preservice teachers (31.4%) described with formulas how to calculate concepts from the left or right side of the transition. For example, a preservice teacher, Lydia, describes in her imaginary dialogue how the difference quotient and the derivative can be calculated with the help of formulas:

“The next step is to build the difference quotient. As the numerator you calculate:  $f(x) - f(x_0)$  and as the denominator  $x - x_0$ . The result is the relative change in the time span from  $x_0$  to  $x$ . The relative change is also denoted by rate of change.

---

<sup>1</sup> “schwupp” in the sense of “voilà”

And now the derivative comes into play. You build  $f'(x_0)$ . Now,  $f'(x_0)$  is the limit ( $x$  approaches  $x_0$ ) of the rate of change. The result is the momentary or local rate of change at the time of  $x_0$ .”

In a similar way Paul writes about the calculation of the rate of change:

“Okay. Now, we can determine the rate of change by a formula. The formula you can find in your documents, of course.”

Or Maria writes about the momentary rate of change:

“Now, we reached the last step. The momentary rate of change at the time of  $x_0$ . That is the first derivative, thus,  $f'(x_0) = \lim_{x \rightarrow x_0} \frac{f(x) - f(x_0)}{x - x_0}$ .”

This aspect – i.e. describing the calculation of concepts with formulas – will be denoted as *calculus aspect* (A1), similarly to the calculus aspect of variables (cf. Malle 1993).

## **A2: The concept identification aspect – different concepts are identified**

In the writings of Lydia and Maria another aspect becomes apparent: They are identifying concepts by their language use. Lydia identifies the concepts “difference quotient”, “relative change”, and “rate of change”. Afterwards she identifies the concepts “derivative” and “momentary or local rate of change”. Similarly, Maria identifies the concepts “momentary rate of change” and “first derivative”. Altogether 16 preservice teachers (45.7%) identify concepts likewise.

Identifying different concepts is denoted as the *concept identification aspect* (A2).

## **A3: The limit aspect – the right side of the transition is described as a limit**

17 preservice teachers (48.6%) describe concepts of the right-hand side as a limit, sometimes with mentioning a process of approaching (see aspect A4), sometimes as a “finished product”<sup>2</sup>. The first case (including the description of a process of approaching) appears in Elena’s imaginary dialogue:

“S1: I see. Now, I understand it and now it is clear for me why one writes  $\lim_{\Delta x \rightarrow 0} \frac{f(x_1 + \Delta x) - f(x_1)}{\Delta x}$ .”

While letting  $\Delta x$  tend towards 0, or  $x$  towards  $x_0$ , respectively, while choosing the interval steadily smaller (note: here she crosses out “choosing it that small to be almost 0”) one obtains the local rate of change, thus, the momentary speed at a certain point of time, if one brings the limit into play at this point.<sup>3</sup>”

Likewise, the process of building a limit is expressed by Jan: “Thus, the secant becomes, so to speak, a tangent by building a limit.” In contrast, as a “finished product” the limit is used in the following writing: “And in step 3 the tangent slope will be calculated as a limit.”

Describing the right side of the transition as a limit is denoted as the *limit aspect* (A3).

<sup>2</sup> For distinguishing mathematics as a product with mathematics as a process (Danckwerts & Vogel, 2006) or concerning the duality of processes and objects (Sfard, 1991).

<sup>3</sup> The German original text is: “wenn man an dieser Stelle den Grenzwert ins Rennen führt”.

#### **A4: The approach aspect – the transition is described as a process of approaching**

More than the half of the preservice teachers, 20 (57.1%) described the transition as a process of approaching. This can be seen for example in Elena's imaginary dialogue above ("While letting  $\Delta x$  tend towards 0, or  $x$  towards  $x_0$ , respectively, while choosing the interval steadily smaller", see aspect A3) or in Patrick's imaginary dialogue below ("we let the secant become shorter and shorter until it vanishes completely for  $x = x_0$ ", see aspect A6).

This aspect – i.e. describing the transition as a process of approaching – will be denoted as the *approach aspect* (A4). It is *not* a subaspect of A3, because there are students who describe a process of approaching without describing the right side of the transition as a limit and the other way round.

#### **A5: The distinction aspect – distinctions between the left-hand side and the right-hand side of the transition are described**

17 preservice teachers (48.6%) described various distinctions between the left-hand side and the right-hand side of the transition. For example, the distinction of having first  $x \neq x_0$  and then  $x = x_0$  is described as follows:

S2: Think about it: You let  $x$  come closer and closer to  $x_0$ . What will happen then?

S1: They are equal eventually.

In another two examples the distinction between having a secant at first and then a tangent is described and additionally, having first two points and then only one on the function graph:

"From the secant it arises a tangent that does not intersect the function any longer, but touches it now in one point."

"(...) you don't want to have the slope of the secant between two points, but the slope of the tangent in only one point."

Finally, the distinction of having at first two points in time (in order to measure speed) and then one, a preservice teacher describes with these words:

"(...) we see that the secant expresses time intervals and we calculated within those the average rate of change<sup>4</sup>. The point P that we approach, is therefore the momentary rate of change at a certain point of time."

This aspect – i.e. describing distinctions between the left-hand side and the right-hand side of the transition – will be denoted as the *distinction aspect* (A5).

#### **A6: The problem aspect – distinctions are considered problematic**

Out of the 17 preservice teachers who described distinctions between the left-hand side and the right-hand side of the transition, 10 preservice teachers (28.6%) considered these distinctions as problematic (in their language use). For example, Patrick uses phrases like "we claim that it would be a smart result" or the adjective "mysterious":

---

<sup>4</sup> Original German text: "sehen wir, dass die Sekanten die Zeitintervalle ausdrücken und wir in diesen die mittlere Änderungsrate berechnen."

“S2: (...) Now, we have 2 problems, for one thing we begin our observation with  $x \neq x_0$ , but afterwards we set  $x = x_0$  and claim that it would be a smart result. Secondly, we let the secant become shorter and shorter until it vanishes completely for  $x = x_0$ , but we claim that it became that way an infinitely long tangent (...) that is a somehow very mysterious and at least not illustrative (...)”<sup>5</sup>

Another preservice teacher let one protagonist face the impossibility of covering a distance at a point of time.

S2: How many seconds or minutes, respectively, had passed at the point of time?

S1: Well, none, that is why one names it POINT of time.

S2: And how can you cover a distance in 0 seconds?

S1: That was mean! Okay, nearly no time had passed, or rather so little time that it makes no difference.

This subaspect of A5 – i.e. considering the described distinctions problematic – will be denoted as the *problem aspect* (A6).

One could go more into depth at this point to differentiate the conceptions of the preservice teachers. For example, it is interesting to see which words are used to describe the process of approaching. But this would exceed the size of this article and therefore is left for a further and more detailed analysis. Similarly, misunderstandings that occurred in the imaginary dialogues cannot be addressed here, because of the length of the article. Instead, the detected aspects shall be compared and evaluated. Table 1 gives an overview of the aspects discussed above:

A1	<i>calculus aspect</i>	the calculation of concepts is described with formulas
A2	<i>concept identification aspect</i>	different concepts are identified
A3	<i>limit aspect</i>	the right side of the transition is described as a limit
A4	<i>approach aspect</i>	the transition is described as a process of approaching
A5	<i>distinction aspect</i>	distinctions between the left-hand side and the right-hand side of the transition are described
A6	<i>problem aspect</i> (a subaspect of A5)	distinctions are considered problematic

**Table 1: aspects of the preservice teachers' conceptions**

## Discussion – vertical and horizontal perspectives

The aspects of the preservice teachers' conceptions detected above indicate two perspectives, a *vertical and horizontal perspective* regarding Figure 1. The aspects A1 to A2 are oriented vertically,

<sup>5</sup> This argument already goes back to Newton's academic teacher Isaac Barrow (1630-1677) (Danckwerts & Vogel, 2006, p. 48).

meaning that concepts or formulas are vertically linked (A1) or different concepts are identified either on the left-hand side or on the right-hand side (A2). Additionally, aspect A3, i.e. describing a limit, is oriented vertically, if the limit is seen without regarding the process of approaching. In contrast, the aspects A4 and A5 have a horizontal perspective, as does A6 as a subaspect of A5. The left-hand side of Figure 1 is linked with the right-hand side, when the transition is described as a process of approaching (A4), when describing distinctions between the left-hand side and the right-hand side of the transition (A5), or when considering those distinctions problematic (A6).

In the author's opinion, those texts that display the aspects A4 to A6 show a *content-related understanding* by the preservice teachers. In particular, when omitting the aspects A4 to A6, the understanding of the transition seems reduced to a temporal "and then" in the sense of: "first you calculate this and then you calculate that". Regarding the reflection depth of the imaginary dialogues (Wille, 2016), exactly those preservice teachers whose imaginary dialogues did not indicate horizontal-oriented aspects (31.4% of the participants) displayed the shallowest reflection depth.

In the course "Didaktik der Analysis" with the help of the imaginary dialogues, it was possible to react to imaginary dialogues, aspect diversity and misunderstandings during the semester. Additionally, some participants themselves regarded the time exposure negative, but mostly they perceived the writing of the imaginary dialogue positive as one preservice teacher wrote in a comment: "It was positive that first, while writing the reflection, it became really clear whether a topic was understood or not."

In summary, the method of imaginary dialogues turned out to be helpful to detect different aspects of the conceptions regarding the transition from the difference quotient to the derivative. In the author's opinion, a profound understanding of preservice teachers should display various perspectives, horizontal and vertical, in order to be able to address the diversity of the students' conceptions later in class.

# Functions: Implicit

Vivica Zweidar

University of Bremen, Germany; [vivica@math.uni-bremen.de](mailto:vivica@math.uni-bremen.de)

*What is the role of the implicit in teaching and learning functions? Functions are a central topic in mathematics classrooms in Germany. The mathematical concept of a function is typically represented by graphs, tables of data, algebraic expressions or by verbal descriptions. Formal definitions of functions only play a minor role in school mathematics. This is one reason why the mathematical content of what a function is, remains implicit when teachers and students talk about functions. Another reason for being implicit about functions in classroom conversation is inherent in the structure of language: in many utterances the implied meaning differs from the literal meaning. I use Swan's (1982) model of translation skills and Grice's (1975) concept of implicatures in order to analyse videotaped classroom conversation in a unit on functions. In this paper, I sketch the concept of implicitness in mathematics lessons.*

*Keywords: Functions, classroom conversation, discourse analysis, implicit meaning, implicature.*

## Introduction

In my research on the implicit in classroom conversation about functions I seek to describe the discourse of learners and teachers in order to reveal the hidden, the unsaid, the implied meaning that has to be decoded to create and follow lessons sensibly. I want to characterize the interplay between the implicit in the mathematical object and the implicit in language when talking about functions. My research questions are: How are functions brought up in classroom conversation? And: What is the role of the implicit in classroom conversation in a unit on functions?

It is common sense that language is important for all school subjects. Mathematics is no exception (see for example Meyer & Prediger, 2012) – it is needed to get access to mathematical matters and to express mathematical concepts. Participating in classroom conversation and getting access to the mathematical content of mathematics lessons can become difficult for the participants on different levels. Apart from obstacles that are immanent in mathematical concepts there may be vocabulary or grammar difficulties, difficulties in the semantics as well as difficulties in a pragmatic sense when learning new contents. In my work, I focus on a pragmalinguistic perspective on classroom conversation about functions. This perspective takes into consideration that not only words or sentences are meaningful when talking but also the context of an utterance. Looking at language that way promises to reveal an unsaid meaning that can be found between the lines. The idea of making the unsaid or the unsayable come to the surface by analyzing the classroom discourse seems conveniently suitable to approach the processes in mathematics classrooms when abstract objects like functions are tried to be made accessible.

## Didactical analysis

In order to link my language analysis to the mathematical content, I analyze the lessons and especially the classroom conversation on a didactical level at first. I seek to figure out what is presumably intended to be taught and learned about functions when working on different tasks and when talking about them.

The mathematical object *function* is very abstract. Looking at the historical development, the understanding of what a function is demonstrates how much functions are attached to their representations (Malle, 1996). Till today in German classrooms functions are a central topic in the curriculum where traditionally the representations like algebraic expressions, graphs, tables of data and (realistic) situations of functional dependencies play an important role. Swan (1982) developed a model to describe the different activities, the so-called translation skills that have to be performed when transforming one representation into another. In my work, I categorize the classroom activities into sequences according to those translation skills. I focus especially on the skills that afford translating a representation of a function from or into situations that are generally closely linked to verbal descriptions. The activities when a representation is transformed from a situation can be summarized as modeling skills and activities when a representation is transformed into a situation can be summarized as interpretation skills.

Furthermore, different aspects of a function can become central in different tasks: you can classify the thinking about function into the following categories (Vollrath, 1989): functional dependency as a point wise relation, functional dependency as a dynamic process and functions viewed as objects or as a whole. The point wise relation takes into consideration that one independent element of a set gets mapped to one dependent element of a set, the dynamic process stands for the change that is produced in the dependent values when changing the independent values and functions as objects look at the given or produced correlation as a whole. Each activity or rather each translation skill can be performed on all of these three levels and form the second dimension for the didactical analysis of the lessons in my investigation.

In *The example*, I demonstrate how I work with this analysis in combination with the linguistic analysis in order to get a description of the implicit in the classroom conversation on functions.

## Linguistic analysis

For the linguistic analysis, I use Grice's *theory of conversation* (Grice, 1975) as the background theory. Central in his theory are so-called implicatures – very generally speaking an implicature is existent when something that is literally said by an utterance differs from what is meant by that utterance. An implicature analysis, as for example suggested by Hagemann (2014), reveals the implicit and what is likely to be meant and understood by the participants. Pimm (1994) claims that Grice's implicatures are also relevant in classroom discourse and Rowland (2002) presents analysis of students' utterances in mathematics discourse using Grice's ideas as a starting point for his theoretical framework.

Grice's concept of implicatures is based on the cooperation principle:

Make your conversational contribution such as is required, at the stage at which it occurs, by the accepted purpose or direction of the talk exchange in which you are engaged (Grice, 1975, p. 45).

Under this assumption nothing that is uttered by a participant of a conversation is assumed to be meaningless and the speaker of the utterance supposes that the conversation partners can decode the utterance meaning. The cooperative principle is formulated very general and leads to more specific aspects about how understanding is produced in conversation. These aspects are the so-called

conversational maxims. Grice formulates twelve maxims<sup>1</sup> that are categorized into the maxims of quantity, quality, relation and manner. Whenever one of the maxims is violated this is a hint at the actual meaning of an utterance. While talking the flouting of maxims is an intuitive process that leads to understand an utterance in a specific way. An implicature analysis explains how a particular intuition is evoked. The following example illustrates the formation of an implicature by infringing the maxim of relation *be relevant*: The setting of the following conversation between two students is a lesson at school. The students are supposed to write down a solution to a textbook task.

- (1) A: I do not have a pencil.  
B: My pencil case is on the table over there.

In example (1) A implicates that she or he needs a pencil and B implicates that A can find one in the pencil case on the table. Both utterances only indirectly hint at the presumably intended meaning. The literal meaning is simply that one student does not have a pencil and that there is a pencil case on the table. The literal meaning is not very likely to be the intended meaning as this meaning would not be relevant in the given context.

To confirm the presence of a conversational implicature in Grice's sense implicatures need to have two characteristics – non-detachability and cancelability. These attributes can be tested as follows (Korta, 1997): the implicature is non-detachable if you find synonym ways of saying the utterance without changing the implicature. In example (1) you could change A's utterance into "I do not hold a pencil." The implicature then remains that A needs a pencil. And the implicature is cancelable if you can neglect the implicature without producing a conflict with the literal meaning. For A in example (1) it is possible to say: "I do not have a pencil, but I do not mean that I need one. In fact, I do not want to write something down."

Both utterances in (1) could have been expressed explicitly, for instance by the following exchange:

- (2) A: Please lend me a pencil.  
B: You can use one of my pencils – take one out of my pencil case on the table.

In this case, the literal meaning and the intended meaning coincide and no implicature is used in this excerpt.

Hagemann (2014) formulates an implicature analysis that refers to Grice's theory of conversation. It follows three steps, which I also use for my analysis: Firstly, contextual elements such as disambiguation and referent assignment have to be determined. Secondly, suspected implicatures have to be tested on cancelability and detachability. Thirdly, a sequence analysis confirms what implicatures are most likely. In example (1) the implicature could be as already suggested above "I need a pencil", but it could also be "I cannot (and I do not want to) write down my solution to the textbook task". The answer of B allows both possible implicatures, but depending on further reactions that may follow this little conversation it can be that one or the other is more plausible. In other words: in the third step you look at what happened before and after the utterance to find out what is most likely intended and understood.

---

<sup>1</sup> Grice's (1975) maxims of conversation: make your contribution as informative as is required, do not make your contribution more informative than is required, try to make your contribution one that is true, do not say what you believe to be false, do not say that for which you lack adequate evidence, be relevant, be perspicuous, avoid obscurity of expression, avoid ambiguity, be brief, be orderly.

## The example

In the following paragraph, I want to demonstrate how I analyze sequences of lessons in order to give a detailed description of what remains implicit in classroom conversation on functions.

### The setting of the discussion

Participants in the presented classroom conversation are the members of a course in secondary school with 29 students and their mathematics teacher. The students are in the 11<sup>th</sup> grade on a high level, preparing for the last two school years in order to get the Abitur<sup>2</sup>. The classroom is equipped with a black board that is used frequently during lessons by the teacher as well as by the students. Tasks are generally handed in in written form on worksheets. The teaching methods and the social forms vary depending on the task. The researcher participates during the lessons only as an observer and does not interfere. The lessons are designed by the teacher without any collaboration with the researcher in order to observe lessons as close as possible to usual lessons.

### The task – Walking functions

The task *walking functions* and the excerpts of the conversation on that task are taken from the first lesson in a unit on functions in the course introduced above.

#### **Walking functions**

Take a chair. This is your benchmark.

You are supposed to "walk" the graphs, i. e. one (or two) of you are supposed to move related to the chair to match the graphs [...]. [...] To your presentation belongs the movement and an explanation why you decided on that movement.

**Figure 1: The task – *walking functions***

The task *walking functions* requires transforming a graphic representation of a function into a suitable realistic situation. That means given graphs have to be interpreted. In the setting when a group presents its movements also the reverse is required for the observers: movements have to be referred to graphs. In this task interpretation skills are in the focus while modeling skills only come

<sup>2</sup> The Abitur is the highest graduation in the German school system that forms the general qualification for university entrance.

up to a lesser extend. The transformation of a graph into a movement demands to have a view on the function as a whole and not only on a certain point of the underlying function. In the example above (see Figure 1), the meaning of straight lines, the meaning of the intersections between the graphs with the ordinate as well as meaning of the parallelism of the graphs must be considered. Also the change of distance to the chair in relation to the change of time has to be taken into account.

When having two representations of a function, it is not immediately obvious that those two representations stand for the same function. In this example it can only be seen implicitly by making clear what certain characteristics of a graph mean in the context of the movement in relation to the chair. The second part of the task asks to give an explanation why the group decided on their specific movement. It is asked to make the relation between two representations explicit.

In my analysis of the classroom situation I seek to reconstruct what is made explicit and what remains implicit when an accepted interpretation of the translation from graph into a situation is debated.

### **The conversation about the task**

During the lesson the students worked in groups of three on the task *walking functions* for about 15 minutes. After working on the task in the groups, three different presentations of movements and explanations were performed. All three groups had different ideas:

In the first group, two students started their movement a few meters away from the chair and walked constantly to the chair. One of them stopped at the chair, the other one stopped at the same time but at some distance to the chair. Their explanation was the following: “Well, we did it that way- well, Paula was the one and Paula started to walk a little earlier because the graph does not start at the zero point. And then Luna came along and then they walked in parallel because they run parallel.”<sup>3</sup>

In the second group, two girls both started in line with the chair and walked vertically to that imaginary line away from the chair keeping the same distance between them. They commented on their movement. A: “Well, not the way that we walk apart, but parallel. But it goes (up) then.” B: “[... ] Because we thought that the x-axis is sort of the position of the chair.”<sup>4</sup>

In the third group, two students walked one after another constantly away from the chair. They started and stopped their movement at the same time and explained: “Well, firstly they did not start at the same point because ehm well you have you see on the y-axis that someone starts further

---

<sup>3</sup> Translated from the German transcript by me. Original: “Also, wir haben die so gemacht weil- also Paula war die eins und Paula ist ein bisschen früher losgelaufen, weil der Graph ja nicht im Nullpunkt startet. Und dann ist Luna mitgekommen und dann sind die parallel gelaufen, weil die parallel verlaufen.”

<sup>4</sup> Translated from the German transcript by me. Original: A: “Also so halt nicht, dass wir auseinanderlaufen, sondern parallel. Aber es geht dann (hoch).“ B: Weil wir gedacht haben, dass ja die x-Achse sozusagen die Position vom Stuhl ist. Dann geht das ja davon weg.”

ahead, well that he is further away from the chair. [...] And they walked at the same speed because the graphs run quasi parallel against each other.”<sup>5</sup>

In the sequence outlined above the students discuss different aspects of the functions in the task. At that point it is not clear which movements and explanations are accepted as a correct translation from the graphic representation into the movement. Subsequently to the presentations, a classroom conversation starts and it is clarified what is considered to be a correct solution to the task. At the end of the discussion, the third group is considered to have presented the best matching movement.

In the following paragraph, I try to reconstruct the process to come to this conclusion and thereby I focus on what remains implicit. The expressions in curly brackets are my interpretation of the intended meaning or rather the implicatures of the utterances.

Finding a suitable movement for the graphs in Figure 1 is not distinct and the different presentations show that the students pick out some characteristics of the graphs and refer them to the movement. All three groups relate the parallelism of the graphs. The first states: “[...] they [the girls] walked in parallel because they [the graphs] run parallel.” Presumably they implicate “they [the two girls] walked in parallel because {that is the meaning when} they [the graphs] run parallel.” The second group also points out that walking in parallel is the correct transformation: “Well, not the way that we [the two presenting girls] walk apart {by mistake}, but parallel.” The third group is the first that relates walking at the same speed to the parallel running graphs: “And they [the two presenting students] walked at the same speed because {that is what is meant when} the graphs run quasi parallel against each other.” In all three explanations they mention different characteristics of the functions apart from the parallelism. That is a hint that they see the function as a whole even though not entirely as they miss mentioning some of the functions’ relevant characteristics that could be observed in the graphic and situational representation. By their performances and their utterances, the groups made clear what they assume to be the correct relation between the representations. They claim this connection without making explicit why that relation is supposed to be correct.

After these three presentations the teacher asks several questions: “What is the origin of the coordinate system? What is on the x-axis? What is the y-axis? And what does parallel mean?”<sup>6</sup> The teacher seems to pick out the characteristic of the functions she considers to be relevant in this task. When looking at the conversation after these questions you can identify the implicatures: “What is {the meaning of} the origin of the coordinate system {in relation to the situation}? What is {the meaning of} the x-axis {in relation to the situation}? What is {the meaning of} the y-axis {in relation to the situation}? And what does parallel mean {in this context}?” She implicitly focuses the conversation on the relations between the representations. The relations between the representations are discussed for about four minutes. Then the teacher also brings a new possible

---

<sup>5</sup> Translated from the German transcript by me. Original: “Also erstmal, ähm, sind die Beiden nicht vom gleichen Punkt gestartet, weil ähm, ja weil hat man halt auf der y-Achse sieht, dass jemand weiter vorne startet, also dass er weiter vom Stuhl entfernt ist. Und dann halt so bald neben dem Stuhl. und die sind beide gleich schnell gelaufen, weil die ehm Graphen halt quasi parallel aneinander laufen.”

<sup>6</sup> Translated from the German transcript by me. Original: “Was ist der Ursprung des Koordinatensystems? Was ist auf der x-Achse? Was ist auf der y-Achse? Und was heißt das mit dem Parallel?”

relation not mentioned before into the discussion: “The graphs go up. That means you walk away from the chair. But it [the movement] is getting faster because {that is meant when} it [the graph] goes up. What do you think of this argument?”<sup>7</sup> This utterance brings the students to see the rising of the graph as the speed of the movement and finally to declare that the movements of group three are best matching to the graphs. At no point in the discussion the parallel graphs are related to movements with the same speed again as suggested by group three at the beginning. Although the parallelism is brought into discussion several times the relation between the parallel graphs and the movements with the same speed remains implicit till the end of the conversation sequence about the task *walking functions*.

## Conclusion and discussion

Such a dense description of the activities in the classroom with the focus on the implicit has the aim to make the implicit accessible. It can be seen as an objectification of the assumptions and normative demands that resonate subliminally in the lessons. In the presented classroom conversation, the convention that parallel running lines in a path-time diagram stand for movement at the same speed is initiated. This relation between the two representations is declared correct by employing many implicit relations and implicatures. This shows that decoding the implicit in the classroom conversation is relevant. An analysis as demonstrated above can help to understand the demands on teachers and students in the classroom to create and follow lessons sensibly.

This analysis of the episode in this paper is just the beginning of my research, my starting point of looking at mathematics lessons with a specific lens – with a lens, which seeks to make invisible demands in mathematics discourse visible. Comparing the analyses of different situations with a similar mathematical content can reveal how the implicit is used in mathematics classroom systematically and give insight into the role of the implicit in teaching and learning of functions. With the help of these analyses I want to develop a local theory on implicitness in classroom talk on functions that links Grice’s vast theory of implicatures to the mathematical topic of functions in mathematics classrooms. Whether the evolving theory holds will not be part of this research, but should be probed by using it for broader classroom observations for example.

Didactical implicatures for mathematics lessons deriving from insights in the meaning of the implicit cannot be given at this point of my research. Only as a final result of further analyses ideas for teaching and learning may be devised. For now, I can conclude that implicatures play a role in classroom conversation on functions and that I am curious about finding out more about the relevance of the implicit in mathematical classroom conversation.

# Which textual features are difficult when reading and solving mathematics tasks?

Anneli Dyrvold

Umeå University, Sweden; [anneli.dyrvold@umu.se](mailto:anneli.dyrvold@umu.se)

*Keywords: Mathematics tasks, reading, solving, textual features.*

Despite the digital revolution much of the mathematics practiced in schools is still tightly bound to two-dimensional texts. This emphasis on text is neither surprising, nor inadequate, since mathematics has developed through a long history with the use of written text, consisting of natural language, mathematical notation and images. Natural language is our native language consisting of letters and words (see e.g., [www.oed.com](http://www.oed.com)). Different features of the mathematics text are also important in written tests, since reading the text is part of the assessment. If the text is hard to read, that difficulty can be relevant as part of assessing the communicative competence in mathematics. Crucial is, however, whether potentially difficult textual features are part of what the assessment aims at. This issue is investigated in the current study, using a synthesis of statistical results and qualitative analyses of task text.

A critical question is where to draw the line between necessary and unnecessary reading demand and how to judge which textual features are irrelevant and therefore should be avoided in mathematics assessments. In the current study this aspect of reading demand is addressed through a small meta-analysis of four studies where different textual aspects in task text are analyzed in relation to task difficulty and task reading demand. The theoretical starting point for the current research is an understanding of language as an essential part of mathematics. It has been argued theoretically that the understanding of a mathematical object develops as the student develops her or his discourse on that object (see e.g., Sfard, 2008). An understanding of mathematics discourse as part of what mathematics is, is in line with the theoretical interpretation of the statistical measure for *demand on reading ability* (DRA) used in the studies included in the meta-analysis conducted in the current study. DRA is a measure of the unnecessary reading demand in a mathematics task, and within this interpretation lays also an assumption of a kind of reading demand that is relevant in mathematics tasks (see also Dyrvold, Bergqvist, & Österholm, 2015). The purpose of the study is to contribute to the knowledge about which textual features in tasks are demanding and whether that difficulty is a mathematics relevant difficulty. The research questions are: i) what conclusions can be drawn regarding reading demand in mathematics tasks in relation to textual features?, and ii) how can the conclusions based on statistical analyses be interpreted in relation to a qualitative analysis of mathematics task text with a high reading demand?

The study consists of a meta-analysis and a qualitative analysis of tasks that stand out in the quantitative analysis. Only four studies are included in the meta-analysis but even such a small meta-analysis do contribute to the development of knowledge since the analysis enables conclusions to be drawn that would not be possible to draw with-out such an analysis. The qualitative analysis has a systemic functional perspective (Halliday & Matthiessen, 2014) and includes also images and mathematical notation.

The meta-analysis focuses on textual features in relation to two quantitative measures; task *demand on reading ability* (DRA) and task *difficulty*. Results in relation to those variables (difficulty and DRA) are relevant to interpret together since they represent different aspects of how a task can be demanding. The measure DRA is obtained through a principal component analysis (PCA) on students' results on PISA reading and mathematics tasks. The result of the PCA is several components that explain different parts of the results on the tasks. The components are statistically disjoint, and therefore the DRA represents demand on a reading ability that is not part of a mathematical ability (see also Dyrvold et al., 2015). Through the analysis, every PISA mathematics task obtains a loading value on that component, a value interpreted as the tasks DRA.

The results reveal several features of the natural language that distinguishes tasks with a high DRA, but also that the images are more tightly integrated with the sentences in tasks that have a low DRA but are difficult to solve. For tasks with high DRA, the sentences are knitted together through the Themes (the topic of the sentence) and Rhemes (what is presented in relation to the theme) something that is not as pronounced in task with low DRA (Theme and Rheme are explained by e.g., Halliday and Matthiessen, 2014). One example of that can be found in the following sentences. The Themes are underlined. “The sculpture is a half circle with the radius 2m. The half circle is inscribed in a square.” Those sentences represent a linear progression since the Rheme of the first sentence becomes the Theme of the next sentence.

The results from the meta-analysis reveal other features than the natural language (words and letters) that are related to difficulty but not to DRA. Tasks with high DRA and tasks with low DRA are alike when it comes to presence of natural language, images, and symbols but for tasks with a low DRA there are more references within natural language and between natural language and images or symbols. In summary, the textual analyses reveal features of the text in tasks with high DRA that enlighten what the high reading demand may stem from, since the textual analyses indicate that the progression between Themes and Rhemes can be a distinguishing feature for tasks with high DRA, whereas references to images may not play such a role.

# Language and risk literacy

Dianne J. Kenton

Brock University, Faculty of Graduate Studies, Canada; [dianne.kenton@brocku.ca](mailto:dianne.kenton@brocku.ca)

*Keywords: Language, risk literacy, developmental research project.*

Recent studies on adult literacy and numeracy raised several key issues some of which are (a) over the last 20 years there has not been significant improvement in adult literacy and numeracy in Canada; (b) regions within Canada will not have enough post-secondary graduates with sufficient literacy skills to fill the jobs created by the Canadian economy; (c) declining numeracy may be due to gender discrimination and skill mismatch in the workplace which in turn, contributes to the shrinking pool of skilled labour; and (d) currently, there are no existing numeracy programs for non-STEM students at the postsecondary level to address the issue of innumeracy or risk illiteracy (OECD, 2013). Like statistical literacy, risk literacy requires familiarity and comprehension of the statistical and risk lexicon that is often confused and/or misused in the public sphere. Bolton (2010) remarks that published statistics are inappropriately used when they are presented without context, use confusing terminology, and misuse or use ambiguous terms. He adds further that, the concept of *uncertainty* is often “lost, forgotten or ignored by authors” creating misleading and/or inaccurate estimates that do not reflect the entire scenario.

## Theoretical framework

Mathematical instruction and comprehension of abstract concepts such as risk, are executed through language and use conceptual metaphor. Language clarifies meaning, making meaning more precise, and executes an operative (process) role in thinking. According to Jurdak, Vithal, de Freitas, Gates, and Kollosche (2016), any level of mathematics instruction is mediated through language. Nunez (2007) explains that, mathematics is predominantly metaphorical and to make abstract mathematical concepts concrete requires the use of conceptual metaphors which are language and cognitive devices. He defines a conceptual metaphor, as a “cognitive mechanism that allows us to reason about one kind of thing as if it were another”, more specifically it is a “grounded, inference-preserving, cross-domain mapping, neural mechanism that allows us to use the inferential structure of one conceptual domain (e.g. geometry) to reason about another (e.g. arithmetic)” (pp .4-6). The instructional resource examines language and conceptual metaphors used in risk instruction focused on developing skills in decoding and understanding publicized risk in legal, social, financial or medical contexts.

## Methods and findings

The methodology of this study was guided by McTighe and Thomas (2003), *Understanding By Design* (UbD) framework for curriculum planning and design that is to (a) identify the desired skills or outcomes required (b) determine the assessment evidence and (c) plan the experience or instruction. The content of the instructional resource comes from the results of literature review and web research, information interviews, document analysis, government publications, curriculum documents, expert critique and informal information gathering from practitioners in the field. Cumulative and summative assessment rubrics in the resource were developed based on Facione

(2011) critical thinking assessment. A small group of independent reviewers examined a lesson on risk and were asked to provide independent written feedback to the lesson questionnaire. The resource was further revised with respect to its structure, content and recommended instructional methodology and reviewer feedback was included in the pilot lesson.

Reviewers commented that the instructional resource was relevant, well-constructed, and raised awareness of risk miscommunication. Respondents agreed the lesson had a logical flow, demonstrated progression and that the background information was indeed necessary to provide context, to follow presented arguments, and to comprehend and make sense of data. All respondents agreed with the type and appropriateness of the lessons assessment also remarking that the self-assessment was very important to verify their own understanding. The findings from this development study confirmed that basic risk comprehension can be achieved by rephrasing risk and expressing probability as a natural frequency within a specified context.

# Professional competences of future mathematics teachers concerning the role of language in mathematics teaching and learning

Nadine Krosanke

University of Hamburg, Germany; [nadine.krosanke@uni-hamburg.de](mailto:nadine.krosanke@uni-hamburg.de)

*Keywords: Language, mathematics teacher education, vignettes.*

The state funded project ‘Professional teaching practice to promote subject-related learning under changing social conditions’ (ProfaLe) aims at improving teacher education at the University of Hamburg at various levels: One objective is to sensitize future mathematics teachers to language difficulties in mathematical learning processes and tasks as well as to promote professional competence in helping students to tackle possible learning barriers based on language difficulties. For this purpose, courses, which integrate aspects of language learning into mathematics education, are going to be developed and their effects will be evaluated in an ongoing PhD study using video-vignettes and interviews.

International large-scale studies like PISA and TIMSS and other studies have repeatedly shown that a connection between the first language, language proficiency and the mathematical performance of students exists. Especially skills referring to a language register described by Gogolin (2009) as academic language (so-called ‘Bildungssprache’) have proven to be vital for educational success. In mathematics classes different language registers are needed and used: everyday language, ‘Bildungssprache’ and mathematical language. Halliday defines register as “a variety according to use; a register is what you speak at the time, depending on what you are and the nature of the activity in which the language is functioning” (Halliday, 1978, p. 31). Consequently there is no translation from one register into another without shifts in meaning and function, but it is often not possible to make a clear separation between the registers. The concept of ‘Bildungssprache’ refers to the ability to employ language skills in order to access knowledge and participation in education discourse (Gogolin, 2009). Language in mathematics teaching and learning has not only a communicative, but also a cognitive function (Maier & Schweiger, 1999) and is for instance very important for developing mathematical concepts. Although teachers should promote language skills according to the German national standards, language is seldom addressed explicitly in ordinary classroom activities (Schütte & Kaiser, 2011) and future mathematics teachers at the University of Hamburg are currently not obliged to attend courses focussing on the subject-specific role of language in teaching and learning. For this reason, elements of inclusive language teaching are going to be developed, tested and implemented into two consecutive courses at the master studies in mathematics teacher education.

The first course refers completely to the role of language in teaching and learning mathematics and offers opportunities to learn about linguistically diverse students from the perspective of intercultural education, applied linguistics and language teaching. The second course accompanies the school internship and, therefore, is more general about mathematics education and pedagogical aspects such as classroom management, nevertheless continuously considering language and its learning. The future mathematics teachers will be enabled to recognise different registers and related to that potential language barriers in written mathematics texts as well as in text-production tasks. For that

aim future teachers analyse mathematical tasks and text-vignettes as well as video-vignettes displaying mathematical solving processes of students. The future teachers will be familiarised with the approach of *Scaffolding* (Gibbons, 2002), which has proven to be effective for language-based learning difficulties and plan lessons or parts of it combining language and mathematics learning. In the second course the future teachers are developing even more awareness of the role of language by reflecting their own or joint classroom observations i.a. in the accompanying course at the university.

The ongoing PhD project aims at examining the changes concerning noticing and beliefs of the future teachers. The main research question is: to what extent can relations be reconstructed concerning the awareness of the role of language in mathematics teaching before and after an intervention? Before and after every of the two courses semi-structured interviews will examine which beliefs about the relationship between language and mathematics teaching the future teacher hold and how these beliefs may change. Based on the situated approach for measuring competencies by Blömeke, Gustafsson and Shavelson (2015) and the concept of noticing (Sherin, Jacobs & Philipp, 2011) the project presented here aims at coming closer to the measurement of the performance of the future teachers by evaluating situation-specific skills with a video-vignette. Interviews (pre-and-post) based on a video-vignette will provide data which linguistic aspects of teaching and learning mathematics future teacher notice, how they would decide to react in a specific situation and how this may change due the two courses. All data will be analysed by qualitative text analysis (Kuckartz, 2014).

# Getting language awareness: A curriculum for language and language teaching for pre-service studies for teachers of mathematics

Carina Rauf and Barbara Schmidt-Thieme

University of Hildesheim, Germany; [rauf@imai.uni-hildesheim.de](mailto:rauf@imai.uni-hildesheim.de); [bst@imai.uni-hildesheim.de](mailto:bst@imai.uni-hildesheim.de)

*Keywords: Language, teacher education, teacher professional knowledge.*

Teaching and learning mathematics is based on the use of language: for introducing and defining new mathematical objects, discussing different ways of calculating, documenting the results of a proof or explaining how to handle teaching materials, different representations are used, but almost always accompanied by language. Language as a medium and an aim of mathematics lessons at school is a well-known object of didactic research. In the last years one can observe a focus on differentiations and transitions between different languages (or registers of one language) used in mathematics (Duval, 2006) or questions of teaching in multilingual classrooms (Ahrenholz, 2010; Prediger, Clarkson & Bose, 2016). On the other side, the professional knowledge of teachers, and questions on how this can be developed in pre-service and in-service lessons gained considerable interest. Beside others “Explaining” was recognized as an important factor of effective instruction (Kunter et al., 2013; Vogt, 2009). Bringing this together, the question is, which language-related competencies a teacher has to have as part of his professional knowledge and when, where and how he can achieve this. Therefore, several universities in Germany designed and developed exemplary trails in preservice teacher-studies in the last years. In most of the cases these are extra, but obligatory courses on “German as second language”. Another approach is followed for example by a project called “Umbrüche gestalten – Sprachen bilden Niedersachsen” (languages educate Lower Saxony) (<http://www.sprachen-bilden-niedersachsen.de/index.php/projekt.html>) of all universities with teacher education in Lower Saxony.

## A “Language Curriculum” (SuM\_MaSt)

Following the approach of the project “Umbrüche gestalten” we developed a pre-service “language curriculum” for teachers of mathematics (based on experiences of the implementation of language studies in teacher studies mentioned above) following four assumptions for learning opportunities (used to guide the curriculum): Learning tasks should:

- (a) be spread from the beginning to the end of the academic studies, like a vertical spiral curriculum,
- (b) be integrated in mathematical lessons, for the technical language of mathematics is best learned by doing mathematics; certainly, there are also a couple of explicit language-related courses,
- (c) evoke an active and reflective handling with language in learning situations and be applied and tested in authentic situations,
- (d) include individual feedback and allow some comparative measurements.

And in addition: It should be transferable to other designs of academic studies for teachers at other universities and to other subjects.

Among the language and language learning competencies are the ability to use the language of mathematics and some of the other languages used in schools (e.g. colloquial language or “Bildungssprache”). This needs to be done adequately to learners and learning situations. After some pre-studies the design based research project SuM-MaSt started fully 2016 at the University of Hildesheim. Around 20 learning task were implemented:

- tasks integrated in mathematical lectures, for example using different registers and representations while explaining main topics, verbalize formulas and write down explanations for pupils, deal with historical sources in the original language (feedback/evaluation (qual.): correctness of the mathematical content and adequacy of language)
- explicit courses about “Language and Mathematics” contenting representations of mathematical objects and concept building, communication and argumentation, language sensitive teaching material; (feedback/evaluation: analysis of the results during the lessons)
- theoretical inputs in lectures, for example “Explaining” in the lecture “arithmetic” (feedback/evaluation (qual.): describing the development of linguistic competencies)
- practical exercises in schools.

Beside further designing, implementing and evaluating of language-focused tasks in the mathematic curriculum in the next terms we will take first steps to a transfer of these tasks to other subjects, beginning with the natural sciences.

# TWG10: Diversity and mathematics education: Social, cultural and political challenges

# Introduction to the papers of TWG10: Diversity and mathematics education: Social, cultural and political challenges

Lisa Björklund Boistrup<sup>1</sup>, Nina Bohlmann<sup>2</sup>, Javier Díez-Palomar<sup>3</sup>,  
David Kollosche<sup>4</sup>, Tamsin Meaney<sup>5</sup>

<sup>1</sup>Stockholm University, <sup>2</sup>Freie Universität, Berlin, <sup>3</sup>University of Barcelona,  
<sup>4</sup>Goethe University Frankfurt, <sup>5</sup>Western Norway University of Applied Sciences

## Scope and focus

Thematic working group 10 is interested in discussing diversity and mathematics education within the realms of the societal, the cultural, and the political. In the work of the group, mathematics education is assumed to refer to more than the encounter between an individual and a mathematical object and is considered to occur in wider contexts than just classroom settings. The group is specifically interested in discussing research that addresses how diversity affects students' possibilities to learn in mathematics education. Diversity also occurs in relationship to who is doing the research and who is being researched, posing methodological issues of an ethical nature. Hence, multiple diversities intersect, and in so doing pose challenges to intended and actual learning and teaching practices in their multiple forms.

## Organisation of TWG 10's work

In the seminars during CERME10, papers were presented in a similar way to what had occurred previously, in that the authors did not present their own paper. Instead each paper was presented by another author giving a description of the main ideas from the perspectives adopted in the paper. The author(s) then had a few minutes to add to or comment on the presentation, with the possibility of pointing out or emphasising important aspects. In the end of each session, there was time for discussing the presented papers. These discussions firstly occurred in small groups and then were shared in the whole group. A poster session with 5 posters was held, in addition to the general CERME poster session. Here each author had 3 minutes to describe the content of their poster. The poster authors then positioned themselves next to their respective posters to engage in discussions with group members.

## The papers discussed

Below are the papers presented during our sessions with the respective presenter(s).

Papers and authors	Presenter
How Sámi teachers development of a teaching unit influences their self-determination by Anne Birgitte Fyhn, Tamsin Meaney, Kristine Nystad, Ylva Jannok Nutti	Anette Bagger
Importance and possibility of integrating gender competence as a key qualification in mathematics teacher education by Anina Mischau, Katja Eilerts	Helena Roos
Cultural diversity as a resource or an obstacle for teaching practices	Tamsin Meaney

in multicultural milieu: Experience of a training course for Italian teachers about Chinese Shuxue by Benedetto Di Paola, Giovanni Giuseppe Nicosia	
---	--

**Table 1: Session 1.**

Integrating critical theory and practice in mathematics education by David Swanson, Laura Black	David Kollosche
Incepted neoliberal dreams in school mathematics and the Chilean experience by Melissa Andrade-Melina	Anne Birgitte Fyhn
Towards cultural responsiveness in mathematics education by Swapna Mukhopadhyay, Brian Greer	Hilary Povey
Content-related and social participation in inclusive mathematics education by Judith Jung, Marcus Schütte	Colin Jackson
Social class and "ability" grouping in mathematics in English secondary schools: A review by Colin Jackson	Sabrina Bobsin Salazar

**Table 2: Session 2**

Subjective theories of teachers in dealing with heterogeneity by Elisa Bitterlich, Judith Jung, Marcus Schütte	Benedetto di Paola
"No, it just didn't work": A teacher's reflections on all-attainment teaching by Colin Jackson, Hilary Povey	Javier Díez-Palomar
The socio-politics of teacher explanation in mathematics education by David Kollosche	Elisa Bitterlich
Diversity in an inclusive mathematics classroom by Helena Roos	John Keogh
"It is only a test": Social aspects of displaying knowledge in mathematics for Second Language Learners (SLL) by Anette Bagger	Melissa Andrade-Melina

**Table 3: Session 3**

Polish parents and mathematics education in Swedish preschools by Dorota Lembrér	Judith Jung
(Wanting to do) Ethical research in a shifting context by Andrea Eikset, Trude Fosse, Troels Lange, Johan Lie, Magni E. H. Lossius, Tamsin Meaney, Elena Severin	David Swanson
Mathematics at the enterprise: Industry, university and school working together to facilitate learning by Hans Kristian Nilsen,	Brian Greer

School mathematics education through the eyes of students in Ghana: Extrinsic and intrinsic valuing by Wee Tiong Seah, Ernest Kofi Davis, Monica E. Carr	Anina Mischau
Teaching practices in a mathematics classroom and their connection to race and racism in the United States by Sabrina Bobsin Salazar	Dorota Lembrér
Exploring Roma learning Mathematics: A sociomathematical view by Javier Diez-Palomar	Wee Tiong Seah
The mathematics teacher's quasi-Darwinism. Problematizing the mathematics education research by Alex Montecino	Hans Kristian Nilsen

**Table 5: Session 5**

## Themes discussed in the TWG

As at previous CERMEs, TWG10 discussed political aspects of mathematics education intensively. One way of addressing political aspects of diversity in mathematics education is by assuming research as always, in one way or another, constituting political acts. This assumption rejects a naive idea of research as politically neutral, providing objective data that is used to rationally guide policy. An example is Fyhn, Meaney, Nystad and Nutti (this volume) who address cultural responsive teaching of mathematics in relation to Indigenous (Sámi) teachers' self-determination. The acknowledgement of the political nature of research constitutes a recognition of how the issues we write and talk about as researchers are inextricably political and framed by world-views. Political aspects also concern how the broader political context of mathematics education, as it is performed in a variety of contexts, affects the teaching and learning of mathematics. Two papers looked at the intersection of school and workplace and the impact of mathematics education (Nilsen & Vegusdal, Boistrup & Keogh). Kollosche (this volume) discusses the role of teacher explanation for student passivity, also in relation to the discipline of mathematics. Another example of addressing political aspects derives from Sweden, where Bagger (this volume) addresses the effects from national testing on students "in special need". Political aspects present in TWG10 also concern how diversity among learners may have consequences in terms of unequal access to the learning of mathematics. This research may include critical investigations of the impact of socio-economic or cultural backgrounds, as well as other background factors, as grounds for unequal mathematics education, because of a sorting of students so they receive different learning opportunities (e.g. Salazar, this volume). A tension here is previously presented research to the group which confronts "the official discourse, which posits inclusion and equity as fundamental goals of mathematics education" (Straehler-Pohl & Pais, 2013, p. 1792, see also Valero, 2013). There are more recent papers

addressing ways of overcoming such tensions in research through collaboration between researchers adopting complementary perspectives, with teachers and students (Black & Swanson, this volume), hearing the voice of parents (Lembrér, this volume) or bringing individuals' voices to the discussion, highlighting potential opportunities to overcome such tensions (Díez-Palomar, this volume). Still, the work in the TWG, with its developments and tensions, can be viewed as constituting part of a resistance to a rampant global homogenization that is central to the neoliberal agenda, which stands in ideological opposition to the group's commitment to valorizing diversity (Mukhopadhyay & Greer, this volume).

The ethics of doing research, in relation to diversity of various forms, has been addressed in the TWG (e.g. Eikset et al., this volume). The TWG is united in a strive for social justice, inclusivity and variety. Consequences of an engagement in ethical considerations is reflexivity in research, where also the researcher's acts are critically observed (Montecino, this volume). Ethics also includes the impact of our actions within the context in which we are conducting our research and many addressed that we must pay attention to the consequences of our research on the end-users' (students, teachers, families, etc.) opportunities to improve their chances to learn mathematics and/or to legitimize their own social and cultural knowledge about mathematics (Mukhopadhyay & Greer, this volume). Diversity as a concept, and the connotations hereof, were problematized in the TWG (e.g. Roos, this volume). One aspect here is that diversity as a concept may assume a norm that there is something normal from which, for example, diverse students deviate, while "diversity" instead should be viewed as the norm itself. A connected matter here are words that mean something similar to diversity, but perhaps with other connotations; difference, heterogeneity, multiplicity, variety, and connected words: democracy, inclusion/exclusion, segregation/integration, empowerment. With an interest in the broader context of settings for mathematics education, the political times of today with neoliberal agendas affecting the framing of mathematics education, has been part of the work of the group during the last CERMEs (e.g. Andrade-Melina, this volume). Aspects here are political decisions governing towards mathematics education to be effective and market based, which are forces where diversity among students may be disturbing, rather than part of the responsibility of the system. We expect such issues to be elaborated more during future meetings, while also addressing the roles of mathematics education in times where populist policy making is becoming more common.

# Incepted neoliberal dreams in school mathematics and the ‘Chilean experience’

Melissa Andrade-Melina

Aalborg University, Denmark; [melissa.andrade.mat@gmail.com](mailto:melissa.andrade.mat@gmail.com)

*This work aims at portraying a rhizome of circulating naturalized truths about who citizens should be and how they should act within neoliberal governmentality. It does this by a historization of an incepted belief entangled in diverse social spheres. It unfolds how the ideas of human capital and welfare become a top right in mathematics education. The ‘Chilean experience’ is used as an example to construct a rhizomatic historization of events, strategies and technics of government that enabled the inception of neoliberal dreams into school mathematics.*

**Keywords:** Governmentality, neoliberalism, historization, rhizome, school mathematics.

## Introduction

*An idea. Resilient... Highly contagious. Once an idea has taken hold of the brain it's almost impossible to eradicate. An idea that is fully formed—fully understood—that sticks; right in there, somewhere (Dominic Cobb, Inception).*

It is intriguing how highly perceived the Chilean models are—economy, education or health systems—to other countries. According to Taylor (2003), Chilean systems have been taken as models ‘worthy of emulation’. Is Chile doing something marvellous? The country has been seen as an example of organization and ‘proper’ policies for economic progress and welfare (Silva, 1993). Its policies are considered as trendsetters among privatized pension systems (see Mesa-Lago, 2012), among health care reforms (see Bruce, 2000), and it was one of the first countries implementing neoliberalism as a framework in education (Aravena & Quiroga, 2016). The results in PISA, particularly in mathematics literacy, have progressively increased over the years—2000 (384); 2006 (411); 2009 (421); 2012 (423). And so, Chile has risen to be seen as one of the most developed countries in Latin America (Gregorutti, Espinoza, González, & Loyola, 2016). Chile is considered, by the World Bank’s annual reports on development, the proven example of the benefits embedded in ‘conforming’ to a neoliberal approach to social policy.

[Chile] is often viewed as a trendsetter in introducing fundamental and far-reaching neoliberal reforms [...] the Chilean example as been heralded as proof of the success to be gained from an uncompromising commitment to neoliberal policy prescription (Taylor, 2003, pp. 21-22)

But... it is not all sunshine and roses! By building on Foucault’s work, this paper aims at portraying how neoliberal discourses about mathematics education have been (re)produced and how they have circulated amongst diverse spheres of human interaction, (re)shaping citizen ways of being and acting in the world. It does this by taking “a critical attitude towards those things that are given to our present experience as if they were timeless, natural, unquestionable” (Rose, 1999, p. 20). This paper deploys a historization of the present of entangled historical events, strategies and techniques that made possible to incept the neoliberalism into school mathematics in Chile. This narration is not a critique about the implementation of educational policies in Chile; rather it is the tracing of naturalized truths in mathematics education as an assemblage of diverse governmentality techniques (Foucault, 1991).

These naturalized truths are traced in five moments. First, regarding the introduction of neoliberalism as a set of political movements. Second, regarding neoliberalism as a system of reason for economic improvement. Third, regarding the specific type of citizen that the new economy requires, a consumer of goods. Fourth, regarding the productive subject of schooling for the market, a competitive subject. And finally, regarding how school mathematics becomes the vehicle to shape the desired subject for economic growth.

The plot of the movie “Inception” inspires the style of writing of this paper. In this movie a series of dreams are unfolded. Each dream should be understood as a new and deeper dream occurring inside the previous one. The dreams do not follow a chronological arrangement. It is not a lineal story; it is a rhizomatic construction. A rhizomatic network allows a non-hierarchical multiplicity of entryways, of dimensions, lines; it has no beginning or end, but always a middle: “The rhizome is altogether different, a map and not a tracing [...] The map is open and connectable in all of its dimensions; it is detachable, reversible, susceptible to constant modification” (Deleuze & Guattari, 1987, p. 12). Hence, all dreams are connected not as a sequence of events, but as continuities and discontinuities. All narrations are entangled, even in different times, even in different spaces, and even in different voices. The paper is written in this form in alignment with Foucault’s rejection of causality.

We consider the understanding of the way one event succeeds another as a specifically historical issue, and yet we do not consider as an historical issue one which in fact equally so: understanding how two events can be contemporaneous [...] History is quite frequently considered as the privileged site of causality [...] But we have to rid ourselves of the prejudice that history without causality would no longer be history. (Foucault, 1999, p. 92)

### **First dream: The Cold War and the neoliberal revolution**

It is the late 60s, in a country apparently far from the War, but close enough to be in the spotlight. There is the danger of it becoming the first socialist nation in South America, and this is threatening for the US. Silent voices were saying: “under no circumstances should Allende be elected!” But, he was... Salvador Allende became the first democratically elected socialist president in the Western hemisphere. What a revolutionary! Fighting for the people! Chile has begun to increase its role in the provision of social services.

By subsidising the reproduction of the labour force through allocating resources to the development of state systems of health, education, housing, staple-food subsidies and social insurance, universalistic social policies tended to reinforce the purchasing power of wages thereby expanding domestic markets for industrial goods. (Taylor, 2003, p. 23)

Something is starting to go extremely wrong in Chile. Suddenly there commenced a crisis that led to most of the population clamoring for improvement. The, so-called, socialist experiment “united capitalists, landowners, the middle classes, and their political party allies against labor, peasants, and leftist part” (Silva, 1993, p. 535). Apparently the US government, also pressuring the World Bank and the Inter-American Development Bank to do the same, minimized the aid they provided to Chile... And so, Chilean foreign reserves plunged from \$400 to \$13 million in one year (Moreno, 2008). Discontent people wanting the president out are growing in number. It is socialism versus capitalism... “\$7 million channelled to anti-Allende groups”, according to a report of the US senate (Moreno, 2008, p. 93). And he was overthrown on September 11<sup>th</sup> 1973, by the military force

commanded by General Pinochet. Now, neoliberal ideas are being forced into Chilean minds that are afraid all the time, afraid for their lives, afraid to raise their voices. Meanwhile, those in favour of the new regime are enjoying the pleasures of the new order (Salazar, 2003).

## **Second dream: The Chilean experiment, Friedman and the School of Chicago**

The year is 1950; the place, Chicago. Milton Friedman is developing a new approach to economy theory. This new theory is in opposition to socially conscious economies, which have been prominent in Western governments after 1929. Friedman believes that “economic benefit could best be optimized if the individual has the autonomy to pursue his or her own self-interest” (Moreno, 2008, p. 92). This new theory was the hope for a group of technocrats that moved to Chicago, the “Chicago Boys” (García & Wells, 1983). In the 70s, Pinochet decides to leave the economical management of Chile on the hands and knowledge of the Chicago Boys. This is going to be the first time that a group of Friedman has “an opportunity to influence governmental policy and put their theories into practices [...] They already have a complete programme aiming to re-structure the economy and to reverse Allende’s social reforms” (Moreno, 2008, p. 94). The military regime and the Chicago boys established neoliberal economic and social policies here (Salazar, 2003). “[T]he market supplanted state intervention in the economy, except in labor relation” (Silva, 1993, p. 527).

Within the first six years of dictatorship, the ‘shock therapy’ was the only approach to curb social policy and state expenditure (Huber, 1996). Chilean reform “has been led by both the advocates of monetarism, located principally in US institutions and universities, and by the Chilean reformers themselves” (Taylor, 2003, p. 22). Neoliberal ideas were taken as a sort of ‘second independence’ and, also, an entrance to the first world of developed countries (Salazar, Mancilla, & Durán, 2014).

## **Third dream: Consumerism as the ever-growing economy**

Here, in this place of earth, everything could be marketed, everything could be sold, and most people would feel the urge to buy it. Health and education are, by constitution, social rights to every citizen. But here, those basic social rights fade into consumer goods. Public and private enterprises competing with each other, providing services for customers willing to pay for them, after all it is their choice (Taylor, 2003). Parents have the opportunity to choose freely the type of school—municipal, subsidized private or fee-paying private schools—and the type of education they want for their children (Mizala & Romaguera, 2000). Free choice... if they can afford it!

Public against private institutions... In a place where private institutions have the right to charge in excess to ensure better and better quality. Private schools enjoy, without any guilt, “having greater resources, enabling a stronger quality of education to be taught, and thereby reinforcing the desire of parents with available income to send their children to such schools” (Taylor, 2003, p. 34). After all, the more you pay the better you get; the less you pay the worst you obtained. In a time and place where education policies are transformed into economic policies of education (Castiglioni, 2001).

## **Fourth dream: Competitiveness in schools, education and freedom of choice**

After the introduction of ‘welfare’ as a method to increase efficiency, “the element of competition and the response of enterprises to public desires as indicated by market forces were suggested to create an optimal allocation of resources throughout welfare provision” (Taylor, 2003, p. 26). The reform of the 80s, under the military regime, changed Chilean education system. Decentralization

was key to encourage private providers to enter the market (Mizala & Romaguera, 2000). And there was more, so much more than that. This reform involved a reformulation of the interplay between state and schools, a voucher system that indirectly funded schools by assigning the resources to students (Parry, 1997). This measurement left schools receiving financial aid depending “on the number of students that they could attract [...]. If schools were unable to compete in this new marketplace environment, they would be allowed to fail and face dissolution” (Taylor, 2003, p. 33). A highly competitive system generated by an educational market and by the policies aiming at improving the quality of education (Mizala & Romaguera, 2000) was shaped. And so, state accountability systems were able to reward and/or punish schools by allocating resources regarding the performance of each school (Elacqua, Martínez, Sontos, & Urbina, 2012). A system in which, schools, teachers, students are constantly competing and being assessed.

### **Fifth dream: The sky is the limit! Mathematics to the people**

Welfare and mathematics, always hand by hand. Here, mathematics has been granted with a great importance and status. In the 60s, logic was taken as the foundation of every science, reasoning accurately and rigorously was the core of any argumentation and of critical thinking (Diaz & Giudici, 1970). Mathematics was the one that helped to develop reasoning and logical thinking and reading proficiency was thought as a tool to better understand mathematical instructions (Ministerio de Educación & CPEIP, 1967). In the 80s, the military regime reformed the curriculum and school textbooks to reflect the regime’s doctrine: “education was recast to promote studies functional to the new productive structures of Chilean society, whereas traditional arts and humanities studies were discouraged” (Taylor, 2003, p. 32). It was indispensable to embody in individuals certain knowledge skills—mathematical knowledge—, and attributes to facilitate the creation of personal, social and economic well-being (OECD, 2001). Economic growth was about human capital.

National assessment started to be taken as the key to achieve economic progress, on the one side, to test current policy changes, on the other, as a mean to set standards. And so, competitiveness and accountability, within school mathematics testing, led to higher performances, higher incomes, higher social mobility and welfare (OECD, 2014). Nowadays, by knowing students’ numeracy proficiency in PISA it is possible to predict, amongst many others, their likelihood of being employed or to calculate how different their hourly earnings would be (OECD, 2015). And so, the promised state of welfare is side by side with mathematics proficiency. Mathematics is now the key for a brighter future, all students have to do is to be good at math and the sky will be their only limit! *[End of dream 5]*

The standardized test SIMCE has been a key element to promote competitiveness and pressure to the system. Since its results are publicly published, it becomes an objective indicator to assess school performances (Mizala & Romaguera, 2000, p. 393). It also enables parents, as consumers, to demand better services for their children (Meckes & Carrasco, 2010), for students to be successful and entrepreneurs. *[End of dream 4]*

School mathematics is now an investment! Reforms have shaped education into a capitalist marketplace, by promoting entrepreneurial profit-minded investment and by remodeling education to consolidate the productive structures of economy (Taylor, 2003). *[End of dream 3]*

And the so-called ‘economic miracle’, product of the economic growth in the late 70s, helped raising the prestige of neoliberalism “under the banner of ‘the Chilean model’” (Taylor, 2003, p. 25). By

now, Chile has become famous for its neoliberal restructuring followed under General Pinochet (Silva, 1993; Aravena & Quiroga, 2016). *[End of dream 2]*

This is it! Chile is no longer an underdeveloped country (Salazar et al., 2014). Chile is now part of the first world, the “tiger” of Latin America (Teichman, 2016). *[End of dream 1]*

## Incepted neoliberalism

*You create the world of the dream. You bring the subject into that dream and they fill it with their subconscious (Dominic Cobb, Inception)*

From a Foucaultian perspective, conduct is governed through diverse techniques, strategies, and devices (Foucault, 1991), within a space of government that “is always shaped and intersected by other discourses” (Rose, 1999, p. 22). In doing so, each individual conducts him/herself by (re)shaping his/her own modes of being and acting in a space of ‘regulated freedom’ and under a promised state of welfare. In this sense, “people are governed by and through their own interests” (Cotoi, 2011, p. 113). This is precisely the idea behind the ‘inception’ of a neoliberal mentality. A set of naturalized truths circulating amongst diverse times and places, knitting a web to govern the self and to regulate habits and desires of cultural and historical subjects through school mathematics. These discourses help governing productive citizens, in the sense that intend to insert subjects in regulatory practices that (re)shape their conduct “without interdicting their formal freedom to conduct their lives as they see fit” (Rose, 1999, p. 23). Reforms, according to Dussel (2003, p. 94), “have to be understood as part of government technologies that intend to shape the way people are to act, think, and feel about the world, that combine the old and the new in unique ways”.

One possible narrative to understand the success of neoliberalism in Chile could be grasped through the articulation of certain discourses about consumerism and competitiveness. SIMCE in mathematics, for example, became the first step of knowledge consumerism and of a marketable education/society. SIMCE’s results are publically published in national newspapers and widely discussed through other means of public communication, so parents and society could judge schools by their performance in standardized tests. ‘Judge’ in the sense of deciding which school is the best option for their children’s future. This marketing of schools and teachers leads to the most utopian non-sense practices. For example, within the belief that welfare is only achieved by a high quality education, parents, in order for their children to be enrolled in those schools with “higher quality”—with good scores in national tests—are willing to stay all night in line, outside a school, to submit the admission application. Figure 1 shows a Chilean newspaper, *Las Últimas Noticias*, reporting the news: “Parents slept on the street under -3,6° Celsius because of enrolment. They are trying to enroll their children in pre-school for next year in Santa María School in Osorno”. One of the parents, who waited in line for 12 hours said: “It is demeaning but what else can we do. This school is good and affordable. I have three kids and they all need to study”.

**Figure 1: News about parents staying all night outside a school**

These discourses are not isolated from the ones of school mathematics. The importance that mathematic literacy has within OECD's indicators help move research to be about how to improve students' performances in mathematics. For example, in order to be successful in SIMCE, students should not be allowed to miss classes. If students are "absent 9 days during the school year (the sample average of absences) reduced performance by at least 23% of the standard deviation of the score on the SIMCE mathematics test" (Paredes & Ugarte, 2011, p. 199). Welfare can also be measured in relation to students' performances in national tests, by correlating SIMCE scores in mathematics to predict a student's future income (Bharadwaj, Giorgi, Hansen, & Neilson, 2012).

The Chilean Ministry of Education released the "Learning standards" in school mathematics to help teachers evaluate "what students should know and are able to do for displaying, in national tests, appropriate levels of achievement" (MINEDUC, 2013, p. 4, my translation). These learning standards categorized students in three levels of achievement that, at the same time, predict their future outcome in SIMCE in mathematics. So, if students do not want to be label at the lowest level, they have to engage in regulatory school practices, they have to compete with their classmates and with themselves. In this fashion, SIMCE in mathematics also operates as a technique to generate 'self-entrepreneurs', "individuals that self-regulate, self-direct and are continuously in a process of redefining their competences" (Cotoi, 2011, p. 116).

As portrayed within the dreams, Chilean neoliberalism have been (re)producing discourses that circulate within diverse time and places in order to obtain economic growth, progress and welfare through school mathematics. School mathematics, since it was thought to shape productive citizens, was taken as the key for Chile to become a developed country. Mathematics needed to be a good that people wanted and were willing to consume. With marketable school mathematics, whomever wanting to achieve welfare would have to pay for higher quality. And, therefore, Chilean economy should increase. This would not have occurred without the dictatorship and Friedman thoughts: Economy would be best optimized if people have the freedom to pursue their own self-interest.

# **“It is only a test” – social aspects of displaying knowledge in mathematics for second language learners**

Anette Bagger

The Department of Science and Mathematics Education, Umeå, Sweden; [anette.bagger@umu.se](mailto:anette.bagger@umu.se)

*This article discusses social dimensions connected to assessment in mathematics for second language learners in Sweden. The data consist of two semi-structured interviews with students in the ninth grade of compulsory school. Foucault’s thinking on discourse and positioning was advocated as a frame for analysis. The units for analysis were students’ statements about caring and the other in connection to the display of knowledge in mathematics. Results show that caring of and for others are important resources in managing assessment and believing in the future.*

*Keywords: Second language learner, assessment in mathematics, opportunity to display knowledge.*

## **Introduction of the problem area**

Measures of achievement are often situated as measures of quality in education (Lundahl & Tveit, 2014) that promote striving towards high quality, yet also threaten equity at times (Llewellyn & Mendick, 2011). An example of this are recent educational reforms including earlier and extended testing in Sweden (Regeringen, 2006). These reforms have led to an enhanced focus on the measures of knowledge, while at the same time school agencies generate reports on inequalities in the measured knowledge and grades in mathematics between schools and groups of students. Differences are connected to gender, class and ethnicity (e.g., Skolverket, 2015). Achievement in national tests is central in grading as the results of the national tests in mathematics often are used to indicate students’ grades (Skolverket, 2016). Not having an approved grade in mathematics at grade nine in Sweden means that a student does not have access to public programs at the upper secondary school in the following year. The opportunity to display knowledge then becomes a critical point of departure for the individual’s possibilities for positive development and positioning in mathematics. This turns the assessment grade in mathematics into a gatekeeper to get access to higher education, and is a gatekeeper that keeps out second language learners (SLL) more often.

This portrayal of circumstances alludes to societal, historical, social and political discourses influencing an individual’s mathematical development and life-choices by making some positions available and other positions not available. Researchers are currently engaged in issues of for whom education functions and thereby which students can have access to success in education and life (Au, 2008; Peters & Oliver, 2009). The focus on disadvantaged groups of students then affords new ways of understanding and approaching mathematics education (Gutiérrez, 2013). Alternative ways of relating to and understanding assessment are needed and in this, listening to the students as opposed to only labelling them, are of core importance (Hodgen & Marks, 2009). Research that is paying attention to students’ stories also contributes to knowledge about the lived and social dimensions of assessment that needs to be paid attention to according to Black and Wiliam (2010).

In this article, I strive to recognize and study the production of (in)equity in connection to grading and national assessment in mathematics. I highlight aspects that might be foreseen in the general debate and work in the area of mathematics education. Through this, I contribute to the identification of possible resources that could promote paths for increased equity. In regard to the concept of equity,

I draw on Boaler's (2006) concept of relational equity. In a school where participants (do not) learn to respect differences and each other in the mathematics classroom, relational equity is (not) lived and taught. This understanding can be applied on both the micro-, meso- and macro-levels of education and opens up studying equity beyond the gap-gazing of diverse achievement levels in mathematics (e.g., Gutiérrez, 2008; Rodrigues, 2001) something that actually might counteract equity and hold disadvantaged groups of students behind (Gutiérrez & Dixon-Román, 2011). Following from this point of departure, resources for producing equity are to be found in lived, diverse, relational and social aspects in the process of assessment and displaying knowledge. I contribute to the identification of some of these resources through the study of social and relational aspects connected to assessment and the opportunity to display knowledge in mathematics for SLL. In this paper, I specifically contribute to the act of listening to and exploring experiences of students within subordinated groups by highlighting experiences of SLL in connection to displaying knowledge in mathematics. The purpose of this paper is to contribute to knowledge about social dimensions of displaying knowledge for SLL in mathematics and how this can be related to future prospects connected to the subject. The investigation examines three research questions: Q1) How do statements about the other and caring appear in talk of displaying of knowledge? Q2) How do statements about the other and caring appear in talk of future prospects connected to the subject? Q3) What discourses are activated and what positions are available in the students' talk? Here, caring refers to both care for oneself and for/from others.

## **Theoretical framework**

A statement works as a mediator of knowledge and truth that exists in a field of power-relations and is embedded in discursive formations with other statements (McIlvenny, Klausen & Lindegaard, 2016). Discourses are understood as governing and positioning individuals through power and knowledge (Foucault, 1994), and positioning is understood as "the discursive process whereby selves are located in conversations as observably and subjectively coherent participants in jointly produced story lines" (Davies & Harré, 2001, p. 264). Therefore, analysing students' statements will reveal discourses that are activated in connection to the display of knowledge and assessment in mathematics. In order to capture social aspects of displaying knowledge in mathematics, the role of *others* and *caring for/by others* are used in this project (Black, Solomon, & Radovic, 2015). Black et al. (2015) have shown that these phenomena may be powerful cultural resources in shaping a positive identity in mathematics. Black et al. (2015) have drawn on Bakhtin. Instead, I use the concepts as signal-words, which reveal the representation of a social and lived aspect of displaying knowledge in mathematics.

## **Method and selection**

This paper presents the analysis of two interviews with SLLs. Their names are fictional. Amina and Ahmed are 15 years old and have both struggled with their learning in mathematics since third grade. They did not pass several of the goals in mathematics in their third and sixth years and have had special support during this time. Amina achieved the lowest passing grade (E) in her ninth grade and was given support in the form of special instruction. In the ninth grade, Ahmed did not receive any special support or adaptations in mathematics and got a D, which is the average grade. The data were collected right before the final choice of program to the upper secondary school was made and the final grade in compulsory school was given. Amina and Ahmed had just finished their last national

tests in mathematics. Interviews conducted on this occasion were assumed to contribute to a concentration of their experiences of displaying knowledge and assessment. This selection of students is meant to bring specific questions concerning assessment in mathematics for SLLs into the forefront.

The interviews were semi-structured. This approach was used to promote the student's possibilities to talk freely and to display as much of their understanding and experience as possible (Kvale & Brinkman, 2014). The students could talk about anything they chose in the areas of support, assessment, national tests, grades, mathematics and the future. For the most part, I asked open-ended questions to follow each theme. Questions were, for example: why do you take these tests; what did you think/feel; did you talk about it to anyone and how; was it possible to get help; if so, how? These open-ended questions were followed up with more specific questions connected to what the participant had expressed, in order to get as good an understanding of and rich information about their experiences as possible. The positions and activated discourses were constructed through analysing statements about caring and the other in the context of displaying knowledge in mathematics. Key markers in students' talk were statements involving others as for example peers, friends, family and school-staff and statements regarding caring about or being cared for by others. These statements also had to relate to assessment and/or displaying knowledge in mathematics. An interpretative reading of statements was done back and forth in order to identify the discourses and positions involved. For this purpose, an adaption of Foucault's (2011) description on how to find discursive formations was used: 1) First, statements regarding caring and others were identified. 2) Secondly, the form of these statements was described. 3) Thereafter, the relations between these statements were described and the correlations and contradictions between these statements were explored. 4) Then, the statements were grouped and the correlations and contradictions between these groups were explored. 5) In the final step of the analysis, the discourses were construed.

### **Ahmed and Amina: Interview data**

The interview data connected to the first two research questions are presented here. This presentation derives from the first four steps of the analysis. Overall, these statements concerned family or peers, and notably teachers were not mentioned at all in connection to statements concerning caring and the other.

### **Statements about the other and caring in talk of displaying of knowledge**

The students talked about care of and from others primarily in relation to peers and as peers as a point of reference for the achievement or possibilities to succeed. Ahmed mentions that the girls talked about when the tests were, and, in a way, that could make each other nervous: "The girls are like: it is mathematics (national test) tomorrow, tomorrow! They mentioned it several times" (transcript 005). But he was not nervous himself but rather preferred to take it all in time and put the test into a larger context of living: "If I make it, I make it... There is no point in worrying, life will continue anyway" (transcript 005). Even if he was at ease, he expressed concern about a friend who did not manage Swedish well enough in relation to the support given and the construction of the tests. The friend was very good in mathematics in his homeland but after coming to Sweden he almost did not pass: "He is not so good at Swedish so he thought it was a Swedish word he asked for help with. The teacher could not do anything but read it aloud again. In his homeland, he had like a high grade and here he barely passed" (transcript 005). Ahmed talks about care of himself in relation to effort and

outcome on the tests: he is at peace himself with not being able to solve all the tasks, since they are constructed for all levels of difficulty. This circumstance also makes it hard for him to know if he passed the test, “I might think it is hard but I am on an E, the ones being on an A may not think it is so difficult. So, I would say it was ok, even if it was hard for me” (transcript 005). In this way, Ahmed refers to peers as a point of reference. Ahmed says that he made a deliberate choice not to study before the test: “I have myself to blame if it went bad, I accept my choices” (transcript 005). Amina talks about care of herself in relation to her knowledge in the subject, her effort and grades. She thinks mathematics is hard but does not think the grades reflect her experience of the subject as interesting and of herself as someone who is interested, learns and works hard: “I think math is easy, or easy, it is hard but I think it’s fun. What comes out shows in the grade... I put a lot of effort in math but I do not get good results. It does not show in the grade. It makes me feel disappointed, but at the same time it challenges me” (transcript 002).

### **Statements about the other and caring in talk of future prospects**

The students’ statements regarding the future prospects are often connected to the family’s care about them. Both students expressed that parents and relatives had high expectations and beliefs in them and their engagement in mathematics. Amina connects the big expectations she has for herself to her parents’ expectations: “I think my expectations come from mum and dad, they expect big things from me” (transcript, 002). The family stressed that they should do what they could to enter upper secondary school. For example, if Ahmed did not get the lowest approved grade, the family would encourage him and not let him give up: “They would be grumpy with me and they would think that I should go back and keep on fighting and not stop” (transcript 005). In particular, Ahmed’s brothers had given him advice on how he should choose a program at the gymnasium in relation to mathematics and also had given him a good trust in upper secondary school, the mathematics involved in the program he chose and the teachers: “I have lots of expectations since I have a family from whom I have taken like a lot of advice. All have said very good things about the school and the one (brother) who studied construction has said a lot of good things about a teacher working there” (transcript 005). He also compared and talked about his siblings and how they succeeded and what they had done in their time at the upper secondary school: “You know, my brother, he says that there are three days of practice a week and that you get to learn a lot out in the field. Three weeks before finishing school he was offered an employment... He is 19 and he has a job” (transcript 005). Motivation was in this way connected to talk about parents’ and relatives’ anticipation of and belief in them and their engagement in mathematics. Although Ahmed could feel that they nagged at him, he understood and appreciated the advice to put effort into the learning in mathematics: “I understand their arguments and so and I really appreciate that they help me there and I understand the point. It seems to be important to get a grade in math” (transcript 005).

### **Statements about the other and caring in talk of future prospects**

Care about themselves in connection to the future were expressed in relation to belief, struggle, worries and seriousness. Ahmed worried about the test a great deal afterwards, if some of the harder tasks would deprive him of his grade, his time in the upper secondary school and stop his journey in life and companionship with friends: “This is life, this is it. I would be very disappointed if I did not pass. Then I will miss a whole year... I do not want to wait a whole life for life to continue” (transcript 005). The students meant that future choices may be limited depending on their knowledge, which

made them both choose a program at the upper secondary school with a low level of mathematics. Statements about expressing care for others concerned peers and primarily gatekeeping functions in the assessment in mathematics, but also their own learning in positive anticipation regarding their ability to develop. Amina talks about her peers as participants in discussions about the grades, something that has been intensified over time as it is connected to mathematics as the gatekeeper to the upper secondary school: “We did not talk as much about it (earlier) but more later. That it is the grades that decide if we get into upper secondary school” (transcript 002). Here, Ahmed points towards the gatekeeping function in the national assessment of mathematics, which is worrying: “If you fail in math, then you are done... That is why I have been lying awake at night and thought about the test” (transcript 005). Both students anticipate that math will be hard in the upper secondary school but they are confident that they will learn. Amina says she is eager and ready to take on the challenge: “I am going to study at the upper secondary school and I have to be prepared that mathematics is the hard thing. I am very excited” (transcript 002). Both Amina and Ahmed are very confident that they can learn the mathematics they need when they finally begin the upper secondary school. Ahmed for example states “but I think that when I finally go to the construction program I will learn it, how to count with area and stuff” (transcript 005).

## Analysis

The analysis answers the third research question and explores the discourses that are activated and the positions available. A *discourse on managing assessment* (connected to statements about peers), a *discourse on progress* (connected to statements about family), a *discourse on future challenges in mathematics* (connected to care about oneself) and a *discourse on fairness* (connected to care about oneself), were construed from the analyses of statements connected with *caring* and *the other* in connection to displaying knowledge and mathematics. The activated discourses led to some available positions for the students.

*The discourse on managing assessment* concerns support, comparison and monitoring of support, grades and tests. Ahmed talked more about his peers and talked overall more than Amina. Amina referred to peers as a help in focusing on the grades and Ahmed expressed care for others. He then positioned both himself and his peers as *disadvantaged test-takers* due to language and the settings and construction of the national test. He also positioned girls as more nervous in their monitoring of test occasions.

*The discourse on progress* circles about responsibility, advice and expectations stemming from the families. Expectations were then blended with demands on focus and progress. *Hard working* and *you can if you want to* were positions connected to the family discourse. These positions had connotations of personal responsibility, achievement and future prospects.

*The discourse on future challenges in mathematics* held statements in which caring about oneself was connected to a position in which limitations in knowledge blended with striving to learn and the outcome that learning was to be conquered.

*The discourse on fairness* connects the student’s individual responsibility, effort and knowledge to the achievement and assessment in mathematics. If the effort is made, the knowledge should be retrieved and following from that, the grades should be accordingly high or low. In *the discourse on future challenges in mathematics* both students positioned themselves as capable of trying and

working on improving, although within certain limits. A position of *struggling while learning* was identified, this position is possible to connect to the *hard-working* and *you-can-if-you-want-to* positions in various combinations. In *the discourse on fairness*, a position of *choosing your achievement* was shown in Ahmed's talk as he chose not to study and accepted the consequences. Amina also spoke out from a discourse of fairness as she questions the grade, and that the hard work should have been seen in the grade. At the same time, she capitulates and says that it is hard for her to learn and remember for example the methods to use – so the grade may be fair after all. This could be described as a position of *being unable* to succeed.

## Discussion

The semi-structured interviews contributed to a trustful and open climate for conversation. This made it possible for the two students to display important social dimensions of displaying knowledge and learning mathematics. One example of this was when Ahmed talked about how his brothers and family supported him: “I took their advice... It seems to be important to get a grade in math” (transcript 005). This happened on an occasion when he was actually skipping school for a day and hanging out with his brothers. This occasion proved to be an important moment in his positioning as a mathematics learner. The main concepts in the analysis were statements about *the other* and *caring* (also see Black et al., 2015). In many ways, it is possible to assume that there are many differences between Roz, the adult mathematician in Black et. al.'s (2015 study and the two students in this study when it comes to opportunities to learn and display knowledge. What they have in common is that the female mathematician and immigrant students are groups both governed by different types of gatekeeping functions in their access to the subject. Interestingly, the same socio-cultural resources as found in Black et. al.'s (2015 study, seem to work well in illuminating prerequisites for a positive development of identity in mathematics among students that have struggled with their learning. The statements about assessment in mathematics and the future were in many ways a narrative drawing on the community of the family and the peers. This could be a sign that relations outside school, in families or between peers, are important resources in the building of a positive identity in and a relation to the subject mathematics.

Both students in this study were willing to learn and develop their skills in mathematics, although they knew that they were in some way limited because of their lack of knowledge at some times. Although struggling with mathematics, they still had a positive way of approaching the subject, which is not always the case for students in need of support in mathematics after nine years in school. The families' expectations and talk with their children about the future and the role of mathematics in it may have contributed to a discourse about struggling when learning. This discourse could contribute to a positive identity in mathematics rather than devaluing the struggling student as a learner in mathematics. This research contributes to knowledge about the social dimensions of testing for SLL. Social and lived dimensions of assessment may get lost in translation if the measures on achievement are interpreted without taking the social, cultural, political and relational contexts into account. Conclusions from assessment that mainly focuses scores and levels of achievement might reveal differences and tendencies of segregation or lack of knowledge but without affording means to counteract these inequalities. Therefore, more research in the socio-political area of mathematics education is needed. This paper joins the socio-political research in mathematics education as I contribute to knowledge about social dimensions of displaying knowledge in mathematics for

disadvantaged groups of students. The aim was to identify valuable resources in providing access to and success in mathematics for all students. I also emphasise an alternative way of understanding assessment beyond measures of knowledge and quality, namely as a means of promoting social and relational aspects of becoming more mathematically able. Since, as the students' statements revealed, it is (not) only a test of knowledge but also an occasion of caring about oneself, caring for others, and being cared about by others.

# Subjective theories of teachers in dealing with heterogeneity

Elisa Bitterlich, Judith Jung and Marcus Schütte

Technical University Dresden, Germany; [elisa.bitterlich@tu-dresden.de](mailto:elisa.bitterlich@tu-dresden.de)

*This article presents initial results of a research project which investigates subjective theories and typical action strategies of teachers and student teachers in dealing with heterogeneity in school with a focus on the subject mathematics. These results are ultimately intended to contribute to the development of future teaching approaches. To reconstruct subjective theories of teachers and student teachers, group discussions were carried out. The initial results show the aspects of heterogeneity the participants deem important and the possible actions they discern for coping with pupil diversity.*

*Keywords: Diversity, heterogeneous grouping, teacher beliefs, group discussion.*

## Fundamental theoretical considerations

The fact that children and young people often differ in terms of their needs and preconditions for learning, and that this heterogeneity of learners sometimes presents teachers with significant challenges, are not new phenomena (Trautmann & Wischer, 2011). The heterogeneity of learners relates to different dimensions, such as cognitive performance, age, gender, linguistic-cultural background, social class and many more (Hinz, 1993). In accordance with current political discourses and social developments, these different dimensions are given unequal attention in pedagogical discussions. The impetus for a renewed focus on heterogeneity in Germany was provided by the results of international comparison studies (in particular PISA, 2000), which highlighted especially the sizeable differentiation in pupil achievement, the alarmingly high number of very-low-achieving pupils, and a close relationship between social background and academic success (Trautmann & Wischer, 2011). The UN-Convention on the Rights of Persons with Disabilities, which came into force in Germany in 2009, made the inclusive schooling of children with and without disabilities the subject of renewed debate. In addition, the phenomenon of increased linguistic-cultural differences among learners has come into focus in the last two years by the increased number of refugees entering Germany. For most student and practising teachers the heterogeneity of learners represents an important problem area in planning and teaching lessons which seems to be complex and fundamental. Askew (2015) expounds that the teacher's ways of thinking and talking about heterogeneity impact how they react to the differences that learners bring to the mathematics classroom. The following questions arise: "Why have so many, essentially well-founded pedagogical ideas not been realised? What prevents teachers from seeing heterogeneity as enriching, and dealing with it productively?" (Trautmann & Wischer, p. 9, translated by the authors). In order to answer these questions and create concepts for future seminars, not only a scientific reflection of this topic is supposed to be considered. Especially the perspective of those facing heterogeneity daily in their pedagogical work is to be included by analysing their subjective theories about heterogeneity, too.

In the framework of the Germany-wide "Qualitätsoffensive" for the improvement of teacher

training, the project “Synergistic teacher education in an excellent framework”<sup>1</sup> at the TU Dresden includes the sub-study “Heterogenität in der Lehrerbildung von Anfang an” (Heterogeneity in teacher training from the start). Based on qualitative questionnaires, group discussions, and participatory observations of everyday teaching in schools, subjective theories<sup>2</sup> and predominating patterns of action among teachers and student teachers will be surveyed in different kinds of school. On the basis of the survey results, the project intends to develop concepts for teaching events to make student teachers sensitive to the different facets of heterogeneity.

The concept of ‘Heterogenität’ (heterogeneity) is defined in various ways in the relevant German-language scientific literature, and indeed is often used without specific definition. A number of terms are used synonymously, ranging from ‘Vielfalt’ (plurality) to ‘Unterschiedlichkeit’ (difference), ‘Unbestimmbarkeit’ (indeterminableness) and ‘Beliebigkeit’ (arbitrariness), or English words like ‘diversity’<sup>3</sup>. In many scientific articles, the focus is placed on only one aspect of heterogeneity (such as language, culture, gender, or disability), and the relevant definitions insinuate a polarisation between ‘normal people’ and ‘the others’. However, authors like Prenzel (2006) and Krüger-Potratz (2011) articulate a different understanding of the concept of heterogeneity. We share this understanding of the concept of heterogeneity, which finds placing the focus on a few ‘dominant’ characteristics to be a reductive approach (Krüger-Potratz, 2011).

Diversity education is based on the ‘indeterminability of people’; it is therefore unable to diagnose ‘what somebody is’ or ‘what shall become of somebody’. It [diversity education] opposes all reification in forms of definitions of what a girl is, or a boy, a behavioural deviant, a Turkish woman... If people must be characterised, then this must be based on their dynamic development and the context of their environment. (Prenzel, 2006, p. 191, translated by the authors)

To analyse teachers’ subjective theories, and to develop concepts for teaching events that are based on the teachers’ views, against our understanding of the concept it nevertheless appears sensible to establish a theoretical categorisation of some of the individual facets of heterogeneity. Some of the existing studies on ‘beliefs’, as well as on teachers’ implicit or subjective theories about heterogeneous contexts in school, show a focus on selected individual aspects of heterogeneity in this way. On the aspect ‘heterogeneity’, in an interview study on belief systems of primary-school

---

<sup>1</sup> This project is part of the “Qualitätsoffensive Lehrerbildung”, a joint initiative of the Federal Government and the Länder which aims to improve the quality of teacher training. The programme is funded by the Federal Ministry of Education and Research.

<sup>2</sup> In the literature, concepts such as subjective theories, implicit theories, or naive theories, as well as teachers’ ideas and attitudes, or “beliefs”, are sometimes used synonymously in accentuating different aspects, and cannot be clearly differentiated (Törner, 2002). In this paper, we will discuss teachers’ subjective theories based on Heymann’s (1982, p. 146, translated by the authors) understanding of “the totality of knowledge elements and orientations affecting teachers’ actions in the conducting of lessons”.

<sup>3</sup> While in the English speaking area, the Term „diversity“ is preferred and well-known, in Germany many publications tend to use only “heterogeneity”. But in some more actual publications we can see that “diversity” is more and more a common term for describing the plurality of pupils.

teachers working with children with special educational needs concerning cognitive development, Korff (2014) identifies a central challenge for didactic activity in mathematics teaching in the establishing of links between different approaches and varying levels of representation. On the aspects of gender and ethnicity, the ProLEG study<sup>4</sup> addresses the question of how ethnic-cultural and gender-related perceptions influence teachers' educational activity (Winheller, Müller, Hüpping, Rendtorff & Büker, 2012). The results show that the respondents overwhelmingly see questions of children's gender as unimportant and considered themselves to be sufficiently competent in this area. In relation to ideas about ethnicity, the respondents attached equally low importance to 'Intercultural Education'.

Topics such as 'Individual Support', 'Social Learning', and 'Inclusivity' are given primary importance, while culturally sensitive approaches have the lowest priority, followed by 'gender-aware education'. (Winheller et al., 2012, p. 10, translated by the authors)

However, Zobrist's (2012) investigation attempts to approach heterogeneity from a broad perspective, without restriction to particular aspects of the concept. Using semi-structured interviews and 'simulated recall' in addition to teaching observation, the author attempts to produce a comprehensive view of the ways teachers deal with heterogeneity in mathematics teaching in secondary school. The results show that teachers tend to define heterogeneity especially in terms of different preconditions for learning and different kinds of social behaviour. Furthermore, special educational needs assessment is seen as highly relevant in dealing with diversity, but personal competences in this area are considered inadequate. Schönknecht and de Boer (2008) point out that in describing heterogeneity student teachers often seem influenced by an idea of polarisations and dichotomisations, as well as a limited perspective focusing on supposed 'problem children'. Also in relation to perspectives on the dimensions of heterogeneity, little differentiation is evident, with the use of a number of generalising (stereo)types (e.g. 'normal' and migrant children). They summarise:

Thus, addressing the construction of normality contributes to dealing with heterogeneity and difference, and can be a significant building block towards realising equality of opportunity in school. (Schönknecht & de Boer, 2008, p. 258, translated by the authors)

Regarding to Garmon (2004), both dispositional factors (like openness to diversity as well as receptiveness to others' arguments and ideas, self-awareness and self-reflectiveness, and commitment to social justice) and experiential factors (like intercultural experiences, support group experiences with individuals who encourage another person's growth and educational experiences) influence teachers' attitudes towards diversity.

## Method

In order to gain a first impression of student teachers' ideas about the concept of 'heterogeneity' in the school context and to discover how they encounter diversity among children, a qualitative questionnaire with three questions requiring written answers was distributed to around 80 student

---

<sup>4</sup> "Professionalisierung von Lehrkräften für einen reflektierten Umgang mit Ethnizität und Geschlecht in der Grundschule" (Professionalisation of Teachers for a Considered Relationship with Ethnicity and Gender in Primary School)

teachers training to teach mathematics. The students answered the following questions in their own words in running text or bullet points: What does the word ‘heterogeneity’ make you think about in the school context? To what extent have you addressed this topic (in your studies)? To what extent do you feel prepared to deal with heterogeneity in the school context?

In addition, we held group discussions with student teachers<sup>5</sup> on the topic of ‘heterogeneity’. The group discussions were video recorded and transcribed and evaluated using the documentary method (Bohnsack, 2010). Group discussions can help to identify and analyse the implicit or tacit knowledge of the participants while they talk about a specific topic (e.g. heterogeneity). Between three and seven participants talked about a given topic for around 60 minutes. They have some special experiences in common or commonalities in their history of socialisation, thus sharing a “conjunctive space of experience” (Mannheim, 1982). The momentum of the discussion process, uninterrupted by the researcher, is important to discover these conjunctive spaces of experience, which become visible through “focusing metaphors” in which the group adjusts itself to those specific topics that are most relevant in their common experience (Bohnsack, 2010).

Concerning group discussions, the immanent meaning comprises that stock of knowledge which is made explicit by the participants themselves. This has to be distinguished from knowledge of experience, which is so much taken for granted by the participants that it must not and often cannot be made explicit by themselves. The participants understand each other because they hold common knowledge without any need to explicate it for each other. (Bohnsack, 2010, p.103)

## Results

For reasons of space, this article will highlight a few clear results of the qualitative questionnaires as well as extracts from the overall transcript of the group discussions with teacher students.

### Qualitative questionnaire

The students gave highly diverse answers to the question “What does the word ‘heterogeneity’ make you think about in the school context?” While one respondent (female, 23 years, fourth semester) answers only with a few key words (“diversity, differentiation, boys and girls, high-achieving, low-achieving”), other students give more complex answers, making clear their awareness of the unbounded, indefinable nature of the concept:

Every class is different (age, background, etc.). Every child therefore has different preconditions for learning, which one should include in the teaching. Differentiation is important (natural differentiation, internal differentiation, external differentiation). The application of learning environments to enable different approaches (with different difficulties/materials, etc.). (female, 21 years, sixth semester).

This student’s response also suggests how she would deal with diversity among children and where she thinks particular emphasis should be placed. On the question of how well prepared the students

---

<sup>5</sup> Student teachers in this way includes teachers who have finished their university degree and are now in training for one or two years before receiving their final teaching license and students who want to become a teacher and who still have lessons in university.

feel to deal with heterogeneity in the school context, the majority of responses are sobering. Most of the students complain about a lack of practical experience, stating that although the university education in many respects provides a lot of theory, there are few opportunities to reflect upon the ideas and to try them out in practice. Furthermore, it is criticised that not enough attention is paid to the topic of heterogeneity (overall) in the study course; it is often covered quickly as a “marginal topic”, but not “dealt with in depth” (female, 22 years, fourth semester). On the basis of their experiences in the course of their studies, several of the students differentiate between the different teaching subjects; for example, one female student (21 years, sixth semester) remarks: “I feel better prepared in maths than in German. For example, by the ‘(Maths) Learning Under Conditions of Heterogeneity’ course”.

### **Extracts from the group discussions**

The participants in the group discussions presented below were student teachers in training for primary-school and high school with the subject mathematics. The students are in the middle to last phase of their studies or have finished their university degree and are in training before receiving the final teaching license, meaning that all have already completed placements in schools. During the 60-minute discussion on the topic “What experience do you already have of diversity respectively heterogeneity among children in school and in teaching?” it becomes clear that those facets of heterogeneity that are dominant in the social discourse, such as native language, disability, social status, achievement and migration background also dominate the students’ discussions.

After a group of five female teacher students for primary school have talked about topics such as German as a foreign language and the meaning of academic language, one of the participants turns to the topic of inclusivity and the schooling of children with special educational needs in regular teaching. The following extract is a part of the discussion that develops on this point. The following transcript extract (the original version is in German) shows how the students encounter diversity among children, the challenges and opportunities they see in such diversity, and what experiences they have already gained in dealing with it.

- Tina: I also think it’s very important how children gain another view of what is actually normal. A person sitting in a wheel chair is just as normal and can also move around. And that simply this acceptance and tolerance can develop amongst each other. That you simply know how to deal with the person and that it becomes natural from an early age on.
- Bianca: I think this is also easier for children. I also always like that about children that they very openly go to other children who are a little bit different. I also think that this should be encouraged but it is also a fact that there are also mentally disabled children. I don’t know if they are also affected by inclusion?
- Sarah: Yes.
- Bianca: Well, I think that is difficult. Well, I was at a school for children with special needs and sat in on classes and I thought it was really bad.
- Sarah: Well, otherwise, in front of the same class plus children with special needs that is not possible, I think. Then also structurally things would have to be changed.

Diana: Well, for all of us it is a challenge to stand in front of a class after finishing our studies. Even if they are top-performing and are all a relatively homogenous group.

Tina: But you will never have this homogeneous group (smiles and shakes her head).

Diana: (nods) Yes. You also don't have that in society. The whole society is extremely heterogeneous.

Extracts from a discussion between four female student teachers for high school shows a similar view on heterogeneity, however with a greater focus to specific problems of the subject mathematics.

Wiebke: The heterogeneity of the teachers also effects the lessons and what the children learn in the end. Therefore, also the teacher's competence of explaining.

Nathalie: (Laughs) Yes, especially in mathematics.

Tamara: And I also think what attitudes the teacher has towards heterogeneity. Meaning, is my attitude that I take everyone along or do I only take the top 50 percent along? Or drastically said, what is my opinion about somebody from a migrant background? That also plays a huge role.

Vera: Yes, that's true.

Wiebke: I mean, at the university this is addressed but how I should really deal with it ... It is nice to say that you need difficult tasks for those who are good and easy ones for those who are not so good at it. Yes, but in the end, all of them take the same test and are marked according to the same grading system.

A third extract is from a group discussion of four female primary-school student teachers which have already been in training at school for a few months. This brief passage of the discussion shows that student teachers who are already teaching in school seem to be more aware that there are differences between the theory they have learned in university courses and the dealing with heterogeneity in real life. Additionally, they critique some aspects of the education in university.

Linda: The only option is individualized teaching, if you want to give every single child the chance to take part in the lesson and to have fun.

Beate: And you have to accomplish this without straining oneself.

Isabel: Exactly! And I would like to know, how that can work (laughs). How can I differentiate without constantly feeling stressed at home?

Linda: Well, when I was at university, I often thought, „Bla, bla, heterogeneity, differentiating. How can this work?“ They [the university teacher educators] always treated this like a big cloud but they never told us specifically. And then, in school, you think, “Well, how does this work?” And only through experienced teachers you understand “Oh, this is how you can approach this!” And it doesn't always have to be three different worksheets. A more open form can work as well.

But I think that in university it was something which existed somewhere up high in the universe but which cannot be implemented.

Denise: In my point of view, such opened instruction was seen [in university] as a kind of sanctuary and I always thought, „No. I can't do it. I somehow am not able to do it at all!“ Because it is a Utopia to do this. But in the end, it is somehow possible and [at university] one should have used that as a starting point. Even though we heard keywords like “weekly schedule work”, we never spoke about this in depth. It was more like scratching the surface.

Isabel: Then we received lots of academic texts about this which we were supposed to read. Afterwards I knew as much as beforehand because the time to really understand the content was too short. This was easier with conversations. But I did not have a concrete plan either.

Beate: But now, in the courses for trainee teachers, we recognized that we all open our lessons. We do not carry out frontal teaching as we always imagined. That's why it is helpful to have somebody with experience, who has stood in front of children for many years and who was able to teach this to us in a normal way.

It becomes clear during the group discussions that the students are aware of the problem of how to judge children fairly despite potentially enormous diversity. They principally discuss the questions of how fairness can and should look in the school context, how it can be realised, and which obstacles and problems can exist in its realisation. They argue that differences play a secondary role for children and that “it is easier for children” to accept and tolerate each other because they are “a lot more open in that”. The participating students seem to agree that it is important to develop a broader perspective of what is ‘normal’ as early as possible. At the same time, they consider it to be difficult to hold collective lessons for ‘normal’ children and children with the need for special education, especially when there is only one teacher in class. Furthermore, they are aware that there is a dilemma between the need to differentiate in school and the society being extremely heterogeneous. While in a school context, every child is supposed to receive the best possible support suitable for its own needs, in society, diversity is nearly never considered or discussed.

## Perspective

The results collected so far already provide initial insights into student teachers' subjective theories and guiding ideas on heterogeneity in the school context. Further group discussions will be carried out in the near future, and questionnaires distributed. The framework will be expanded to include practising mathematics teachers in different kinds of school in Saxony. Thus, data on teachers' and student teachers' subjective theories on diversity in pupil populations will be available for comparison. Consequently, individual teachers who participated in the group discussion will be selected to receive classroom visits. Through participatory observation we hope to be able to undertake a comparison between the collective opinion emerging in the group discussion and the models of activity that are actually applied by teachers for dealing with diversity. All these data will ultimately serve the development of concepts for events for student teachers with the aim of making them more sensitive to heterogeneity and more prepared to deal with it.

# Teaching practices in a mathematics classroom and their connection to race and racism in the United States

Sabrina Bobsin Salazar

University of Michigan, United States of America; [ssabrina@umich.edu](mailto:ssabrina@umich.edu)

*In this paper I introduce critical realism to investigate the relationship between a mathematics classroom and the broader social context in which it is inserted. To ground the new approach, I focus on race and racism, and use critical race theory to guide the use of critical realism in this investigation. This is a report in an ongoing study about the work of teaching and social change with respect to race and racism in the United States. Data comes from a laboratory mathematics classroom held every summer by a large research university in the United States. Although more analysis is still necessary, initial results reveal how broader social context can influence and be influenced by broader structures of race and racism. Moreover, the framework shows potential to illuminate the relationship between classroom interactions and social systems of inequality.*

*Keywords: Racism, teaching practices, critical race theory, critical realism.*

## The problem

This study starts from a perspective that education and schooling play a role in our society that can serve both to sustain and reproduce dominant social structures or to challenge them and promote change (Freire, 2015). It is generally accepted that our social world is unequal and unjust, and under such a view, education is frequently seen as a source of and/or a solution to social inequalities. It is therefore important to educational research, mathematics education research in particular, to better understand the relationships between educational and schooling practices and the broader social context they are situated in.

In this study, I want to zoom in on classroom practices and investigate how mathematics classroom practices can reproduce or challenge macro social systems of inequalities, which I understand as social structures that privilege certain social groups over others. Racism in the United States is for example generally characterized by a set of social privileges rather than by individual acts of hate or prejudice (Bonilla-Silva, 2006). Even though individuals being overtly racist still exist, I am referring to a different problem, in which Whites enjoy better social opportunities only because they are White, such as African Americans being incarcerated in disproportionately higher rates than Whites (Barish, DuVernay, & Averick, 2016), and Latinxs having disproportionately fewer opportunities to obtain higher educational levels in comparison to Whites (Yosso, 2006).

The main purpose of this paper is to report the application of critical realism in an ongoing study to offer new possibilities to understand the relationship between classroom interactions and the broader social context they are inserted in. I am particularly investigating race and racism in this first exploratory study, because it brings interesting dynamics between local social situations and broader social institutions. Such dynamics come from the fact that racism is deeply ingrained in American society (Ladson-Billings, 1999). I hope that a critical realist lens can help to illuminate how racism occurs within classroom interactions, specifically I want to investigate how racism can be challenged or disrupted in mathematics classrooms through teaching practices. In this study, I am particularly trying to answer the research question: How can the critical realist concept of norm circles help us

better understand how teaching practices in a mathematics classroom (can) challenge and/or disrupt structural racism? In this paper, I will present the framework, describing a few core concepts of critical realism and critical theory and discussing how these two theories can be combined to better explain the connection between classroom teaching practices and structural racism, and then I will illustrate the use of the framework with initial findings.

## **Conceptual framework**

Mathematics education research has focused its interest on the social and political dimensions of mathematics and education for quite a while now. To better understand such dimensions, some researchers are now foregrounding power relationships in research and using a variety of critical perspectives and methods in what has been called a sociopolitical turn (Gutiérrez, 2013). In her argument, Gutiérrez (2013) describe some of the theories used by critical scholars to address power relationships in society. Critical realism is not directly indicated in her article, but it is a possible sociopolitical theory. Critical realism is a philosophy of science originated out of the need for better theories to understand the social world; in particular, critical realism explores power relationships in the social world. Specifically the focus of this study, critical realism proposes a new approach that can illuminate the relationship between social structures and micro social interactions by elaborating an analytical mechanism that focuses on the interaction between individual agency and social structure (Elder-Vass, 2010). Such a mechanism has its foundation in the critical realist concept of emergence and is operationalized in terms of norm circles. These theoretical constructs however, are not tied to any specific method to conduct research though under a Critical Realist approach. What I expect in this study is that Critical Race Theory can provide theory and methods to investigate the relationship between mathematics instructional practices and racism, and that Critical Realism can complement CRT supporting the explanation of mechanisms of (re)production and disruption of racism.

## **Critical realism**

The basic premise of critical realism is that the world is made by real things that have real causal powers (Bhaskar, 2008). Phenomena are interpreted as outcomes of causal powers of such real things. At a first glance these ideas look very similar to positivist ideas, but they are not. In positivism phenomena can be completely determined by scientific laws, whereas in critical realism, phenomena are only influenced by scientific laws. The main idea is that these laws impose constraints and prevent possibilities otherwise available, describing a tendency rather than a certain outcome. The example cited by Bhaskar (2008) is that the path of his pen does not violate any law of physics, nevertheless it is also not determined by such laws (p. 95). There is a limitation of what a pen can do that is described by the laws of physics, yet such laws do not determine what is being traced by the pen. What is important in these basic ideas is that the world, which includes the social world, is made by real things; and that scientific laws, even social laws, describe tendencies rather than determination.

One concept that is central for critical realism and that will be very relevant for this study is the concept of emergence. Here, I am particularly adopting the compositional version of emergence as described by Elder-Vass (2010). In this version, the real things in the world can be combined in a way that, because of their structure and not only its individual properties put together, a new thing emerges in the world. Elder-Vass (2010) also refers to this new thing as an ‘entity’ or whole, and it

possesses “properties or capabilities that are not possessed by its parts” (p. 4). The idea is that the whole is not just the sum of its parts, but it is something else, with a new causal power that is, of course, derived from the individual properties of its parts, but not only this, the way the parts interact and relate with each other is also responsible for the emergence of the new thing.

The concept of emergence is what forms the layered or laminated view of the world under the critical realist perspective. A particular whole is said to be in a higher level or layer than its parts. The same whole, however, can be a part of another emergent structure; in this case the whole is in a lower level than the new emergent structure. In our social world, an individual can be interpreted as the lowest level, and the whole society as the highest level, with many intermediate levels in between, such as social institutions. The immediate higher level to an individual is, in Elder-Vass’ (2010) definition, a norm circle. The norm circle is defined by the group of individuals who hold a normative belief of endorsing a social practice. By endorsing, he means that each individual in the norm circle acts to reinforce the norm and discourage behavior that does not conform to the norm. Elder-Vass (2010) argues that the shared endorsement of a norm

when combined with these sorts of parts, provide a generative mechanism that gives the norm circle an emergent property or causal power: the tendency to increase conformity by its members to the norm. The property is the institution and the causal power is the capability that the group has to affect the behaviour of individuals. That causal power is implemented through the members of the group, although it is a power of the group, and when its members act in support of the norm, it is the group (as well as the member concerned) that acts. (p. 124)

With this argument, Elder-Vass (2010) is explaining why the norm circle is actually an emergent structure rather than only a group of people. He is explicitly pointing out what is the new causal power by showing the tendency it describes: to increase conformity to the norm.

Particularly relevant for this study is how agency is viewed in this critical realist account of the social world in which the social wholes with causal powers are norm circles. It is important to consider that causal power in critical realism describe tendencies, so the fact that a norm circle enforces compliance with a particular norm indicates that someone in this norm circle will have the tendency to act in conformity to such norm, but this is not determined. With respect to the focus of this study, race and racism, and the guiding provided by critical race theory, a central aspect of this investigation will be, in a context of racialized circumstances, the situation of an individual being in different and conflicting norm circles, i.e. individuals that are part of norm circles that enforce opposite norms, and how the study of this conflicting positions can reveal routes for social change.

### **Critical race theory**

Critical race theory is a theoretical framework for research that foregrounds race, racism, and racialized experiences. Critical race scholars ground their argument in the idea that racism is a social construction and is different than individual prejudice. Gloria Ladson-Billings (1999) reports that race is a complex social construct that goes beyond the color of skin, citizenship, and individual acts of prejudice, forming what can be called a system of racial inequality usually hidden under a colorblind discourse (Bonilla-Silva, 2006). To overt the practices of colorblind racism, critical race scholars anchor their work on five tenets: permanence of racism, Whiteness as property, interest convergence, critique of liberalism, and counter-storytelling (DeCuir & Dixon, 2004). I will briefly

describe three of these tenets because they will be more salient to the preliminary results to be presented later on this paper.

Whiteness as property refers to the idea that that Whiteness can be viewed as a set of social (privileged) possessions, that can operate similarly to property in a capitalist society. In the context of education, Whites have some sort of control of what is valuable knowledge and who gets access to it, which can be interpreted as a kind of intellectual property. Critique of liberalism is a direct critique to liberal economic-based ways of understanding and living in the world, grounded in free-market ideologies, under which people believe that best outcome for all is achieved when there is no external regulation of the market. Meritocratic and individualist discourses are frequently associated with liberalist discourses (Solomona, Portelli, Daniel, & Campbell, 2005). Counter-storytelling is the main methodological strategy used by critical race scholars to challenge inequality and White privilege. One important aspect of counter-storytelling is the double-consciousness or angled vision attributed to individuals living in the margins of society (Anzaldúa, 1999) that is going to be one of connections between critical race theory and critical realism.

Before I discuss the issue of marginality in society in light of critical realism and critical race theory, I will briefly elaborate in another connection between the two theories. Such connection will not be the focus of this study, yet it is necessary to understand why the two theories are compatible and suited to be thought together. Ladson-Billings (1999) says that racism describes a norm in current American society and “because it is so enmeshed in the fabric of our social order, it appears both normal and natural to people in this culture” (p. 12). This idea is the gist of *permanence of racism*. So, in a critical realist account of it, there must be a norm circle enforcing and endorsing racist practices. To present one example of a norm in this circle, I will need to unpack the idea of discourse within the critical realist framework.

Dave Elder-Vass (2012) elaborates on the concept of discourse as discussed by Michel Foucault (1969). He emphasizes the idea that Foucault is concerned with the content of what we express using language norms. Moreover, he refers to Foucault asserting that there are normative practices that dictate what we can say and what we should not say, and, in some way, they also dictate how we should act. Elder-Vass (2012) constructs a realist ontology explaining how discourse in this sense can have causal powers. He argues that discourse is shaped by the normative rules enforced by members of a discursive circle through the discourse such members produce. Discourse, therefore, is the means to what the causal power of a discursive circle exerts causal effect.

With this idea of discourse, I will point the emergence of a racist norm circle to the slavery system in the colonial period. As an example of a racist norm originated in the colonial United States, I point to the normative discourse that says “African American are less than Whites”. Specifically in educational contexts, such a discourse is reported in the autobiography of the former slave Frederick Douglass (1892) as a way to justify slavery. Once the norm circle reinforcing this discourse had emerged, it started to operate downwards, constraining the individuals in the circle to act accordingly. The way the discourse is reinforced has changed throughout time. For example, in the beginning of 20<sup>th</sup> century, IQ tests (Karier, 1986) helped to disseminate the idea that Blacks were less intelligent than Whites; and recent research reports such as Robert Berry (2008) reveals that African American boys are more likely to be placed in lower track courses in mathematics, in comparison to their White peers, as they advance their studies.

Critical race scholars ground their argument in this kind of normative racism in opposition to individual and overt prejudice. Theoretically, they understand this kind of racism as a social construction that brings real consequences to people of color (Chapman, 2013). This view gains a total new meaning under a critical realist perspective: Social constructions are real and have real causal powers.

Now, focusing on norm circles and searching for routes for social change, I will discuss the double-consciousness or angled-vision usually explored through counter-storytelling by critical race theory (Anzaldúa, 1999). This is usually a characteristic attributed to individuals that live in the margins of society. This place is viewed as a space of conflict of identity, a space of belonging and not belonging at the same time (Anzaldúa, 1999). In a critical realist perspective, I interpret the angle vision as a product of participating in conflicting norm circles. It is at this conflicting space that critical realism leaves room for human agency to act in a way that might not conform to a social norm. Elder-Vass (2012) discusses that when an individual participates in two or more conflicting norm circles, the outcome in terms of individual behavior can be very poorly predicted in the sense that the individual can decide for either norm, or can even create an innovative action to escape the ambiguous situation:

In contexts of complex normative intersectionality, skilled social performances depend upon the possession by the individual of a sophisticated practical consciousness of the diversity, applicability and extent of the normative circles in which they are embedded, and indeed of others to which they are exposed, even though they may not be parts of them. Whether or not they are able to articulate this consciousness discursively, members of such societies depend upon it whenever they act. (Elder-Vass, 2010, p. 133)

My idea in this study is to explore the norm circles with respect to race and racism that exist in a mathematics classroom environment. Particularly I want to investigate what are the norm circles the teacher participates in, what are norm circles created in the context of the classroom interaction, and how particular teaching moves are interpreted in light of agency within complex normative intersectionality.

## **Methods**

I am conducting my research as a secondary case study on a summer program held by a large research university in the United States, in which an experienced teacher publicly teaches lessons to a group of elementary students. This summer program serves different purposes: one is to be a site of learning for practicing teachers and teacher educators, because of the nature of the public teaching and the professional development sessions that follows it; another is to be a site of research for both student learning and teaching practices.

The student body of the laboratory is composed by a sampling of students from one school district in the Midwest United States. It is made to represent the demographic distribution of this district. Its composition counts with students of different ethnicities, but mostly are African American; all (or most) students come from low-income households; the students have different levels of English proficiency; and their mathematical proficiency is homogenously low.

Because the EML is a site of research for student learning and teaching practices, different types of data are collected by the research team organizing the EML. The data set includes video records of instruction, video records of pre-brief and de-brief meetings with learning teachers, copies of students

notebooks, pictures of classroom records such as charts, lesson plans, etc. Since I am analyzing data already collected, I did not engage in a relationship with the participants. I am observing and respecting their voices the best way I can by triangulating different sources of data. The data corpus is composed by video records of classroom interaction (approximately 2.5 hours per day across 10 days), detailed lesson plans for each class, copies of student work (notebooks, homework, and assessments), and photos of every collective record produced in classroom (such as charts and white board records). The high quality documentation of the laboratory classes allows detailed observation of classroom interaction that are usually not possible in regular school settings. Also, the composition of the student body, the qualification and experience of the teacher, and the laboratory setting provide a fruitful environment for the existence of multiple norm circles operating in this same space, which is important for this research.

I am following an analytic induction approach (Erickson, 1986) to code and interpret the data. The videos are being watched with a focus on interactions that involve students of color. Written records similar to fieldnotes are produced and used to identify episodes. Each episode is then re-watched; better-detailed descriptions are produced and interpreted according to the conceptual framework. In the next section I will illustrate how the episodes are interpreted in light of the conceptual framework. I will focus particularly on episodes that feature three Black girls.

### **Illustrating the framework**

The initial analysis was focused on the interactions involving three Black girls, and findings show they can engage in mathematics discussions, and are interested in learning mathematics. These findings firstly challenge the idea that girls, specifically Black girls, are not suited for mathematics. In one example, one Black girl is behaving in a way that could have been interpreted as if she was not listening to what the teacher was discussing about the conditions of a problem they were about to work on. She was not looking to the teacher at the board and she was not quiet in her seat, but she promptly raised her hand when the teacher asked for a “wrong answer”. She correctly shared a solution to the problem that violated one of the conditions, making it a wrong answer. This example reveals a Black girl accessing mathematical content, usually a White intellectual property (Moses, & Cobb, 2001). This girl, however, was only accessing such content because the teacher ignored her apparently disruptive behavior and believed in her raised hand. The calling of the student to share her answer was a choice of the teacher; she had other students with raised hands to call at that moment, still she decided to call on that Black girl. She was at that particular moment deciding her action based in different norm circles, one that told her the student was not paying attention to the lesson, and another that told her the student knew something and wanted to share with the class.

Initial findings also reveal that the teacher consistently engages in what Boaler (2008) calls assigning competence. This means that the teacher calls a student to publicly share an answer to a problem to raise their mathematical status among their peers. To do that, the teacher specifically points to an aspect of the proposed solution and indicates why that aspect is mathematically relevant. In one example, the teacher called on a Black girl to share how she had recorded an answer to a mathematics problem in her notebook. The teacher focused in how she wrote the answer using complete sentences, and that writing complete sentences foster writing clearly and is an important mathematical practice. This girl was not positioned as a competent mathematics learner or doer, other students in class frequently did not listen to what she was publicly sharing. In this example, the teacher had to intervene

so all students were actively listening while she was showing her notebook. The students were also asked to comment what was good in her answer. With this move, the teacher raised her status as a mathematics learner and doer among her peers. The teacher was actively pushing back some kind of liberalist practice in classroom. In a liberalist practice, the teacher might pursue a meritocratic ideal and let the classroom “regulate itself”, without intervening in the social relationships being (re)produced there. By raising the mathematical status of some students, in particular two Black girls, the teacher might be changing the power relationships being established among students, which can promote some sort of local socio-mathematical justice. By consistently engaging in assigning competence, this teacher is actively challenging liberalist norm circles.

### Concluding comments

The implementation of this new framework still brings methodological challenges. As it stands, the framework shows potential to illuminate the relationship between mathematics classroom practices and the broader context they are inserted in. The theoretical articulation of critical race theory and critical realism can help to refine both theories, providing methodological tools to apply critical realism in empirical research, and providing new analytical tools to understand how racism can be challenged. Particularly, the first example showed how the concept of norm circles was helpful to interpret a teacher action that counter racist discourses, and the second example show how a teaching practice can be used to counter liberalist practices that promote racism. I expect that such initial results can be elaborated with the further development of this study, providing more refined analysis. Finally, I expect that this study, when completed, can provide a more detailed description of classroom interactions in light of the social context they are inserted in.

# The context of workplaces as part of mathematics education in vocational studies: Institutional norms and (lack of) authenticity

Lisa Björklund Boistrup<sup>1</sup> and John Keogh<sup>2</sup>

<sup>1</sup>Stockholm University, Department of Mathematics and Science Education, Stockholm, Sweden;  
[lisa.bjorklund@mnd.su.se](mailto:lisa.bjorklund@mnd.su.se)

<sup>2</sup>Institute of Technology Tallaght, Dublin, Ireland; [john.keogh@ittdublin.ie](mailto:john.keogh@ittdublin.ie)

*This paper presents an analysis of institutional norms and the authenticity of out-of-school contexts that are reflected in a film about mathematics teaching in a comprehensive in-service vocational studies programme. The analysis was performed through the lenses of a theoretical framework of learning in different contexts and an empirically derived framework of mathematics as part of workplace complexity. The comprehensive in-service programme, which is available on internet, aims to improve mathematics teaching and learning, nationwide in Sweden. Through our analysis, we highlight a dissonance between the pedagogical approach displayed in the film, and how its authenticity may be compromised from the perspectives of our analytical frameworks.*

*Keywords: Workplace mathematics, vocational studies, institutional norms, authenticity.*

## Introduction

A key assumption in this paper is that school, as an institution, has much to learn from workplaces. We adopt the view where mathematical notions are not only applied *at* workplaces but also are developed *in* workplaces (Wedeg, 2013). One argument presented is that the context of any workplace stands in stark contrast to a formal mathematics classroom, where calling on authentic everyday experience may inhibit school mathematical sense-making (Gellert & Jablonka, 2009). Simultaneously, the performance of different jobs may be underpinned by the similar mathematics concepts as in the school context, but often interwoven in complex activities. The difference is not only in the type of work done, but in the sophistication of their contexts, such that unproblematic transfer of knowledge and skills may be highly unlikely. From an educational perspective it is rather about recontextualisation (Bernstein, 2000, see also FitzSimons & Boistrup, 2017). Through recontextualisation, a practice (for example mathematics) is transformed, rather than transferred, to an education context. In support of professional development for mathematics teachers in vocational programs in upper secondary school, Skolverket (Sweden's Education Authority), produced, among articles and the like, a number of short films, each demonstrating ways of teaching and, in the case of this paper, taking relations between contexts of school mathematics and workplaces into account. Our contribution is concerned with how the institutional norms present in one such film may restrict authentic meeting points between workplace mathematics and school mathematics, and the possible implications for such a film. Our research question was: "What institutional norms may be construed through analysis of such a film, and what are the implications for vocational students of mathematics as part of their future work?" Through a description of our analysis, we highlight the dissonance between the pedagogical approach displayed in the film and how its authenticity may be compromised from the perspectives of our analytical frameworks.

## Literature on mathematics: In work and in school

That the mathematics knowledge, skills and competence that underpin work may be denied, or dismissed as common sense may be a testament to its invisibility rather than its absence from the workplace (Boistrup & Gustafsson, 2014; Keogh, Maguire, & O'Donoghue, 2014; Williams & Wake, 2007). Mathematics may be something that workers use to solve problems or manage mathematics-containing situations, and may be observable as numerate behaviour (e.g. Gal, van Groenesteijn, Manly, Schmitt, & Tout, 2003). In contrast, school mathematics is topic-specific, determined by curriculum, shaped by prescribed text, built on layers of escalating complicatedness, taught to the rhythm of the semester, and formally assessed as a *passepourtout* to the next level of complicatedness. Whether its transferability is enabled by the context in which it is learned or contained by it, is disputed (Evans, 2000; FitzSimons & Wedge, 2007). The introduction of 'real-world' mathematics to the classroom offers the prospect of easing the transformation from formal mathematics learning to its application in work situations. Nevertheless, it is often constrained and reduced to mathematics word-problems surrounded by 'real world' conceits, that may be "inauthentic... fragmented, static bits of tasks.. that are neither contextualized nor intellectually challenging" (Wiggins, 1989, p. 711).

In Keogh, Maguire, and O'Donoghue (2016), a Workplace Context Complexity Protocol (WCCP) is presented. It identifies workplace competence, in relation to mathematics, as being shaped by strands such as familiarity and stressors. The ability to capture and calibrate the features of many workplaces, informed by the students, may enable teachers to build a platform to establish authentic, credible and familiar workplace contexts in which to set and explain mathematics as part of workplace complexity. In Boistrup (2016), a case of a nursing aide is presented drawing on different sociological frameworks, indicating connected notions as in Keogh et al. (2016). In the analysis of the study presented in this paper, we drew on findings from these two studies.

## Analytical framework

Selander (2008) presents a design theoretical perspective of learning when he explains how learning may take place in relation to its communicative constituents and associated processes, and where the design of a setting affects possible learning. This perspective is underpinned by Institutional Theory (e.g. Douglas, 1986), which emphasizes how society is surrounded by institutions which condition the actions that are possible to take. The perspective is similarly influenced by multimodal social semiotics as described by Van Leeuwen (2005) and others, where emphasis is put on the ways in which communicative resources are used, such as speech, artefacts, gestures displays and the like, and the roles they might occupy in the setting. From this perspective, learning is considered to take place in all kinds of settings, for example, the situation as reflected by the learning required to buy a bus ticket in an unfamiliar city. It could also encapsulate a workplace, where, typically, the main institutional norm is to "get the job done", part of which includes some learning.

Selander (2008) also specifies this theory in terms of a formal setting of learning, such as a mathematics lesson. In this paper we draw on the following selection of facets of this theory, highlighted in italics:

- We analysed the *institutional framing* of the lesson of the film, and the purpose of the chosen *curriculum*. We also paid attention to the *learning resources* that were present.
- We analysed the *social interaction* between teacher and students in terms of displayed *interest* in the communication, informal *assessment acts* and *teacher interventions*.
- We analysed how, and through which communicational resources (e.g. speech and hand gestures), teacher and students *presented* the *processes* undertaken during a problem solving activity. In addition, we analysed how, and with what focus, students were *meta-reflecting*, i.e. reflecting on their own actions.

In the analysis, we adopted the WCCP protocol by Keogh et al. (2016), using attributes from the strands comprising the model, e. g., *accountability*, *clarity*, *familiarity*, *stressors* and *volatility*, to capture the matrix of factors that are thought to define, enable and constrain performance in work.

## Methodology: Case study and analysis

This is a case study (Yin, 1984) wherein the primary data source is a film that is part of a ‘module’ on mathematics in vocational studies, upper secondary level, within a larger nationwide in-service program. The vocation of the students participating in the film is not made clear. However, as the context is introduced by the teacher as being concerned with a patient and her medication, we found it reasonable to infer that the students in the film are prospective nursing aides. We do not seek to analyse what the teacher is saying and doing *per se*, but rather to examine the messages being projected by the Swedish Agency for Education to teachers, albeit through the medium of an abridged video provided for teachers in the agency’s official website. Secondary data, analysed for interpreting the film’s message from its institutional context, stem from a discussion template to guide teachers’ in discussing the film, an interview with a home-caring nurse, potential parts of the module where the vocation of home-caring nursing aides are described, and the national syllabus for mathematics in upper secondary school, vocational studies (Skolverket, 2013).

The design theoretical perspective of learning was used in the analysis of the different processes in the film, which helped both in describing the lesson, and in the construal of institutional norms as reflected through the filmed lesson. The theory offers a framework with which to analyse learning with a particular focus on instances of institutional norms that are ‘there’ from the ‘beginning’, shaping, and perhaps containing the possible setting and learning activity. The perspective does not focus, specifically, on the content being taught and learnt. In our analysis we coordinated the design theoretical perspective with the framework by Keogh et al. (2016) in order to address how the teaching objective being illustrated, e.g. relations between workplace mathematics and general mathematics, is presented.

We transcribed the film multi-modally (Van Leeuwen, 2005), documenting what was being said and done, by whom, and identifying the artefacts that were being used and how. In the first step of analysis we both analysed the data through the two different frameworks i.e. Selander’s perspective and Keogh’s WCCP (Selander, 2008; and Keogh et al., 2016) separately. In this analysis, we

compared the transcript of the film with the concepts of the frameworks and with the secondary set of data. In a second step of analysis, we focused specifically on institutional norms while building on the findings from the previous analysis. The kind of institutional norms that we construed concerned relations between school mathematics and workplace mathematics. In this paper, we account for our analysis of the teacher's introduction and our analysis of the first student's contribution and whole class discussion.

## **Analysis and findings: A mathematics lesson claiming to draw on workplace 'reality'**

This section describes our first step (description and analysis) and second step (construal of institutional norms) of analysis while indicating elements in the analytical frameworks using italics.

### **Description and analysis of film title and the teacher's introduction**

The purpose of *curriculum*, in this case the topic claimed by the title of the film, is to go from the particular workplace mathematics to general mathematics. One central *learning resource* in the lesson is a screen at the front of the classroom where the teacher's computer is mirrored. In the beginning there is a picture of, and a short text about, a patient, called "an Irma" by the teacher. The problem is presented in writing as follows:

Irma who is 90 years old has high blood pressure. In order to lower the blood pressure, Irma takes medicine with the active substance bendroflumetiazide. She has been prescribed 15 mg, which she should take each morning.

Each morning, she should take 9 pills in total. Help Irma to fill the 'dosett' [a dosage unit]:  
HOW MANY PILLS OF EACH KIND SHOULD SHE TAKE?

The teacher checks with the students whether they are familiar with the active substance (*social interaction*). The students do not respond to this, and there is no sign of communicated *interest* in the topic from the students. There is more evidence of engagement when the teacher asks them to say the name of the dosage unit. There is not much *assessment* communicated to the students in this first part.

When we analysed the data with the WCCP framework (Keogh et al., 2016) one main point to consider was *familiarity*. The familiarity strand of the framework refers to how *specific* an activity is and to what extent the activity is a *regular* or irregular *occurrence*. In our interpretation, the context in which the problem is set is totally *unfamiliar* with regard to the students' future vocation, especially in connection to potential *accountability*. Firstly, it is not a nursing aide's *responsibility* to distribute pills into dosage units. Secondly, it is not feasible to restrict the patient to an exact number of different types of pills. This kind of *decision making* is not authentic. Thirdly, the way the teacher in the film begins his introductions, by referring to the picture of the patient as "an Irma", is not interpreted as reflecting any *familiarity*. This way of objectifying patients is not authentic from the perspective of a nursing and caring workplace (see also Boistrup, 2016).

### **Institutional norms construed from the title of the film and the teacher's introduction**

The *institutional norms* that frame the setting of the lesson are construed from the title of the film and from how the teacher introduces the work. One institutional norm is construed as (1) "It is

important to introduce general mathematical methods based on particular workplace problems". The basis for this construal is the title of the film, which is presented at the agency's website where teachers are invited to find and use the film. A second institutional norm is construed as (2) "It is important to find mathematics in the context of the students' future vocations and build on that". This norm is construed from the teacher's way of starting the lesson with the patient, Irma, where he describes the problem with her pills. This norm is part of the institutional framing also, since it is stated in the national syllabus that mathematics in vocational upper secondary school should be strongly influenced by the future vocations of the students (Skolverket, 2013). A third institutional norm is construed as (3) "It is not really important to secure the authenticity of contextualized tasks". The basis for this is described above in relation to Keogh et al. (2016) and Boistrup (2016), where it is clear that this is an example of un-familiarity with a workplace context, rather than a lesson where the mathematics teacher is making an effort to acknowledge the context of future workplaces of the students.

### **Description and analysis of first student and whole class discussion**

After the introduction the teacher starts a new sequence (*teacher intervention*), where he invites the students to discuss, in pairs (*social interaction*), possible solutions to the problem. At this point, the teacher is still standing at the front of the classroom, looking at the students. The students are looking to their front. The teacher repeats the problem and tells the students to discuss it for 30 seconds. The *resources* the students are offered to use are speech, writing, and calculators etc.

The teacher *intervenes* and initiates a whole class session. The teacher asks a student to *present* how she solved the problem. The student *represents* her previous solving of the problem with *resources* as speech and gaze when *presenting* her solution to the teacher and the class. Her first *meta-reflection* occurs when she says that her answer may not be correct. She then *presents* that she doubled the pill with 1.25 mg substance, to make 2.50 mg comprising 2 pills. She then added one of the 2.50 mg pills, to make 5 mg comprising 3 pills. She then took this times 3 which makes 15 mg and 9 pills, as required in the problem. In the film there is no further *discussion*. Instead the teacher *intervenes* telling the class, while pointing at the screen, "The method that Jasmine mentioned here is building on those numbers being easy". He elaborates for 10 seconds on this and continues, "but there is a general method. And this we call a system of equations, i.e. to set up a system of equations." This can be viewed as feedback, which constitutes an implicit *assessment*.

When analysing with the framework by Keogh et al. (2016) one point was again *familiarity*. The student in focus solves the problem in a way that could be the case for a nursing aide (Boistrup, 2016). (Here, briefly, we assume that the problem is authentic.) *Accountability* attributes are present in her reasoning, for example she takes the *initiative* and she uses the *concreteness* that suits this particular situation. The teacher stresses *theoretical concepts* and *abstract thinking* while stressing that the student's method only works with "easy numbers".

### **Institutional norms construed from first student and whole class discussion**

The instance of the first norm regarding the high relevance of introducing general mathematical methods, is construed as present in the end of the sequence described. Implicitly, we regard the third norm, i.e. the lack of relevance to secure authenticity, to be apparent in the sequence. The teacher indicates that the student's solution is not good enough since the method would not work well with

other numbers. However, it was taken for granted that a problem with a certain number of pills was relevant in the presumed context. We also construed a fourth institutional norm: (4) “All relevant power and knowledge resides with the teacher”. The basis for this construal derives from the way that the teacher assessed the student’s answer, seemingly dismissing her practical and correct solution to the problem as posed. In addition, the teacher did not allow much opportunity for the students to *meta-reflect* and discuss during the whole class session.

## Conclusions and discussion

The findings derive from our analysis of a filmed lesson, which is part of a library of resource material for in-service training for mathematics teachers. Authenticity is key from the vocational mathematics learner’s point of view. In summary, we conclude that the workplace context presented in the instructional video is transparently contrived, dehumanised and shaped by an unrealistic aim, e.g. that a patient should be required to take exactly 9 pills. Furthermore, it is not the nursing aid’s job to decide medication. That this description of the setting is patently false to the students, risks discrediting the underlying content and, ultimately, may undermine the intended learning outcome.

In the film, a teacher introduces how vocational students can use a system of equations when solving problems in their future work as nursing aides. From our analysis and findings, we conclude that the film depicts a mathematics lesson where little time is spent on student interaction and student meta-reflection. The teacher is the most active person who intervenes most often. The overarching content promotes the benefits of solving workplace problems with formal school mathematics. Our analysis and findings reveal that the claimed workplace context, in fact, is not authentic to any significant extent. Nothing of the workplace complexity, shown in previous research (e.g. Keogh et al., 2016), is present and the teacher does not use the students’ knowledge about the work as nursing aide as a help to achieve authenticity.

We view the construed institutional norms as a series of essential messages (from the National agency to mathematics teachers), that can be interpreted from the film as:

1. It is important to introduce general mathematical methods based on particular workplace problems
2. It is important to find mathematics in the context of the students’ future vocations and build on that
3. It is not really important to secure the authenticity of contextualized tasks
4. All relevant power and knowledge resides with the teacher.

To a large extent the construed institutional norms coincide with a typical school mathematical discourse as described in Gellert and Jablonka (2009). Looking at the first norm, we argue that it is important not to exclude vocational students from general mathematical methods, but whether it is always important to build on workplace problems or not may be disputed. If it is essential to acknowledge the complexities of mathematics in work, as described in the first sections of the paper, it may be more suitable to introduce systems of equations intra-mathematically rather than drawing on inauthentic problems. The inherent risk of inauthentic contexts is it may serve to undermine rather than support the learning outcome. Regarding the second norm, there are a number of studies (e.g. FitzSimons & Wedege, 2007) revealing that in order to secure the authenticity of workplace mathematics, a way forward is enabled by cooperation between the stakeholders,

including mathematics teachers, vocational students, and workplaces. Such projects may create opportunities to find relevant pathways from workplace problems and ways to solve them with general mathematical methods.

The primary data source of our analysis was a filmed example for a module on mathematics in vocational studies within a larger nationwide in-service program. The film is used in this study as a starting point for a discussion. Our analysis acknowledges that there is not much in the module, as a whole, that reflects a balanced account of the work done by nursing aides. Hence, we find it hard to see that a teacher-discussion based on this film alone, without, for example, alternative films for comparison and contrast, would challenge a school mathematical discourse, where out-of-school contexts are not meant to be taken as ‘real’ (cf. Gellert & Jablonka, 2009). Rather, we see a risk that a film like this perpetuates existing institutional norms. We concur that much more work is needed in the future, both in terms of professional development and research, to enable and facilitate mutual learning opportunities between school practice and workplace practices. In such work, our use of the design theoretical perspective of learning (Selander, 2008) may be of use in the analytical description of mathematics lessons with an interest in institutional norms, teacher interventions, communication and roles of modes. In addition, the framework is useful for comparisons within and between workplaces since the perspective also includes informal and semiformal settings, such as workplaces. Additionally the WCCP framework (Keogh et al., 2016) may be useful for identifying authentic mathematics with reference to the complexities of workplaces with an interest in the factors that define, enable and constrain performance in work.

# Exploring Roma learning mathematics: A socio-mathematical view

Javier Díez-Palomar

University of Barcelona, Faculty of Education, Spain; [jdiezpalomar@ub.edu](mailto:jdiezpalomar@ub.edu)

*In this paper, I discuss six case studies of Roma people who have overcome inequalities to learn mathematics. I explore which elements may explain their success, as well as which ones appear to be barriers that makes learning more difficult for students belonging to an ethnic minority. I draw on their testimonies using a qualitative methodological approach. The analysis of the data reveals that social representations about Roma have a major impact on these six Roma people attitudes and beliefs towards mathematics and schooling, which also affects their strategies to learn mathematics. The six narratives that I discuss in this paper suggest that success happens when Roma children are not segregated from the mainstream, but receive the same mathematics curricula as their peers.*

**Keywords:** Roma, mathematics learning, successful learning trajectories. SLT.

## Roma within the literature on mathematics education

In the field of mathematics education there are few studies about how Roma children perform in mathematics (Chronaki 2005, 2008; Stathopoulou & Kalabasis, 2007). Stathopoulou and Kalabasis (2007) analyse the relation between Romanó (Roma language) and the learning of mathematics in Greece. According to them, language is a form of cultural identity for Greek Roma children, and they use it to resist the homogeneous discourse of the school. Stathopoulou and Kalabasis define the academic Roma culture as an “oral” culture, which they use to justify reputing the claim about a “lack of written Roma language”. Starting from this statement, they argue that Roma children are proficient at oral calculation methods connected to their cultural roots, because Roma culture is mainly based on oral tradition.

Chronaki (2008) suggests introducing hybrid practices<sup>1</sup> as a way to break with the hegemonic discourse of the school (Matusov, 2009). Drawing on Bakhtin’s (2010) concept of polyphony, Chronaki argue that we need to develop dialogic practices to include the voices of all students in the classroom, including students from minority groups, not only the ones who share the monologist hegemonic discourse.

There is a lack of scientific literature on the type of actions performed by Roma children that appear to be successful in terms of achieving academic success and developing, what I call, successful learning trajectories (SLTs). Drawing on previous research (Flecha, 2014), I define SLTs as the set of practices and interactions conducted by an individual to pass his/her exams, successfully obtaining his/her school certificate(s). I use the “grading of a test, exam or any other assessment procedure” as indicator of success, for the lack of a better indicator of “learning.” According to the European

---

<sup>1</sup> *Hybrid practices* has been used in linguistic and cultural studies to characterize situations within the school (or the classroom) in which participants draw on different social and cultural backgrounds (Gutierrez, Baquedano-López & Tejada, 1999). It includes formal practices (school like practices) and practices related to what Luis Moll calls *funds of knowledge* (Gonzalez, Moll and Amanti, 2006). Chronaki (2008) uses the term in that sense, in the context of Roma culture.

authorities in education, the minimum level of education expected for everyone is compulsory education (goals of the *Horizon 2020* Program), generally up to age 16<sup>2</sup>. For this reason, “early leaving” and “dropping out” of compulsory education is considered “failing” in this approach.

## Methodology

This study was part of a larger research project investigating the response of individuals from ethnic minorities to overcome the social inequalities they face in the formal educative system when learning mathematics. This research interest emerged in the frame of analysing how children at risk of facing these inequalities can find their way to gain successful scores at school. The data was collected in Barcelona and its metropolitan area. When conducting this study, I realized that Roma people developing SLT (in mathematics) made use of strong support from their relatives. In order to better understand their process of learning, I decided to conduct a series of interviews with six Roma individuals, previously identified as “successful cases” in the sense that all of them had obtained good grades in mathematics during their academic trajectories (until the last course taken) (see table 1).

Pseudonym	Year of birth	Academic trajectory	Current situation
Federico	1984	University degree	PhD candidate
Joana	1990	University degree	PhD candidate
Joaquim	1988	Elementary degree	Access > 25 years old
José	1979	VET degree	Access > 25 years old
Antonio	1978	Secondary degree	Access > 25 years old
Aroa	1996	Upper secondary degree	Working

**Table 1: Description of the participants in the study**

To collect the data, I used personal interviews, an instrument with questions oriented to identify the elements that explain participants’ success in learning mathematics, according to their personal (subjective) point of view. Drawing on Chase (2005),

Contemporary narrative inquiry can be characterized as an amalgam of interdisciplinary analytic lenses, diverse disciplinary approaches, and both traditional and innovative methods –all revolving around an interest in biographical particulars as narrated by the one who lives them. (p. 651)

This method of inquiry is rooted in previous work, of researchers such as Thomas and Znaniecki (1918/1927), Garfinkel (1967) and Mills (1959). It involves collecting the testimonies of participating people using a number of instruments of data collection, including life stories, self-reports, oral biographical memoirs, testimonies, in-depth interviews, recorded narratives and life review (Mertens, 2009). This method of inquiry starts from an epistemological approach of individuals as primary sense-making agents (Giddens, 1991; Riley & Hawe, 2005). Personal narratives allow us to see first hand the interpretations made by the protagonists of their own life experiences. As Bruner (1990) claimed, we understand our world through the lenses of personal narratives. In addition, we also make meaning (and even build meaning) through those narratives. This type of method (inquiry)

<sup>2</sup> Almost in one of three European countries “compulsory education” goes up to 16 years old. For more information, see: [http://eacea.ec.europa.eu/education/eurydice/documents/facts\\_and\\_figures/compulsory\\_education\\_EN.pdf](http://eacea.ec.europa.eu/education/eurydice/documents/facts_and_figures/compulsory_education_EN.pdf)

led me to include the voices of the participants within the wider study. All information was transcribed for further analysis.

I selected six participants for the purposes of this paper. All met the requirement of having developed a SLT. As we can see in table 1, two of them are now enrolled in PhD programs. Three more, Joaquim, José and Antonio, are preparing to access university degrees, through the exams set up by the Government for people over the age of 25. Finally, Aroa is a girl (the youngest one in the group) who after finalizing her studies in the high school, decided to start working.

In order to analyse the data, I used narrative and discourse analysis (Mertens, 2009), drawing on a communicative methodological approach (Aubert 2015, Sánchez, Yuste, de Botton, & Kostic, 2013). This approach focuses on the analysis and interpretation of the discourse from the dialogue with the participants, using validity claims (Habermas, 1984). The interpretation is organized in two different dimensions of analysis: transformative and exclusionary. Transformative dimension includes all aspects that will enable the subject of the study to answer positively to the research question. Exclusionary dimension has the opposite meaning: it includes all aspects that will avoid (or make more difficult) answering the research question. For the study reported in this paper, the transformative dimension includes all aspects leading the participant to achieve a SLT, whereas the exclusionary dimension refers to all aspects making difficult (or even avoiding) the subject to achieve a SLT.

		Attitudes	Beliefs	Contents	Strategies	Social Representations
Individual	T*	1	2	3	4	5
	E**	6	7	8	9	10
Teacher	T*	11	12	13	14	15
	E**	16	17	18	19	20
Family / Community	T*	21	22	23	24	25
	E**	26	27	28	29	30

\* Transformative dimension

\*\* Exclusionary dimension

**Table 2: Coding categories for data analysis**

Interviewers and interviewees established a dialogue to explore the data collected, which allowed us to identify meaningful topics regarding interviewees' learning trajectories. In a subsequent interview, I asked them to further clarify those topics. Drawing on this dialogue I elaborated a key to codify all data collected (see table 2).

The categories (codes) emerging from the discussions include: attitudes, beliefs, content, strategies and social representations. The first two concepts were defined in McLeod's (1992) terms. Content is referring to the mathematics itself (the curriculum). Strategies are defined in Maehr's (1983) terms

(see also Ames & Archer, 1988). Social representations correspond to the Moscovici's (1981) definition.

## Discussion

Next I provide first an inductive analysis of the data collected through the interviews. Then I try to create a tentative model to make sense all the relevant variables identified by the participants in the study, explaining their 'learning process'.

### First step: Inductive analysis

Federico provides a good example illustrating the type of answers obtained from all six Roma interviewed. He claims:

In my case, the key aspects were, one I was passionate [about mathematics] and I really like science, so my motivation was somehow 'natural', or 'intrinsic'. In addition, my teachers of mathematics and biology used to give me extra homework. I remember that in 4<sup>th</sup> grade - ESO [secondary education – middle school] I used to solve problems of 1<sup>st</sup> grade - *Bachillerato* [secondary – high school], and this was very motivating for me. It was the opposite in Catalan or English, teachers used to reduce my tasks so I could pass them [with no work]. Not the case for Spanish: I also used to get difficult homework to do in the classroom or at home. (Federico)

In his words, we can see that aspects particularly positive in his academic career include effort, a challenging curriculum, a personal motivation (passion) for some of the academic topics (such as mathematics or biology), whereas no enthusiasm at all is devoted toward other ones (Catalan or English). From a very tentative entry point, we can infer here that 'motivation' is, somehow, connected to 'grading' (as learning 'indicator'), given that Federico (for example) got excellent grading in mathematics and biology and, in fact, he started 'biology' for his minor at the university. But he also declares that his family (specially his mom), took a relevant part in his learning process.

In an informal way, my mom taught me mathematics in the kitchen, or when shopping. Topics like volume, arithmetic, counting, prices, change, [...] My dad, as he was in the construction sector, taught me how to calculate budgets, how to calculate the price for square meters, how much does it cost the staff, rates. (Federico)

He and Aroa, Antonio, José, Joaquim and Joana as well, explain that their good grades in mathematics were consequence, mainly, of their family involvement. Their parents were the ones teaching them to develop mental calculation skills, estimation skills, etc., which were highly valued in the school framework. Stathopoulou and Kalabasis (2007) also provide clear examples in the case of Greek Roma, confirming this finding. However, this is not a main strategy for learning mathematics for any of our six cases. What they claim is that in order to obtain good grades in mathematics, they basically had to study hard, to put a lot of effort, using academic strategies to better learn: outlines, summaries, use of key words, or other mnemonic strategies, practice, problem solving, homework every day, etc.

However, drawing on the data that I collected, it seems that certain social contexts could become sometimes a barrier limiting the opportunities of some Roma individuals to successfully perform in their grades. Joana, for instance, felt isolated from the 'Roma world', whereas Joaquim resists and rejects school because "[school] it is not Roma". Teachers are crucial. According to Federico, some teachers really do not help Roma students because they feel that Roma are not interested in education.

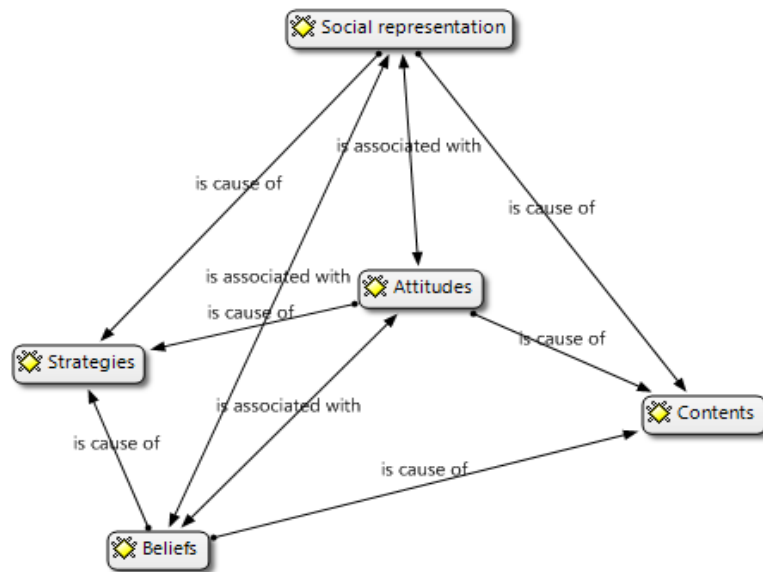

Joana holds a similar view. She explains how for many of her Roma friends teaching was just a matter of “being happy attending the school”, rather than “being a place for expand their learning”. According to Joana, that was the consequence of some teachers’ prejudices against Roma children:

Not always, but in some cases, yes. It was not the case with me; my teachers always encouraged me to continue studying. But most of the times they did not identify me as Roma, and I have come to hear some pejorative comments towards my people from my teachers. In the classroom, I never had so many Roma peers. But I know other Roma girls who explain to me that, in their high schools, teachers, instead of teaching them the lesson, they lead them to see the *telenovela* [soap operas on TV]. I guess that it is the easiest solution and they think that doing so, the girls would be happy of attending the school every day. But I think that it is the opposite in fact, because the girls and their families know that they are not learning anything, so attending the school is useless. If things are like that, then they can stay at home and see the *telenovela* over there. (Joana)

Looking at the testimonies of the six individuals interviewed, what they highlight as the most exclusionary factor is segregation, the separation of Roma students from the mainstream. This is due either to stigmatization from some teachers, or because genuine wishes of some teachers to better help them, hence they use “separation into homogeneous small groups” as a way to ‘concentrate’ additional support. However, according to Federico and Joana, those efforts are useless, since taking Roma children away from the mainstream does not help them to better learn mathematics, but the opposite; this practice leads the Roma students to be labelled by their peers and teachers, creating a stigmatized social representation about Roma. Therefore, this process somehow “announces” the academic performance of Roma children even before they conduct the tests. It is like a “self-fulfilling prophecy”. This perverse effect has been proved many times in the field of mathematics education research with children from vulnerable groups (Secada, Fennema, & Byrd-Adajian, 1995; de Abreu, Bishop, & Presmeg, 2001). When the school creates ability groups to segregate vulnerable groups children from the mainstream, creating low level groups, or designing segregated paths tracking, the consequence is that these children fail.

### **Second step: Creating a model of analysis**

Drawing on the analysis of these testimonies, after coding them with the qualitative software package *Atlas.ti*, I produced a tentative model to describe SLT. I called this scheme *Learning Core Matrix* (LCM), as in figure 1, drawing on the variables identified by McLeod (1992), Maehr (1983) and Moscovici (1981), as reported earlier in this paper. The sum of all these components forms what I call LCM. I use this scheme to understand how every SLT works. On the subjective level of analysis, personal attitudes are shaped by social representation of being Roma. Social representations include values, ideas, metaphors, and beliefs (in the sense of Moscovici’s notion) related to learn mathematics being Roma. Strategies refer to the practices that individuals (Roma students, teachers, etc.) perform to teach, learn, resist or avoid mathematics. Attitudes include positive or negative evaluation of people, objects, events, activities, ideas, etc. in the frame of teaching and learning mathematics.

**Figure 1: Components of the Learning Core Matrix (LCM) associated to a SLT**

Beliefs include personal mental states regarding people, objects, events, activities, ideas, etc. Finally, contents refer to the mathematics curricula. According to the data collected, it seems that a ‘positive’ social representation of Roma may explain why some teachers do not segregate Roma addressing them to low-achievement groups with poor content (in mathematics), whereas other teachers holding ‘negative’ social representations about Roma use segregation strategies with them, lowering the curriculum, for instance. It is also the case that the same teacher may also project good expectation in one particular Roma student, whereas segregating other ones. Having a positive or negative social representation depends on the teacher attitude towards Roma identity, which is closely interlinked to teachers’ personal beliefs. From the student point of view, the model works accordingly: confidence in the school (positive belief) is attached to a positive attitude in the classroom, as well as to the use of a variety of strategies to learn mathematics (such as prepare exams some days ahead, do homework, look for extra work, etc.). This is associated to a teacher’s positive social representation of Roma as successful learner (in mathematics), as well. The individuals who show positive components in this LCM use to hold SLTs more likely than the ones who, at some point of their lives, had a (mainly) negative LCM.

## Conclusion

The six narratives I have discussed here suggest that success happens (or is more likely to happen) when they have had positive LCMs. When all of the five components of the LCM (or most of them) are positive, then it is more likely that an individual would develop a SLT. On the contrary, when the negative component is prevailing, then it is hard to see SLT as a result. Joaquim, for instance, at some point of his life dropped out the school because he was feeling resistance against the school institution. According to him the main reason to explain such attitude was his negative social representation of “school” as something alien to his identity. This feeling could be, somehow, the result of being segregated by certain teachers holding negative expectations towards Roma students.

The role of the family plays a crucial role to overcome the difficulties and barriers that some Roma students face along their school trajectories. A significant amount of these barriers is connected to prejudice and negative social representations about Roma. Family may be a resource. However,

sometimes this is not true because the members of the family did not have any opportunities or possibilities to study themselves. For this reason, they cannot become ‘resources’ to help their children to solve their mathematics assignments. But, according to Hoover-Dempsey et al. (2005), the families can look for further resources to reinforce their children’s learning. Recent studies suggest that family engagement in the school has major impact on learning than just appointing family members in the school to ‘report’ on children’s behaviour (Díez-Palomar, Santos, & Alvarez 2013).

LCM may have the potential to explain both Roma’s SLTs or the failure of many Roma children in the school, as narrated by Joana, Federico, Joaquim and the rest of their peers. In their narratives, they explain how many of their Roma peers used to be re-allocated to low-level classrooms, how teachers use to decide to lower the grades for them, cutting down on the curriculum, or asking them to do *naïve* work (like painting) rather than problem solving or other high-mathematics-oriented tasks. However, examples like the narratives by Federico or Joana may help us to understand how holding a positive identity connected to showing positive attitudes in the school, using different strategies to overcome the difficulties related to mathematics itself (epistemological, ontological, etc.), combined with high quality curricula and classroom organization, may end in the development of SLTs.

The model that I presented here is not generalizable. We need further quantitative studies to either accept or reject this approach. This would be the next step in the near future.

*This paper describes the features of ethical research and how we attempted to undertake this kind of research. Our contention is that the aim of ethical research should be to produce action for change. Our understandings of ethical research led us to pause our negotiations for setting up two new projects, in kindergartens in Norway. By taking seriously our potential collaborators' concerns, we were alerted to how kindergartens were simultaneously seen as both the cause and the salvation for several issues. In media discussions, which often originated with the Minister for Education, there was a perception that there was a need for more learning, particularly of mathematics and language, to overcome difficulties that children, especially immigrant children, may have when they begin school. These discussions were often contradictory with kindergartens being placed in an invidious position of navigating these discussions for their work with children.*

**Keywords:** *Ethical research, multilingual children, ICT, play, learning.*

### **Ethical research**

In August 2016, we were in the early stages of setting up two projects involving dialogue between ourselves, as mathematics education researchers, and the parents and teachers of multilingual children in kindergartens in Norway. As described in the next section, our initial discussions with an organisation about one project made us stop and reconsider what we wanted to do and why. To do this, we clarified our ideas about the kind of research, ethical research, which we wanted to undertake. In this paper, we discuss how implementing its principles resulted in us investigating the shifting landscape of priorities in Norwegian kindergarten policies.

Our definition of ethical research includes a number of aspects, some of which are inspired by critical research. Critical research has a social justice aim and as such requires researchers to be comfortable with the ambiguity connected to working against oppression. Proposing bricolage as way of conceiving the range of research methodologies needed for conducting critical research, Kincheloe, McLaren, and Steinberg (2011) stated that “comfortable with the ambiguity, bricoleurs as critical researchers work to alleviate human suffering and injustice even though they possess no final blueprint alerting them as to how oppression takes place” (p. 173). We consider that ethical research involves more than evoking sympathy for participants. Like Harris (2013), we want to work with participants to produce “action for change” (p. 87). Nevertheless, we are aware that concerns about misinterpreting interactions and situations have led some researchers to withdraw from “action for change” research in case it produces undesirable outcomes, due to a lack of knowledge about the context in which they worked (Sultana, 2007).

Thus, we consider that to design research that would produce action for change, academic researchers need to negotiate the research process with participants (Potts & Brown, 2005). In accepting this requirement, we recognise that this may make us uncomfortable. Operationalising social justice as action for change means we must live with ambiguity associated with how data should be collected and analysed. Our uncomfortableness with this ambiguity is likely due to preconceptions that research

should provide definitive responses to issues; a reflection of the discourses that surround us as academics. It is also due to how we operate within the power relationships connected to being researchers, who tell the stories of participants (Etherington, 2007; Harris, 2013). Ethical research requires us to interrogate these power relationships and not assume we know the truth.

Therefore, reflecting on our decision-making in the research, both with and without our participants, is an important component in ethical research. Reflexivity has been promoted as important in that it makes transparent any dilemmas in the research.

Reflexivity is ... an ability to notice our responses to the world around us, to stories, and to other people and events, and to use that knowledge to inform and direct our actions, communications, and understandings (Rennie, 1998; Wosket, 1999). When we extend that skill [reflexivity] into the practice of reflexive research, we need to be aware of the personal, social, and cultural contexts in which we (and others) live and work and to understand how these affect our conduct, interpretations, and representations of research stories. (Etherington, 2007, p. 601)

In summary, ethical research is connected to action for change, but to achieve it we need to negotiate with participants what the research should be and how it should be conducted. This requires us to have a rich understanding of the context surrounding the site of the research. We must also accept uncertainty and be reflexive about our roles so that the power imbalance in our relationship with participants does not result in a covert control. We have a responsibility as researchers to find out about the relevant contexts and not just expect our collaborators to be the ones to inform us. We must also be aware that the negotiation can result in the research being “productive failure” (Harris, 2013, p. 89), rather than the change that we jointly want to work for.

### **Unease and the project proposal**

In the negotiation of new projects with organisations that we had not previously worked with, our understandings of ethical research made us pause when some unease was shown. In the projects, we wanted to work with kindergartens teachers and parents of multilingual children. In one project, we hope to develop and trial playful mathematical apps that would encourage children to discuss them with kindergarten teachers in Norwegian and with their families in their shared languages. The change that we want to produce through having children engage with the apps is for them to develop both their Norwegian and home language(s) for discussing mathematical ideas.

However, in the initial meeting, the complexity, connected to combining ICT, through mathematical apps, with the development of children’s mathematical register in more than one language as well as a request to involve immigrant parents, seemed to overwhelm those we talked to. The response was positive in that they felt the kindergartens would want to participate, but there was a constant stream of questions about what would happen and what the teachers would have to do. Although we tried to explain our aim of negotiating the project with the teachers and the parents, there was unease about why we did not have a clear plan for what we wanted (the teachers) to do. This unease made us reflect on the context of kindergartens in Norway, to determine what might provoke a need for certainty.

Our reflection indicated that the projects came at a time when those working with kindergartens face much uncertainty and it became important to identify the features of the shifting landscape which affect kindergartens teachers’ work. We considered that an increased awareness of this landscape

would support us to be more respectful of the circumstances and improve our possibilities to negotiate with kindergarten teachers and parents about how the projects should be implemented.

## **The shifting landscape**

In this section, we present our understandings of some of the features of the shifting landscape including discussions about changing the role of kindergartens as one of preparing children for school, through supporting children to learn better mathematics and Norwegian and by incorporating ICT into children's play. Each issue has been the subject of much debate over the last few years. Our investigation indicated that in discussions about kindergartens, teachers were often positioned both as responsible for the problems and simultaneously also the solvers of the very same problems.

## **Changes to curricula philosophy for early childhood**

In Scandinavian kindergarten curricula, the focus has traditionally been on the whole child, emphasising their integration into society (Bennett, 2005). A revision of the Norwegian curriculum for kindergartens, the so-called Framework Plan (Kunnskapsdepartementet, 2011), that sets out their responsibilities has been ongoing for some years. However, in 2016 the Minister for Education rejected the draft, which followed the philosophy of play-based learning, proposed by contracted early childhood professionals. In particular, this delay to revising the Framework Plan seemed to result in our potential collaborators being uncertain and frustrated. However, the Minister had decided that his department would write the Framework Plan (Kunnskapsdepartementet, 2016a; Støbakk, 2016) in line with a white paper that he had commissioned about providing “better content” in kindergarten (Kunnskapsdepartementet, 2016b). Although this suggestion has received significant criticism from those working in the field, the Minister continues to talk about kindergartens needing to prepare children for school. As noted in some of the critiques (Bae, 2016), play – although in the title of the white paper (Kunnskapsdepartementet, 2016b) – is almost completely missing from the discussion with the attention being on what children are to “learn”. This indicates a deliberate change to situating kindergartens’ primary role as preparing children for school. This interpretation was reinforced with the revelation that Norway was to participate in the first round of PISA tests for 5 year olds starting in 2017/2018 (Moss et al., 2016). In Norway, five year olds attend kindergartens and comparing them on international tests will emphasise the importance of school knowledge. Mathematics will be one of the knowledge areas assessed in these International Early Learning Studies (Moss et al., 2016).

## **Mathematics and the “realfag” strategy**

In a series of initiatives contributing to shifting the focus of kindergarten away from the social policy pedagogical tradition (Bennett, 2005), another report, specifically about improving mathematics and science subjects, “realfag”, in kindergartens and schools, was commissioned by the Minister and released in August 2015 (Kunnskapsdepartementet, 2015). The Minister in justifying and promoting this policy had linked Norway’s future financial well-being to a need for more focus on mathematics in kindergartens (Lange & Meaney, 2016). This prompted discussion about whether moving more towards a “readiness for school tradition” and away from the “social policy pedagogical tradition” is appropriate for Norwegian kindergartens. Like the white paper about better content in kindergartens (Kunnskapsdepartementet, 2016b), this report and its recommendations have been criticised by those working in the field even before it was published (see for example, Pettersvold & Østrem, 2014;

Schaanning, 2015). A question arises about what improving the content in kindergarten means when the current Framework Plan (Kunnskapsdepartementet, 2011) already contains goals for providing mathematical learning opportunities to children (Digranes, 2014). The implication was that kindergarten teachers were not doing enough to support children to learn the necessary mathematics knowledge for school. For kindergarten teachers and the administrative leadership, there remains uncertainty about how to implement the “realfag” strategy while they wait for the Framework Plan to be finalised. Although the outcomes are clearly connected to “improvement”, perhaps assessed through tests of 5 year-olds, the lack of information for kindergartens about how to work with this report remains a source of frustration.

### **Multilingual children in Norwegian kindergartens**

Alongside discussions about the role of mathematics within kindergartens, there have also been discussions about the children needing to learn “good” Norwegian language. These discussions are diverse and in some ways contradictory. Some of them refer to the white paper on better content in kindergarten (Kunnskapsdepartementet, 2016b), which includes the push by the Minister to introduce mandatory language testing of kindergarten children, such as in Fladberg (2015), and to the legislate requirements for Norwegian language skills of employees in kindergarten as noted by Haugsvær (2016). The Minister’s justification for the testing was that a significant proportion of children begin school without good Norwegian skills (Svarstad, 2015). Although the suggestion for mandatory language testing was rejected by the parliament in June 2016, uncertainty about how kindergartens should work with children’s language development remains (Fyen, 2016; Schaanning, 2016).

Connected to these discussions, although often implicitly, is the issue of immigrant children and their learning of Norwegian so that they would be ready for school (Redaksjonen, 2016). Children who have another language than Norwegian as their home language are given the same tests as those who have Norwegian as their home language. Unsurprisingly perhaps, the results generally indicate that multilingual children are not as competent as children who speak Norwegian at home. However, in this debate, the kind of language development seems to be implicitly about ensuring conversational language. Language to discuss mathematics is not specifically mentioned either in discussions about more mathematics in kindergartens or in discussions about improving language development.

Linked to the issue of multilingual children’s Norwegian language skills is a long running debate about family payments that parents can use for children to attend kindergarten or to look after them at home (Rosa, 2007). Recently, attendance by immigrant children in kindergartens has increased (Barne-, ungdoms- og familiedirektoratet, 2016), providing them with increased opportunities to learn Norwegian. The discussion about insufficient Norwegian for school has been linked to children who are kept at home during the kindergarten years, although the Minister rarely acknowledges this. Still, there is some evidence that children may not be learning conversational Norwegian while in kindergartens. The responsibility for improving the situation lies with the municipalities which oversee kindergartens.

At the same time, there also has been criticism about the lack of effort by kindergartens to achieve the Framework Plan’s (Kunnskapsdepartementet, 2011) requirement to develop all of the children’s languages (Sundby, 2016). Nevertheless, it is acknowledged that it is difficult for kindergarten staff to do this if they are not be fluent in these other languages (Otterstad, 2016). Again, kindergartens are

situated as being responsible for not doing enough but with no clear pathway for how they could improve their possibilities for supporting children's home language skills. There is no discussion about using home languages for discussing mathematics.

### **ICT and kindergartens**

ICT is an area that children in kindergarten are also supposed to have experiences with, according to the Framework Plan (Kunnskapsdepartementet, 2011). Yet the discussion about whether or how to incorporate ICT in kindergartens continues to circulate, partly because of the constant changing of hardware and software. For example, the rapid increase in the use of touch-screen devices by children at home (Hardersen & Guðmundsdóttir, 2012) has not been matched by their use in kindergartens (Bølgan, 2012). As well, research in information literacy skills connected to ICT has shown that older students who speak other home languages than Norwegian are likely to have less of these skills than those who speak Norwegian at home (Hatlevik & Guðmundsdóttir, 2013).

In seeming contradiction to the Framework Plan's requirements, the Minister has been critical of the unbridled enthusiasm for ICT in kindergartens and schools, suggesting that there is limited research evidence to show that ICT contributes to children's learning (Todal, 2015). During a visit to a kindergarten, he described his fondness for paper books over digital ones (Ruud, 2016). For kindergartens deciding how to use ICT with children, there are mixed messages about if and how they should integrate ICT into possible learning opportunities for children.

### **What did we learn from mapping the landscape?**

Although as researchers we were aware of the debates raging around kindergartens, it was not until we investigated them that we understood how they may be affecting the possibilities our potential collaborators saw for negotiating with us. As teacher educators, we also face major changes to our working environment, initiated by the Minister of Education. However, our standing as academics, which provides us with recognition and discussions beyond our immediate working environment, perhaps made us blasé about the impact that uncertainty had on kindergartens' perceptions of what they could do. Kindergarten staff, even though many have a Bachelor degree, are often not given the same status as those working in universities or even schools by the general public. By investigating what was being discussed and in what ways, we better understand the uncertainty that kindergarten staff saw in how we presented the potential project to them.

The debates, around kindergartens and what their focus should be, situate kindergarten teachers and administrative leaders as being both responsible for the problems and also their solutions. As discussed in the previous section, kindergarten staff were being presented in the media debates as not preparing children well enough for school. Official reports situated them as not developing the children's, especially multilingual children's, language(s). They were also not providing children with the mathematical understandings that they needed to be successful at school and this was endangering Norway's economic well-being. Within these debates, kindergarten staff were positioned as not being competent, with kindergarten assistants' Norwegian language skills needing to be tested.

Simultaneously, the debates constantly shifted and changed, providing contradictions and no clear guidelines about what kindergarten staff should focus on and how they should implement any of the reports. Instead, they may have felt their competence was further being tested by whether they could

work out appropriate solutions to these issues. Having been judged as contributing to the problems, they are now being judged on whether they could become the kindergartens' saviours through finding solutions to those exact same problems. Being the focus of so much media attention, with limited possibilities for responding and positioning their work in positive ways, may have affected their willingness to engage with us, as outside researchers. It is not surprising that they seemed to want a specific plan for their participation in the proposed projects. Following someone else's plan not only would allow them to show they were working on solving the issues, but if the plan did not work then we would be responsible.

Yet ethical research demands that we negotiate with kindergarten staff and parents if action for change is to be achieved. Our investigations showed us that we needed to accept their concerns as genuine and be mindful about how we situated them in our negotiations. Recognising this shifting landscape provided some indication about how we could be respectful of their contexts. Still there remains significant ambiguity for us on how to conduct, not just the negotiation, but also the project itself.

*Five teachers from a Sámi lower secondary school participated in two workshops on culturally-responsive mathematics teaching. During the first workshop, the teachers chose to focus on developing a unit about lávvu, the Sámi tent, to be taught between workshops. Their experiences are analysed with respect to Self-Determination Theory, which claims that all humans have a basic need for autonomy, competence and relatedness to others. The analysis of teachers' written notes reveals that the need for autonomy appeared as a need for inspiration and for courage. The need for competence concerned relating mathematics teaching to the two community resilience factors i) Sámi language competence and ii) traditional ecological knowledge. The need for relatedness to others was linked to Indigenous peoples, other teachers at their school, and teachers at other Sámi schools.*

*Keywords: Sámi, teacher, self-determination, indigenous, culturally-responsive teaching.*

## Introduction

This paper explores teachers' perspectives on culturally-responsive mathematics as it is imagined and utilized in the design and implementation of a teaching unit on the Sámi<sup>1</sup> tent, *lávvu*. This artefact, its design and its building, carries important connections to the Sámi people's intangible cultural heritage by embodying cultural traditions and ceremonies as well as rules for behaviour. To many Scandinavians, however, the *lávvu* is merely a tent; a cone-like building made with some poles that are covered by cloth. In modern Sámi societies, traditional knowledge of *lávvu* is not necessarily widespread as people use modern, factory-made *lávvut* with metal poles. Reindeer herding families use *lávvu* regularly and often are more familiar with traditional knowledge about *lávvu* than other Sámi. The younger Sámi generation consists of a variety of people with different interests.

*Guovdageainnu nuoraidskuvla* is the lower secondary school in the village Guovdageaidnu, Kautokeino, in Norway. North Sámi is mother tongue of more than 90 % of the students and it is the school's official language. The teaching is translated into Norwegian by an assistant teacher for students who do not understand Sámi well. The school follows the Sámi curriculum, which is equivalent to the national one. The school's teachers realised that *reahpen*, the north Sámi word for the smoke hole in the *lávvu*'s top, was considered a strange word by many grade 10 students. In order to increase students' cultural and mathematical knowledge, the teachers developed a culturally-responsive teaching unit about *lávvu*. The teaching unit was carried out in the period between two

---

<sup>1</sup> The Sámi are an Indigenous people of the Arctic. They live in the northern parts of Norway, Sweden and Finland and on the Kola Peninsula in Russia. The Sámi is a heterogeneous group of people with different occupations.

workshops about culturally-responsive mathematics teaching. At the first workshop, the teachers planned the teaching, and, at the second workshop, they presented the outcomes. We consider this work to contribute to this group's self-determination as an Indigenous group.

Smith (1999/2006) highlights the importance of self-determination for Indigenous people, by describing it as the aim of a non-linear developmental process that departs from survival and recovery. We consider that self-determination is important in understanding Indigenous mathematics teachers' motivations for developing and implementing culturally-responsive teaching. Previous research about teachers' reflections about Sámi-fization of school mathematics identifies several important issues. Jannok Nutti (2013) noted teachers' ability, drive and possibility, while Fyhn, Jannok Nutti, Nystad, Sara Eira and Hætta (2016b) describe relations between teachers' *autonomy* and their development. Fyhn, Jannok Nutti, Sara Eira, Børresen, Sandvik, and Hætta (2015) point to the importance of including teachers from other subjects, when the context for the teaching is related to their area. According to Kirmayer, Sehdev, Whitley, Dandena, and Isaac (2009), self-determination also relates to resilience, as general discussions of identity tend to underemphasize the role of social action or collective agency in the production of well-being. Nystad, Spein, and Ingstad (2014) investigated a Sámi society in Northern Norway and identified community resilience factors including Sámi language competence, use of recreational and natural resources, and traditional ecological knowledge, such as reindeer-husbandry-related activities. These cultural factors appear to strengthen adolescents' ethnic identity and pride. Knowledge about *lávvu* and skills in how to raise a traditional *lávvu* are examples of traditional ecological knowledge in Sámi societies. Kirmayer et al. (2009) point out that resilience has a collective as well as an individual dimension.

Self-determination theory has provided empirical support for the proposition that all human beings have fundamental psychological needs to be *competent*, *autonomous* and *related to others* (Deci & Ryan, 2012). *Autonomy* refers to the perceived origin or source of one's own behaviour; it concerns acting from interest and integrated values. *Relatedness* is the psychological sense of being with others in a secure community. *Autonomy* is emphasized in traditional Sámi child rearing (Hoëm, 1976; Balto, 2005) and Balto (2005) highlights *autonomy* as a Sámi value. *Relatedness* to others is connected to holistically sharing and developing knowledge and so it is also considered an Indigenous value. The theoretical framework is constituted by the three categories *competent*, *autonomous* and *related to others*. Following Glaser (2001), we identified subcategories connected to each category by comparing incidents and named them using the teachers' own words. In this paper, we analyse five teachers' expectations and experiences of the two workshops. Our research question is, how does teachers' self-determination appear in their workshop notes?

## **Culturally-responsive teaching**

Before discussing the workshops, we briefly describe culturally-responsive teaching which was the inspiration for the workshops. Gay (2013) described culturally-responsive teaching as “using the cultural knowledge, prior experiences, frames of reference, and performance styles of ethnically diverse students to make learning encounters more relevant to and effective for them” (pp. 49-50). Gay suggests that as part of culturally-responsive teaching, teachers conduct their own analyses of textbooks, the Internet and other sources. The investigation should include how different knowledge sources affect teaching and learning and reconstruct or replace existing presentations of issues and situations in the various resources with cultural knowledge and insights. This approach is in alignment

with Smith's (1999/2006) description of self-determination. Gay (2013) considered that interdisciplinary work with teachers of other subjects supported collaboration and provided different insights. Nevertheless, implementing culturally-responsive mathematics teaching needs to be done with care so that cultural artefacts are not simplified, to the detriment of both the culture and the mathematics. An example of simplification is to claim that the tipi, which is similar to the Sámi's *lávvu*, is a cone:

That is surely wrong; the tipi is not a cone. Just look at a tipi with open eyes. It bulges here, sinks in there, has holes for people and smoke and bugs to pass, a floor made of dirt and grass, various smells and sounds and textures. There is a body of tradition and ceremony attached to the tipi, which is completely different from and rivals that of the cone. (Doolittle, 2006, p. 20)

According to Doolittle, there is a risk that Indigenous students who are presented with such oversimplifications feel that their culture has been appropriated by a powerful force for the purpose of leading them away from their culture. Thus, a teaching unit about *lávvu* has to respect the tradition and ceremony attached to it. Traditionally, a *lávvu* consists of two cloths that are wrapped around a set of poles and is a place for sleeping, working, relaxing, storytelling and even more (Nergård, 2006). It is easy to set up and take down and its permanent material, cloth and skins are transported when the family moves between living places. Other materials are gathered from the area where the *lávvu* is placed, making it local as well as mobile. There are rules for where to sit in the *lávvu* for parents, grown up children, workers and smaller children. In the old days, the innermost area was sacred and only the bear hunter returning from a successful hunt was allowed there (Pettersen, 1905/1979). He entered from the back bringing the bear meat with him. Nowadays, people sleep anywhere and in modern *lávvu*, the floor is covered with carpets and stoves are used for cooking. Still, the tangible and the intangible cultural heritage remain important.

## **The workshops**

Teachers from two Sámi schools participated in two two-day workshops, with six months in between. The workshop participants were a) teachers from the three subjects Sámi language, mathematics and *duodji*, Sámi handicraft at *Guovdageainnu nuoraidskuvla*, b) all teachers for grades 1-10 from a small Sámi school in another municipality, and c) some pre-service teachers from Sámi University College, who had a practicum at *Guovdageainnu nuoraidskuvla*. The teachers joined the workshops so they could contribute to the further development of culturally-responsive teaching in their schools. *Guovdageainnu nuoraidskuvla* had already started developing culturally-responsive mathematics teaching (Fyhn et al., 2015; Fyhn et al., 2016b) and the principal is one of the mathematics teachers. The two workshops included lectures and school-based group work. The group work was about the culturally-responsive mathematics teaching done in the period between the workshops. At the first workshop, the mathematics teachers who participated in the earlier project (Fyhn et al., 2015) presented their work. In addition, researchers presented theoretical perspectives connected to Indigenous mathematics education, mainly through examples from Sámi and Māori classrooms. The second workshop continued with theoretical perspectives and included an online lecture with two Indigenous mathematics teachers and researchers from New Zealand. At the first workshop, each school chose a theme for the culturally-responsive mathematics teaching and started the planning. The schools presented the results of their culturally-responsive mathematics teaching at the second workshop. *Guovdageainnu nuoraidskuvla* focused on *lávvu* and eight teachers from this school co-

authored a paper about their work (Fyhn, Sara Eira, Hætta, Juuso, Skum, Hætta, Sabbasen, Eira and Siri, 2016a).

### **The teaching unit about *lávvu***

During workshop one, the Sámi language teachers suggested to focus on *lávvu*, because many students did not know the names of central parts of the *lávvu*. The mathematics teachers agreed that *lávvu* would provide possibilities for teaching mathematics, among other things by having the students make a small *lávvu* model. Students could discuss different aspects of mathematics related to *lávvu*. Consistent with cultural symmetry (Trinick, Meaney, & Fairhall, 2016), the teachers designed the teaching unit so that it started with a history section that discussed *lávvu* and *goahti* (another common Sámi housing) and central concepts regarding these. The teachers highlighted the different parts of the *lávvu* construction and how each part functioned. Each part was connected to specific traditions and the students had to learn the North Sámi words for them. In this way, the teaching valorised the local culture, as recommended by Trinick et al. (2016) and Doolittle (2006).

The mathematical aspects of the unit focused on the three *válldahat*, the structural poles, the location of *árran*, the fireplace, and the size of the floor. The *válldahat* have a Y-shape in one end and are the first three poles raised. This triangular construction is common for Sámi frameworks; as constructions made by three sticks are stable and reliable (Fyhn et al., 2016a). Locating the *árran* can be done through eye estimation, which includes trial and error for those who are not skilled. *Árran* may also be located just below a *skerttet*, a special iron hook that hangs in a chain from the top of the *lávvu*. Locating *árran* can be connected respectively to a numerical approach or a geometrical approach, with both providing appropriate answers. The size of the floor depends on how many people are to stay in the *lávvu*; the steeper the walls are, the smaller the floor's area. In earlier times, people could determine from a distance how many people lived in a *lávvu*, based on the angle between the wall and the ground. The *lávvu* floor is covered with layers of *duorggat*, twigs in appropriate length that are cut from willow or birch. Eye measuring is used to estimate the amount of *duorggat* needed. The students used a trial and error approach to determine this, while skilled people fetch the correct amount first time.

The students raised a *lávvu* near the school. The teachers focused the students' attention on the three *válldahat*. The students also made a mini *lávvu*, which became a gift that the students enjoyed giving to an old people's home. The model's scale was 1:8. Afterwards the teachers regretted that they had chosen this scale, because the task would have required more mathematics if the students had to decide the scale themselves. Still the model proved mathematically challenging for the students, who had to choose materials and decide how to make everything in correct proportions.

### **Method**

Five teachers from *Guovdageainnu nuoraidskuvla* participated in both workshops and their responses to the workshop are analysed in this paper. They work in a school where North Sámi is main language and were educated as Sámi teachers. The five teachers Bigga, Duiir, Vide, Sire and Aile are north Sámi native speakers and experienced teachers who teach two, three or four subjects each. Two of them teach *duodji*, four of them teach mathematics, and four teach Sámi language. The work between the workshops contributed to strong cooperation between the teachers in these three subjects. Sámi language and *duodji* are subjects that, among other things, aim to strengthen the students' cultural

identity. At the bequest of the researchers, the participants wrote about their expectations and experiences of the workshops at the beginning and end of each day. Fyhn et al. (2016b) studied relations between teachers' *autonomy* and their development of a culturally responsive mathematics exam. In this study, we chose to focus on more aspects of self-determination. In alignment with self-determination theory (Deci and Ryan, 2012), we analysed the teachers' writings in regard to a) being *competent*, b) being *autonomous* and c) being *related* to others. Designing and implementing a culturally-responsive teaching unit about *lávvu* requires the teachers to have the necessary *competence* about how to integrate cultural knowledge with mathematics teaching; this is an example of what Kirmayer et al. (2009) call community resilience. As well, the teachers need a capacity for and a desire to experience *autonomy*; that the work is regulated by themselves and that their integrity is kept through the work. When teachers from one school work together as a group, they are *related* to others and not alone in facing possible resistance or other difficulties in implementing a culturally-responsive teaching unit.

### The teachers' experiences of self-determination during the workshops

The teachers' expectations and experiences are analysed with respect to the three issues *autonomy*, *competence* and *relatedness* to others (see Table 1). *Competence* was identified as the ability to include two community resilience factors i) Sámi language competence and ii) traditional ecological knowledge in the teaching of mathematics. *Relatedness to others* could be separated into three categories, relatedness to other teachers at their school, relatedness to teachers at other Sámi schools and relatedness to (teachers from) other Indigenous peoples. Before the workshops, the teachers' expectations mainly concerned their individual *autonomy* and *competence*, but during the workshops, most of their discussions of their experiences focused on *relatedness to others*. The analysis of the written notes reveals the teachers' need for *autonomy* manifested itself as a need for encouragement and for ideas or inspiration. These findings are in line with Fyhn et al (2016b).

Autonomy	Competence	Relatedness to others
Inspiration/ideas from others Becoming encouraged Awareness about competence	Include resilience factors: a) Sámi language and b) traditional ecological knowledge in mathematics teaching	Other teachers at their school Teachers at other Sámi schools Other Indigenous peoples

**Table 1: Framework**

The first morning, the teachers expressed their expectations towards the workshops. Sire and Aile referred to a need for supported *autonomy*, "I hope that I dare to do more interdisciplinary work", (Sire, expectation notes, March 2, 2015) and "Hope it motivates to more interdisciplinary work", (Aile, expectation notes, March 2, 2015). Vide, Aile and Duiri expected to hear about experiences with including resilience factors in mathematics teaching, "to get some ideas and hear about some experiences with culture-based mathematics", (Duiri, expectation notes, March 2, 2015). Aile expected ideas about how to connect different subjects, and Vide (expectation notes, March 2, 2015) wrote "To get input from other teachers about how to integrate more subjects in an interdisciplinary work where all subjects feel included". The teachers' references to interdisciplinary work are in line with Gay (2013), who points out that interdisciplinary work leads to collaboration, plus expectations

about knowledge. Interdisciplinary work in this setting means mathematics that treats Sámi traditional knowledge with dignity and respect. Nystad et al. (2013) identified traditional knowledge as a community resilience factor. Ability to integrate resilience factors was among Bigga and Sire's expectations. Bigga (expectation notes, March 2, 2015) expected to "be able to base more of the subject mathematics on culture".

In the experience notes, four of the teachers explicitly referred to a lecture about other Indigenous people, "We have learned about others' challenges, Indigenous thinking and perspectives", (Duiiri, experience notes, March 2, 2015). This is categorized as *relatedness* to other Indigenous peoples, "we have learned that other Indigenous peoples have many things similar to us, the same challenges", (Sire, experience notes, March 3, 2015). Four of the five teachers had experiences that concerned their *relatedness* to other teachers at their school, like "the final part with concrete reflections and discussion/talk about *duodji*/mathematics at our school was very useful.", (Bigga, experience notes, March 2, 2015) and "good to focus on culturally based mathematics again, so that we can coordinate it in our school's plans", (Vide, experience notes, March 2, 2015). The second day of workshop one, the notes mainly concerned *relatedness* to other teachers at their school and to other Indigenous peoples, "the group work constitutes a basis for further work at our school. Informative to see that other Indigenous people have similar thoughts about this work. We see that they have similar challenges" (Aile, Sire, Duiiri and Vide, experience notes, March 3, 2015). Bigga also noted that she experienced *relatedness* to teachers at the other Sámi school.

None of the teachers referred directly to being *competent*, but three of them made implicit references to this: "Alan Bishop's six fundamental activities makes us teachers more aware of our actions, teaching and thoughts about mathematics and language", (Duiiri, experience notes, March 3, 2016), "I become more aware of my solid knowledge about Sámi culture. I can base more of my teaching on this knowledge... The theoretical part was more useful this time" (Sire, experience notes, March 2, 2016). Three of the teachers referred to supported *autonomy*, which was caused by the increased awareness about their *competence* and the fellow teachers' positive attitude and contributions to the workshop. These are examples of overlap between the basic needs *autonomy* and *competence*; the three basic needs do not constitute distinct categories.

The analysis of the second workshop's experiences mainly reveal *competence* and *relatedness* to others. Four teachers pointed at *competence*, Aile wrote, "the lecture about language and mathematics was very interesting, because I could see relations between Sámi language and mathematics", (experience notes, October 21, 2015). "I become more and more conscious about my own solid knowledge in Sámi culture, I can use this in my teaching", (Sire, experience notes, October 21, 2015). All five teachers pointed to the importance of *relatedness to others*. "The sessions where each school worked together, was very developing for us... The sharing of experiences was useful, between schools as well as within each school" (Vide, experience notes, October 21, 2015). Sire wrote, "It has been informative to learn about the international, and gives a wider spectre to think about other people's situations". The teachers had to start the last day one and a quarter hours earlier, in order to have a Skype meeting with two Māori mathematics teachers/researchers in New Zealand. The Skype meeting took place the day after the workshops' final conference dinner and the early morning attendance confirmed the participants' commitment to talking with the Māori teachers/researchers. They really looked forward to this meeting. The analysis reveals that three of the teachers experienced

*relatedness* to other Indigenous people from the Skype meeting: “This day has been useful in many ways ... what Uenuku [Fairhall] said about the importance of how you teach mathematics ... throw away the textbooks and teach mathematics at theme level :-)”, (Aile, experience notes, October 21, 2015).

## Conclusion

The teachers expected increased *competence* and supported *autonomy* when they joined the workshops. They had no expectations regarding *relatedness* to others, but this seemed to become their most characteristic way of describing their experience. The analysis of the teachers’ needs for *autonomy*, *competence* and *relatedness* to others identified the ways in which these needs appeared. Subtypes of the three needs revealed information about the important factors that the teachers considered that they needed to succeed in developing their self-determination. Regarding *autonomy*, the teachers expected and experienced inspiration and being encouraged. They experienced *competence* in regard to relating mathematics teaching to the two community resilience factors i) Sámi language competence and ii) traditional ecological knowledge. *Relatedness* to others was linked to: Indigenous peoples; other teachers at their school; and teachers at other Sámi schools. The teachers’ notes also revealed that they would have benefitted from group work related to the introduced theory, but this was not fulfilled. They wanted and expected to learn more about how to integrate culture in their mathematics teaching; culturally responsive mathematics teaching.

The use of self-determination theory as a methodology for understanding teachers’ perceptions about culturally-responsive mathematics teaching reveals that the teachers’ development is influenced by several cooperating factors; inspiration and encouragement, working with theory and experiencing relatedness to other Sámi teachers as well as to other Indigenous people. Future workshops need to link culturally responsive mathematics teaching more closely to teachers’ group work.

## Acknowledgments

The Norwegian Research council funded the workshops that made this paper possible. The teachers at *Guovdageainnu nuoraidskuvla*, Kautokeino lower secondary school, have shared their experiences.

# Class, ‘ability’ groups and mathematics in English secondary schools: A review

Colin Jackson

Independent academic, England; [colinfjackson@hotmail.com](mailto:colinfjackson@hotmail.com)

*In an age where neoliberalism reigns, the predominance of ‘ability’ grouping as an organizational strategy in mathematics classrooms in England is now virtually unchallenged: it is seen as natural and ‘common-sense’ by the population at large and by the vast majority of mathematics teachers. This is despite the large volume of research which shows it has no effect on attainment overall but has a deleterious effect on the well-being of many children. ‘Ability’ grouping is a social justice issue as it always disadvantages someone. In this review, I examine how it continues to disadvantage working-class children in England.*

*Keywords: Ability, ability grouping, all-attainment.*

## **Preamble: Class, schooling and the legitimization of inequality in a neoliberal age**

Why does education, “increasingly positioned as the new panacea for the masses”, lead to the majority of working-class students feeling “a sense of educational worthlessness?” (Reay, 2006, pp. 296–297). To answer this question we must first understand that since the mid-seventies, particularly in the UK and the USA, neoliberalism has been the dominant governmental discourse. Neoliberalism is a political ideology that seeks to reduce and limit the role of government in all areas including in the public sector, believing that markets result in greater efficiency and “inequality is a result of individuals’ inadequacy” (Hursh, 2005, p. 4). Neoliberalism has appropriated the desire to want to “get on” translating it into “aspiration”, a device that disguises the social and economic barriers that hinder the working class from doing so, shifting the responsibility for “people’s opportunity to succeed or fail from the state onto individuals” while replacing “political concepts such as class, democracy, exploitation, solidarity, justice, dignity and rights” (Tyler & Bennett, 2015, p. 6). Thus students, lacking an alternative, come to accept as natural the unequal way that society is structured. This process, termed the legitimization of inequality by Bowles and Gintis (1976), leads those at both the top and bottom of society “to see themselves as largely responsible for their own places in it”. Reay (2006) sees class as

everywhere and nowhere, denied yet continually enacted [...] while the privileged, for the most part, continue to [...] ignore its relevance to lived experience. (p. 290)

The education system currently works in favour of the middle classes and is underpinned by their values (Zevenbergen, 2001). Reay (2006) says working-class students are frequently positioned as inadequate learners with inadequate cultural backgrounds: she says ‘ability’ grouping is used to “fix failure in the working classes while simultaneously fixing them in devalued educational spaces”, making some students “feel stupid” (p. 298). It is ‘ability’ grouping which is the focus of this paper.

## **Introduction**

In England, only around the top 60% (Ofsted, 2012) achieve a ‘pass’ grade at age 16. Working-class students are significantly over-represented in the other 40% (Gillborn & Youdell, 2000). Further, only 24% of white working-class boys on free school meals gain five good GCSEs (the public

examination at 16) including mathematics (Wigmore, 2016). This matters not least because, intentionally or otherwise, mathematics is used as a filter to many vocations and academic institutions (e.g., Stinson, 2004). One major barrier to achievement is putting students into ‘ability’ groups.

The aim of the study on which this paper is based was to explore the available research on ‘ability’ grouping and included reports on overall attainment and personal and social outcomes. In the main, the study focussed on research and reviews of research undertaken since the start of the eighties although important research studies from earlier periods were also included. The review included both quantitative and qualitative studies. The review was initially conducted using Google Scholar and the British Education Index database. The references of relevant articles were then scrutinised systematically for further pertinent references which were similarly scrutinised and followed up. The arguments and conclusions presented in this paper draw on the whole study; limitations of space mean that only a minority of sources can be cited.

Research on ‘ability’ grouping indicates that it has little, if any effect, on attainment overall but has long term detrimental effects in terms of personal and social outcomes (Nunes, Bryant, Sylva, & Barros, 2009; Boaler, 2005). Moreover, the social effects of ‘ability’ grouping “exact a social price, as ability levels largely overlap with socioeconomic differences” (Cahan, Linchevski, Ygra, & Danzinger, 1996, p. 30): It is inequitable and needs to be challenged. As Slavin (1990) argues, ‘ability’ grouping can be seen as an affront to basic ideas of democracy. ‘Ability’ grouping is a social justice issue because it always disadvantages somebody; and in England, amongst others, it disadvantages working-class children: this is what I explore here in the context of secondary mathematics.

### **Class and ‘ability’**

On arrival in secondary school, many middle-class children are already academically more advanced than working-class children as their education-conscious middle-class parents will have endeavoured to ensure their children have secured a place in the best performing junior schools (Lacey, 1970, p. 35). In addition, teachers' beliefs frequently lead to lower expectations of working-class children (Zevenbergen, 2003). Working-class students lack the social and cultural capital that the middle classes possess. This difference in capital legitimates the failure of working-class students with middle-class students' success being seen as the result of hard work or natural ‘ability’ rather than class-based inequalities (Bourdieu, 1992). Hence many working-class children start school at a disadvantage compared to many of their middle-class peers as they are less well equipped with the tools necessary to do well in school. One pattern of response to this is that of rebelling against a system that predisposes them to do badly, committing themselves to behaviour patterns which means that their work will stay poor (Lacey, 1970, p. 58).

One important effect of grouping by ‘ability’ is that middle-class children have minimal contact with those working-class children who are less well behaved (Ireson, Clark, and Hallam, 2002). Students who lack the social knowledge for what is seen to be appropriate behaviour (Zevenbergen, 2003) by teachers will tend to populate the lowest sets. Those who do succeed in making it into the higher ‘ability’ groups soon discover that to succeed in school they must conform to the accepted middle-class behaviour norms; failure to do so causes a descent into the lower attaining groups. Thus there is a self-correcting mechanism for dealing with children who do not conform.

Underlying the issue of ‘ability’ are issues of power and culture and hence whose ways of knowing are dominant. ‘Ability’ grouping is not a neutral disembodied organisational practice. ‘Common sense’ conceptions of ‘ability’ and intelligence are at the heart of schooling and the ‘ability’ discourse is part of an ideological battle defining children with lower socio-economic status (SES) as being expendable (Oakes, Wells, Jones, & Datnow, 1997): Attainment grouping serves purposes in schools other than that of teaching and learning. Schooling is designed to reproduce the current social, political and economic systems rather than to provide a meritocratic route to success in adult life (Oakes, 2005). Further the performativity regimes (Ball, 2003) imposed on schooling have created a climate whereby failing to conform to prevailing discourses carries huge risks to schools and to individual teachers. ‘Ability’ grouping measured by some form of assessment is seen as risk free and, in mathematics, is virtually unquestioned (Hallam and Ireson, 2003).

Contemporary English society assumes that middle-class values are superior to working-class values and hence the working classes need to ‘aspire’ to join the middle classes (Jones, 2011). The values that working-class children bring to school are neither recognised nor valued by schools while the abilities they bring to school are ignored at best and indeed are thought to be detrimental to a good education (Delpit, 2006). This feeds into the informal judgements about intellectual ‘worth’ noted above. In addition, in general, working-class students will not understand the mechanisms required to succeed in the curriculum as they will not have the cultural capital to ‘play the game’ that is involved in the learning of mathematics (Bourdieu & Passeron, 1990).

### **Student attainment and the idea of ‘ability’**

‘Ability’ is currently used as a proxy for intelligence (Wilkinson & Penney, 2014) and ideas that would normally be discarded are taken as ‘common sense’ when the discourse is about ‘ability’ rather than intelligence. Viewing ‘ability’ as innate has been a long established presumption, held to be true by the general population and by many teachers (Marks, 2016). This ‘common sense’ view leads directly to putting children in groups of the same predetermined ‘ability’ in order to teach them effectively (Francis et al., 2016). For many children this approach is damaging academically and socially; it is damaging nationally and is contrary to the stated aim of raising overall attainment.

Dweck (2000) has challenged this view of fixed ability, showing that a belief in growth mindsets, that progress is in large part down to effort and is not restricted to those with ‘ability’, enables students to make more progress and achieve higher. Grouping students heterogeneously is supported by a very large body of research which indicates that it improves educational outcomes (e.g., OECD, 2013). Despite this the current climate is unfavourable to all-attainment teaching. Indeed, it is often viewed as inimical to good teaching. The pressure on schools to conform to this view coupled with the tendency of teachers to replicate how they have been taught ensures that ‘ability’ grouping is almost universal in mathematics classrooms in England in contrast to much of the rest of the world.

‘Ability’ grouping sends a clear message that only some can do mathematics and that this is due to some type of ‘natural ability’ (Marks, 2016), a message some children (currently about a third) receive as early as age 4. Early research reviews (e.g., Sukhnandan & Lee, 1998) found that studies on ‘ability’ grouping produced few conclusive or consistent findings but recent research (OECD, 2013) indicates that where students are highly stratified, as in the case of setting, there is a wider range of achievement than when they are taught in heterogeneous groups. Hoffer (1992) reports that “the

conditions under which [‘ability’] grouping benefits all students (or at least helps some and does not hurt any) do not generally exist” (p. 223).

Comparisons between countries may be misleading and in analysing the effects of ‘ability’ grouping it can be difficult to separate out factors. Nevertheless, research carried out in England and in the USA does show significant similarities: in the USA students in high tracks gain more than students in lower tracks (Slavin, 1990) while, in England, there is a consistent tendency for children of all ‘ability’ levels who are placed in lower sets to attain less than if they had been in heterogeneous groups (Bartholomew, 2001). A consensus is emerging that, whilst not necessarily raising the level of outcome for higher attainers, all-attainment teaching does not significantly suppress it (Francis et al., 2016).

### **Allocation of children to ‘ability’ groups**

Early grouping by ‘ability’ has long-term implications for children’s educational opportunities (Boaler, 2005). Once a child is placed in a particular group it is very difficult to change because of differences in curriculum content and the pace of teaching (Wilkinson & Penney, 2014). The allocation of children to ‘ability’ groups is claimed to be objective with children being allocated on the basis of their prior performance; the process is portrayed as highly refined with children accurately allocated. However, in English secondary schools, although perceived ‘ability’ is found to be the main predictor of set, it is a relatively poor one. Schools have multiple reasons for the allocations, many informal and based on insubstantial evidence. Children with higher SES and/or ambitious middle-class parents are more likely to be assigned to higher sets. Children seen as disruptive or poorly behaved, the perception of which is linked to class (Bartholomew, 2001), are more likely to be in bottom sets (Muijs & Dunne, 2010). Boaler, Wiliam, and Brown (2000) found that working-class students in the UK tended to be placed in a lower group than would be expected on the basis of their attainment alone as a result of the school’s desire not to alienate the most powerful (and highly valued) constituencies of parents (p. 130), a pattern also found in schools in the USA (Oakes, 2005).

### **‘Ability’: Beliefs and practices of teachers**

In Britain, many teachers are philosophically opposed to mixed ‘ability’ and even where children are in mixed ‘ability’ classes the teachers practice in-class grouping (Marks, 2016). Oakes (2005) suggests that people unquestioningly continue the practice of ‘ability’ grouping because it is seen as being part of the ‘natural’ order of schools (p. 191). Lacey (1970) reports that the teachers gave the following reasons as justification for the introduction of streaming in *Hightown grammar*: It would make the teaching

more efficient and [...] facilitate the learning process for all [...] [working in] the best interests of the individual pupil, even when relegating him to the bottom stream. [If he remained in the same group he would] either hold them up [higher attaining pupils] or [...] become demoralised, and fall further behind. [...] He would be able to proceed at a more suitable pace [...]. (pp. 74–75)

Oakes (2005) evidences that the assumptions on which ‘ability’ grouping is based are unjustified, while teachers’ perception that “teaching is easier when students are grouped homogeneously” may be because this is the classroom organisation they are used to. If they embraced the use of different organisational structures where the students cooperate they might similarly find teaching is easier in heterogeneous classes. Moreover, she says “these [classroom] differences are institutionally created

and perpetuated by tracking” (p. 194). Most of the benefits of ‘ability’ grouping are benefits for teachers and schools whereas most of the disadvantages concern the negative effect on students (Hallam and Ireson, 2003). Teachers treat children differently depending on their conception of their ‘ability’ (Bartholomew, 2001). Low attainers and high attainers who produce work of a similar standard find their work viewed quite differently (Marks, 2016). Higher attainers are constructed as well motivated, hardworking, well behaved and capable of independent working and thought whereas low attainers are constructed as poorly motivated, badly behaved (Wilkinson & Penney, 2013), incapable of independent working and thought and in need of repetitive tasks which require lots of practice (Watson & De Geest, 2005). In addition to this, there is a tendency for teachers assigned to high ‘ability’ groups to be both more competent and more motivated.

Hence the set a pupil is in can be crucial to their attainment. Students in top sets are expected to work faster covering work in more depth while pupils in low sets have a reduced curriculum where there is less discussion, more repetition and more structured work including merely copying off the board (e.g., Boaler et al., 2000) with lower attainers being deprived of role models of more successful learners (Hornby & Witte, 2014). Lower attainers find it more difficult to acquire ‘basic’ knowledge in sets compared to non-setted groups (Fuligni, Eccles, & Barber, 1995) while high level content may only be made available to high attainers (Cahan et al., 1996). Lower expectations of low attainers are communicated through a number of mechanisms. They are given easier work which they frequently repeat and the work they are given is broken down in smaller steps so they cannot make for themselves the connections needed to understand the mathematics they are doing. Their teachers talk *about* them differently and talk *to* them differently. They are described as being incapable of concentrating and teachers adopt a more authoritarian mode of talking to them (Watson & De Geest, 2005). Moreover, behaviour is constructed very differently in high attaining and low attaining groups. Bartholomew (2001) and Marks (2016), for example, report that teachers’ focus on *learning* in high attaining groups while in low attaining groups they focus on *behaviour*.

### **‘Ability’ grouping: Concluding remarks**

Four main conclusions emerge from the literature review. Summing up:

1. *‘Ability’ grouping remains a class issue* as working-class students are disproportionately placed in lower sets (Bartholomew, 2001) becoming demotivated and underachieving as a result. The preponderance of middle-class children in the upper sets show that grouping by ‘ability’ favours the middle class. In a socially just world all students would have *the opportunity to attain equally*, unrestrained by external factors such as perceived ‘ability’. It is the case that when children from the working class have the same opportunities as middle-class children they can attain as highly (Boaler, 2005) though lower attaining students may need additional support so they can reach the higher expectations (Rubin & Nogura, 2004).
2. *The beliefs and practices of teachers* may be key to improving the outcomes for working-class students. They need training in order to teach all-attainment classes effectively. Teachers who hold conventional conceptions of ‘ability’ and intelligence may be the greatest obstacles to reform as they actively resist changes to the curriculum. Their beliefs can lead to resistance to change (Hynds, 2010) and they may enlist *the support of parents who are part of the dominant class* and who fear change will disadvantage their children (Oakes et al., 1997).

3. If ‘ability’ grouping worked as its supporters claim it works, then social class would be of no import, a child’s behaviour would be irrelevant and each child would be able to develop appropriately. *Allocation to ‘ability’ groups* would be commensurate with students’ current attainment and they would be constantly monitored and re-assigned to the correct group throughout their school careers with a mix of working-class and middle-class children reflecting the profile of the intake. However, as well as middle-class children having more economic capital they also have more cultural and social capital than working-class children. Middle-class children’s *understanding of the rules of the game* that is school is much more profound and they can use the rules much better to their advantage.
4. ‘Common sense’ conceptions of ‘ability’ are at the heart of schooling. A technicist approach to reform will not work as it assumes resistance to changing ‘ability’ grouping is rational. ‘Ability’ grouping is an ideological battlefield. Teachers in the main are, unsurprisingly, convinced by the powerful dominant discourse of individualisation accompanied by a natural ordering produced by ‘ability’. Alongside, powerful high-SES parents use issues of intelligence, ‘ability’ and merit to exercise power and control enabling them to secure high ‘ability’ groups for their often less than qualified children. A wholesale restructuring of school expectations and culture is required (Oakes et al., 1997) in order to succeed in providing a more just experience for working-class students in secondary mathematics classes in England.

# Content-related and social participation in inclusive mathematics education

Judith Jung and Marcus Schütte

Technical University of Dresden, Germany; [judith.jung1@tu-dresden.de](mailto:judith.jung1@tu-dresden.de)

*In the 1980s, the WHO presented a differentiated model of disability. The central feature of disability according to this model is not the impairment but the resulting limitation in social participation. The UN Convention on the Rights of Persons with Disabilities (CRPD) goes a step further by demanding that persons with disabilities must have access to an inclusive school education together with persons without disabilities. From our point of view, not only social but also content-related participation is important for an inclusive school education. The following theoretical paper seeks to explore a theoretically grounded concept of participation in mathematics classes for a planned exploration of how these forms of participation are implemented in inclusive mathematics education in Germany.*

*Keywords: Inclusion, student participation, interaction.*

## Introduction

In Germany, most children first attend primary school from the age of five or six to nine or ten and are then separated by a supposedly achievement-based selection process into different school forms. This is a system that has long been criticised in several respects (Muñoz, 2007). Furthermore, from the mid-18<sup>th</sup> century a parallel branch of schooling for children with special educational needs was established alongside primary school and the four types of secondary school. The special needs school system continued developing into the 2000s, with different schools specialising in particular needs, e.g. social-emotional development, learning, language, vision, hearing, or mental development. In the 2009 school year in Germany, a total of 483,267 pupils with special educational needs went to school. Of these, 387,792 (80.24%) were schooled at special needs schools and 95,475 (19.76%) in regular schools (Sekretariat der Ständigen Konferenz der Kultusminister der Länder, 2016a).

With the EU's ratification of the UN Convention on the Rights of Persons with Disabilities, this praxis of the separated school system came under renewed criticism and also its legality came into question. The UN Convention requires that persons with disabilities should not be excluded from the general educational system because of their disability (CRPD, 2007, article 24). This legal right surpasses the mere freedom of choice to attend a regular school. According to the UN Convention, adequate arrangements have to be made within regular schools in order to ensure the educational success of each individual. Though the ratification of the Convention potentially necessitated little change in other countries, in Germany it opened a political and social discussion on structural changes to the school system. Since 2009, a policy of inclusion – in the sense of integrative schooling of pupils with special educational needs in the regular school system – has been implemented in the German states. Thus, in the 2015/16 school year, 322,518 (62.34%) out of the 517,384 pupils with special educational needs attended a special needs school and 194,866 (37.66%) a regular school. The ratification of the convention therefore appears to have led to a thorough implementation process, as the number of children with special educational needs in regular schools has doubled in only six years. However, looking at the figures on the background of demographic developments, which have seen a reduction in pupil numbers, the proportion of pupils with special educational needs in the total number of pupils

in Germany clearly rose between 2009 (6.17% of all pupils between Years 1 and 10) and the 2015/16 school year (7.1%). Thus, the proportion of pupils with special educational needs who are taught at special needs schools has barely fallen. Above all, children who were attending regular schools in any case are now more commonly being given special educational needs status (Sekretariat der Ständigen Konferenz der Kultusminister der Länder, 2016a, 2016b; Klemm, 2013).

So, it seems there is still a long way to go to achieve a school system that can be described as inclusive. We follow Katzenbach (2012) in holding that there is little difference between the terms integrative and inclusive in school life. However, there are some clear conceptual differences: the idea of integration depends on a categorisation of people. There are “normal” people and “the others”, the non-disabled and the disabled who need to be brought together. The concept of inclusion, however, is based on the premise of diversity. Disability is only one characteristic among many, and school is a place where people with extremely different characteristics intermingle. Following UNESCO’s (2005) understanding of the concept, inclusion can be understood as an ongoing process to find better ways of responding to diversity.

Towards providing an empirical base for this process of changing a traditionally strongly separated school system such as that in Germany, in respect to content-related – here mathematical – learning conditions, this paper discusses some theoretical considerations on mathematical learning and learning under inclusive conditions, and synergises these for a planned research project. According to Prediger, Bikner-Ahsbals and Arzarello (2008), different networking strategies can be used to connect theories. The first strategy they mention, “having an understanding of the different theories”, can be seen as the starting point for all other strategies, allowing them to be compared, combined or integrated in a further step. Therefore, in a first step we will present specific theories for mathematical learning and inclusion theories separately before we coordinate them with each other. This can be done because the theoretical concepts have consistent assumptions. The coordination creates a conceptual framework that helps in identifying the students’ participation in inclusive settings and learning in mathematics.

## **Mathematics learning from an interactionistic perspective**

For our understanding of content-related learning in school we refer to Miller’s (1986) antagonistic differentiation between the research traditions of genetic interactionism and genetic individualism (Schütte & Krummheuer 2012). However, this is with the goal of bringing the two positions closer together. According to Miller (1986, p. 17), learning can either be anchored in the individual as a process of monologue, in the sense of genetic individualism<sup>1</sup>, or be understood as a process of dialogue between individuals, in the sense of genetic interactionism<sup>2</sup>. Miller considers genetic interactionism, in contrast to genetic individualism, to have a more convincing empirical and theoretical base, at least in relation to learning processes in the early development of individuals,

---

<sup>1</sup> Genetic individualism is in the tradition of the later Piaget and Kohlberg (Miller, 1986, pp. 15 ff.).

<sup>2</sup> Genetic interactionism draws from the basic assumptions of sociological and psychological studies such as those of Durkheim, Mead, the early Piaget and Vygotski. These studies see social cooperation or interaction as fundamental to individual learning processes (Miller, 1986, pp. 15 ff.).

which he considers “fundamental”<sup>3</sup>. Above all, in primary school, where young learners come together, Miller sees learning processes taking place which are primarily collective and based on dialogue. Miller (1986, p. 223) describes individualised learning processes as “autonomous learning” and attributes them to the later development of the individual, locating these processes in moments of reflexive consolidation of things originally learned collectively. From a social-constructivist perspective, learning cannot be seen as a primarily internal cognitive restructuring process. Rather, it is a dualistic process which takes place both within the individual, in the sense of cognitive restructuring, and within interaction processes in which the person participates, which go before these restructurings (Sfard, 2008).

This kind of sociological or social-constructivist consideration of learning processes has in recent years gained increasing influence in the theoretical design of content-related learning, and has been taken up and further developed in mathematics education research (Lerman, 2000). Both nationally and internationally, mathematics has increasingly come to be seen as a cultural tool, constructed and mediated through language (Schütte, 2014). Since the mid-1980s interactionistic approaches of interpretive (classroom) research in mathematics education have engaged with the sociologically based social-constructivist perspective on learning processes (e. g. Bauersfeld, 1988; Krummheuer, 1992) using theories of symbolic interactionism (Blumer, 1969). With this kind of basic theoretical understanding of content-related learning the concept of collective argumentations gains central significance in the analysis of mathematical learning processes. According to Krummheuer and Brandt (2001), pupils are usually engaged in interaction processes in the classroom conversation, producing an argumentation in the totality of their actions. In this way, participation in a collective argumentation concerning statements about (mathematical) content, terms and/or methods creates the basic conditions for learning opportunities. This interplay of individual and social constituents is difficult to describe. If participation in collective argumentation provides orientation and convergence, then learning success can be seen as the improved coordination between individual attributions of meaning and the results of the interactive negotiation of meaning in the respective group. On an interactional level, this is manifested in an increasing adaption of the (verbal) acts of the learners to argumentations established collectively over the course of several interactional situations. The coordination of an individual’s interpretations and actions can be reconstructed empirically as the increasingly autonomous adoption of steps of action within the collective argumentation. The learning of mathematics can thus be described as the “progress” of participation in mathematical collective argumentations. This idea of learning through participation can be linked back to the notion of equal opportunities for participation in educational institutions, according to the Convention on the Rights of Persons with Disabilities. Thus, the following will seek to explain how participation in learning processes in school can be understood from an inclusive-educational perspective.

### **Increasing participation as a goal of inclusion**

Among the goals that are being set by the increasing implementation of the inclusion concept in

---

<sup>3</sup> These kinds of learning processes concern the development of “rationality, or rational knowledge structures” (Miller, 1986, p. 15).

teaching, ignoring for a moment the thoughts outlined above on the different understandings of the learning of mathematics, it can be noticed that providing all pupils with equal opportunities for participation in learning processes occupies a central position. This reflects UNESCO's principle whereby

Inclusion is seen as a process of addressing and responding to the diversity of needs of all learners through increasing participation in learning, cultures and communities, and reducing exclusion within and from education. (UNESCO, 2005, p. 13)

This principle, formulated in the framework of the UNESCO "Guidelines for Inclusion", is reflected in the UN Convention on the Rights of Persons with Disabilities (CRPD), ratified by Germany in 2007. The Convention states:

Persons with disabilities are not excluded from the general education system on the basis of disability. Persons with disabilities can access an inclusive, quality and free primary education and secondary education on an equal basis with others in the communities in which they live. (CRPD, 2007, article 24)

In addition, the Convention asserts that children/persons with disabilities should be supported within general education, according to their needs, to best progress their education. A "full and equal participation in education" (CRPD, 2007, article 24) should be made possible for them. Some years previously, Booth and Ainscow (2002) already published an "Index of Inclusion", which is intended as a tool to support an inclusive school development and contains a detailed description of how barriers to learning and participation for all learners can be dismantled. Here, too, the goal of a "greater participation of students in the cultures, curricula and communities of their schools" is cited (Booth & Ainscow, 2002, p. 2). In summary, according to the mentioned literature inclusion can be understood as an unending process of increasing learning and participation for all students (Booth & Ainscow, 2002; UNESCO, 2005) – and thus also as an ideal, which will never be fully realised but is already applied with the start of the process of increasing participation. However, it seems necessary to clarify at this point what is understood by full and equal opportunities of participation. Therefore, in the following the concept of participation in learning processes is developed. According to Booth and Ainscow (2002, p.3), participation can be understood as "learning alongside and in collaboration with others in shared learning experiences". They see participation as demanding active involvement in learning processes and the opportunity to express one's own learning experiences.

Adopting a broader definition developed to consider social structures, according to the German sociologist Bartelheimer (2008) five requirements can be distinguished for a sufficiently defined term of participation. These five requirements for a general social concept of participation can be transposed onto teaching processes in the classroom as follows. First, Bartelheimer states that participation is only to be understood as historically relative. Transposed onto the school situation, participation in processes that enable learning is to be understood only in relation to the given education system and fundamental features of the educational processes and paths that currently predominate. Secondly, participation is multidimensional and there are always different forms of participation. One approach to consider participation in teaching processes in various dimensions is provided by Roos (2014), who distinguishes a spatial, social and didactical/content-related dimension. Thirdly, participation does not describe a simple in or out; rather, there are always gradations of

unequal participation. Furthermore, participation appears as a dynamic concept, rather than a condition at a given moment. Lastly, Bartelheimer (2008) emphasises that participation is active, that is, it is striven for and realised through action and in social relationships. Summarising the last three points of Bartelheimer's participation concept for teaching processes, an exclusively quantitative description, that is, a definition of participation in the sense of "takes part/does not take part", appears inadequate. As far as possible then, the description of participation must be considered qualitatively over a longer time-frame, and might only be valid for the respective participating individuals within this time-frame, since this is a question of a dynamic concept that is constantly changing.

The underlying research project is concerned with describing scenarios from the process of progressing inclusion in German schools, and on this basis to design steps to further this process. To enable a description of this process the concept of participation in inclusive mathematics learning needs to be rendered more precisely, in order to open it to empirical description and analysis. For this purpose, in the next section the theoretical understanding of mathematics learning and the theoretical conception of participation in inclusive discourse, discussed individually above, are brought together.

### **A theoretical concept of participation in mathematics education**

With the goal of describing the process of inclusion in mathematics learning in German schools using a participation-theoretical model, we take the above theoretical considerations on inclusion as a starting point and link these to our essential theoretical assumptions on mathematical learning. Taking Bartelheimer (2001) into account, it seems important to adopt a longer-term perspective on participation (cf. also Brandt, 2004). Although Krummheuer and Brandt (2001) go so far as to attempt an interactionistic theory of participation in mathematical learning, focusing also on individual learning using their system of categories, content-related learning and individual cognitive restructuring unfortunately seem to fall out of focus. Yet, our research is also and especially guided by looking at content-related learning. In this context, we are not trying to leave the basic interactionistic orientation. Instead we are trying to connect the ideas of learning and participation within interaction with individual learning. From an inclusion-theoretical perspective, realising inclusive teaching is a question of increasing participation. In order to make this useful for empirical investigations, Bartelheimer's (2008) more general participation-theoretical model is taken as a basis and combined with the participation-theoretical understanding of mathematics learning (e.g. Krummheuer, 1992; Sfard, 2008). To be able to describe participation in inclusive mathematics learning in Bartelheimer's perspective, one has to view it in relation to its historical context. The image of mathematics learning for all learners is taken to represent present conditions. Whereas at the end of the 1970s, national and international research on mathematics in primary schools was still focusing above all on the learning of skills and isolated concepts of a 'complete mathematics', with an emphasis on arithmetic, a shift took place around the mid-1980s. A new understanding of mathematical learning developed. According to this, children in school not only needed to acquire mathematical skills, but also to discover and understand the mathematical concepts behind them, and to argue and communicate with teachers and classmates using these concepts in order to ultimately be able to autonomously give reasoning for mathematical actions (Boyd & Bargerhuff, 2009). However, in adopting an orientation towards this image of mathematics learning we nevertheless acknowledge that it is (still) controversial for learners with special educational needs in special needs schools. The above-described changes in the understanding of mathematics learning can certainly be

seen also in the area of special needs education in mathematics (Sullivan, 2015). But these changes are the subject of heated debate and are taking place in the context of a (tried and tested) teaching tradition which is characterised by a reduction of learning content, an isolation of difficulties and a “small-steps” approach with specified solutions to problems (Boyd & Bargerhuff, 2009). In addition, Bartelheimer describes participation as an active process. Participation is pursued and achieved through social action and within social relationships. Therefore, it is observable in everyday mathematics teaching as active participation in classroom interactions. Bartelheimer also describes participation as multidimensional, which we have linked to Roos’ (2014) spatial, social and didactical/content-related dimensions in the above theoretical section on inclusion. The spatial dimension of participation, according to Roos, relates fundamentally to how much time a student is spending in the same room as his or her classmates. However, in our perspective it also relates to the spatial configuration during time spent learning together in the mathematics classroom, for example in rotating through different tasks or group work. The social dimension focuses on social relationships (with fellow pupils, teachers and pedagogical staff) which emerge in mathematics teaching and which mediate to a great extent an increasingly autonomous participation in collective argumentations. The third dimension addresses participation in didactical/content-related negotiation. Didactical inclusion relates to pupils’ participation in subject teaching, focusing on their engagement with the teaching approach and content, as well as any explanations or material supplied by teachers to support the learning process. For the purposes of analysis of didactical/content-related participation, the approaches developed in mathematics education for determining participation in collective argumentations (Krummheuer & Brandt, 2001) can be made use of. With reference to Goffmann (1981), Krummheuer and Brandt (2001) distinguish two types of involvement in a lesson: the active, verbally productive act, and the passive, receptive non-verbal act. The aim is to identify the type of authenticity, originality and responsibility of speakers, and to identify for recipients the type of non-active participation. This means that mathematical learning through active participation can be distinguished from learning through non-active participation, which explains “quiet” yet successful pupils. Learning situations become beneficial for learning, according to Krummheuer and Brandt (2001), when children participate increasingly in ways which permit a shifting from minor responsibility for content and form towards greater responsibility. In this way, participation in a collective argumentation concerning statements about (mathematical) content, terms and/or methods creates the basic conditions for mathematical learning opportunities in inclusive learning settings. Since this model remains more of a formal analysis of the content-related negotiation in the conversation, it will be complemented by the curricular concept of mathematical activities, developed by Bishop (1988), in order to approach also the mathematical content of the activity children participate in. Bishop (1988) differentiates six activities – counting, locating, measuring, designing, playing, explaining – which are used for the analysis of moments of subject-specific mathematical participation, following Brandt (in press) and Johansson (2015). In addition, Bartelheimer (2008) focuses on the principal dynamic, i.e. the changeability of participation over time, and the impossibility of a dichotomous categorisation of inside and outside, participation and non-participation. These considerations are in tune with an interactive understanding of mathematics learning and are taken into account within the research project by the theories and methodologies being used. This theoretical conception of participation will be used to address the empirical aspect; the theoretical conception will be further developed through the interrelationship between theory and

praxis, with the goal of enabling a description of participation processes in inclusive mathematics. This is while acknowledging that the goal of inclusion, which has the principle of egalitarian difference (Prenzel, 2006) at its base, cannot be for all children to participate actively in class in the same way. The barriers to participation should be reduced for all children, and they should be given the opportunity for participation according to their abilities, so that they move forward in their mathematical learning process.

# The socio-politics of teacher explanation in mathematics education

David Kollosche

Goethe-Universität Frankfurt, Germany; [kollosche@mathematik.uni-frankfurt.de](mailto:kollosche@mathematik.uni-frankfurt.de)

*Despite efforts for a more student-centred teaching in mathematics education, data from interviewed German students suggest that teacher explanation is the most dominant form of introducing new knowledge and skills. From a Foucaultian standpoint and on the basis of the interview data, it is firstly argued that explanation belongs to an institutionalisation of mathematics education in which explanatory power is reserved for the teacher, leaving students with a passive role both towards learning and towards questioning mathematics as a discipline. It is secondly argued that such an organisation of teaching might be functional in identifying well-disciplined and fast-learning students through their achievements in mathematics. Thirdly, the point is made that the ignorance of research concerning the socio-political role of explanation is effective in the conservation of the socio-political functions of school mathematics.*

*Keywords: Mathematics instruction, theory practice relationship, teaching styles, student interview.*

## The role of explanation in pedagogical theory and practice

Under ‘explanation’ I understand the verbal and embodied communication of knowledge and skills from one person to another with the purpose of enabling the other to do something which the first person is already capable of. This understanding of the term is narrow, as in a wider sense, for example, explanatory texts, recorded speeches, videos and other media, where experts explain something to an anonymous audience, might be considered explanation as well. This paper has an even narrower focus on the explanations which mathematics teachers provide for their students, and it is mainly based on the situation in German schools and in the German research community.

Historically, explanation by the teacher had been a method central to any school teaching (Tenorth, 1988/2000). For example, the German philosopher Johann F. Herbart (1806/1897) developed a teaching methodology based on explanation, exercise, application and abstraction. Its popularity among both educational theorists and practitioners of the 19<sup>th</sup> century elucidates the traditional importance of explanation within the pedagogical discourse. The discussions around Herbart’s pedagogy also stand exemplarily for the problems that modern pedagogy has developed with explanation. Claiming to follow Herbart’s tradition, a group of educators, now referred to as the Herbartians, reduced Herbart’s pedagogy to its methodological aspects and developed a strict teaching plan which was dominated by teacher presentations and copying by the student. The consequent critique of the Herbartian approach at the turn of the 20<sup>th</sup> century circled around the problems of the passive and obedient role of the learner, especially on the devastating effects on learning outcomes and democratic agency. Especially writers in the tradition of German *Reformpädagogik* such as Johannes Kühnel (1916/1950) considered the passivity that learners were introduced to as expressions and requirements of the civil obedience in the German Empire which allowed for the economic misery of the masses and the outbreak of the First World War in the first place. Ausubel (1968) argues that the fight against this passivity in learning has fuelled not only *Reformpädagogik* but many alternative pedagogical agendas up to that of discovery learning in his times, and that, over time, explanation has been increasingly denounced as a teaching method which

supports despotism, ignores the individuality of learners and denies them the benefits of self-regulated learning. Explanation, suspected to conflict with the aims of liberal education, has gained a negative connotation.

We run the risk that the condemnation of teacher explanation blocks the discussion of very different roles that explanation might have in teaching, reaching, for example, from introductory explanations followed by exercises over formalising explanations in the course of individual or collective explorations to summarising explanations at the end of learning activities, from whole-class talks to individual conversations, from short inputs to extensive presentations and so on. Recent developments in educational research however aim at a rehabilitation of explanation. Kathrin Krammer (2016, p. 76; all German quotes translated by D. K.) remarks in a teacher journal's special issue on "teaching":

Many reform initiatives in the area of classroom development aim at the expansion and high-quality arrangement of self-regulated learning. Which meaning is yet assigned to teacher-centred, instructive phases – do they disappear, are they preserved, or are they rediscovered and altered?

In mathematics education research and educational policy, explanation as a teaching method is not a central field of study. The federal German educational standards for mathematics education in the grades 5 to 10 (KMK, 2003) may serve as an influential example of the discourse of educational policy. There, "explanation" is not mentioned once, nor are any other activities of the teacher. Instead, it is demanded that mathematics education provides "competences which students acquire in active involvement with manifold mathematical contents" and that it aims at "self-regulated learning" (p. 6). In the German academic discourse, recent introductions to mathematics education for prospective teachers (e.g., Bruder, Hefendehl-Hebeker, Schmidt-Thieme, & Weigand, 2015; Reiss & Hammer, 2013) do not even address how to *explain* knowledge and skills to students, and the only German book on teaching methods for mathematics education (Barzel, Büchter, & Leuders, 2007) presents 30 different methods but does not cover teacher explanations. The only recent studies in the German field discuss explanation from an epistemological (Wörn, 2014) and discursive (Erath, 2016) perspective, but could not be included in this study due to a lack of access to the publications.

The marginal position of explanation in mathematics education research and educational policy is confronted by the dominance of explanation as reported in empirical studies. The TIMSS video study (Stigler & Hiebert, 1999) compared the national teaching "scripts" of the USA, Germany and Japan, showing that both in the USA and in Germany, teachers usually introduce new knowledge by explanation. Recent empirical data, which will be presented here, propose that, at least in Germany, the situation has not changed. Despite continuing efforts in mathematics education research and educational policy to change the classroom culture towards forms where the teacher and her explanations play a less central role, interviewed 9<sup>th</sup> grade students from a variety of German schools report consistently that new contents are usually introduced by teacher explanations. Thereby, teacher explanations are not only political as they tend to establish distinct hierarchies concerning the distribution of knowledge, they are also political due to the tension between their dominance in school and their taboo in research, resulting in a structurally fostered unpreparedness of prospective teachers and a lack of support by research on this form of teaching. In this contribution, these issues are studied through an analysis of the subjectivities which students express in relation to teacher explanations in the mathematics classroom. The leading question is what role explanation plays in the development

of the students' subjectivities and where the socio-political dimensions of these forms of subjectivity may lie.

## **The student perspective**

As part of a research seminar at the Universität Potsdam in 2016, master students orally interviewed 23 students from grade 8 to 10 in regular public schools in and around Berlin. The interviews were conducted in school rooms in private, recorded and transcribed. All students but two, who went to the same class, attended different schools. The semi-structured interviews focussed on the students' relationships to mathematics and included the prompt "Describe what a typical maths lesson looks like!" and question "How content are you with your maths teacher?", which appeared in the interview as items 2 and 3 of 12 stimuli in total. These items triggered answers which mentioned teacher explanations. Although explanation was not a topic that was explicitly addressed in the stimuli, we found it surprising that *all* students reported that their teachers usually explain new topics to the class. Only four students stated that other ways of introducing new topics, such as solving problems individually, in small groups or in whole-class conversations, were frequent, but in all cases these approaches were said to be followed by teacher explanations as well. We were also surprised that 19 students associated their confidence in their teachers with their qualities in explaining.

For my argument, it will prove important to discuss the ontological status of the students' reports and the epistemological approach taken in the analysis of the data. Here, I want to apply a Foucaultian view (Foucault, 1982, 1978/1991, 2011) to understand mathematics education as a disciplinary institution where teachers apply certain techniques for the conduct of the self and others in order to produce the expected behaviour in students, and where students, for their part, develop and enact certain technologies of the self in order to cope with these demands. The reports of school experiences and relations to mathematics cannot be understood as an objective account presented in a depersonalised language, but belong to distinct discourses around school mathematics, which are shaped by a shared knowledge of the actors. These discourses comprise values, interpretations and supposed truths whose paramount function is not to provide academic insights into any objectivity of the mathematics classroom, but to allow each individual to weave her experiences and relations into a meaningful web of explanations. Under these circumstances, each student's report should not be read as a mere account of a real experience, but as the expression of a permanent struggle to articulate experiences and relations which, from our point of view, are usually scarcely verbalised.

Given the incidental manner in which the topic of teacher explanation was touched in the interviews and the consequently low data base, this contribution will have to limit itself to the presentation, interpretation and discussion of a selected set of themes, and for that I chose to discuss the relations between teacher explanation, power relations in the classroom and the subjectivity of the learner.

## **Explanation and power relations**

The central role which teacher explanation plays in all of the 23 interviews does not only provide insights in the unbroken dominance of a teaching method which large initiatives of pedagogues have fought against for decades, but first of all documents how students integrate the teacher into their narratives of success and failure in learning. Rebecca (all names changed while still indicating the original gender), a high-achieving 10<sup>th</sup> grader, describes her teacher as "really good", "the absolute burner", who "puts it across really well", "tries to adjust and can explain really well", and holds these

attributes responsible for the learning success of her and her classmates. On the downside, the teacher's explanation qualities are also considered the source of serious complication and failure:

Interviewer: And how content are you with your maths teacher generally?

Ingo: Huh, I would say it could be better. Well, I find, some things he doesn't explain well at all. Then at home, I have to sit down and look in my book. Yeah, he does not really explain it. So, when I hear what other classes tell, they have better teachers, they all understand.

Interviewer: Is there something you'd like to change in your mathematics classes? [...]

Ingo: [If I were the teacher] I'd adapt myself to my students much more than my current maths teacher does. So, I'd go to them and ask if there's anything they don't understand, I'd do difficult exercises with them, those you need for exams [...].

Apparently, students such as the 9<sup>th</sup> grader Ingo find their learning troubled by insufficient explanation. They also show awareness that the quality of explanation varies from teacher to teacher. Rebecca and Ingo follow a narrative in which their learning and achievement depend directly on the quality of their teachers' explanations. Ingo is not content when his teacher leaves him with difficult exercises after having explained the easy ones; he demands series of explanations which also cover the most difficult tasks. Simon, also a 9<sup>th</sup> grader, is even more explicit concerning these demands:

Simon: The teacher should, when he comes to the students, when he sees from the front that students have problems, then he should go to the students or the students to him and ask. The teacher should try to explain as simple as possible, so easy, perfectly easy, so that the student understands very quickly, so that he can go on with the exercises.

Patrick, another 9<sup>th</sup> grader, says that he was "actually very content" with his teacher, who "can explain well, so that we actually all understand", but later he adds that the difficulty of the contents has been increasing since primary school:

Patrick: I believe that what he does is actually really good, our teacher, but we, with us it's simply, no idea, that we simply don't understand when he tells something. And in front, well, there are a few of our students who understand and try to somehow explain it to the others, but that doesn't help either.

The position that teacher explanations hold in the narratives of the students has specific consequences for the power relations between teachers and learners. The dependency of Rebecca's and Ingo's learning on the quality of teacher explanation documents the monopoly of expertise which lies with the teacher. Especially, the students do not report any other promising sources for understanding such as textbook study, collaborative work or learning videos. In Patrick's case, the students of his class apparently attempted to support each other, but failed. Indeed, in the narratives the teacher is presented as the only agent the students can turn to in their struggle to understand. This narrative puts the teacher in the position of an exclusive 'knower' without whose expertise and goodwill no learning is possible, and thus it releases the students into passivity. The student, whose only hope is to be presented an understandable explanation, cannot do anything but wait for that explanation. Ingo's and Simon's cries for ever better explanations show the lack of alternatives they see.

From the perspective of traditional critique as brought forward already by the *Reformpädagogik*, we could argue that these experiences simply give empirical evidence that the traditional teaching methodology of explaining and exercising leads to passive and obedient students who are denied the flexibility and effectiveness of self-regulated learning and socialised into passive and obedient social agents. From the perspective of Foucauldian governmentality, we could add that the institution of mathematics education is successful both in channelling the conduct of the students into a form where their learning is totally dependent on the teacher, and in establishing a discourse in which this organisation of the learning of mathematics is considered inevitable. Here, it is interesting to note that both teachers and learners are constantly reproducing this organisation and narrative. At this point it is only possible to guess where the motivation for this behaviour come from: While the teacher may be led by the will to be the social centrepiece of the classroom collective, channelling all power on herself, the students might eventually enjoy their passivity. Ingo's reluctance to "have to sit down and look in my book" indicates that students may indeed resist to take a more active position in their learning. This resistance is connected to a constantly reinforced economy of learning in which students aim to "go on with the exercises" and pass "exams" with as little effort as possible.

Apart from the traditional critique of teacher explanation focussing on its consequences for learning and democratic agency, the exclusiveness of approaching mathematics through the teacher leads to a specific relation to the discipline of mathematics itself. In the reports of the students, mathematics is not presented as a discipline which can be approached and understood individually, but as a discipline whose understanding depends on the support of experts. The presentation of mathematics as a discipline which is only mastered by experts and cannot be fully understood by laymen, despite all efforts of specially trained teachers, adds to the construction of mathematics as an obscure, elitist and indisputable discourse which may be used as a tool of power throughout our society. Mechanisms leading to this image of mathematics have been identified before (Dowling, 1998; Skovsmose, 2005; Kollasche 2014), but to my knowledge they had not yet been associated with distinct styles of teaching.

### **Subjectivities of listening**

Changing the focus from the teacher to the learner opens up a wide field of experiences of receiving explanations. Christian, a 9<sup>th</sup> grader, excels in some subjects but has problems in mathematics:

Interviewer: What do you think is different in maths; what's the reason you don't like it that much?

Christian: Well, I've never liked maths. Maths was never what I was good at, I always had my difficulties there. Though my parents think I'm somewhat lazy, which is true for the most part, it also gets more and more difficult and I seldom keep up with it, also because the teacher is bad at explaining.

Interviewer: How does a typical maths lesson look like at your place? Can you describe it?

Christian: Yeah well, the teacher comes in. Consequently, it's noisy of course, because she can't assert herself. In between, you're also getting distracted, and I'm no different, I admit I'm also getting distracted, doesn't let you work well, doesn't let you pay attention. [...] Everything depends on paying attention deliberately.

It may be argued that it is the teacher's task to establish the quiet environment necessary for the students' understanding of any teacher explanation. But apart from the fact that such a narrative reproduces the active role of the teacher (who has to tame the students) and the passive role of the students (who have to be tamed), this narrative does not consider the subjectivities necessary to follow this form of teaching. "Paying attention deliberately" is a technique which students have to master, not only to follow teacher explanation individually, but to establish a fruitful learning environment in the classroom in the first place. Consequently, mathematics courses which build on teacher explanation give advantages to self-disciplined learners, especially when grouped together in socially segregated schools. The privileged school marks, which such advantages may result in, may then be taken as indicators for the self-discipline of an individual. In this sense, the pervasiveness of teacher explanation in mathematics education may have an underestimated economic function.

Yet of course, concentrated listening does not guaranty understanding. Students also have to be able to understand the presented contents in the pace in which the ideas are presented. Anna, a 9<sup>th</sup> grader, claims that her teacher's explanations are too fast for her to understand:

Anna: [...] And I just find maths difficult, I don't understand it that fast. And of course, she [the teacher] does not have the patience for so many students to explain that to everybody separately. And some are simply faster in understanding concerning maths exercises, and I need a little longer and don't understand that fast.

Interviewer: [...] If your teacher realises that several students put up their hands, will she then explain it again for all of you?

Anna: She is somewhat strange in this respect. She just says that she explains in a way that we all have to understand, and then we have to cope with the exercises somehow.

Anna realises that structural constraints in the organising of her teacher's approach hinder her to offer every student an understandable explanation. But instead of questioning the methodology of teaching altogether, some teachers succeed in hiding the problem. In Anna's case, the teacher's imperative that the students "have to understand" leaves the problem with the students, who do not seem to know how to cope with it. In the case of Emma, an 8<sup>th</sup> grader, the teacher asks the students to put up their hands if something is unclear, but "as we just know that she somehow cannot explain it properly", nobody would put up a hand.

In contrast to that, 9<sup>th</sup> grader Laura explains that her mathematics teacher has successfully taught her to indeed raise questions if something is unclear:

Laura: I had her in the fifth, sixth and seventh [grade]. I liked her. She was my favourite teacher. She's retired now. She has taught me to raise questions again and again, and that's it. Or to become more self-confident, because you don't know the others, you don't know the teachers. You still have some respect for them. [...]

Interview: What do you believe the teacher could do against it [students not daring to ask]?

Laura: Oh god, that's difficult. He could pose questions, answer questions. But some don't really dare to ask. They have their private afternoon lessons, but actually this is also like a teacher. I think it's this collective. In class, you always have a position to fulfil. You are either the cool one or the somewhat quiet one or the class clown.

[...] You also notice that when fewer students are in class, the class is quieter and can work better. I believe, this also depends on the fact that you do not have to prove yourself and that you can rather concentrate on your stuff.

Laura's story documents that there are slight variations in the forms in which teacher teach through explanation, and that these variations can have severe consequences. In opposition to Emma's report of her classmates not asking in order to avoid further explanation, Laura has learned to demand further explanation if she is not confident with the explanation presented. Thus, her teacher enabled her to take a more active part in her learning and to add elements of conversation to teacher explanations. In addition to that, Laura outlines a sociological explanation for problems with explanatory phases. Exposed to the whole class, students may have an intense urge to fulfil their social role within the learning group, and that role might hinder them to engage in a lively discussion on mathematical contents.

## Discussion

The findings presented first of all shed light upon black spots in mathematics education research. Firstly, the prevalence of teacher explanation shows that decades of academic and political initiatives aiming at changes in teaching and learning arrangements have hardly affected the reality of the mathematics classroom. Although several nation-wide and regional projects have focussed on introducing learning environments focusing on active learning in Germany, teacher explanations are still reported to be dominant in the mathematics classroom. Considering the apparent ineffectiveness of previous interventions, it would be useful to dedicate more research to the understanding of the didactical and social role of teacher explanation *before* any new interventions are planned. Secondly, in light of the central role of teacher explanation in the mathematics classroom, the marginality of the topic in mathematics education research leads to blind spots in our understanding of teaching practice. Especially the socio-political dimensions of teacher explanation, which might prove antagonistic to pedagogical ideals and nevertheless functional in a systemic sense of society, deserve further study. Deeper insights could lead the way to a teaching practice which incorporates teacher explanation without constructing the student as a passive subject to mathematics. Apart from that, it may be wise to critically prepare prospective teachers for the role that they apparently assume anyway, namely that of the explaining authority.

Further research should also focus on the psychology and the socio-politics of teacher explanation. Firstly, why would teachers contribute to the narrative that it would be possible to allow a large proportion of the students an understanding through central explanation, while counter-arguments are obvious in teaching practice and have been discussed in literature for decades? Why would students contribute to that narrative against all obstacles they experience in their learning and in spite of the passive role they have to assume in this learning arrangement? And secondly, how does teaching through explanation contribute to the narrative that the understanding and mastery of mathematics is reserved to higher authorities, who can share their knowledge and skills to the extent they wish and whose expertise has to be trusted in due to the lack of approachable alternatives?

## Acknowledgment

I am grateful for the support of the master students in my research seminar at the Universität Potsdam in the winter semester of 2015/16. Without them this publication would not have been possible.

# Polish parents' views on mathematics education in Swedish preschools

Dorota Lembrér

Western Norway University of Applied Sciences, Bergen, Norway; [dorota.lembrier@hvl.no](mailto:dorota.lembrier@hvl.no)

*This paper describes the results of a survey of Polish immigrant parents' views on mathematics education in preschool. In alignment with the Swedish preschool curriculum, the results show that parents viewed learning as being connected to play. The parents to a large extent see similar frequency of mathematical activities occurring at preschool and at home. Parents often commented on children's involvement in collaboration when playing. Swedish preschools' pedagogical practices about learning through play seem to have been adopted by parents. The findings suggest that parents, like children, can be socialized into the norms and values of Swedish preschools through their children's attendance of them.*

*Keywords: Immigrant parents, mathematics, preschool, socialization.*

## Introduction

Mathematics education, as a part of everyday life, is embedded within a variety of settings. These settings include institutions, such as schools and preschools, but also homes. Within each setting, there are structures and expectations which contribute to the development of norms and values (James, Jenks, & Prout, 1998). Therefore, Swedish preschool as being framed by institutional norms and values (Skolverket, 2011), must also be considered as shaping society's understandings about the world of children and their families. As James et al. (1998) state: "Childhood diversity considers the infinite variety of the social context in which children live, leading to a deconstruction of childhood's conventional, singular and reductive form" (p. 34). As a consequence of migration, culturally diverse societies can represent different views of what kind of childhood is available and thus the learning that children should receive in Swedish preschools. Therefore, newcomers' perspectives on mathematics education in preschool can contribute to a better understanding of the variety of children's childhoods, when those views are recognized as legitimate. As part of a wider project investigating this topic, I aim in this paper to provide insights into Polish parents' views about mathematics in Swedish preschools. In 2012 Polish immigrants were the third largest group of immigrants in Sweden (Statistics Sweden, 2012), yet their views on education have rarely been investigated. My research question is: How do Polish parents view mathematics activities in Swedish preschool and at home?

## Socialization and parents' views on mathematics education

The theoretical framework for this study is socialisation, through which people who inhabit a society create it (James et al., 1998). Socialisation processes have two components, the production and reproduction of (1) norms and values and (2) skills and knowledge. Socialisation processes situate society members as needing to acquire relevant knowledge to sustain society over time and involve reproducing culture from one generation to another. As well, as the milieu in which a society operates changes, a need arises to produce new ideas and culture. Ebrahim (2011) stressed that social interactions contribute to the production and reproduction of rules and structures within a society.

Children acquire the understanding, skills and awareness of different mathematical concepts, through their experiences outside educational institutions (see for example, Brenner, 1998). This provides opportunities for children's own experiences to be the basis for developing their mathematical thinking in preschools (Lembrér & Meaney, 2015). In the Swedish preschool curriculum (Skolverket, 2011) four goals are related to mathematics: one is connected to content; while three require preschools to provide opportunities for children to develop mathematics skills, abilities and concepts. It also suggests that children should use their interests and experiences when acquiring mathematical knowledge and skills in preschool.

However, the institutional values and norms of Swedish preschools may constrain immigrant parents from being able to recognize experiences from their country of origin as being valued in the new setting (Lunneblad, & Johansson, 2012). This may have long term implications for families' involvement with educational institutions in new countries. For example, Giovannini and Vezzali (2011) focused on how contact between teachers and immigrant parents affected children in elementary schools. They found that parents' views about their role in the relationship with school can define boundaries of that role. The education institution has a role in changing those boundaries. In Goodall and Montgomery's (2014) study, parents' reflective involvement in their relationship with schools was strengthened by an acknowledgement of their contribution to children's learning. Yet language differences may impede these possibilities. Civil, Bratton and Quintos (2005) suggested that the dominant language spoken in school, can affect children's interest in identifying with their home language. As a result, children can have difficulties talking with their parents about their school work.

With an increase in immigration, there can be challenges around gaining the active participation of immigrant parents into the education system. Kaur (2010) suggested: "creating strong links between families and early childhood settings extends children's learning, fosters a sense of community and acknowledges the expertise of families" (p. 53). It has been found that when refugee and immigrant parents are included in education systems, there are academic benefits for their children (Krasteva, 2013). Yet, Whyte and Karabon (2016) found that relationships between home and school are often built on one-way communication, with information going from school to home. This creates boundaries between families and school. Wager and Whyte (2013) investigated how preschool teachers valued children's home experiences of mathematics. They found that preschool teachers act in two different ways to children's home mathematical experiences. The first involved only recognizing activities already familiar to the preschool teachers. In this way existing norms and values are recreated. The second integrates children's home experiences into new activities, providing opportunities to create new norms and values. Wager and Whyte's study raises a question about whose ideas are used in mathematical activities, also how these ideas are recognized as valuable. Understandings about socialization indicate that institutions need knowledge of immigrant parents' norms and values. Otherwise, opportunities offered by institutional settings and arrangements focus on integrating into the existing Swedish societal norms and values and not considering possibilities for creating new norms and values to match the changing milieu. Preschools have the opportunity be influenced by parental views, which could contribute to widening the variety of mathematics activities that can be based on children's own interests.

## Method

The data were collected through a digital survey, consisting of 16 questions in August, 2016. The survey was provided in Polish and Swedish. Participants were identified through a snowballing approach (Cohen, Manion, & Morrison, 2000). First a Polish organization and an internet forum for Polish citizens living in Sweden were provided with a link to an anonymous online questionnaire. People who completed the digital survey were then asked to share the link with others. All participants had a Polish linguistic and cultural background and were immigrants to Sweden. They had children who had attended preschool in Poland and/or in Sweden. The participants were a convenience sample and cannot be considered representative of the population of Polish parents in Sweden. As such, the survey results can provide information (Coyne, 1997), which can be investigated in more in-depth studies at a later date. At the time of the survey, the participants had lived in Sweden between 2 and 19 years. 31 participants responded to the survey (1 male, 30 females), aged between 22 and 47 years. Participants were described in the study as: P1–P31.

The survey's questions were divided in three parts. The first part consisted of demographic information: gender; age; number of years living in Sweden; if participants' children attended preschool in Sweden (30 did, 1 did not); and if participants themselves had attended preschools in Poland (23 did, 8 did not). In the second set of questions, participants were asked to describe their experiences of learning mathematics, including their experiences of learning mathematics in preschools in Poland (Question 6). Question 7 asked about the experiences of both themselves and their children. Questions 8 and 9 asked about situations in which children could learn mathematics at home and at preschool in Sweden. The next question was about possible mathematical situations, in Polish preschools. However, only one participant had children attending preschool in Poland so this data were excluded from the analysis. The third part used multiple-choice questions (Questions 11 and 12) to investigate parents' perspectives of mathematics activities. Five activities were suggested as occurring at preschool and at home and these were based on what had been found in research by Bottle (1999) of observations, at home and outside home. In Bottle's research, parents talked about mathematics activities such as: number and counting; doing puzzles; making towers; putting things in and taking them out again and things like full, empty and half full. The multiple-choice responses in the questions about parents' perceptions of mathematical activities were: counting rhymes; jigsaw puzzles; counting things; playing with sand and water; and building with blocks. Participants were also asked to express what was important for them based on their own experiences of mathematics (Questions 6, 13 & 16) and to describe the importance they attached to their children learning language and mathematics (Questions 14 & 15). The final question was open-ended and provided parents with a possibility to share something about their children's learning of mathematics with teachers in preschools.

Two analyses of collected data were done. The initial quantitative analysis was of parents' views about mathematics activities at home and at preschool. The second, qualitative analysis used the socialisation components of production and reproduction of societal norms and values (James et al., 1998), to understand parents' views about mathematics in preschool. By analyzing the parents' responses, it was possible to identify the norms and values that parents held about mathematics in kindergarten and consider how these were related to production and reproduction.

## Quantitative analysis

Asking about particular activities was seen as a way of concretizing what could be considered mathematics for the parents. The questions were “Which of these things do you do at home, which you think might help children learn mathematics?” and “Which of these things do your children do at preschool, which you think might help them learn mathematics?”. The parents could provide more than one answer.

**Figure 1: Frequency of home or preschool activities**

Figure 1 shows which activities been chosen by parents as being present at home and at preschool. From most parents' perspective, the children engaged in similar types of activities at home and at preschool which would contribute to them learning mathematics. For example, 27 out of 31 participants considered that Activity C: counting things, was something that parents considered children would do at preschool and home and would support their learning of mathematics.

The only significant difference between perceptions of what kind of mathematics activities are present at preschool and home was for activity D: playing with sand and water. Parents did not chose this activity, as something their children engaged in at home. Although more research on this is needed, a simple explanation may be that they did not have the facilities at home for it. Similarly, none of the participants, when they responded to question about describing their own ideas about how and when children learn mathematics, suggested playing with sand and water.

## Qualitative analysis

In this section, I describe parents' views about mathematics education for their children, as expressed in the survey. Analysis highlights why parents considered it is important for children to engage in mathematics activities in preschool and at home. The focus is on parents' perceptions of the institutional norms and values in Swedish preschool through their responses to the survey questions.

Parents' experiences, from their children attending Swedish preschool, seemed to have shaped their views about mathematics activities. This is clear in statements, such as the one made by P2, where mathematical experiences seemed to be transferred from preschool to home.

P2: Children learn basic shapes while playing. Shapes are used in different situations and aspects. My child comes home and continues asking us about different shapes "which is a shape of"? (in relation to various everyday objects).

It would seem that P2 in this statement is reproducing the norms and values about the importance of children knowing about shapes and about learning through play. Learning through play situates children as being active participants in the socialisation processes. It is unclear whether P2 had the same set of norms and values before her contact with Swedish preschools, but it is possible to claim that they are in alignment with the Swedish preschool curriculum (Skolverket, 2011).

The parents' reflections of their experiences from the institutional practices of the preschool in Poland, were evident in some of their answers. For example, P11 referred to ways of learning in preschool by saying:

P11: They (her children) attended (Polish preschools) and learnt exactly the same ways as I did at their age.

P11's perception was that Polish preschools had not changed in the generation since she had attended preschool. This suggests that she did not see Polish preschools as sites for producing new norms and values, just of reproducing the same ones across time.

The milieu in Swedish preschool was seen as a source of knowledge and learning of mathematics for children.

P21: It seems to me that the Swedish preschool have a big focus on mathematics. There is always enough mathematical activities, children usually have access to lots of toys/games which also are developing their mathematical skills.

The emphasis on preschool materials focusing on mathematics is viewed positively. P21 highlighted the mathematics that could be learnt through playing with toys at preschool. Opportunities for learning mathematics are in the environment and children have the possibility to explore them, as active agents reproducing societally-valued understandings about mathematics. However, it is unclear what the responsibility of a preschool teacher is, apart from making activities and toys available to children. It is unclear how the children learnt that what they are doing is mathematics.

P28 made reference to how everyday situations could support children's curiosity. Like many of the parents, points such as these were linked to the importance of children playing. The norm of Swedish preschool is for children to play and interact together. Play is *considered* as a stimulus for learning in interactions. Children's own knowledge can initiate interaction in play and, as Ebrahim (2011) stated, children can bring in imaginary characters during play. In this way, children produce and reproduce knowledge and understanding about their lives.

P28: Children learn through play with toys and friends in everyday situations. Children should be allowed to use their curiosity and discover new things so they can learn more easily.

A particular aspect of play that parents highlighted was that children could make their own decisions, situating them as active participant in the socialisation process. P13 expressed how much she valued this aspect of Swedish preschools.

P13: I like it here (in Sweden), that children have a lot of freedom in choosing and directing their play activities.

Responses such as this are in alignment with values expressed within the institutional practices of preschool (Skolverket, 2011). Children being active participants in activities, which they design or adapt, seems to be a shared value in Swedish society about what is normal for childhood. Children are socialised into this shared norm while engaging in these activities.

Parents' views of how children should learn mathematics through play is in alignment with the Swedish preschool curriculum (Skolverket, 2011). Parents mentioned play explicitly as an approach which was beneficial for learning generally, including the learning of mathematics.

P29: In preschool, play is the main form of learning. Children are enthusiastic and learn about the world around them through play. They should receive many interesting incentives in order to actively gain knowledge about the world in general, as well the mathematical world.

In responding to the final open-ended question in which they could share something about their children's learning of mathematics, the parents highlighted the importance of mathematics in everyday activities, such as: counting things; classifying objects; doing arithmetic; recognizing numerical symbols; building with Duplo. P30 reported that children gained a better understanding of mathematics while playing, but seemed to equate counting with mathematics.

P30: Through play children learn to count and get to know the numbers. I think that play is a good way to learn mathematics.

Counting objects during play, can be about making sense of existing knowledge. Awareness of this knowledge (counting) involves an active process of interpretation of this activity as mathematical. Similarly, P11 referred to everyday activities and emphasizing the value of learning mathematical terms and problem solving.

P11: Learning mathematics, vocabulary and mathematical concepts is necessary for children. They develop their abstract thinking, analyzing, reasoning and decision-making processes.

P11 emphasises what children need to learn, and why that is important. This indicates what this parent considers to be the valuable knowledge that children need to reproduce. What is interesting is that these practices reflect the goals and guideline in the curriculum, "develop their ability to distinguish, express, examine and use mathematical concepts and their interrelationships; develop their mathematical skill in putting forward and following reasoning" (Skolverket, 2011, p. 10). As in the first example in the results, it is unclear if this parent held these views of mathematics before coming to Sweden, but the fact that they are so closely aligned indicates that more research is needed to investigate this further.

These parents viewed play as a vehicle for learning and children's participation in mathematics activities as an active form of play. This is in alignment with the Swedish preschool curriculum (Skolverket, 2016), which state that play should be a stimulus for children learning and development. By expressing children's possibilities to make choices and decisions, parents show that they accept that children should be active participants in the socialisation processes. They also

had expectations that their children would have opportunities to engage in a variety of mathematics activities. They exemplify activities that promote the learning of knowledge of mathematics which is socially-valued. Within this perspective, socialisation appears as a process of recreating knowledge.

## Conclusion

In this paper, I have presented the views of a set of Polish parents about the mathematics activities their children engage in at Swedish preschools. The findings suggest that, in alignment with the Swedish preschool curriculum (Skolverket, 2011), the parents emphasized that young children's engagement in mathematical tasks in preschools should focus on learning through play. However, whether the parents' views had changed since they arrived in Sweden is unclear. It is also unclear if this group of parents can be seen as representatives of Polish parents in general, living in Sweden. Therefore, more research is needed to investigate if and how parents' views of mathematics in preschools are before and how opinions change once their children begin preschool in Sweden.

We need to gain a better understanding of how immigrant parents align with the pedagogical structures in the new country of residence. Much of the research based on work with immigrants' families (e.g. Civil et al., 2005; Giovannini & Vezzali, 2011), show gaps and struggles with parent's involvement with educational institutions. The group of Polish parents in this study show the opposite. This article gives a very brief indication of what is the potential for the group of immigrants from Poland. Their views are interrelated with their children attending preschool. They seem to interpret and adopt the Swedish preschool norms and values, through their children participation in preschool.

The educational structure, in which both children and parents adopt the norms and values of the society in their present country of residence, can be seen through processes of socialisation. Parents become learners of educational and pedagogical practices by using their experiences to recognize and work towards an understanding of the present. Socialisation is a complex and dynamic process with range of interconnected aspects operating simultaneously. Thus, more research is needed to understand the complexity of this process.

# The mathematics teacher's quasi-Darwinism: Problematizing mathematics education research

Alex Montecino

Aalborg University, Denmark; [alexm@plan.aau.dk](mailto:alexm@plan.aau.dk)

*This paper discusses the configuration of a quasi-Darwinian view of mathematics teachers, where the survival of the fittest is the cornerstone of a network of practices and discourses. It aims to contribute to the problematization of how mathematics education research and its discourses have effects of power in the fabrication of mathematics teachers' subjectivities, by unpacking naturalized truths of research – truths regarding a productive and successful mathematics teacher. It deploys a Foucault-inspired discourse analysis, and it argues how the research on the mathematics teacher becomes a practice that governs mathematics teacher's subjectivities through the enunciation of the desire subject, a productive, successful and effective teacher.*

*Keywords: The mathematics teacher, effects of power, quasi-Darwinism.*

## Introduction

Providing quality mathematics education has been a concern within the mathematics education community, research on education and international agencies. It is argued that the quality of education and the development of mathematical knowledge is essential for society and social development (Gellert, Hernández, & Chapman, 2013; OECD, 2010b). The idea is circulating that success in school mathematics is a prerequisite for personal and social success. Nowadays, it is considered that mathematics is a powerful mean to understand and control one's social and physical reality (OECD, 2010a), by being a tool and skill that helps people to undertake diverse tasks and problems of everyday life, and of their contexts (OECD, 2014b). However, according to OECD (2014a), modern societies valorize individuals not for what they know, but for what they can do with what they know, in other words, by their *mathematical literacy*:

Mathematical literacy is an individual's capacity to formulate, employ, and interpret mathematics in a variety of contexts. It includes reasoning mathematically and using mathematical concepts, procedures, facts, and tools to describe, explain, and predict phenomena. (OECD, 2010b, p. 4)

Research in the field of mathematics education is seeking to modify reality – in the frame of social changes – through its findings, proposing rationalities, knowledge, and ways of improving education practices – for ensuring the quality of teaching and learning of mathematics. Furthermore, OECD (2014a) stated that “[h]igher educational achievement benefits both individuals and society, not only financially, but in the well-being with which it is also associated, such as better health outcomes and more civically engaged societies” (p. 104). In this fashion, the mathematics teachers become relevant, since they are considered as a central element in the establishment of quality education (Jong & Hodges, 2015; Luschei & Chudgar, 2015; OECD, 2005, 2014b). Several studies have argued on the relation between the quality of the mathematics teacher and the shaping of successful students (cf. Castro-Rodríguez, Pitta-Pantazi, Rico, & Gómez, 2016; da Ponte & Chapman, 2008; Hemmi & Ryve, 2015). Also, it is argued that the teacher is open to policy

influences, whereas factors regarding students and the classroom context are not open to the same policy influences, at least in the short run (OECD, 2005).

All the aforementioned, the circulating discourses around ‘success’ in mathematics, are positioning a way of thinking and understanding mathematics education through the configuration of valid methods of doing research and of arguing about the diverse issues involved in the teaching and learning of the mathematics. For example, “[a]ll research is built around a set of assumptions about the world and how it should be understood and studied” (Jablonka, Wagner, & Walshaw, 2013, p. 41). Thus, this paper problematizes mathematics education research and its effects of power on teachers’ subjectivities and fabrication. A discourse analysis, inspired by Foucault’s ideas, is deployed to unpack the naturalized truths and discursive formations about the effective and competitive mathematics teacher.

### **Movements to examine the mathematics teacher as a discourse formation**

According to Pais and Valero (2012), mathematics education research produces languages and tools that shape what researchers see and say in the world of education and of mathematics education. Mathematics research as a field of inquiry is not an innocent or a neutral activity (Halai, Muzaffar, & Valero, 2016); it has been considered a “social institution which is inseparably linked to power” (Jurdak, Vithal, de Freitas, Gates, & Kollosche, 2016, p. 10). In this fashion, mathematics education, and also its practices, is considered to be political because it operates within governmentality techniques. Hence, by building on these techniques of government, this paper aims to understand how mathematics education research fabricates the mathematics teacher’s subjectivity through regulatory practices embedded within naturalized truths. In other words, it addresses how research sees and talks about the mathematics teacher, by establishing regimes of power/knowledge.

According to Foucault (1972), “[w]e shall call discourse a group of statements in so far as they belong to the same discursive formation” (p. 117). Hence, discourse as a group of statements, provides a particular language and knowledge, assembling regimes of truths. Circulating discourses describe rules and enunciations of a particular body of knowledge from specific spatiotemporal conditions (Arribas-Ayllon & Walkerdine, 2008). This paper deploys a “research on research” (Pais & Valero, 2012) strategy built on Foucault’s discourse analysis. This analytical strategy helps to unpack naturalized truths within research, that seek to generate a productive and successful mathematics teacher, and, at the same time, to trace the power effects on the fabrication of mathematics teachers’ subjectivities. So, by problematizing the discourses, it is possible to understand research as a practice that governs subjectivities through the enunciation of the desired subject.

First, repeated statements about the ‘must be’ of the mathematics teacher are identified. Second, these statements are analyzed to trace their knowledge/power relationships, and their continuities and discontinuities amongst each other. It does this by analyzing published studies about teaching and learning of mathematics. The empirical materials consist of research about mathematics teachers released within the last four years of three journals: *Journal of Mathematics Teacher Education*, *ZDM Mathematics Education*, and *Educational Studies in Mathematics*.

Finally, it problematizes how research and its discourses have effects of power in the fabrication of mathematics teachers’ subjectivities. It does this by portraying how certain rationality is circulating

within research in mathematics education. As will be described, such rationality promotes a quasi-Darwinism, in which the survival of the fittest and the idea of evolution are the cornerstone of a network of practices and discourses.

## **The mathematics teacher research and the survival of the fittest**

In navigating through the discourses that are circulating about the mathematics teacher, amongst the materials analyzed, it is possible to identify some enunciations that are continuously repeated. By following a Foucaultian chain of thought, these particular enunciations constitute statements about how mathematics teachers are supposed to act and be within their practices, their ‘must be’. Such statements respond to concerns raised by research in the field of mathematics education. For example, who is taken as valid for arguing about mathematics teachers, what does a mathematics teacher ought to do, and how to seek for the improvement of the teaching and learning of school mathematics. From the analysis, some discourses about the ‘must be’ of the mathematics teacher are configured as truths. These truths are advertised as desired features that teachers should have if they want to perform successfully, namely: a high knowledge (Fauskanger, 2015), an updated repertoire of techniques (Subramaniam, 2014), and a personality consistent with their practices – personal aspects such as beliefs or attitudes (Jacobson & Izsák, 2015).

These discourses are naturalized under a competition and comparison system of reason. International standardized testing – PISA and TIMSS –, and its reports are examples of how competition and comparison become part of society, by shaping social discussions, decisions, efforts, and initiatives. At the same time, through those tests’ outcomes, diverse countries could monitor themselves to improve the weakest areas, since “[a]ll countries are seeking to improve their schools, and to respond better to higher social and economic expectations” (OECD, 2005). In this fashion, a variety of studies, that seek to improve the teaching of mathematics (see Boston, 2013; Lewis, 2016; Pang, 2016), are aimed to identify how mathematics teachers could achieve a successful practice by analyzing their students’ achievement on national and international tests. But, as discussed elsewhere, what is taken, by research, as a successful practice leads to a system in which teachers compete against others teachers, against what is considered as a desired teacher, and, also, against themselves (Montecino & Valero, 2016). So, research discourse is raising comparison as a mean for knowing the characteristics of competent and effective teacher – the fittest teacher –, effective practices or successful experiences. Within these discourses, it is possible to see statements such as:

By comparing and contrasting the practices of LS [Lesson Study] in mathematics in different countries, it will be possible to explicate the local theories of teaching and learning of mathematics, highlight educational values in each culture, and understand why and how these values support certain teacher development processes that are unique to the culture. (Huang & Shimizu, 2016, p. 394)

In the unpacking of naturalized truths of the analyzed materials, it is possible to see that some statements highlight mathematics teachers’ deficits and flaws. These statements pay attention to what teachers need to improve in their lessons for increasing students’ achievement (Spitzer, Phelps, Beyers, Johnson, & Sieminski, 2011). On one hand, by emphasizing that teachers need to achieve a higher expertise on school mathematical topics (e.g. Karakok, Soto-Johnson, & Dyben,

2015; Magiera, van den Kieboom, & Moyer, 2013). On the other hand, by focusing on the need for developing more effective teacher's practices (see Lee & Kim, 2016). This type of research acknowledges that mathematics teachers have a 'responsibility' for students' performances and, therefore, teachers ought to be highly trained. Alongside the statements about what needs to be improved, other statements exist that pay attention to what teachers lack, in other words, to skills that teachers are required to develop to reach what those studies perceive as 'successful professional development': on the one hand, studies regarding teachers' belief system (e.g. Conner, Edenfield, Gleason, & Ersoz, 2011; Cross Francis, 2015); on the other hand, studies regarding teachers' attitudes (e.g. Hannigan, Gill, & Leavy, 2013; Jong & Hodges, 2015).

According to some research, "[h]ow teachers perceive and adapt their roles will have great impact on overall classroom interactions, such as the teachers' questioning strategies or feedback patterns" (Lee & Kim, 2016, p. 366). This implies that teachers' decisions have an impact on students since it is believed that students' intellectual autonomy could be favored by teachers' practices (Goldsmith, Doerr, & Lewis, 2014). And so, the decisions made by the mathematics teacher have a high impact not only on students but also on their learning (Stockero & Zoest, 2013). This type of research shows that mathematics teachers should be constantly seeking to improve their professional development, practices, knowledge and skills not only for themselves but also for the sake of their students (Afamasaga-Fuata'i & Sooaemalelagi, 2014). Since professional development has been understood as a form of lifelong learning in which mathematics teachers are responsible for their own development and achievements, these types of statements, from a Foucaultian approach, are tracing the ways in which the mathematics teacher should become an effective and competitive teacher, through processes of self-regulation.

According to these studies, teachers should aim at improving, by themselves, diverse personal and technical aspects. Such aspects are supposed to encourage the development of a more effective and competent teacher, by recognizing their own deficits and flaws with the goal of overcoming them. This naturalized truth resonates not only within research but also amongst other discourses on education. For example, OECD (2012) states that effective teachers are a key to close achievement gaps between advantaged and disadvantaged students. And, therefore, the aim should be to (re)train and (re)shape teachers to become the desired effective teacher. In this regard, research is tracing a sort of 'evolutionary line' for mathematics teachers, in which at the end of the line rests the desired mathematic teacher. Teachers should evolve when they achieve the desired levels of knowledge and skills established by society, becoming the productive, successful and effective teacher. However, these desired levels are in constant movement, being redefined by new social interests, concerns, desires and demands as well as new mathematical knowledge that the modern citizen should have. This means that mathematics teachers have to govern themselves into a constant process of change, of (re)training and (re)shaping. As Deleuze (1992) asserts, currently nothing is considered to be finished; all is in a constant becoming.

The idea of the 'evolutionary line' helps to tell the narrative of the becoming of the mathematics teacher as the survival of the fittest, since research in the field highlights the features of the 'fittest subject'. This portrays that the survival of the fittest – the desired mathematics teacher – involves practices of self-regulation, but also of competition against other teachers, practices that could lead to the exclusion of certain teachers labeled as 'inferior subject', unproductive, unsuccessful, and

inefficient. For example, Lee and Kim (2016) have argued that mathematics teacher training programs “should include more specific investment in the effective use of classroom dialogue for learning” (p. 378), a ‘fittest subject’ should evolve in an effective classroom communicator whereas the ‘inferior subject’ will not evolve as a classroom communicator, and, will therefore be taken as ineffective. Consequently, the survival of the fittest governs the self and conducts mathematics teachers’ practices towards the desire to evolve, (re)shaping the research about mathematics teachers within a system of reason rooted in a quasi-Darwinism, since it traces the paths for teachers to increase their abilities to survive, compete and evolve.

### **Quasi-Darwinism of mathematics education research and its effects of power**

The analysis deployed has pointed to the existence of statements on the desired mathematics teacher, a self-regulated and evolved subject. These statements have been (re)producing certain truths about who the effective teacher is. For example, mathematics teachers should perceive themselves as responsible for others – i.e., their students’ performances –, as promoters of social change – i.e., by closing achievement gaps –, and also, as responsible for themselves – i.e., tracing their professional development and learning the best possible way. These statements are building a quasi-Darwinian view of mathematics teachers; an ‘evolutionary line’ that is embedded within the above discourses and shapes the fabrication of the fittest subject.

The quasi-Darwinism (re)shapes mathematics teachers’ ways of being and acting at a particular time and place, through discourses that are produced and reproduced under certain *regimes of power/knowledge* (Foucault, 1982). The naturalized truths are constituted, on the one hand, within a particular regime of knowledge, which delineates who is the one to discuss about the mathematics teacher and how, and in what way the knowledge regarding the teacher should be generated. On the other hand, within a regime of power which defines what understanding is meaningful to be studied – what discourses are taken valid regarding certain issues or aspect of the mathematics teacher – and which practices, knowledge and techniques should be targeted. Therefore, a quasi-Darwinian view (re)produces what the mathematics teacher should be – the becoming – towards the development of the ‘human capital’ (OECD, 2001). Human capital voices the value that subjects have in correlation with their knowledge, skills, education and preparation for the future, which translates into personal, social and economic well-being. Alongside, a quasi-Darwinian view (re)shapes a discourse aimed at optimizing the becoming of the teacher. Moreover, the research on mathematics teachers seeks to minimize all aspects that could lead to an ‘inferior subject’. In order to be the fittest, teachers should engage in practices that turn them into accountable and measurable agents.

In this regard, it is possible to state that research in the field of mathematics education becomes a technology of the self (Foucault, 1997) that regulates mathematics teachers’ conducts towards the shaping of the desired mathematics teacher. By promoting ‘cultural thesis’ (Popkewitz, 2008) about the desired mathematics teacher, the analyzed research has effects of power on teachers subjectivities, meaning how mathematics teachers understand themselves and their becoming. Only the ‘fittest subject’ is the one able to develop the skills and knowledge that society demands and requires, is the only one who can evolve in a ‘superior subject’; subjects able to adapt themselves to the new social and professional demands. In other words, teachers are to evolve in subjects that

have the tools, skills, and knowledge to survive to all social changes and challenges; becoming a successful, effective, competent and fittest subject.

Thus, within the circulating discourses is configured a narrative in which if the mathematics teacher does not adapt or evolve, he/she is excluded or labeled as deficient. The teacher who survives through social changes and challenges is neither the knowledgeable teacher, nor the successful teacher, nor the most intelligent teacher; rather he/she is the most adaptable to change.

# Towards cultural responsiveness in mathematics education

Swapna Mukhopadhyay<sup>1</sup> and Brian Greer<sup>2</sup>

Portland State University, Oregon, USA;

<sup>1</sup>[swapna@pdx.edu](mailto:swapna@pdx.edu); <sup>2</sup>[brian1060ne@yahoo.com](mailto:brian1060ne@yahoo.com)

*We describe ongoing work on the Culturally Responsive Elementary Mathematics Education (CREME) project, in which we work with teachers and students in two schools with contrasting student populations and communities. We present core principles of our emergent theoretical framework as we partner with the teachers and students to realize (in both senses of ‘understand’ and ‘make happen’) what culturally responsive elementary mathematics education might be. The backdrop for this activity is the educational/political arena within the United State, in particular in Oregon where we work, and in the schools themselves. We outline future development of CREME, and end with what we see as the implications of our experience with CREME for the ethical and political responsibilities of educational researchers.*

*Keywords: Culturally responsive, mathematics education, multiculturalism, educational politics, assessment.*

## Introduction

As an extension of the paper presented at CERME9 (Mukhopadhyay & Greer, 2015) we describe our continuing work on the *Culturally Responsive Elementary Mathematics Education* (CREME) project, at the core of which is a long-term exercise in teacher development, embedded in the schools and their communities.

We are not doing research in the narrow sense of stating research hypotheses, gathering data, conducting analysis. On the one hand, the paper provides a “thick description” (Geertz, 1973, pp. 5-6) of the evolution of a community of practice (Lave & Wenger, 1998), and, on the other, describes an effort to actualize a conception of culturally responsive elementary mathematics education (Greer, Mukhopadhyay, Powell, & Nelson-Barber, 2009) in a particular environment. As such, it can be characterized as raw material contributing to an emerging theory, elements of which we describe. As a development from the CERME9 paper, we devote more attention to educational politics within the United States, in particular the state of Oregon, making the argument that research cannot be considered politically neutral, and we raise meta-theoretical issues about the ethical and political responsibilities of researchers.

## Principles and values of CREME

CREME is very much work-in-progress, but many influences are clear. Within mathematics specifically, we acknowledge Critical Mathematics Education (albeit fuzzily defined), and Ethnomathematics as major inspirations. Within critical education more broadly, we have worked to establish the centrality of mathematics (not always recognized) within multicultural and intercultural education (e.g., Greer & Mukhopadhyay, 2015).

Of particular relevance is the concept of “Funds of Knowledge” (Gonzalez, Moll, & Amanti, 2005) which is “based on a simple premise: People are competent, they have knowledge, and their life

experiences have given them that knowledge” (Gonzalez et al., 2005, p. ix). As an example, we studied Sandoval-Taylor’s (2005) account of her development of a curriculum module for a second grade bilingual class composed mainly of Native American and Hispanic students, on the theme of local building construction. We later had the opportunity to talk about this work with her when she visited our class.

More recently, a related concept termed “Funds of Identity” has been developed (Esteban-Guitart & Moll, 2014), introduced by the authors thus (p. 31):

We use the term funds of identity to refer to the historically accumulated, culturally developed, and socially distributed resources that are essential for a person's self-definition, self-expression, and self-understanding. Funds of knowledge – bodies of knowledge and skills that are essential for the well-being [sic] of an entire household – become funds of identity when people actively use them to define themselves.

This statement provides a concise rationale for the emphasis we put on identity work in CREME and in this paper.

From the above, it will be appreciated that CREME, both in terms of the development of a theoretical framework and as a form of political activism, is very much work-in-progress, guided by beliefs and values, such as a commitment to asset pedagogy and to valorizing diversity in all its forms (Mukhopadhyay & Greer, 2015). The very different natures of the two schools described below is illustrative of the diversity pointed out by Skovsmose (2012), relating not only to ethnicity, class, language, forms of life, and so on, but also to: variety of sites for learning mathematics (in contrast to the stereotype of the *prototype mathematics classroom* (p. 345); variety of forms of mathematics in action; variety of educational possibilities. The two schools represent two examples of the demographic and sociopolitical variety in schools within the US and, *mutatis mutandis*, anywhere else. Accordingly, the concept of culturally responsive mathematics education (Greer et al., 2009) must be adapted to the particular contexts of schools and communities. In the case of School A, one major focus of our work is support of cultural identity for the children who are recent immigrants, often as refugees. We have become acutely aware of the tensions for immigrants between the pressing issues of adapting to a new society and the practicalities of day-to-day existence, and the maintenance of cultural identity. (Other kinds of tensions for non-dominant groups in relation to dominant groups were discussed in Mukhopadhyay and Greer, 2015). In School B, two important aims are to enable the children who are White to become more aware of cultural diversity, and to model the use of mathematics as a tool for addressing issues of social justice. These contrasting foci are illustrated in activities being carried out at the two schools, as discussed below.

## **National political background**

In Mukhopadhyay and Greer (2015), we sketched the political landscape for mathematics education globally and within the United States. No matter where you are, developments within the US are likely relevant because of the extent to which they directly or indirectly influence what is happening in your country. One point of this paper, accordingly, is to offer an example of how mathematics education and realpolitik interact within a particular context. Readers will recognize parallels with what is going on in their own contexts.

The importance of demographic changes within the United States is made clear by the fact that White children (as officially defined) now constitute less than 50% of the school population – while it is still the case that about 80% of the teachers are White. The legislation called *No Child Left Behind* that was passed in 2001 did address diversity among students in that it required the reporting of performance on standardized tests broken down by ethnicity, a major change welcomed by, for example, African-American organizations as a means to identify and then address inequity. However, the subsequent information on differences in standardized test scores (generally referred to as “achievement gaps”, a term that connotes a blatantly deficit model) was instead used to label schools, teachers, and students as “failing” without providing resources to reduce the differences; instead, the data provided fodder for denigration of teachers and the furtherance of privatization (encrypted as “choice”). Now NCLB were has been replaced by the *Every Student Succeeds Act* (ESSA), a change that can be characterized as rebranding (Karp, 2016), with the continuing requirement to administer standardized tests to all students each year from Grade 3 to Grade 8. At the same time, there is a growing national movement against the excessive, inappropriate, and expensive use of standardized testing (Hagopian, 2014).

An overwhelming political fact is the increase in wealth and income inequality over recent decades in the United States and many other countries (OXFAM, 2017; Piketty, 2014). Education, far from the conception that it should act as a force to reduce such inequality through offering something like equality of opportunity, is now acting as an accelerator, as has been clearly shown in the United States by the statistical analysis carried out by Reordan (2011). In the period 1979-2009, the gap in academic achievement (as conventionally measured) between poor and rich children grew by about 40%.

For many reasons, the election of Donald Trump as president magnifies all of these issues, particularly given his choice as Secretary for Education of a billionaire supporter of the privatization of schools. All indications are that education will become, to an even greater extent, a driver of economic inequality and a generator of corporate wealth.

## Local political background

One potentially positive aspect of ESSA is that it grants more power to states to make decisions. It remains to be seen whether this degree of autonomy will be sufficient to counteract federal policy under the new president.

In 2014, the Oregon Department of Education (ODE) issued a call for proposals for the *Culturally Responsive Pedagogy and Practices Grant* whose stated mission was to work towards formation of a culturally responsive teaching force in the state. CREME was the only project funded within this initiative focused on mathematics.

In June 2015, an extremely progressive and constructive statement on assessment, titled *A new path for Oregon* was published (Oregon Education Investment Board, Oregon Education Association, & Oregon Department of Education, 2015). This document represents the work of a very broad coalition that worked together over an extended period of time and consulted widely with teachers and others. It clearly shows the influence of Stiggins (2014), who acted as consultant.

From our perspective, *A new path for Oregon* is particularly notable in the attention it pays to “culturally responsive assessment”. It is stated unequivocally (p. 8) that:

A successful system of assessment should not simply highlight problems or generalize about groups; nor should it ignore conditions that influence performance. Instead, a successful system of assessment recognizes the myriad strengths of various learners within their respective communities and within the collaborative nature of the classroom. In addition, such a system is culturally responsive, and implemented by teachers who are assessment literate. (Emphasis added).

As just indicated, the report also highlights the concept of “assessment literacy”, not just for teachers and students, but also for families, community members, educational officials and policy-makers, and – perhaps most importantly of all – politicians. The *Oregon Education Association* (teachers' union) is actively leading further efforts to develop quality assessment, and we anticipate working with them and other important actors in exposing and undoing the negative effects of excessive standardized testing, and in developing culturally responsive assessment. Mathematics is of particular importance in these efforts, given the prominence that it is accorded within standardized testing.

At the time of writing, a bill is being promoted in the Oregon Senate that would require educational state agencies to ensure that educators are providing culturally responsive education.

### **CREME schools, students, and teachers**

The project is based in two urban schools in Portland, Oregon. Though less than three miles apart, the schools are contrasting in many respects. One (which will be referred to as School A) serves a very diverse population of children speaking more than twenty languages at home, many of whom are recent immigrants and came to the US as refugees, with indications that many have experienced trauma (Sottile, 2015). The other school (School B) is a public charter school within the Portland Public Schools system. Unlike many charter schools that are corporate, this school adheres to the original concept of charter schools as test beds of alternative approaches to education. It is based on a progressive set of principles such as constructivism and democratic education and serves mainly White children, not particularly affluent.

School A is required to follow the prescribed textbooks and other instructional materials adopted by the district, and adhere to strict testing requirements. As a result, as CREME teachers have testified, there is excessive emphasis on test preparation. Although the children are smart and creative, as evidenced in many of their open-ended projects, their performances in tests do not reflect that. And although the teachers from School A are kind, caring, and full of creative ideas they are compelled to follow the curriculum and testing regime thrust upon them.

For School B, not only is the demographic different, the curriculum and pedagogy are also in stark contrast. The teachers have intellectual freedom in designing their curricula, with minimal emphasis on performance on standardized tests. The teachers design and develop project-based curriculum spanning weeks at a time. Thus, while the students were learning how to respond to standardized test items in School A, their peers in School B were learning about election and democracy in a national program called Every Kid Votes 2016 (<https://www.studiesweekly.com>).

The participating teachers contribute to the richness of diversity of the project. They differ ethnically and linguistically, and in years of teaching experience. CREME is a teacher development project that differs in major respects from many endeavors labeled as such. It is not formulated as a group of researchers/academics proscribing, as experts, curricular content or teaching styles for teachers to follow. Rather, over two years and continuing, it is a collaboration founded on mutual respect wherein the mathematics educators propose ideas to the teachers, while the teachers and their students educate the academics about the realities of the circumstances in which they are teaching and learning. In the slow and organic development towards the idea of teachers as intellectuals, the teachers have had the opportunity to interact face-to-face and electronically with the advisors for the project, Marta Civil, Geneva Gay, and Danny Martin, and other scholar activists. And they are beginning to attend and present at conferences and to write papers.

## **What happens in CREME**

We present here some examples of activities that we have collectively carried out (see Ford et al., (in press) for more details).

In School A, a very simple exercise with powerful effect has been to ask children to record, on paper and audio, numbers from 1 to 20 in their home language. Ongoing discussion was related to the large world map that hung in the room: In which part of the world is this language spoken? Where else is this language spoken? The list of languages spoken at home was long: Arabic, Bulgarian, English, Fulani, Kirundi, Korean, Oromo, Portuguese, Russian, Spanish, Sudanese, Swahili. (For a similar activity in Greece, see Chronaki, Mountzouri, Zaharaki, & Planas, 2016).

As a more general approach to identity work within an asset pedagogy, the children at both schools record, on strips of paper, lists of what they can do, including but not confined to school achievements. These lists are placed in ‘talismans’, old medicine bottles that are decorated by the children. Recently, all the children and their teachers wrote autobiographical poems based on the prompt “I am from”, and drew self-portraits. A compilation has now been published as “We are from”, and the book was launched in the library at School A with children reading their poems and the self-portraits on display.

Another aspect of identity that we work on is that of being a potential college student. In School A, in particular, students tend not to have a clear notion of what college is like. Accordingly, we have organized field trips for students to Portland State University, during which children interacted with students and faculty in Architecture, Engineering, and Earth Sciences.

In School B, an example of teaching to make students aware of other cultures is that the teacher, having covered a standard account of the Lewis and Clark Expedition of 1804-1806 that opened up the West to colonizers, then presented an account from the perspective of the Native Americans. We have also connected teachers, through visits to the Portland Art Museum, to Native American artifacts that illustrate the richness of design that serves as a context for the study of geometrical concepts, in particular symmetry.

School B has a tradition of working through Storyline projects, an approach in which students, together with their teacher, explore a theme in depth through creating characters within that theme. Koopman (in press) describes such a project that began by students looking at the labels on their t-

shirts to see where they were made. The places were recorded with pins on a world map. Koopman reports that looking at the concentrations of pins in particular areas came as a revelation even to him. From there, the class collectively did extensive research about factories in the early 1900s where t-shirts were originally made. They used extensive arithmetic in calculating, based on historical data such as the prices of groceries and payscales at that time, the cost of living of a family in relation to the pay. They took on roles of workers and factory owner, and acted out situations of conflict. Koopman (in press) related the conflicts enacted by the students to his own experiences during a teacher strike when he was coerced by the school district to substitute for striking teachers. Later the principal of the school joined in the activity. The project culminated with research into contemporary conditions for workers in sweatshops in countries such as Bangladesh.

Another such project involved students building models of food carts (for which Portland is famous). Students created characters for the cart owners and operators, and devised detailed business models. They filled in actual forms relating to hygiene requirements, for example, for these simulated businesses. The teacher posted reviews on Yelp.

In these and similar projects, a great deal of arithmetic was done in context, illustrating how, in elementary school, students may:

- (a) Be introduced to the conception of mathematics as a tool for interrogating sociopolitical issues, thus appreciating at an early age a sense of agency that will stand them in good stead as citizens.
- (b) Consolidate computational and planning skills in complex contexts that afford relevance, interest, and motivation.
- (c) Learn and practice mathematics integrated with other school subjects (science, obviously, but also art, social studies, language arts) – something that elementary teachers are in the best position to do.

## **Future of CREME**

At the time of writing, we have submitted proposals for further funding to continue CREME, but it is a measure of the group solidarity that the teachers are keen to keep the project going even without funding. As we continue, we plan to pay more attention to explicit mathematical content, always within the framework of culturally responsive pedagogy (see Ford et al. (in press) for more details). We also plan to explore and expose cultural biases in assessment, including the more subtle ways in which they are manifested. In light of the extremely encouraging political developments within the state, we are developing links with important actors within educational politics in Oregon. And we will continue to foster identity, agency, and autonomy in the CREME teachers, and to help them develop into mentors of new teachers joining the project.

## **Final comments: Ethical and political responsibilities of researchers**

The naive conception of research and researchers as politically neutral, providing systematic objective evidence for the guidance of state educational policy, if ever viable, is certainly not sustainable in the circumstances that pertain in the United States, as a neoliberal agenda is pursued – as, in the face of global corporatization and economization, is happening in many parts of the world (Spring, 2015). The experiences described in this paper makes clear that as educators we are

confronting issues of ethnic and cultural diversity, inequity, massive social engineering through the mechanisms of mass testing, the characterization of education as a market with huge profits to be made, the use of education as a means to maintain and even exacerbate economic inequality. The role of mathematics in all of these issues is particularly important, and we hold to a vision of mathematics education as providing people with tools for understanding and acting upon issues important in their lives and those of their families and communities. Along with mathematicians and mathematics teachers (D'Ambrosio, 2009), mathematics education researchers cannot absolve themselves from ethical and political responsibilities.

# Mathematics at the enterprise: Industry, university and school working together to facilitate learning

Hans Kristian Nilsen<sup>1</sup> and Anne Vegusdal<sup>2</sup>

<sup>1</sup>University of Agder, Department of Mathematical Sciences, Kristiansand, Norway  
[hans.k.nilsen@uia.no](mailto:hans.k.nilsen@uia.no)

<sup>2</sup>University of Agder, Department of Natural Sciences, Kristiansand, Norway  
[anne.vegusdal@uia.no](mailto:anne.vegusdal@uia.no)

*Based on a pilot study, this paper reflects upon how the industry, university and school can work together to facilitate learning of mathematics. Through a project called MathEUS (Mathematics at the Enterprise, University and School) a modern energy recovery enterprise, Returkraft, the University of Agder and a school collaborated to offer pupils (in 8<sup>th</sup> and 9<sup>th</sup> grade) an opportunity to engage with mathematics contextualized at an enterprise. Through comparing the 2015 edition with our re-design in 2016, we discuss the outcome of the project. In particular, we focus on the factors necessary for such a project to succeed. Findings suggest that mathematics contextualized at an enterprise as an isolated event has limited value. Further, findings seem to indicate that working together with the enterprise over time, by including a pre-project, strengthens pupils' experience of mathematics as a relevant subject.*

*Keywords: Diversity, relevance, authenticity, out-of-school contexts, enterprise.*

## Introduction

Diversity in mathematics education relates to political, cultural and linguistic aspects. In this paper, the issue of diversity will be addressed in terms of different sites where mathematics education potentially could take place. Meaney and Lange (2013) emphasize the importance of transitions between different contexts and that such transitions “can be a fairly minor issue for learners if they perceive similarities in what knowledge is valued and how learners and others should interact together and with the mathematical content” (p. 169). Throughout the decades, a growing body of research has been carried out, focusing on the learning of mathematics in different contexts (Masinglia, Davidenko, & Prus-Wisniowska, 1996). By linking mathematical tasks to an enterprise, we hope that the pupils experience mathematics as important, also outside the classroom, and in turn this influences their motivation for learning mathematics at school. In Norway, there has been an increased focus on how mathematics could be taught in ways that is perceived by pupils as relevant and more related to their own reality and experiences (Det Kongelige Kunnskapsdepartement, 2011). Diversity in teaching methods and arenas of learning has been important issues in this debate (Norges offentlige utredninger 2015, p. 8). Pupils in Norway are mixed together heterogeneously until grade 10 and with the curriculum focus being academic, offering pupils few perspectives on, for example, vocational and professional practice. In the attempt to diversify such experiences, we found that the processes going on at the energy recovery enterprise, Returkraft, bear the potential of visualizing mathematics at a working place. Further, *Mathematics at the Enterprise, University and School* (MathEUS), in some sense should be regarded as a response to the identified need of moving the teaching of mathematics in a more practical and vocationally-oriented direction. The last two years (2015 and 2016) funding from Regional Research Fund Agder enabled research to be carried out on the

MathEUS project. In this paper, we pose the following research questions: 1) *Which factors are of importance in the collaboration between school and industry for the pupils to experience the mathematics involved as relevant and authentic?* 2) *What might prevent the pupils for experiencing the project as relevant and authentic?* Our discussions focus on the differences in outcome between the first year and the redesigned project run in the second year.

## Theoretical background

The idea that learning is *situated* within a certain context and practice was in many ways coined by Lave and Wenger (1991) and in mathematics education, research has shown that the environment in which activities takes place is of great importance for the outcome (Nunes, Schliemann, & Carraher, 1993). In the MathEUS project, mathematics is contextualized and linked to the activities at an energy recovery enterprise, Returkraft. *Situated* in this case alludes both to the physical environment at Returkraft (which surrounded the pupils while they were doing their activities) and to the mathematical content, which was consequently linked to the enterprise. By establishing this link between content and context, it is our aim that the mathematical tasks and activities provided appear more *relevant* and *authentic* to the pupils. When applying the concept of relevance, we draw on the work of Hernandez-Martinez and Vos (submitted) where the main point is that “it involves a judgment of value that is made by a person involved in the activity” (p. 26) and that the “judgment is connected to the motive or object that drives the activity” (p. 26). Nyabanyaba (1999) and Dalby (2014) point to the complexity of the relevance concept in mathematics by listing a number of different ways mathematics could be conceived of “relevant”, depending on contextual, content-related and affective factors. Authentic has to do with the nature of the activity and has several somewhat distinct definitions. In the case of MathEUS, we find the definition from Gulikers, Bastiaens and Martens (2005) to be useful, “An authentic learning environment provides a context that reflects the way knowledge and skills will be used in real life” (p. 509). Here both the contextual aspect and the use value are emphasized, which is fully in line with the purpose of the MathEUS project. To achieve the goal of authentic tasks, considered relevant to the pupils, we aimed also to overcome some of the typical challenges that guided tours of enterprises often entail. Recent research, both national and international, shows that the “classical” excursion day, where pupils use a day to visit an enterprise in terms of a guided tour, is often disconnected to what they normally do at school and leads to some didactical challenges. The pupils easily become passive, engaging in artificial and low-quality tasks (like memorizing and duplicating information posters) due to the lack of preparatory and follow-up work (DeWitt & Storksdieck, 2008; Remmen & Frøyland, 2014).

## Methods

In 2015, two schools were participating, each with one secondary class of 9<sup>th</sup> grade pupils (14-15 years old).

### The implementation of the MathEUS project

The schools’ visiting day at Returkraft took place in March on two different days, one day for each class. Before the day of visit, student teachers completing a master degree at the university had designed and prepared mathematical tasks for the pupils. After a guided tour at Returkraft, the student teachers constructed the tasks over a period of two weeks, and during this period staff from Returkraft was available for helping them with information concerning the enterprise. Teachers from the

participating schools were also available for commenting on their suggestions. The premises for these tasks were that they should in some way be linked to the enterprise at Returkraft. These tasks were given to the pupils on their day of visit, and they were given approximately two hours to work with the tasks in groups of four to six pupils. The tasks were solved in a ‘classroom’ at Returkraft. Following an evaluation of MathEUS as it had been carried out in 2015, we decided to make some changes in an attempt to improve the project (see also the section “results and discussion”). We wanted to strengthen the quality of the tasks so that the pupils experience them as more relevant. In addition we wanted the pupils’ experience with Returkraft and the mathematics they engaged with to be more than just an isolated event. Aiming towards this, we invited the class to take part in a pre-project (lasting for six weeks), with a representative for Returkraft coming to their class early in the semester to initiate the following assignment: “How can we improve peoples’ habits, when it comes to sorting their garbage for recycling?” To solve this assignment, the pupils developed questionnaires and went out to different geographical locations to interview people about their sorting habits. Due to the lack of responses during oral interviews the pupils posted the questionnaires on social media, and the number of response escalated rapidly. Their empirical data were treated in spread sheets, resulting in different diagrams, and the results were presented at the university in front of an audience consisting of both the student teachers and employees from Returkraft. In turn, this pre-project served as an important source for the student teachers when they designed the tasks for the pupils. In 2016, one secondary class of 8<sup>th</sup> grade pupils (13-14 years old) participate in the project.

### **Methods and data collection**

We (the authors of this paper) were responsible for carrying out research and at the same time we planned the implementation of the project together with the participating schools and employees from Returkraft. We also provided the framework conditions for the student teachers’ elaborations of the tasks. The pupils, the student teachers, the teachers (at the participating schools) and the employees at Returkraft all served as informants for our research. In this paper, we mainly focus on data from the pupils. Conducting research at the same time as we are responsible for carrying out the project situates us within the domain of *action research*. Bryman (2012) describes this as “an approach in which the action researcher and client collaborate in the diagnosis of a problem and in the development of a solution based on the diagnosis” (p. 709). We conceive of this definition to be in line with our agenda, where we use data from our experiences to discuss, develop and improve the forthcoming editions of the project.

To measure parts of the outcome of the MathEUS project, we developed a web-based questionnaire which the pupils should answer after the project was carried out. Except from minor changes and some reformulations, we used the same questionnaires both years of research, for the sake of comparison. The questions were mainly statements that the pupils were asked to scale from 1 to 6, based on their “degree of agreement” and in total there was 34 statements to be evaluated. Mainly these statements aimed to inform our research questions mentioned earlier in terms of measuring the pupils’ own experience of their learning outcome, their motivation and beliefs and whether they consider the project meaningful and relevant. In addition, some open ended questions were posed where the pupils had the possibility to comment on these aspects. Since two school classes were involved in 2015, and just one in 2016, the sample size varied and in 2015 there was 44 respondents to the questionnaires, while 23 responded in 2016. But in 2016 we collected some additional data by

including a semi-structured interview with three of the pupils. These pupils were randomly selected among those who volunteered when we visited the class. In this interview, we went deeper into the pupils' own experiences related to the project, and to the content of the tasks and activities provided for them by the student teachers. Both in 2015 and in 2016, interviews involving representatives from the three collaborators (the enterprise, the university and the schools) were conducted, mainly focusing on the outcome of the project. Both years we made observations and voice recorded all the group work sessions at Returkraft. As part of our research, we also conducted interviews with some of the student teachers responsible for designing the tasks.

## Results and discussion

Since the scale on our questionnaires ranges from 1 to 6, we sort the results in two halves for the sake of overview. The “low achieving” half ranges from 1 to 3 and the “high achieving” half ranges from 4 to 6. Figure one gives an overview of some of the questions we consider as most significant.

**Figure 1: Pupils scaling (in per cent) in 2015 compared to 2016**

One can observe from the first columns in the diagrams (1a) that the majority of the pupils both years felt that they understood the mathematics being taught. About half the pupils felt that they discovered new aspects of mathematics in the 2016 edition of MathEUS, a slight improvement compared to 2015 (1b). An improvement related to the experience of mathematics used in a real-life setting is visible (1c), while the experience of mathematics as being meaningful is almost unchanged (1d). Finally, there is a clear improvement on almost 20 per cent related to the appreciation of mathematics as a consequence of the MathEUS project (1e). Since the number of pupils forming the basis of these results is limited and varying one should be careful to draw strong conclusions only from this data set. But since statements in the questionnaires consequently were higher rated in 2016 compared to the year before, a positive trend could be suggested. In addition to the scaling of different statements, there was also a possibility for the pupils to add comments and give some additional justifications for their scaling. In 2015, about half the pupils wrote critical comments, especially related to the question of whether or whether not their expectations had been fulfilled. “I thought they would try to make this fun”, “it was extremely boring, tiring and difficult maths” and “I thought we would learn more. The tasks were just like a typical maths tests”, serve as examples of such comments. Despite that 43 out of 44 pupils in 2015 expressed themselves positively about learning mathematics at a working place, about half of the pupils responded in negative terms related to the question about the fulfilment of expectations, in line with the previous quotations. These comments mainly implied that a negative experience with the content of the tasks. Even though the tasks were designed with the purpose of being relevant, in terms of creating a link between school mathematics and the enterprise, the pupils did not seem to perceive this the same way. Dalby (2014) emphasizes that even though a realistic

context is provided, the impact on pupils can vary since “the context itself is often no more than a metaphor to illustrate an aspect of pure mathematics rather than authentic use of a scenario as a source of mathematics” (p. 90). In the aftermath of MathEUS in 2015, we saw that several of the student-designed tasks could represent examples of contextualized tasks, but with little authenticity.

### Task 3 – payments

When the trucks arrive, the garbage is deposited in a big container. We know that each year about 130 000 tons of garbage arrives at Returkraft. Returkraft is paid for receiving our garbage. Juliette works at the counting department. Now you are going to help Juliette with the bill for Lillesand County. The prize is 1750 kroner for 1 ton of garbage.

- a) How much do they have to pay for 2 t (tons) of garbage?
- b) How much do they have to pay for 4 t (tons) of garbage?
- c) What relations do you observe, between the numbers indicating the tons of garbage and the bill that the county receives?

### Excerpt 1: Excerpt from task, 2015

The task above serves as an example of a task where the context was reduced to serve only as a metaphor, rather than an authentic use of Returkraft as a source of mathematics.

When revising MathEUS 2015, we wanted to improve especially on two aspects: 1) Make the content of the tasks more relevant and authentic for the pupils and 2) Engage the involved pupils and student teachers earlier in the process, so that the visit to Returkraft became something more than just an isolated event. In this process, we build on DeWitt and Storksdieck’s (2008) “boarder visions on field-trips” (p. 181) and their research-based conclusions that field trips and out-of-school context ought to be embedded in teaching, more holistically. Even though their focus was on natural sciences, we found these ideas to be relevant for mathematics and in the 2016 edition of MathEUS we included a pre-project (as described in the “methods” section). Due to the pre-project, the student teachers designed tasks were also used earlier in the process.

From the web-based questionnaires, illustrated in figure 1, there are some indications that pupils’ experiences in general were more positive in 2016 compared to 2015. Interviews with some of the pupils, also involved statements that could be interpreted as having to do with relevance and authenticity.

Interviewer: Earlier in the interview, you said something about “mathematics in practice”...was this something which characterized the tasks at Returkraft, or did you feel that you just as well could have done this at school?

[...]

Pupil: Since we had been to Returkraft and the content was about Returkraft, and the numbers used were the same as we had learned about...the numbers weren’t just made up, in a way.

This pupil emphasizes the experience of working with “real” tasks, in terms of pointing to a close connection between the context and the content of the tasks. Since the student teachers had followed their pre-project and had access to all their results and data, they were also able to build on pupils’ own data from the pre-project when designing the tasks, and in this case provided a more authentic context.

### Task 6 - diagrams

This example is from your survey. Discuss what type of diagram you want to use and why:

#### Excerpt 2: Excerpt from task, 2016

By using numbers from the pupils own pre-project, this task illustrates how one student teacher applied these data to discuss statistical issues. Based on observations from the pupils engaging with this task, we see this as an example of successfully creating a link between the context and the mathematics involved. Pupils judged this as “relevant” since an authentic connection between the mathematics involved and the context is provided in terms of linking the task to something familiar, namely their pre-project.

From this relatively brief analysis, we suggest that pupils’ experience of relevance, and the authenticity of tasks provided in an out-of-school context not only depends on the tasks themselves, but also on the pupils’ possibilities to *relate* to the content. For the context to “reflect the way knowledge and skills will be used in real life” (Gulikers et al., 2015, p. 509) a preparatory phase, where pupils are offered the possibility to become familiar with the context seemed to be advantageous.

### Conclusions

Providing out-of-school contexts like excursions and field trips are, unfortunately, often being carried out as isolated, stand-alone events (DeWitt & Storksdieck, 2008; Remmen & Frøyland, 2014). There are few reasons to believe that this is different in mathematics. Our findings tend to show that if mathematics in out-of-school contexts is treated like stand-alone activities, the outcome when it comes to authenticity and pupils’ experiences of relevance is limited. Pupils’ experience of relevance changed in a positive way when a preparatory phase in terms of a pre-project was implemented. Nyabanyaba (1999) argues that pupils and teachers’ conceptions of relevance often differ. In line with this, we suggest that even though mathematics in out-of-school contexts through excursions days at enterprises as stand-alone activities is carried out with good intentions from teachers, such activities ought to be more substantiated in teaching. Authenticity entails reflection on knowledge and how it could be used in real life (Gulikers et al. 2015) and for such a reflection to happen, Meaney and Lange (2013) point to the necessity of being able to make transitions between these different contexts. From our experience a pre-project substantiates the out-of-school context and better prepare the pupils for the subsequent visit to the enterprise. Hence, the connection between the mathematical content and the context provided are perceived by pupils as more relevant. “Making connections between mathematics and life that appear authentic and convincing for students” (Dalby, 2014, p. 91) serves as core criteria in the question of relevance and learning, also when it comes to the subject of mathematics.

## Implications and possibilities

From a societal and political perspective, this paper addresses issues concerning the contextual nature of mathematics teaching and learning. One aspect is the pupils' outcome of experiencing mathematics in an out-of-school setting, but in a boarder perspective, MathEUS also contributes to strengthen the bond between school and industry, which according to Sjaastad (2013), is "too weak" (p. 16).

The results and reflections in the wake of the two previous editions of MathEUS serve as a basis for further developing our collaboration strategies. We found that by involving the enterprise at an early stage, pupils to a larger extent were able to make connections between the context and the mathematical content. The pre-project also entailed interdisciplinary activities, where mathematics became an important contributor and ICT was applied by the pupils as a crucial tool in the process of visualizing their findings. The interplay between mathematics and natural sciences in particular played a significant role in the pupils' activities, both during the pre-project and at their visiting day at Returkraft. The topic concerning recycling of garbage also links our project to local and global environmental issues. People's attitudes towards recycling of garbage, were a valuable outcome also for the enterprise, as Returkraft aims to reach out to the public with messages concerning the importance of such issues. These are all, from our point of view, valuable synergistic effects worth looking deeper into. Task-design is a topic of research on its own, and the process of developing tasks and activities within this particular context could also be worth mentioning as potential, forthcoming research.

## Acknowledgments

In the process of developing MathEUS, the Norwegian Centre for Science Education has played a vital role as contributor both scientifically and technically. We want to thank them especially for their professional and didactical input which eventually led to the pre-project, and for assisting us in the development and in the treatment of questionnaires. Kristiansand municipality, educational centre and Node Southern Cooperate should also be mentioned for their support both pedagogically and administratively. Finally, our gratitude goes to the enterprise Returkraft, which has opened the doors and met us in all our requests.

# “No, it just didn’t work”: A teacher’s reflections on all-attainment teaching

Hilary Povey<sup>1</sup> and Colin Jackson<sup>2</sup>

Sheffield Hallam University, England

<sup>1</sup> [h.povey@shu.ac.uk](mailto:h.povey@shu.ac.uk); <sup>2</sup> [colin.jackson@shu.ac.uk](mailto:colin.jackson@shu.ac.uk);

*Setting – the practice by which learners are allocated to different classes on the basis of perceived ability – is a social justice issue. Despite overwhelming evidence that, overall, setting is educationally harmful and in discriminatory ways, the practice is almost universal in English secondary mathematics classrooms. To gain insight into this apparent contradiction, we offer the story of a single teacher’s ultimate rejection of all-attainment teaching.*

*Keywords: Ability grouping, equity, ability thinking.*

## Introduction

In this paper we begin by arguing that setting by ‘ability’ is a social justice issue. Despite overwhelming evidence that, overall, setting is educationally harmful and in discriminatory ways, the practice is almost universal in English secondary mathematics classrooms. In order to understand this apparent contradiction, we offer the story of a single teacher who, early in his teaching career, embraced all-attainment teaching<sup>1</sup>; continued to think in fixed ability ways and therefore supposed that there should be differential teaching for different levels of ‘ability’; found himself overwhelmed by such a task; and finally abandoned all-attainment teaching because “it just didn’t work”. We conclude with a brief discussion.

## Setting and ‘ability’ thinking<sup>2</sup>

English education in terms of both policy and practice currently takes for granted hereditarian assumptions; and a discourse of ability is used very widely to place children in sets for mathematics in secondary schools (Wilkinson & Penney, 2014). The belief in fixed amounts of ‘ability’ and the consequent grouping of children according to how much they are perceived to ‘have’ is taken as natural and common sense (Francis et al., 2016). The idea that ability is a given and that only some students can be high achievers discourages many students (Boaler, 2005) and communicates and reinforces damaging fixed mindset beliefs (Boaler, 2013).

In almost all instances the methods used to allocate children to sets are claimed to be objective and based solely on their prior performance. However, in practice, in English secondary schools prior attainment is found to be a relatively poor predictor of set. A wide range of social factors come into play which privileges those with greater cultural power and systematically disadvantage others

---

<sup>1</sup> We use the vocabulary of “all attainment” rather than the more common “mixed ability” to avoid endorsing so-called “ability thinking” (see, for example, Boylan & Povey, 2014).

<sup>2</sup> In this section, we draw substantially on Jackson (2017).

(Muijs & Dunne, 2010; Bartholomew, 2003; Hallam & Parsons, 2013; Ireson, Clark, & Hallam, 2002; Macqueen, 2013; Wilkinson & Penney, 2014).

Teachers' expectations of children in lower sets tend to be low and these pupils are usually offered a restricted, narrow and instrumental curriculum which further inhibits performance. They are constructed as poorly motivated, badly behaved and incapable of independent working and independent thought and therefore in need of repetitive tasks which require lots of practice (De Geest & Watson, 2004). In contrast, those in the top set are constructed as well motivated, hardworking, well behaved and capable of independent working and independent thought and are given a more demanding curriculum and much richer opportunities to succeed (Bartholomew, 2003). Thus setting and ability thinking construct that to which they claim to be responding.

While 'ability' grouping has been shown to have little consistent effect on attainment (Francis et al., 2016), it is known that it has detrimental effects in terms of personal and social outcomes (Nunes, Bryant, Sylva, & Barros, 2009). The effect of setting continues into adulthood resulting in more limited horizons and stunting life opportunities (Boaler, 2005). Thus, as Slavin (1990) argues, 'ability' grouping can be seen as an affront to basic ideas of democracy. Involved here are issues of power and culture: 'ability' grouping is not just a neutral organisational practice. Oakes, Wells, Jones, and Datnow (1997) maintain that common sense conceptions of ability and intelligence are at the heart of schooling and, in regimes where neoliberalism holds sway, the ability discourse is part of an ideological battle defining children from lower social and economic status groups as expendable (Oakes, 2005). Further, the performativity regimes (Ball, 2003; Povey, Adams, & Everley, 2016) imposed on schooling have created a climate whereby failing to conform to the common sense view of the world carries huge risks to schools and to individual teachers; and grouping children by 'ability' as measured through some form of assessment, endorsed by policy makers, is seen as risk free.

A technician approach to reform will therefore not work as it assumes resistance to changing 'ability' grouping is simply a rational choice by relatively free agents. We offer here a story of a single teacher, Jim, and his changing relationship to setting. (Pseudonyms are used throughout and some details have been changed to protect participant anonymity.) Before doing so, we consider very briefly the role of storying in the construction of knowledge.

## Telling stories

We are telling this story about Jim, much of it in his own words, because we believe that stories help us understand more about the world. There is an "unavoidable moral urgency" (Clough, 2002) in stories which fits our purpose in this paper. Jerome Bruner (1986) wrote about two different kinds of knowledge: *paradigmatic knowledge* and *narrative knowledge*. Whilst the former is expressed through logical propositions, the latter is expressed through stories. He argues that it is characteristically human to think in stories and that they provide us with a way to make sense of experience. Stories imply, and attempt to lay bare, intentional states, that is, to offer insights into why we do what we do.

In constructing this story, it is, of course, our categories, concepts, constructs and so on which frame and shape the work. However, we have tried to stay as faithful as we can to Jim's own constructions, accounts and perspectives as far as we have been able to elicit and hear them. We

have also tried to offer sufficient detail to allow others to test out the trustworthiness or otherwise of the account and to judge, for example, whether the intentions suggested make sense.

### **Jim's story - or our story about Jim**

Jim is a highly committed, very hard working teacher who has the interests of his students very much in the forefront of his thinking. On a personal level, he is open and his stance towards visitors to his school and department is always one of welcome. He has kept in touch with the university where he completed his initial teacher education and continues to work frequently and supportively with its current students. He agreed to be interviewed (with a close colleague). The interviews were recorded and transcribed. Working with the transcripts in variety of ways, we began to be compelled by Jim's story as honest, contradictory and telling about teachers' relationships to the issues of setting; we tell a version of this story below.

Jim's final teaching practice at McVee High had not been a happy one. He had clear ideas about how mathematics should be taught and wanted to create his own lessons and his own resources. He wanted the scope to try out different and novel approaches and to avoid the routine use of an indifferent textbook.

I don't know what I was expecting. I didn't really enjoy working at that school at all and I was really glad to leave. The head of department didn't like me. He didn't like my teaching ... He'd get a face on if I wanted to move the tables around, even just move them anywhere. He just wanted them where they were and if I didn't want to use a textbook he would have a face on about that as well. Like "Why are you not using that page?" – "Because I've made this instead". He didn't like that. It was *Lock Maths* and all you did was you started on page one and the scheme of work was just ... go through the book. And if you didn't go through the book, then you were an idiot apparently. But that was how it was and it was just a waste ... I didn't practice being a teacher at all. You'd practise administering "Do page 12."

Part of the way through Jim's initial teacher education course, his tutor, Barry, left in order to take up the post of head of mathematics at Broadbent School. Broadbent serves a large, white working class, social housing estate in an ex-industrial town with overall attainment below the national average. The mathematics department had had a chequered past and when Barry was appointed there were vacancies in the department. Barry and Jim kept in touch and Barry approached Jim to ask him to come and have a look round the school with a view to starting his teaching career there. After the visit Jim was offered a post at Broadbent School as a newly qualified teacher and accepted the offer.

I didn't want to work in a posh school. I didn't want to do that ... Like Our Lady's where the kids are all little robots. I didn't want to work there. I wanted to work in a bit more challenging area and I already knew Barry as well ... I'd always said that I would start my career in a more challenging school and probably end in an easier school because I just wouldn't have the energy...

Broadbent offered Jim six week's work in the second half of the summer term preceding his permanent appointment in September so he could get to know the school and the pupils a little. It is clear that Jim was already confident about his mathematics teaching and keen to begin practising.

It was intended I think that we were supposed to come and like just have a look about and observe and stuff, but I couldn't do that in the end because I was spending most of my time with a woman called Marion, who'd got a full-time maths timetable but she had no real maths qualification at all. She was an art teacher and I was just watching her teach all these lessons and just thought "I can't really let her do it because she's doing it wrong." So I just ended up teaching for six weeks ... I just said "I'll do them for you and you can go and do something else." ... She couldn't teach them. She was just teaching them drawing. They were drawing things and she would let them sit there and do nothing while she would like paint portraits of them and I was like no, we can't be having that.

Jim had wanted to be a secondary mathematics teacher for longer than he could remember and he looked inward to his own thoughts and backwards to his own experiences as a school pupil to frame and understand his practice. For him, Broadbent offered the freedom to develop in his own way as a practitioner, a freedom he highly valued, and one which was "quite liberating actually".

I didn't enjoy going to university at all. I didn't even want to do anything there. I just hated the whole experience. And I didn't like going to college, didn't like doing my [school exams]. I just wanted to be a maths teacher and I just wanted to get there, so it was quite nice to get there and have your own classroom and then actually start teaching. I'd wanted to be a maths teacher since I was [a child]. So everything just seemed like in the way of trying to get there ...

Thus, Jim did not respond to and make use of the mathematics education approaches and understandings offered to him by his university tutors during his initial teacher education. At a slightly later date, when offered a professional development opportunity linked to a local university, he asserted with confidence that he had "never read a book". This seemed important to him in constructing his way of describing himself in the world.

He had a complex and contradictory relationship to his school experiences of mathematics.

All my maths teachers had been rubbish. Every last one ... I wasn't really taught maths because I always followed the ... [resource based] scheme of work ... never did a teacher really stand at the front and say "This is how you do this."

Despite this, Jim had kept all his mathematics books from school "because I knew I was going to be a teacher" and he remembered working together as a whole class on investigations, material which he was continuing to use at Broadbent. Not only that, at school he had "just really enjoyed maths and always have". In the context of this paper, two things stand out about Jim's account of his school experiences. First, he had been taught in all-attainment groups using an individualised scheme and, despite his assertion that all his teachers were "rubbish", he said that "everybody did well because you had appropriate tasks". This "completely differentiated" approach seemed fundamentally to inform his thinking about all-attainment teaching. Second, he spoke about himself as having a fixed level of mathematical ability and he linked his understanding of his own competence as a mathematician entirely to external markers.

I've never been like really good at it, but I just really enjoy doing it. I mean I only got a level 5 in my primary school SATs and I got a level 7 in my secondary school SATs and I got a B at GCSE. I got an E at A Level ...<sup>3</sup>

This was echoed in the way Jim talked about the Broadbent pupils. Throughout the interview, the pupils were referred to by Jim in a variety of ways all of which seemed predicated on fixed ability thinking: “lower foundation type students”; “the very brightest students”; “ten kids that should definitely do high maths”; “their [SES] data ... regardless of social context that is the grade they should get based on [results from primary school] ... regardless of whether their mum’s on drugs or they’re on free school meals”.

Coinciding with Jim’s arrival at Broadbent, Barry introduced all-attainment teaching for the first year classes.

We all knew what Barry was about ... it’s not like he kind of hides it under a bushel. He would say in meetings what was his kind of pedagogy and what he wanted to achieve.

But this claim seems to have related to using a more open and problem-solving approach rather than providing any sort of challenge to fixed ability thinking. Barry prepared packs of materials which were full of ideas that offered a more investigatory approach than the one with which the teachers were familiar organised around broad topics. When asked for an example, Jim said

... the first half term ... you would do a unit on triangles and you’d do a unit on cubes ... and you could do them in whichever order you wanted to. [But] you didn’t have to use any of it. You could use none of it, some of it, all of it, your own stuff ... Some of the resources I didn’t like so I didn’t use them ... [I used] a combination. We had textbooks, so sometimes I’d use those, sometimes I’d make my own and sometimes they’d do it off the board and sometimes ... just find something on the internet and re-purpose something if you like.

Towards the end of the year, Barry asked his department if they would like to continue working in this way with the pupils during the following school year, thus extending his all-attainment project into the first two years of the school.

Did we want to continue the kind of thematic approach? Did we want to continue the mixed ability approach? And we all said yes. We enjoyed it. We enjoyed doing it, so we said yeah.

However, for Jim, teaching all-attainment groups was synonymous with providing differentiated materials. On occasions he was able to make this work effectively for him and his class:

If you really wanted to differentiate, particularly when we used to teach mixed ability and we were doing fractions ... I just had the [levels of difficulty] on the board and they would just pick whichever one they wanted ... most people just try and go for the one that’s quite challenging. Some of them knew that there was no point in trying the level 8 one because they were a level 4

---

<sup>3</sup> These are all public examinations in the English school system. The curriculum and the associated SATs were structured into levels. Jim’s results are mostly above average but not excellent. The final school leaving mathematics grade is lower than average for those who take the examination.

kid or something, but they didn't go for the easy option. They went for an appropriate level one and I think they quite enjoyed it. They liked it ... and I think they liked having the choice as well.

But overall the task of trying to provide differentiated materials across the attainment range, rather than adopting a fundamental pedagogy for attainment for all, proved overwhelming and undoable.

My experience of [the second year groups] was at that point the difference between the highest and the lowest had increased dramatically and it was becoming a strain ... They'd all made progress, but the higher ones had made more progress and so I was having to differentiate more and then do the same for my new first years ... it was becoming very fraught and time consuming and I wasn't doing it as good as I could have... No, I wasn't teaching as well as I should have been teaching because I was spending too much time doing too much differentiation ... I just couldn't do it effectively ... there was just so much planning and I was kind of making do I think.

Jim did not give up easily and shortly afterwards when Barry had moved on and Jim was given responsibility for the department, he even extended the all-attainment teaching to a third year. However, and unsurprisingly, this did not last.

The kids bottomed out, teachers were over stressed, over worked. I don't understand why I did it in the first place ... I mean I can look back now and think "You stupid idiot!" I obviously already knew that it was really difficult to differentiate across two different year groups and it was a lot of planning, so I don't understand why I did it.

It is interesting to follow how Jim justified and explained the policy reversal when looking back several years later. The initial cohort of students who had had two years of all-attainment teaching – and experienced all the initial commitment and enthusiasm – had done remarkably well in both the high stakes, external tests they took, one at the end of their third year and one at the end of their fifth. The following year group was a much more challenging cohort and were problematic throughout the school. But the difficulties Jim and the department experienced were not seen in this light. Rather, they became the basis for a rejection of an all-attainment approach. And we see again the role that all-attainment teaching as individual differentiation played in making life impossible.

It just didn't work. The kids weren't getting the grades or the marks or the levels, whatever, and behaviour was awful. No, it just didn't work ... you could physically see that there was more stress on teachers' faces because not only were you having to deal with challenging behaviour, but you were trying to deal with trying to get X to get a level 8 and Y to try and count up to 5 in the same class and it was too hard. It was too hard and it didn't work. It failed. Everybody was more than happy [to go back to setting] ... The year after we taught just setted by ability and they got much higher results.

Jim is now firmly of the opinion that, at least in a school like Broadbent, there is no place for all-attainment teaching:

I would just set them. I'm definitely now not a mixed ability fan in a challenging school. It's just too much.

## Discussion

Our aims in this paper are modest. We do not expect stories like this to have any traction with policy makers and we very much welcome alternative approaches that may have the “requisite symbolic power” (Francis et al., 2016, p. 13) to do so. Here our purposes are rather different. Our intention has been to tell a story of a single teacher which illustrates how “powerful discursive productions of the ‘obvious’, ‘real’, and ‘natural’” (Francis et al., 2016, p. 10) work in practice to shape this teacher’s thinking about ability. Jim is striving to make sense within this discursive framework. He conceives the pupils as simply *being* such and such a level *person* in mathematics and so inherently needing a differentiated approach to learning: the pupil’s essence determines within fairly narrow limits what she or he can do. With such a view, offering a more open curriculum in which the unpredictable is expected makes no sense and the task of all attainment teaching becomes simply unmanageable: Jim is led to validate practices with respect to pupil grouping that reinforce inequalities despite the honourable intentions to do otherwise.

If fixed hierarchies exist - of who can understand and achieve what in mathematics - and there is a predicted and predictable limit to what can be expected from any particular individual, as current policy technologies insist, then the possibility of creating a pedagogy where all can succeed, and where success is attributed to the learning community rather than to individuals, is precluded:

the production of hierarchies of ability via a discourse of ‘natural order’ acts as a technology of privilege, and renders alternative accounts (including research evidence) unintelligible. (Francis et al., 2016, p. 12)

Knowledge, discursive practices and both deep and espoused beliefs all interact in complex and layered ways in shaping how we think and what we do. A two-fold argument follows from Jim’s story. First, changing practice alone is unlikely to engender ways of being in the world that challenge established ‘natural’ hierarchies. Second, there is a need for research-informed, counter-hegemonic knowledge and understandings to be foregrounded, alongside curriculum innovation and the re-imagining of pedagogy, if the dominant and unjust practices of grouping by ‘ability’ are to be effectively countered in the countries in which they currently prevail.

# Diversity in an inclusive mathematics classroom: A student perspective

Helena Roos

Linnaeus University, Växjö, Sweden; [Helena.Roos@lnu.se](mailto:Helena.Roos@lnu.se)

*This paper reports on a study exploring inclusion in mathematics education from a student perspective. The theoretical and analytical approach in the study is discourse analysis. The results presented in this paper are based on 8 interviews with students from lower secondary school and 4 observations of mathematics lessons. The teachers describe the students as students in special needs in mathematics (SEM). The results show that, from a student perspective, the teaching and learning of mathematics in an inclusive classroom is complex and diverse. At the same time, as these students are similar in that they are SEM-students, they are different when it comes to how they themselves want to be included in the mathematics. These differences regard both the organization and the content. Thus, diversity among students demands diversity in the mathematics education.*

**Keywords:** *Inclusion, diversity, equality, access to mathematics.*

## Introduction

A growing body of research in mathematics education is focusing on access and equity. This can be seen in some of the research books that have been published in recent years, for instance *Diversity in mathematics education: Towards inclusive practices* (Bishop, Tan & Barkatsas, 2015), *Towards equity in mathematics education* (Forgasz & Rivera, 2012), and *Mathematical literacy: Developing identities of inclusion* (Solomon, 2009). In addition to this, at school-level, the issue of the need to meet every student's needs in the mathematics classroom according to the preconditions and needs of each and every one has been recognized (Roos, 2015). This task, to be able to meet all students' needs and create opportunities to learn, is not at all an easy task. Some teachers even say that it is impossible to meet every student's needs in an inclusive classroom because of the diversity. On the other hand, one could look upon teaching diversity as Frederickson and Cline (2009) do, claiming that teaching is interesting because of the diversity among students, but it is only possible because of the similarities among students. This implies that even if there is diversity among students in our mathematics classroom the teaching does not have to be different for each and every student, but by being aware of the diversity as a teacher you can develop a sensitivity towards equality in the teaching. In that sense, you put the students' needs at the forefront in the explanations and tasks given.

In mathematics education one of the motivations to strive for inclusion and access to mathematics for all is that it is a human right to know mathematics to achieve participation in society (D'Ambrosio, 2010). Most often inclusion is discussed and researched from this ideological perspective even though it is often used as a method in schools. Hence, there is a need for studies investigating inclusion in practice, which this research aims at. This leads to the research questions of this paper, which are: how do students experience an inclusive mathematics classroom and when do they express having optimal opportunities to learn mathematics?

## Diversity and Inclusion

What does diversity and inclusion in mathematics mean? It seems that when scholars talk about diversity in mathematics, they almost always speak of inclusion in the same breath (e.g., Bishop, Tan & Barkatsas, 2015), indicating the two notions are closely related. When investigating further, inclusion, if used as a tool in classrooms, can be seen as a way of meeting diversity, supporting all learners within a local community (Booth, Nes and Strømstad, 2004). Diversity on the other hand is not often defined, but used together with gender and culture (e.g., Forgasz & Rivera, 2012). It is also used together with specific subject area in mathematics and students' performances within this area (e.g., Hopkins & de Villiers, 2015); hence diversity is here connected to some kind of ability in mathematics. Accordingly, diversity can be connected to different things. In this paper diversity is connected to inclusion on the level of optimising students' performance in mathematics.

An inclusive classroom is in this paper defined as a classroom that is not grouped by ability but instead as a classroom in which students struggling with mathematics as well as students in need of more challenges in mathematics are taught working with similar tasks and the same mathematical content. Hence, diversity from an ability perspective is prioritized. This puts demands on the teacher, being aware of the diversity (Solomon, 2009), to have equitable instructional quality. This quality can be seen in the teachers' mathematical knowledge and their preparation for the teaching of mathematics as well as their beliefs about and skills in teaching diverse students (Allexsaht-Snider & Hart, 2001). So, in having equitable instructional quality, students' opportunities to learn mathematics might increase. But according to Rousseau and Powell (2005), there are factors that can work as barriers for increased opportunities to learn mathematics: large class sizes, high-stake-standardized tests, absenteeism and mobility of students and a lack of a high-quality curriculum. All these issues arise from a teaching or organisational perspective. Hence, it becomes important to also listen to the students' voices, enabling teachers to understand processes of exclusion and inclusion in the mathematics classroom like Solomon (2009) highlights.

One important issue arising when talking about the ability of individuals is labelling. There are many teachers that claim that in order to be able to meet the diversity of students they have to "label" them in some way. Though, Askew (2015) claims that meeting diversity does not imply that we have to label the students, because labelling might perpetuate exclusion instead of promoting inclusion. One way to meet diversity and create an inclusive classroom is to support cooperative learning (Askew, 2015) by building a sense of belonging and safety where diversity is valued (Reid & Valle, 2004). This implies that the teacher and the pedagogy the teacher uses in the classroom are really important to create this learning community. Then, as Liasidou (2012) points out, pedagogy is an important dimension of inclusion. All this implies that diversity and inclusion are intertwined, and if striving for inclusion one has to respect diversity (Booth, Nes & Strømstad, 2004). Accordingly, in this study the objective is to investigate diverse students' experience of an inclusive mathematics classroom.

## The current study

The focus in this research is on students in special educational needs in mathematics (SEM-students). Special educational needs are here defined as a need of another teaching than the regular mathematics teaching. This is not unproblematic, since it signals a labelling of students in the

research. To be vigilant in terms of that issue, the teachers in the study have made the selection of students. In this research, inclusion in mathematics is investigated from two different SEM-directions: students struggling with mathematics, and students in need of more challenges in mathematics. This kind of selection is information-oriented and used to “obtain information on unusual cases which can be especially problematic or especially good in a more closely defined sense” (Flyvbjerg, 2006, p. 230).

An ethnographic approach is used, meaning the researcher participates directly in the social setting collecting data without meaning being imposed on the participants (Brewer, 2004). The ethnographic approach also offers in-depth study (Hammersley & Atkinson, 2007), which can be used to follow a process in a particular case, such as to be included in mathematics teaching and learning. An ethnographic study usually investigates people’s actions and accounts in an everyday context. In this study, a Swedish lower secondary school (students are 13 to 16 years old) that sets out to work inclusively is observed. That is, the school strives to have all students in the classroom, even the students assumed to be in special educational need of any kind. To be able to meet all students’ needs, they strive to have at least two teachers in the classroom for each lesson. The school is an urban school with about 500 students, located in the outskirts of the city.

One grade 7 and one grade 8 class were observed. The mathematics teachers in a discussion with the researcher selected the classes and the students. Grade 7 was selected based on the criteria that working inclusively might be new for them. Grade 8 was selected since they have been working inclusively for a year. Students from grade 8 and grade 7 that struggled with mathematics as well as students that needed more challenges were chosen and interviewed several times. Ethical considerations were made both before and during the process. Both the students and their guardians gave written consent. As a researcher, I reflected on what ways I affected the students and the research. Another aspect was that the students in the classes would be able to handle a researcher in the classroom.

## **Methodology**

The approach used in this research is Discourse Analysis (DA) and the data consists of observations from two classes.

### **Discourse Analysis**

Discourse Analysis is chosen as approach because of the power of DA to focus on language in interaction and language above or beyond the sentences (Gee, 2014a) and its explanatory power of social contexts and meaning making. The focus of DA is on language and text, what we actually can see, hear and read. In this study, ethnography was applied together with DA in order to make students’ expressions of mathematics teaching and learning visible. DA and the ethnographic approach complement each other in this research; DA provides theoretical and analytical notions, while ethnography provides a way to conduct research.

In this paper, DA is used from the perspective of Gee (2014a, 2014b), since this focus is descriptive and I intend to describe how students want to participate in an inclusive mathematics classroom to be able to have optimal opportunities to learn. From Gee’s perspective, DA covers all forms of interaction, both spoken and written, and he provides a toolkit for analysing this interaction. These

tools put focus on the communication and ask questions of the text. Hence, in this research, the toolkit is used as a methodological tool.

Gee (2014a, 2014b) also provides theoretical notions, such as *big and small discourses* (henceforth referred to as Discourse with capital D and discourse with lowercase d), where Discourse is looking at a wider context, social and political. Discourses are always embedded in many various social institutions at the same time, involving various sorts of properties and objects. For example, a Discourse can be “assessment in mathematics.” Discourses are always language *plus* “other stuff” (Gee, 2014a, p. 52). This other stuff comprises actions, interactions, values, beliefs, symbols, objects, tools and places. Small d discourse is focused on language in use, what *stretches of languages* we can see in the conversations or stories we investigate (Gee, 2014a). In this research, big and small discourses will be the theoretical perspective. Hence, DA is used both as a theory and a tool and provides a set of methodological and theoretical lenses.

## Procedure

During one semester (January to June 2016) I observed the two classes at the chosen lower secondary school. I was present at least one mathematics lesson each week for each class doing observations. After observations, I conducted interviews with the selected students. Since I had both ethical and organisational issues to take into consideration, the interviews were done when the students wanted to and had time, and the teachers allowed it (they did not want me to interview them when they had their ordinary lessons). The interviews took place in a room next to the classroom when the students had “class time” once a week. The interviews were based on the close in time observations; hence, they were situated and narrative. I asked questions about situations and tasks and showed photos of tasks on the blackboard. We also looked at tasks in their textbooks. The first and the last interview were based on a questionnaire about their mathematics education.

## Data analysis

In this paper, eight interviews and four observations have been used in the analysis, two interviews with a student in grade 7 named Billy and two interviews each with three students in grade 8, Edward, Ronaldo and Jeff. The teachers perceive Ronaldo and Jeff as students in struggle with mathematics and Billy and Edward as students in need of more challenges in mathematics. In the interviews the students got questions about what they wanted from the teaching in mathematics, how they learned mathematics best and also got questions arising from the previous mathematics lesson, which were the four observed lessons. The observations were used as contextualisation for the interviews as well as for supporting identification of big Discourses. When analysing the data by asking questions to the text, both small and big discourses appeared. That is, while examining the text, I used Gee’s toolkit by asking specific questions. Depending on the type of text, different questions were asked. For example, when using the subject tool, I asked, “What are they talking about here, and why?” When using the deictic tool, I asked, “What is pointed out in the text, and what is the listener assumed to already know?” When applying the fill-in tool, I asked, “What needs to be filled in to achieve clarity? What is not being said overtly, but is assumed to be known or inferable?” Then, stretches of language(s) appeared when finding answers to the questions, which signalled for small discourses. When adding analysis of the data from the observations, such as text on the blackboard and the actions of the teachers, big Discourses could be identified.

## Result and analysis

In the analysed data, three themes, or using Gee's (2014b) terminology, three "stretches of languages" emerged. The first theme was about how students wanted to participate from an organisational perspective. The second theme was about tasks they did or did not like and the third theme was how the student wants a mathematics lesson to be like for an optimal learning opportunity.

### Organisational aspects

In the interviews, stretches of languages about organisational aspects were showing. In the first interview Ronaldo says, "We are starting to *go outside [the classroom]* into small groups, like we did not do before, and it feels much better now. I am concentrating a lot better [in a small group] and like that." He also explained why it felt better to be in a small group: "It feels better actually, you get peace and quiet and then... like me... if they talk a little there [inside the classroom] I lose concentration right away and listen to what they [the other students] are saying; when it's smaller groups I am able to concentrate better and learn more." In Jeff's first interview he also highlights the possibility of being able to *go outside the classroom*: "... if it's a test or something I would rather be outside [the classroom] since I am more focused then." Edward also talks about the organisation, but within the classroom when he is discussing cooperation. "It is not very easy, since I have often come a long way, so I always explain to them, it never gets to a discussion for me... I mean, with somebody else, that we discuss and so on [...]." When the researcher asks Edward if it is hard to discuss with everybody he says, "It depends on whom I am sitting next to." He also expresses that he does not *sit next to someone who can challenge* him, and says that he would like to do that more. "I think I would get more out of it."

### Tasks

Other stretches of languages showed talk about tasks. Billy explicitly talks about his need of *more challenging tasks* in the classroom. "I like those [tasks] which are harder, those that challenge you." "[I would like to have] more challenges [...] at the lessons." He explicitly talks about *problem solving tasks* as something challenging: "I like it when we have problem solving. You get to think for yourself and then talk to friends [about it]." Ronaldo also talks about *problem solving* but in a rather different way. "I hate problem solving tasks more than anything! I just cannot do it." He also describes why he does not like it: "It is hard with reading comprehension and like that, and to connect it with like the task and the text, it gets too much. It is often that kind of task I fail at on the tests." Jeff talks about tasks that he likes. These are tasks he knows "how to calculate and tasks that I understand." He mentions geometry tasks as tasks he likes. The type of tasks Edward likes the most is Algebra tasks. "To be able to find out all the variables, it is fun to figure out what it is." Here we can notice a difference to how Ronaldo thinks about algebra tasks when he states that he thinks that it is hard with "like all this with X and Y and everything ... it is terrible."

### A good mathematics lesson

A third stretch of language is the talk about what the students want from a mathematics lesson in order to be able to learn mathematics the best. Jeff states that what is most important for him in a mathematics lesson is "if they [the mathematics teachers] explain good ... and thorough, if they write step by step." He also says if he knows what to do it "feels good, I know what to do and I get

on with it right away.” Meaning, for him the *thoroughness and structure in the instructions* is important. Ronaldo likes to have a lesson when you “first work a little [by yourself] and then some ‘going through’<sup>1</sup> and then you *work a little by yourself and then you do some group work* with those you sit with [...]. It is more fun when you are in a group and cooperate.” Edward on the other hand thinks that it is hard to cooperate and “extremely hard to get something from the others in the class.” Instead, he like *lessons “with variation* so that you don’t get tired.” He also likes “a going through or something like that, gladly a game or something. You should [also] count a little by yourself I think.” Billy thinks that the lessons are best “when you get to *explain to others* [students] how you have done it.” He likes when “we have like problem solving.” He also stresses that he wants “more challenges at the lessons.”

### Identified discourses and Discourse

The three themes appearing in the data – organisational aspects, tasks and a good mathematics lesson – can be interpreted as small discourses (Gee, 2014a) in the students’ talk of their mathematics education. There are aspects in this talk from the different students that overlap, such as wanting to be in a small group sometimes, which both Jeff and Ronaldo stressed. Another aspect that overlaps is collaboration. Both Billy and Ronaldo highlighted collaboration, but Edward on the other hand felt that his peers did not challenge him in the discussions, but he said that he thought he would get more out of it (meaning the discussions) if he sat by a peer that had the possibility to challenge him. There are aspects that diverge, such as what type of task they want to have. Billy says he wants more problem solving and Ronaldo “hates” problem solving. Edward likes algebra tasks and Jeff likes geometry; hence there was no consensus on types of tasks or mathematical content they prefer. Another aspect that appears in the students’ talk was the organisation of the lesson. To attend a structured lesson, with both explanations by the teacher and work by yourself or together with others seemed to fit them all. Jeff is more explicit about his wishes for structured lessons, indicating a need of structure to explain what to do. Even though all these small discourses contain diversities, they together indicate a big Discourse. When looking at the observation notes from the lessons you can identify support to this big Discourse, in terms of talking about tasks, organisational aspects such as “talk to your neighbour” or when the special teacher attending the classroom walks outside the classroom with some students; also, the type of task being addressed at the blackboard, and the way the teachers structure the explanations at the blackboard and the talk of what to include in an explanation. This big Discourse can be named “mathematics in school”: what mathematics in school is or means for the students and what they want from the mathematics to be able to learn best.

### Summary of results

The result shows both overlapping and diverging issues regarding how students experience an inclusive mathematics classroom and having optimal opportunities to learn mathematics. Regarding organisational aspects, Jeff and Ronaldo stressed the need of *being in a small group outside* the classroom from time to time even though the school promotes physical inclusion, and Billy and Edward highlighted *collaboration* in order to have opportunities to learn. Diverging aspects are type

---

<sup>1</sup> Going through is “genomgång” in Swedish, which is when the teacher is explaining something on the blackboard.

of tasks; for example, where Billy wants *challenging tasks* in the form of *problem solving*, Ronaldo hates problem solving. How the students want a mathematics lesson both diverges and overlaps: *thoroughness and structure in the instruction; work a little by yourself and then in a group; lessons with variation* and *explain to others* were expressed as good ways of learning.

## Discussion

A diverse picture of how students want to participate in an inclusive mathematics classroom to be able to get optimal learning opportunities appears in this research. Although this is not unexpected, it is important to highlight this diversity and address the question of how the organisation and the education can support this diversity in order for students to be included in mathematics. This is not just only spatially included, but is also included in the teaching and learning of mathematics. The diversity of how students want to participate in the mathematics classroom that appears in this research stresses the need for diversity in mathematics education at school. One thing that is striking is that students expressed a need of being in a small group outside the classroom from time to time. The school promotes physical inclusion, and it did not seem to always benefit these students. You might say that diversity among students demands diversity in mathematics education. But, as Fredrickson and Cline (2009) stress, even though students are different, teaching is only possible because students are similar in some ways. This research supports this, because even if the results showed diversity among the students (both within and between students that are perceived as students in need of more challenges in mathematics and students that are perceived as struggling students in mathematics), the results also showed similarities between the students. These similarities are something the teaching can take advantage of, in the organisation and planning of the mathematics education in order to get equitable instructional quality. However, barrier factors such as large class sizes, high-stake-standardized tests (Rousseau and Powell, 2005), etc. can be prohibitive to the work of equitable instructional quality. If the organisation is responsive to the diversity among students and is aware of barrier factors it might be dynamic and adjust accordingly to improve access to mathematics and an increased inclusion in mathematics.

# School mathematics education through the eyes of students in Ghana: Extrinsic and intrinsic valuing

Wee Tiong Seah<sup>1</sup>, Ernest Kofi Davis<sup>2</sup> and Monica E. Carr<sup>1</sup>

<sup>1</sup>MGSE, The University of Melbourne, Australia; [wt.seah@unimelb.edu.au](mailto:wt.seah@unimelb.edu.au)

<sup>2</sup> Institute of Education, University of Cape Coast, Ghana

*1256 students from 18 primary and secondary public schools across urban and rural settings in the Cape Coast Metropolis of Ghana responded to the “What I Find Important (in my mathematics learning)” questionnaire. The data analysed suggested that students in Ghana valued in their mathematics learning: achievement, relevance, fluency, authority, ICT, versatility, learning environment, strategies, feedback, communication, fun, connections, engagement, applications, and accuracy. The students’ embracing of these attributes is explained by reflecting on the societal and pedagogical norms in Ghana. When compared to high performing economies in East Asia, it was found that most of the Ghanaian attributes represent extrinsic (versus intrinsic) valuing. Implications and suggestions for policy-making and for classroom teachers are provided.*

*Keywords: Values, Ghana, extrinsic/intrinsic valuing, East Asia, WIFI.*

## Mathematics education in Ghana

Students value attributes of mathematics learning (e.g. *practice* and *understanding*) differently, with implications for the quality of mathematics learning that takes place (Matthews, 2001). The extent to which a student values *understanding*, for instance, may influence how relational understanding may be preferred over instrumental understanding, the extent to which the development of algorithms is important, and indeed, the extent to which s/he is interested – and perseveres – in knowing how these algorithms or formulae came about. In other words, what and how much an attribute of (mathematics) learning and teaching is valued influences a student’s development and/or application of cognitive knowledge and skills, as well as the maintenance of affective states.

Drawing from relevant seminal literature, Smith and Schwartz (1997) have argued that, while values are abstract concepts, they are not so abstract that they cannot motivate behavior. The ability to identify, review and facilitate/modify what students value in their mathematics learning should optimise the cognitive and affective-based pedagogical strategies that support learning.

This paper reports on Ghana’s participation in a 19-country study on what students valued in their mathematics learning experiences. Focussing on this West African country, and analysing and interpreting the data collected there, was aimed at achieving an understanding of the Ghanaian mathematics education system, both in its own right and also through comparisons with other countries. This is especially significant, since Ghanaian students’ mathematics performance has been low by global standards (Enu, Agyman & Nkum, 2015). For example, in the TIMSS 2011, Ghanaian eighth grade students ranked last amongst 45 participating countries in mathematics achievement (Mullis, Martin, Foy, & Arora, 2012).

Ghanaian students’ transitions between school and out-of-school mathematics have not been without its issues. In the home context, the units of measurement of money and of capacity are different from the metric ones being taught in schools. The schools’ language of instruction from

Grades 4 and above is also different from the languages used by students at home and outside in public. A further complexity when considering school mathematics education in the Ghanaian context is in the way students there experienced fractions differently in school and in out-of-school contexts. For example,

the majority of the students were able to identify half in the out-of-school activity perhaps due to that fact that it is the only unit fraction that has local name (fã). However “fã” does not mean equal halves, it means about mid point. Thus three-fifths may also be categorised as “fã”. Students’ difficulty in naming the other units fractions may be due to the fact that in out-of-school setting they do not differentiate unit fractions. Thus with the exception of half which could mean about midpoint all the fraction are described as less than whole (sin). (Davis, Seah, & Bishop, 2009, p. 69)

## Values in Mathematics Education

Values are “the principles and fundamental convictions which act as general guides to behaviour, the standards by which particular actions are judged as good or desirable” (Halstead & Taylor, 2000, p. 169). Essentially, then, values reflect what we think are important to us, and are thus distinct from beliefs, which reflect what we think are correct. Values can be viewed as a form of culturally-based tools with which we mediate our actions and behaviour in the learning process.

In the field of mathematics education, we adopted Seah and Andersson’s (2015) definition that

values are the convictions which an individual has internalised as being the things of importance and worth [...]. Valuing provides the individual with the will and determination to maintain any course of action chosen in the learning and teaching of mathematics. They regulate the ways in which a learner’s/teacher’s cognitive skills and emotional dispositions are aligned to learning/teaching in any given educational context. (p. 169)

What are valued by the individual, as these are shaped and refined by life’s experiences (including classroom learning experiences), impact on subsequent decisions and actions. They do so by affecting the ways the individual reasons and feels about the task or problem at hand. As the quote above suggests, this volitional force can be quite powerful, manifesting themselves in the form of will and determination.

When the individual interacts with others (e.g. teachers interacting with their students in the classroom), it is inevitable that there would be differences in what each person values. Such differences can potentially lead to conflicts, and one or more of the people involved will seek to negotiate and resolve these differences, achieving a level of cognitive harmony that is acceptable by most if not all involved.

In terms of the types of attributes of mathematics learning and teaching valued, Bishop (1996) had categorised these into mathematical values (i.e. regarding the mathematics discipline), mathematics educational values (i.e. regarding the pedagogy of mathematics), and general educational values (i.e. regarding the moral and civic virtues). Earlier, Bishop (1988) had conceptualised 3 pairs of complementary mathematical values, namely, *rationalism* and *objectism*, *control* and *progress*, and *openness* and *mystery*.

Prior to 2010, research of values and valuing in mathematics education had focussed on small-scale studies of what teachers valued (e.g. Chin & Lin, 2000). The setting up of the Third Wave Project in 2008 not only brought together a group of researchers internationally to support – and collaborate with – one another on research studies into valuing, but it also shifted attention to the examination of what students value in their mathematics learning (e.g. Seah & Wong, 2012).

On the other hand, much research related to PISA and TIMSS had been conducted by or with education systems which have performed relatively well in these tests, with relatively little research attention paid to mathematics education systems at the other end of the performance spectrum. Yet, the experiences of these countries can also serve as an important reflection on what (else) contribute to effective mathematics learning. As such, a study named “What I Find Important (in mathematics learning)” (WIFI) was designed to investigate what students in 18 different economies value when they were studying mathematics, Ghana being one of these economies. This paper reports on the Ghanaian data of the WIFI study, and how the findings address two of the research questions posed to guide the Ghanaian study, namely:

1. What did school students in Ghana find important when learning mathematics?
2. How might the valuing amongst the Ghanaian students be similar to or different from what their peers elsewhere in the world valued?

## Methodology

The first research question suggested a need to ‘map the scene’ for Ghana (and indeed, for the other participating economies too). As such, the questionnaire survey method was adopted. The validated WIFI questionnaire has four sections. A Likert-type scoring format was used for the first 64 items in Section A, in which students were asked to indicate how important mathematics pedagogical activities such as small-group discussions (item 3), connecting mathematics to real-life (item 12), and mathematics homework (item 57) were to them. A five-point scoring system was used, ranging from absolutely important (1 point) to absolutely unimportant (5 points). Section B consisted of 10 continua dimensions, each related to two bipolar statements and respondents were asked to indicate along the continuum the extent to which their valuing leans towards one of the two statements. Section C consisted of four scenario-stimulated items; and Section D items asked for students’ demographic data. The English language version of the WIFI questionnaire was administered, English being the medium of instruction in Ghana. In this paper, only the responses to Section A will be presented.

Student participants were sourced from public schools at the primary, junior high and senior high levels in the Cape Coast Metropolis of Ghana. Stratified random sampling procedure was used to select students from a mix of schools, by achievement levels and by rural versus urban settings. In all, 1256 research participants comprising 414 primary four, five and six pupils, 426 junior high school pupils and 416 senior high school students from 18 schools participated in the study.

In line with the data analysis conducted by the other 18 participating economies, a Principal Component Analysis (PCA) was performed.

## Results

The data gathered from the 64 Likert-scale items of the WIFI questionnaire was cleaned prior to data analysis. They were first analysed to identify any missing values. The eleven missing responses identified out of the total possible 80,384 (i.e. 64 X 1256) was acceptable, and each of these was replaced with the value “9”.

The Kaiser-Meyer-Olkin (KMO) (Kaiser, 1970) measure of sampling adequacy was 0.947 and Bartlett’s test of sphericity (BTS) (Bartlett, 1950) was significant at the 0.001 level and so, factorability of the correlation matrix was assumed, which demonstrated that the identity matrix instrument was reliable and confirmed the usefulness of the principal component analysis.

### Principal component analysis

A principal component analysis (PCA) with a varimax rotation and Kaiser normalization was used to examine the questionnaire items. The significance level was set at 0.05, while a cut-off criterion for component loadings of 0.45 was used in interpreting the solutions. Items that did not meet the criteria were eliminated. According to the cut-off criterion, 23 items were removed from the original 64. The analysis yielded 15 components with eigenvalues greater than one, which accounted for 52.73 % of the total variance. Each component can be considered to be an attribute that were valued by the students in Ghana, with the relevant questionnaire items regarded as describing the characteristics of the attribute. Accordingly, the three researchers discussed and agreed on the value labels for the 15 components based on the nature of the corresponding items.

The first component consisted of 17 items that together accounted for 13.31% of the total variance. Questionnaire items included in this component included “doing a lot of mathematics work” (item 37), “knowing the steps of the solution” (item 56), “knowing which formula to use” (item 58), and “understanding why my solution is incorrect or correct” (item 63). Guided by our Ghanaian collaborator’s recommendation, we subsequently labelled this component as *achievement*.

The second component is made up of 6 items which together accounted for 6.64% of the total variance. The questionnaire items included “stories about mathematicians” (item 61), “explaining where rules / formulae came from” (item 40), “mystery of mathematics” (item 60), “stories about recent developments in mathematics” (item 18), and “using concrete materials to understand mathematics” (item 48). Given these items, we propose to name this component as *relevance*.

The third component is made up of 2 items which together accounted for 4.35% of the total variance. The questionnaire items were “explaining my solutions to the class” (item 19) and “practicing how to use maths formulae” (item 13). So, we named this component as *fluency*.

The fourth component is made up of 3 items which together accounted for 3.40% of the total variance. The questionnaire items were “learning maths with computer” (item 23), “learning maths with internet” (item 24) and “explaining by the teacher” (item 5). It was named *authority*.

The fifth component is made up of 2 items which together accounted for 3.04% of the total variance. The questionnaire items were “using calculator to check the answer” (item 22) and “using calculator to calculate” (item 4). Given these items, we named this component *ICT*.

The sixth component is made up of 2 items which together accounted for 2.75% of the total variance. The questionnaire items were "looking for different possible answers" (item 16) and "being lucky at getting the correct answer" (item 27). We named this component *versatility*.

The seventh component is made up of one item which accounted for 2.69% of the total variance, it being "mathematics debate" (item 9). It has been named *learning environment*.

The eighth component is made up of 2 items which together accounted for 2.69% of the total variance. The questionnaire items were "shortcuts to solving mathematics problems" (item 55) and "given a formula to use" (item 38). Given these items, we named this component *strategies*.

The ninth component is made up of one item which accounted for 2.50% of the total variance. The questionnaire item was "investigation" (item 1). We interpreted this component as *feedback*.

The tenth component is made up of one item which accounted for 2.22% of the total variance, which was "outdoor mathematics activities" (item 34). We named this component *communication*.

The eleventh component is made up of one item which accounted for 2.00% of the total variance. The questionnaire item was "mathematics games" (item 25). It was given the label *fun*.

The twelfth component is made up of one item which accounted for 1.92% of the total variance: "relationship between maths concepts" (item 26). We named this component *connections*.

The thirteenth component is made up of one item which accounted for 1.80% of the total variance: "stories about mathematics" (item 25). We named this component *engagement*.

The fourteenth component is made up of one item which accounted for 1.77% of the total variance: "looking out for mathematics in real life" (item 39). We named it *applications*.

The fifteenth component is made up of one item which accounted for 1.66% of the total variance: "getting the right answer" (item 50). Given this item, we named this component *accuracy*.

## Discussion

1256 primary and secondary school students from 18 public schools located in both urban and rural areas of the Cape Coast Metropolis had responded to the WIFI questionnaire, thus allowing us to map the attributes of mathematics pedagogy that were valued by these students. The PCA has led to the identification of 15 attributes which the students valued in their mathematics learning in Ghanaian schools, explaining 52.73% of the total variance. These attributes are *achievement*, *relevance*, *fluency*, *authority*, *ICT*, *versatility*, *learning environment*, *strategies*, *feedback*, *communication*, *fun*, *connections*, *engagement*, *applications*, *accuracy*.

Most of the students in Ghanaian schools come from a farming background, where all available helping hands are needed on the farms especially during the harvesting periods. That the respondents of the WIFI questionnaire were still in school might explain why *achievement* was so highly valued by these students. For them and their families, it is thus not surprising that *relevance*, *applications*, *engagement* and *connections* of what is taught at school in relation to the knowledge and skills that are needed at home and in the farms are valued. Given the frequent use of expository teaching in schools (Enu et al., 2015), the students have probably learnt to value *authority*, *fluency* and *accuracy*. Yet, this dominant teaching style is not likely to meet the expectations of students

and their families if they have chosen to continue staying in school. Novel and effective learning styles will be important, and these are likely to involve the valuing of *ICT, versatility, learning environment, strategies, feedback, communication* and *fun*.

These 15 values may be compared with the attributes of mathematics learning that students in high performing PISA2012 economies which took part in the WIFI study valued (e.g. Zhang et al., 2016). Students in these high performing economies (all of whom are East Asian, since Finland did not participate in the WIFI study) valued *connections, understanding, communication* and *recall*. Though students in Ghana also valued *connections* and *communication*, they were less valued than at least 9 other attributes, such as *achievement, relevance* and *fluency*.

This distinction above had invoked in us the notions of intrinsic and extrinsic motivations. Emerging from the analysis we were reminded of Ryan and Deci's (2000) assertion that "intrinsically motivated behaviors [...] are performed out of interest [...] [whereas] extrinsically motivated behaviors [...] are executed because they are instrumental to some separable consequence" (p. 65). In the context of our data here, we can interpret the top performing East Asian economies' valuing as being intrinsic to mathematics itself (*connections* and *understanding*, for examples, deepen the students' mathematics knowledge), and that the top values that were held by the students in Ghana to be more extrinsic to the mathematics discipline. Although *achievement, relevance, fluency* and *authority* were also attributes of mathematics learning and teaching, they were not so much about what was important about mathematics, but rather, what was important about what can be done with mathematics.

The contrast thus seems to be that of extrinsic versus intrinsic valuing. The top performing East Asian economies are located in places where mathematics study has traditionally been taken up for its own sake, and where problem solving and the study of proofs are regarded as tasks that maintain one's mental agility. Against this sort of tradition, then, it would not be surprising that East Asian students appreciated the structure and form of the discipline, and grew to value aspects of mathematics which reflect the nature of the discipline. On the other hand, education systems such as Ghana's might emphasise the utility function of the mathematics discipline, perhaps to satisfy the needs of local economies. Thus, the aspects of mathematics learning that are regarded as important would reflect this utility function and extrinsic valuing.

Given the large sampling size in this Ghanaian study, the findings above raised the question of the extent to which Ghanaian students' extrinsic valuing of mathematics and mathematics pedagogy might affect their mathematics performance. At the same time, how might the students' intrinsic valuing in places such as Shanghai, Hong Kong, Korea and Singapore be related to the high level of mathematics performance shown in TIMSS and PISA? To what extent might the attributes of mathematics education valued in the international assessment exercises be aligned with intrinsic valuing associated with the East Asian students?

## Conclusion

Primary and secondary public-school students across both urban and rural settings in the Cape Coast Metropolis of Ghana valued *achievement, relevance, fluency, authority, ICT, versatility, learning environment, strategies, feedback, communication, fun, connections, engagement, applications*, and *accuracy* in mathematics learning. Comparing these against what students in high performing East

Asian countries valued, we propose that many of the attributes that were valued by Ghanaian students represented extrinsic valuing (versus intrinsic valuing in East Asia). Might the Ghanaian students' valuing of extrinsic attributes in part explain their relatively poorer performance in mathematics? Further analysis is being carried out, such as to investigate how the valuing differed according to student gender and school locations.

These and other related questions will be especially meaningful for Ghanaian policy-makers to consider. If extrinsic/intrinsic valuing is indeed a key variable of mathematical performance and achievement, the inculcation of intrinsic valuing amongst students would require strong and determined leadership at all levels of the society to model these values across the intended, implemented and attained curricula. In the meantime, the classroom teacher can be more mindful about espousing the intrinsic valuing of mathematics education. For example, teachers often do not sound very convincing to students that the content taught in class can be applied in life. Instead, it may be worthwhile for teachers to explain how the experience of learning mathematics might instill in students such attributes as *rationalism*, *openness* (see Bishop, 1988) and/or *understanding*. These are the very things which can be applied in life.

This knowledge should also be valuable to overseas (including European) researchers/experts who are involved with development work in Ghana, such as the British government's Transforming Teacher Education and Learning Project. Not only does it lead to a greater understanding of the local context, understanding what Ghanaian students value can also develop meaningful perspectives upon which culturally-appropriate and effective programs are designed and delivered.

# Integrating critical theory and practice in mathematics education

David Swanson<sup>1</sup> and Laura Black<sup>2</sup>

The University of Manchester, UK

<sup>1</sup>[david.swanson@manchester.ac.uk](mailto:david.swanson@manchester.ac.uk); <sup>2</sup>[laura.black@manchester.ac.uk](mailto:laura.black@manchester.ac.uk)

*Recent years have seen many valid and important critiques of mathematics, mathematics education and mathematics education research (M, ME & MER). However, we also discern in some of these critiques a tendency toward one-sidedness and passivity. Unrelenting stress on the negatives of M, ME and MER can lead to a dismissal of the possibility of improving ME and a dismissal of those who attempt to do so. The separation of critical theory from critical practice which follows is then in danger of rendering critique sterile, becoming a mere pseudo-radicalism. As an alternative, we explore here the mutual relation between critical pedagogy and critiques of society, and the relationship between reform and more radical change, in wider society and ME. We argue that this analysis encourages a stress on joint activity, between individuals and organisations with a wide range of perspectives on what change is needed, to tackle the problems a critical perspective raises.*

*Keywords: Critical mathematics education, theory and practice.*

## Introduction

A growing body of research in mathematics education has explored critically the socio-political function of school mathematics in terms of its role in the mobilisation and production of capitalism (e.g., Kolloosche, 2014; Pais, 2013, 2014; Swanson, 2016; Williams, 2012) leading to the reproduction of inequalities in education along the lines of social class, gender and ethnicity (e.g., Jorgensen & Niesche, 2008; Solomon, 2008; Black, 2004; Noyes, 2007). This work suggests that school mathematics (and associated qualifications) serves as a ‘gatekeeper’ in that it enables society and its dominant institutions (e.g., universities, employers etc.) to select and sort individuals under the rationale that ‘mathematical ability’ is a valued source of human capital. This critique is highly relevant to the current situation of mathematics education in England, where a new, more challenging curriculum has come into play since 2014 which serves to further substantiate the elitist position of mathematics in schools. At the same time, there is widespread concern in policy and in the mathematics education research community about achievement gaps (i.e. between rich and poor, or the most and least deprived) – a concern which has been said to further produce social inequalities – Gutiérrez (2008) refers to this as “gap gazing”.

Whilst such critiques of mathematics and mathematics education are important and necessary to challenge dominant ideologies (including those pertaining to education more broadly), at the same time, we argue, there is a need to propose an ideologically grounded alternative. This paper presents a case for an alternative way forward by first looking at the potential mutual relation between critical pedagogy and critiques of society. We then examine the relationship between reform (i.e. improvement whilst remaining within the same overall framework) and more radical change, in terms of wider society, education and mathematics education. What follows from this exploration, we argue, is the need for activity which tackles the problems a critical perspective raises. In

particular, it suggests joint activity between those with a wide range of perspectives on what, and how far, things need to change. We then look briefly at the Stand Up for Education campaign in the UK, which brings together trade unionists, teachers, academics and parents, to show that what we outline here is not a purely abstract or ideal position. Spaces for the much required interrelation of critical theory and research with practice can and do exist, and we conclude by discussing why that matters for critical researchers.

## What might a critical perspective on education look like?

We begin by looking at the relationship between critiques of education or society and critical mathematics pedagogy<sup>1</sup>. Arguably the most radical perspective here is to imagine and work towards a society beyond capitalism (e.g. Bowles & Gintis 1976; Counts, 1978; Freire, 2005) i.e. a change that involves a complete transformation of society. Discussions of what form education would take in such a society face certain limitations however. For instance, if we assume, as we should, that moving beyond capitalism entails the democratic collective control of society by the majority, then we who are so shaped by, and operate in, capitalist society are not best placed to either decide or predict what may happen. Nevertheless, we can speculate on how an alternative future education might work by taking the reverse of the features of capitalist education which are seen to lead to negative consequences today, for example the individual-competitive exam system which produces ‘losers’ who internalise their failure as objective qualities of themselves (for others, see Swanson, 2016). Then, we can combine these with the aspects of education that others have fought for (e.g. in school student strikes against corporal punishment, oppressive uniform policies or privatisation, see Lavalette & Cunningham, 2016) and at times, implemented (e.g., the banning of homework and exams in revolutionary Russia, see Karp, 2012).

Among the features we might expect to see are i) democratic collective control of education by teachers, students and other education workers, within the wider framework of its democratic shaping for society’s needs; ii) much greater control by individuals over their own learning within that, but with an emphasis on social rather than individually competitive learning; iii) an end to exams and their production and reproduction of societal inequalities; iv) an equivalent end to the performativity culture of continual measurement to judge teachers and other education workers, v) an increase in societal resources (such that, for example, class sizes reduce to the levels seen only within private education in this society), and vi) a closer integration of education with wider life, reducing both the formal detachment of schooling from the world outside, and the artificial separation of subjects from one another.

The perspective above can loosely be termed the *revolutionary perspective* in education. We would define reformist perspectives, and these are far more common than revolutionary perspectives<sup>2</sup>, as

---

<sup>1</sup> We use pedagogy here and throughout to mean teaching *and* learning combined due to the lack of an adequate single word in English.

<sup>2</sup> This is true even when reformist political organisations are weak or non-existent. However recent years have seen an important revival in reformist organisation with new parties such as Podemos in Spain, or around individuals in existing organisations, such as Corbyn in the UK and Sanders in the U.S.

those which may agree with some, many or even all of the elements above but which are accepting of greater limits as to how much things can change, for example limiting the possible changes to within one classroom, or to what is possible within capitalism. Although this covers an enormous range of possible beliefs (e.g., the free schools movement in the U.S., see Miller, 2002, or on a small scale, Boaler's work on reform pedagogy in the US, Boaler & Staples, 2008) and in Australia (Sullivan, Jorgensen, Boaler, & Lerman, 2013), in general we view such perspectives as radical and important. Fighting for fewer exams or less influence of exams on education clearly overlaps with fighting for no exams. We explore the general relationship between reform and revolution in a later section, but first we look at the relationship between the radical perspectives discussed so far and a particular type of reform, that of improving mathematics pedagogy.

### **The relationship between critical mathematics pedagogy and (active) critiques of society**

We can see within critical mathematics pedagogy (in the broad sense of the term critical) parallels of many of the more general demands of radical educationalists. For example, we see pedagogies which aim to promote: a more active role for students in learning through open problem solving (e.g. Barron et al. 1998); teaching for understanding rather than for grades (e.g., Schoenfeld, 1988); an emphasis on dialogue and social learning (e.g., Lerman, 1996); and a more meaningful mathematics connected to the world outside of school and student experiences and concerns (e.g., Gainsburg, 2008). In doing this, pedagogy acts to counter some of the worst effects of capitalist education, even if it cannot overcome them fully. Here we argue, perhaps contra to some perspectives in critical MER, that it is worthwhile to subvert spaces, such as the classroom, as much as one can in these directions. Various forms of critical mathematics education which attempt to provide curricula and pedagogies which offer 'use value' to low status, disadvantaged or 'poor' learners and communities (e.g., Skovsmose & Greer, 2012; Gutstein, 2006) have much to offer. They can potentially challenge the 'gatekeeper' role of mathematics described above and can maybe transform the function of education, that is, rather than the learner serving the school/education system, education can begin to serve the community/learner (Williams & Choudry, 2016). Perhaps more importantly, attempts at developing critical thinking within the mathematics classroom have the potential to be generalised and transferred to other aspects of life, for example, to a pupil's future life in the workplace (see Black et al., 2010). The experience of critical thinking, of challenging everything, of weighing up arguments can assist in developing the confidence to do so elsewhere.

The possible connections between critical pedagogies and critical perspectives on society can work in the other direction too. The real limitations which schooling imposes on such pedagogy means that it is difficult to sustain critical educational activity if it is solely limited to the individual classroom. Teachers attempting to develop or sustain attempts within their classroom will come up against obstacles. For example, a head of department on a professional development course led by one of the authors was instructed by management to reverse pedagogical changes because students were now talking too much in class. However, arguably, the experience of these obstacles can make teachers open to looking beyond their immediate situation to help them achieve the changes they want. If teachers are connected to networks which challenge how schooling is generally organised and which also show sympathy for progressive forms of pedagogy, they may potentially move

towards engaging in critical activity outside the classroom, whether still directly related to pedagogy or beyond that. Such networks can also give teachers the confidence to persist with their efforts in their own classroom. (e.g., Volosinov, 1976, on the relationship between an individual's critical ideas and collective agency in such circumstances).

Taken together these points mean: Firstly, that it is in the interests of those who are critical of society to encourage meaningful activity in the classroom and to work alongside others who wish to do this, and, secondly, it is in the interests of those who want more meaningful activity in the classroom to work with those who have a critical perspective on society, precisely because they bring an understanding of the obstacles, and, usually, experience in organising networks to overcome these obstacles. A central task therefore for those who are critical of society and who work within mathematics education, is to help create, develop and shape organisational forms which encompass both these components.

## **Reform, revolution and the united front**

The relationship between the particular reform, of developing more meaningful pedagogy in a classroom, and wider social struggles, rehearses similar arguments to that which can be made about the general relationship of reform to revolution. In general, reform and revolution are clearly different perspectives. As Luxemburg (1986) puts it:

[T]hose who pronounce themselves in favour of the method of legislative reform in place of, and in contrast to, the conquest of political power and social revolution, do not really choose a more tranquil, calmer and slower road to the same goal, but a different goal. Instead of taking a stand for the establishment of a new society, they take a stand for the minor modification of the old society. (p. 56)

However, many of the elements key to a revolutionary strategy— for example, maximising active involvement and democratic control of movements; overcoming the division between purely economic and political struggles; attempting to connect up and generalise different struggles; developing an understanding of the interrelated nature of societal problems; and an emphasis that change comes from below, are not necessarily alien to those holding reformist ideas when they are engaged in struggles for particular demands (see, e.g., an account of the 2012 Chicago teachers' strike in Gutstein & Lipman, 2013). At the same time, revolutionaries are also in favour of reforms. First because they improve immediate circumstances, but also because it is through the struggle for reforms that people develop the consciousness and confidence required to transform society: "The struggle for reforms is its means; the social revolution, its goal" (Luxemburg, 1986, p. 5). This overlap in immediate situational objectives, and the potentially shared belief in activity to achieve them, can provide a basis for joint activity.

This joint activity between those who seek reform and those who aim for more fundamental change is central to a revolutionary approach and is termed the united front strategy. The strategy was explicitly formulated by the third congress of the communist international in 1922 as capitalism restabilised following the revolutionary wave around the end of the First World War. However, it has its roots in earlier practice. For example, during the Russian revolution of 1917, the unity of revolutionaries and reformists in repulsing Kornilov's attempted coup was central to the

development of the revolution, and the key organisational form of the revolution, workers councils or soviets, can be viewed similarly as a united front (see Trotsky, 1989).

For revolutionaries, there are two key aims of the united front strategy. The first is simply to increase the likelihood of success of the particular struggle through uniting the maximum number of people and organizations. Secondly, it aims to convince those involved in reform activity of the need for more radical change through i) joint experience of the benefits of revolutionary methods, ii) joint frustration at the limitations of reformist strategies, and iii) exposure to revolutionary ideas in ongoing dialogue. For these strategies to work, the unity and dialogue must be genuine of course, with the possibility of reformists winning revolutionaries to their strategy instead (see Trotsky, 1989). Although often from an alternative perspective, many with a reformist outlook on change equally see the importance of working together with others who hold different ideas to help achieve particular aims.

### **Implications for critical mathematics educators**

Taken together, the arguments outlined so far imply the need for forms of organization which bring together various groups in mathematics education such as teachers, teacher educators, critical academics, parents, students and other education workers in common activity (a united front). This includes those who are particularly concerned with teaching and learning *and* those who are trade unionists; those who want to transform the world completely *and* those who just want to make things a little better. Through such activity radical mathematics educators can both assist in improving immediate circumstances in schools, classrooms etc., and also increase the numbers of those who see the necessity of more radical change (e.g., Gutstein & Lipman, 2013). We speculate that such an organization in relation to mathematics education is more likely to arise as part of, or emerging through, more general forms developed for the field of education as a whole. To illustrate that organisational forms such as this can exist, we now briefly describe the emergence of a network, local to the authors, which brings together the various forces described above.

### **Stand up for Education**

The Stand up for Education campaign by National union of teachers (NUT) (2014) first emerged as a campaign launched by the National Union of Teachers (the largest teaching union in the UK), in the build up to the 2015 UK general election, to influence educational policy discussions and mobilise NUT members and others. Through that campaign, a network of academics supportive of the NUT's aims was formed called Reclaiming Schools. Together Reclaiming Schools and the NUT jointly published a collection of short articles from academics and researchers in support of the campaign (see NUT, 2015). The Reclaiming Schools network continued, with a website devoted to putting research in accessible form for teachers and others campaigning to improve education, and with occasional meetings in local areas which bring academics and teacher activists together and promote the website's activities. At one such meeting in Manchester, partly inspired by recent parent campaigns to remove their children from standardised testing (the Let Our Kids be Kids campaign, see <https://letthekidsbekids.wordpress.com>), the idea emerged for a local conference to be held which could pull together wider forces. NUT activists organised a follow up meeting, which included some parent groups and academics, to plan the conference. The primary aim of the conference was to share and develop understandings of key issues affecting schooling; to develop

and expand the different networks involved (parents, teachers, teacher educators and other academics), and to bring those networks together to promote mutual activity and campaigning. The conference (see <https://www.facebook.com/standupforeducationmcr>) united precisely the range of people that this paper has outlined, and, importantly, it discussed questions of organised activity, political issues *and* pedagogy. In future work we will discuss this movement in more detail, and in particular explore its potential in relation to critical mathematics pedagogy in particular. But we describe it briefly here to show that such networks can and do exist and are not merely an abstract desire of the authors.

## Critical theory and critical practice

So far we have argued that i) critiques of ME and MER also require ideologically grounded alternatives; ii) both ‘revolutionary’ and ‘reformist’ alternatives exist; iii) critical pedagogy in mathematics (a particular reform) can be an integral part of both perspectives; and iv) this inter-relationship between reform and revolution is a general one. These last two together entail v) the importance, and possibility, of united front activity and organization within the field of mathematics education for all those who are to any extent critical of how things currently are, whether their initial motivation is teacher wages and conditions, less stressful exams for children, or more meaningful activity in the classroom.

We conclude with the particular relevance of the above for critical mathematics educational researchers. Marx argued that “Practice without theory is blind. Theory without practice is sterile”, and this point is relevant for those who wish to criticise the world of mathematics education without attempting to change it. Arguably though, theory and practice always form an interrelated unity. No practice is uninformed by theory, (it may be unconscious of course). And no theory is unshaped by practice. The question for educational researchers is which practice shapes their theory – academic practice with its demands of publication and superficial novelty, or genuine critical practice and the needs of those trying to transform education. Critical theory detached from critical practice may provide useful insights, but ultimately its quality and usefulness will suffer from the separation. Uniting critical theory and critical practice, on the other hand, can enrich theory and research, and contribute to the development of the critical practice which can transform education.

# **Cultural diversity as a resource or an obstacle for teaching practices in multicultural milieu: Experience of a training course for Italian teachers about Chinese Shuxue**

Benedetto Di Paola<sup>1</sup> and Giovanni Giuseppe Nicosia<sup>2</sup>

<sup>1</sup>Dipartimento di Matematica e Informatica, UniPa, Palermo, Italy; [benedetto.dipaola@unipa.it](mailto:benedetto.dipaola@unipa.it)

<sup>2</sup>ISGEm, RSDDM, I.I.S. Aldini Valeriani Sirani, Bologna, Italy; [gg.nicosia@gmail.com](mailto:gg.nicosia@gmail.com)

*Keywords: Culture, diversity, multicultural education, Chinese students, Shuxue.*

## **Introduction**

This contribution, examining the increasing presence at school of East-Asian students and the related didactical complexity rising from the contemporary presence of Western and non Western cultural heritages, presents an experience of a training course for teachers (from Pre-Primary to Secondary school grades) about the didactical problematic of teaching in a multicultural context (in particular with Chinese students).

## **Diversity as resource**

According to Bishop's perspective, the notion of '*Multicultural Classroom*' has to be interrelated as the place where a variety of cultures come together and mixes, creating hybrid identities, epistemological and linguistic conflicts (real or potential), and a range of ways of valuing or devaluing mathematics as an academic subject (Bishop, 1988). In this sense, in many cases, working in a multicultural context is seen by teachers as an obstacle! *How to manage it? How to teach with different cultures and language's students?* These questions, for example, are often posed by western teachers of Chinese students. Their cultural reference system is in fact completely different from the western one (Bartolini Bussi, Di Paola, Martignone, Mellone, & Ramploud, 2016; Spagnolo & Di Paola, 2010) in language (as structure and as function in life), norms and social values and political references (Jullien, 2006). In the last ten years, researchers from all over the world have developed an ever increasing amount of work on the 'comparison' of student's performance in mathematics (Di Paola, Battaglia, & Fazio, 2016), especially between American and far-eastern countries' pupils such as Chinese, Japanese, and Korean ones (Leung, 2001). However, in Italy there is little research on this subject and all of them are aimed to deeply study the complexity of teaching/learning activities related to different cognitive processes emerging from different students' cultural references (Chinese in particular) in classrooms, assuming diversity as a resource for learning (Bartolini Bussi, Sun, & Ramploud, 2013; Spagnolo & Di Paola, 2010). A small amount of this research is focused of the training teacher.

## **A training teaching course as a need for mathematics multicultural classrooms**

Following these assumptions, working in conjunction with other colleagues from East and West of CTRAS (*Classroom Teaching for All Students Research Working Group*), we designed a training 60 hours long course for Italian teachers (from Pre-Primary to Secondary school grades) which we implemented during the month of June 2016. It was organised almost entirely in small working groups, using activities with teachers and educators of different school grades (each one of them

chose independently to attend the training course). Aiming to analyse how diversity is seen through the trainees' eyes and trying to answer the research question posed before, we discussed with them some theoretical aspects related to their own epistemologies of the discipline. We then showed some experimental research conducted in Italian and Chinese classrooms, some Chinese textbooks strongly different from the Italian ones and finally some videotapes of some well implemented Italian teaching practices in multicultural contexts with Chinese students (K-12). According to our aim we discussed with trainees about the analogies and the differences coming out from these videotapes about the teaching/learning mathematics (*Shuxue*) in the two cultures. At the same time we tried to reflect with them on the possibility to 'use' this new knowledge to 'transform' the presence in classroom of 'other' cultures from an obstacle to a resource. All the proposed activities were videotaped and later carefully analysed. We can briefly say that the stimuli we offered permitted trainees to reflect on the complex situation of the simultaneous presence of Chinese and Italian students in their classrooms and to promote the desirable process of connecting different types of students solving strategies emerging from cultures.

# **Reflections of Fröbel in discourses about mathematics in Scandinavian early childhood education and care**

Andrea Eikset

Western Norway University of Applied Sciences; [anei@hvl.no](mailto:anei@hvl.no)

*Keywords: Fröbel, mathematics, kindergarten, paradigm shifts.*

## **Finding reflections of Fröbel's ideas in Scandinavian ECEC**

My research project is about how Friedrich Fröbel and his ideas have been used across time and place to present different perspectives about mathematics in early childhood education and care (ECEC). Fröbel continues to have an important role in discussions about ECEC in Scandinavia, and is often referred to when people talk about ECEC. In his writings, he discussed the inclusion of mathematics, through activities connected to his 'gifts' (Balke, 1995). In my project, I will identify how adaptations of his ideas (that I refer to as reflections) have been used to support ideological discussion about mathematics in kindergarten.

May (2016) used the metaphor of a swinging pendulum between two poles, to describe the history of early childhood education policy and pedagogy:

Broadly the 'poles' characterise contesting paradigms of childhood: the child as nature whose holistic development is a natural process and who learns through play and discovery – construction. The child as a reproducer of knowledge, who as an empty vessel is filled with agreed knowledge, skills and cultural values – instruction. (p. 20)

Over time, this pendulum swings between the two sides, construction and instruction, because of economic, political or professional factors (May, 2016). Meaney (2014) highlights how different ideologies affect what content, such as mathematics, in kindergartens could be. "In the last 15 years, the focus of early childhood centres on supporting children to learn through play has been replaced in some countries by a more formal preparation for school" (Meaney, 2014, p. 1007). By analysing how key elements from Fröbel's theories, for example his 'gifts' or views of mathematical pedagogy, are reflected in discussions about ECEC I will be able to discuss where proponents of the reflections are situated on the pendulum swing. Identifying how Fröbel's ideas have been used in different ways in the past and across countries will provide understandings about how rhetorical devices are used to promote ideologies.

An example is how the Norwegian minister of education and research, Torbjørn Røe Isaksen, used Fröbel explicitly in a public debate in a Norwegian newspaper (Isaksen, 2014). Lange and Meaney (2016) argue that Isaksen uses Fröbel to promote mathematics in kindergarten as a common sense understanding which has always been a part of kindergarten. Thus, Isaksen uses a reflection of Fröbel and his mathematical 'gifts' to argue that having more mathematics in ECEC is a continuation of an existing tradition. By doing this, he tries to influence the trajectory of the swinging pendulum so that it swings more towards the pole of instruction and away from current kindergarten policy, which has been swinging more towards the constructive approach (Lange & Meaney, 2016).

Another example is from Sweden at the end of the nineteenth century, from a magazine for women about their home life. In this example, Fröbel is on one hand, used to argue for readiness for school and working life but on the other hand his toy gifts can make the child able to bring gifts to their family (Cristel, 1892). The author of the article reflects Fröbel, his gifts and view of mathematics, into the article in a different way than Isaksen did in 2014. Cristel (1892) argues that families can purchase the boxes of gifts “and in that way let the ideas of this high-minded pedagogue into their home” (p. 244, own translation). This again creates a different trajectory for the pendulum. The purpose of the gifts is presented here as a way of bringing the child closer to their family, and making them able to produce something by their own desire in their own lives. The pendulum here swings more towards the constructive pole.

The aim of my project is to look for reflections of Fröbel in Scandinavian kindergarten history and to identify how these reflections have been used to create momentum for the pendulum that swings in different directions. By studying the relationship between production, form and reception of a discourse, I can investigate the myriad of effects around the discourse in question (Fairclough, 2003). Initial investigations suggest that Fröbel is reflected in different ways, in order to argue for different agendas about how and why we should do mathematics in ECEC. As a mirror can reflect an image that is distorted or mostly correct, the reflections of Fröbel are more or less representative of his original views. However, this project is not about judging how valid the different reflections are. Rather by critically analysing the discourses on Fröbel and his ideas, I can identify factors that affect the paradigm shifts about mathematics in kindergarten.

# Collaborative learning in multigrade mathematics education at primary level

Rachel-Ann Friesen

Technische Universität Dresden, Faculty of Education, Dresden, Germany;

[rachel-ann.friesen@tu-dresden.de](mailto:rachel-ann.friesen@tu-dresden.de)

*Keywords: Multigrade classes, collaborative learning, teacher training.*

## Background

In Saxony, predominantly in rural areas, social and political challenges are being posed by a declining number of pupils. To prevent especially younger pupils from having to travel long distances to school, organisational and curricular alterations are being considered. One suggestion is the merging of grades to establish multigraded classes. Multigrade education is also being discussed for its pedagogical advantages; for example, it can make the first phase of primary school more flexible by allowing pupils to remain within the same multigraded class for either one, two or three years. However, even in learning groups which are homogeneous in age, the differences between pupils' preconditions for learning can be up to four years (Hirt & Wälti, 2008). Yet, when making learning groups heterogeneous in age, the diversity of learning preconditions increases, and with it also the necessity for differentiation through diverse tasks with various levels of difficulty. For a subject like mathematics, which is strongly guided by a systematic course, this often means extremely individualised and separated learning (Nührenbörger, 2007). However, interaction is seen as foundational constituent of learning in early years (Miller, 1986; Schütte, 2009) and should not be neglected. More specifically, for mathematical learning to occur it is of great importance for the pupils to participate increasingly in collective reasoning within classroom interaction (Krummheuer, 2011). To enable individualised learning to take place in cooperation with others, *substantial learning environments* hold great potential both for mathematics education in general and specifically in multigrade mathematics education because they offer the opportunity for *natural differentiation*, which means that learners all work on the same task and the differentiation is not predetermined by the teacher but chosen by the pupils themselves (Scherer, 2013). The possibility for students to learn with and from others by communicating and helping each other is also seen as one of the pedagogical arguments for purposeful mixed-age grouping (Wagener, 2014).

## Project

The question this research project wants to address is how collaborative learning takes place in multigrade mathematics education at primary level. Therefore, firstly student teachers at the TU Dresden are asked about their experiences with multigrade education by using a questionnaire. Then, an interview study with individual teachers who teach in multigraded classes in Saxony will be conducted in order to identify their attitudes and concepts concerning multigrade mathematics education. Based on these empirical results, concepts and learning environments for multigraded learning within mathematics education for grades 1–6 will be developed in cooperation with teachers and student teachers in order to prepare them for the future challenges they will face when teaching mathematics in multigraded classes. Later these learning environments will be applied with pupils

in practice to test the suitability of the tasks. The collaborative processes the pupils use to solve the tasks will be filmed, transcribed and then analysed from an interactionist perspective (Krummheuer, 2011) to reconstruct constituent characteristics of successful multigrade mathematics education. This process will be accompanied by the development of seminars for student teacher concerning collaborative learning in multigrade mathematics education.

## Initial results

The initial results of a questionnaire with student teachers at the TU Dresden show that less than 40% have experienced multigrade education in some form (e.g. during an internship, while being a student themselves). Even though they are all able to reflect about possible advantages and disadvantages of multigrade education, many of them say that they would feel overwhelmed, unsure or not prepared to teach in a multigraded class during their traineeship. These results need to be assessed in more detail but they emphasize the necessity of training teachers more specifically for multigrade education.

## Acknowledgement

The project “Collaborative Learning in Multigrade Mathematics Education at Primary Level” is part of a greater project called TUD-Sylber (Synergistic teacher education in an excellent framework) at the Technical University of Dresden, which is funded by the German Federal Ministry of Education and Research in the framework of the joint state and federal “Teacher Education Quality Offensive”.

# Supporting young children's mathematical register learning in two languages: ICT possibilities

Troels Lange<sup>1</sup> and Tamsin Meaney<sup>2</sup>

Western Norway University of Applied Science; <sup>1</sup>[trl@hvl.no](mailto:trl@hvl.no); <sup>2</sup>[tme@hvl.no](mailto:tme@hvl.no)

*Keywords: ICT, kindergarten, bilingual mathematical language development, parents.*

## Language as a resource

We have recently begun a project where we assume that digital games/apps have the possibilities to utilise family and kindergarten language resources to support multilingual children's development of mathematical registers. In so doing, we adopt the perspective of "language as a resource" in which languages act as pedagogical resources in the learning of mathematics (Planas & Civil, 2013). Developing children's fluency in their home language as well as Norwegian is an aim of the Norwegian Framework Plan, the early childhood curriculum (Kunnskapsdepartementet, 2011). Research suggests that in regard to learning and using content knowledge such as mathematics, multilingual children benefit from developing both their home language(s) and the majority language for discussing abstract ideas (May, Hill, & Tiakiwai, 2004). However, when children speak a different language at home to the one in their kindergarten, it is difficult for teachers who do not speak the children's other languages to know how to provide support for developing the home language. Parents on the other hand have the language resources for developing the mathematics register in the children's home languages, although their contribution to their children's engagement with mathematics is often under-rated (Civil, Bratton, & Quintos, 2005).

## Digital games as prompts for mathematical language learning at home

There is little research about using apps/games to prompt dialogue about mathematics among young children, however what there is suggests that affordances of digital games/apps can promote discussions (Lange & Meaney, 2013; Lembrér & Meaney, 2016; Palmér & Ebbelind, 2013). Plowman, Stephen, and McPake (2010) found that children's engagement with digital tools at home were richer than those in kindergartens, partly because the children asked more questions and could learn from watching other family members using the devices.

In order to find out what digital games/apps were being used in multilingual families and to gain some understanding from parents of multilingual children (aged 1-5 years) about what they considered to be the mathematical register demands and affordances of the apps/games, we set up an online survey, using a snowballing sampling method. The survey had 8 questions that asked about the age of the children, the languages that they spoke and the digital games/apps that they played with.

56 parents identified the features of the digital games/apps that made them attractive to their 74 children and what they would include in a digital game/app if they were designing one. The features of the digital games that the parents would include were not the same ones as they recognised that their children valued. Digital games were recognised as providing children with opportunities to use aspects of the mathematics register. Although puzzles was frequently cited as a digital game that the children played, this did not seem to result in the features of shapes being discussed to the same

degree as other mathematical ideas (about half the number of parents considered their children talked about this as compared with attributes for classifying things).

The parents identified that being successful or being surprised prompted children to talk about the digital game. Having features in new digital games which would produce such feelings in children appears likely to develop discussion with adults about mathematical ideas. As the language of the game can influence the children's use of language, it seems best not to include any language so as not to restrict the choice of language.

# **Bangladeshi rural secondary madrasa (Islamic school) children's participation in higher mathematics optional course: A close look through gender lens**

K.M. Nabiul Alam

UCL Institute of Education, University of London, United Kingdom; [nabiul40@yahoo.co.uk](mailto:nabiul40@yahoo.co.uk)

*Keywords: Bangladesh, gender, higher mathematics, influence, rural madrasas.*

## **Background**

Compared to boys, a small number of girls study higher mathematics optional course in Bangladeshi rural secondary madrasas beyond the requirement of compulsory mathematics. The overall participation rate of girls in higher mathematics is also low when compared to other optional subjects.

## **Research questions**

1. How do Bangladeshi rural secondary madrasas influence children's participation or non-participation in higher mathematics optional course?
2. How do these influences vary with respect to children's gender?

## **Research design**

Quantitative data have been collected from 500 children of grades 9 and 10 across eighteen rural madrasas using a Bangla translated version of the Fennema-Sherman Mathematics Attitudes Scales (Fennema & Sherman, 1976). Qualitative data have been collected from three case studies using focus group discussions with fifty children and semi-structured interviews with three principals, five math teachers and fifteen parents. Nine mathematics lessons have also been observed to capture teacher-student interactions and their engagement. Purposive sampling process, rather than recruiting a representative sample, was used in order to reflect the aspect of diversity in the population and to carry out comparisons among different groups.

## **Conceptual framework**

Following conceptual framework is adapted from Ker (2016) to present multiple levels of factors for mathematics participation and achievement (in Table 1). Selection of most of the factors is based on the suggestions from educational effectiveness literature. From the economic point of view, educational effectiveness is a production process of schools or madrasas, which is a transformation of inputs to outputs. The inputs include school resources, students' characteristics and instructional hours. The process includes school factors, teacher factors and student factors as shown in Table 1. The outputs can be measured by the number of children participating in higher mathematics course and their achievement in the subject. Therefore, madrasa and classroom characteristics, student's background and home environmental support, time allocated for each subject, and teacher's instruction to engage the students are very crucial to achieve the popularity of an academic course like higher mathematics.

**Table 1: A multilevel conceptual framework for mathematics participation (and achievement)**

<b>School level</b> →	<b>School climate</b> -School academic climate -School discipline & Safety	<b>School Resources/ Instructional Hours</b> -Instruction affected by math resource shortage -Total instructional hours per week/year -Computer availability -School composition by student background		
<b>Teacher level</b> →	<b>Teacher Preparation</b> -Years of teaching experience -Career satisfaction -Confidence in teaching maths	<b>Instruction</b> -Collaboration to improve teaching -Instructions to engage students -Math instructional hours per week	<b>Climate/Facility</b> -Emphasis on academic success -Safe and orderly school -Working conditions	
<b>Student level</b> →	<b>Student Background</b> -Gender -Parents' highest education level -Parents' profession	<b>Environmental support</b> -Home educational resources -Number of home study support	<b>Student's school experience</b> -Students engage in math lesson -Students bullied at school	<b>Motivation/ Attitude</b> -Students like learning maths -Students value learning maths -Student's confidence in maths

### Themes identified in preliminary analysis

- There is a shortage of good professionally committed teachers for higher mathematics. Most of the mathematics teachers are engaged with private tuition as an extra earning source. Children have no other option than taking private tuition as the support from madrasa for both general and higher mathematics is inadequate.
- Parents' religious belief is one of the reasons for sending their children to madrasas instead of usual schools. Parents wish some of their children to become an Imam, a teacher in a madrasa or an Islamic scholar. They want their daughters to learn Quran reading and hadith, pray Salah regularly and get married with a man of their choice as soon as possible. In doing so, studying higher mathematics is not in their priority list as their daughters and even sons can pass other subjects easily.
- Children seem to have confusions and frustrations about the value of their madrasa education compared to the education from general schools as there are local discourses that government is less interested about their madrasa qualifications.

# Culturally-inspired mathematics and science education

Shipra Sachdeva<sup>1</sup>, Per-Odd Eggen<sup>2</sup> and Halvor Hoveid<sup>3</sup>

<sup>1</sup>Norwegian University of Science and Technology, Program for Teacher Education, Trondheim, Norway; <sup>1</sup>[shipra.sachdeva@ntnu.no](mailto:shipra.sachdeva@ntnu.no); <sup>2</sup>[perodde@ntnu.no](mailto:perodde@ntnu.no); <sup>3</sup>[halvor.hoveid@plu.ntnu.no](mailto:halvor.hoveid@plu.ntnu.no)

*Keywords: STEM education, culturally relevant education, student centered curriculum, intercultural communication, student diversity.*

## Background

The relation between culture and mathematics education has been evident since long but taking advantage of pupils' cultural identity to increase students' engagement has not been focused much in Norway. Culture is closely interwoven with children's routine. It can provide a gateway to connect mathematics and science education to their daily life experiences. Culture, in this project, is not mainly or only centered towards pupils' ethnicity but will employ their personal cultural identity (interests, leisure activities, hobbies etc.) as a stimulating source for designing the teaching activities. Due to increased immigration, many different cultures have been introduced in Norwegian schools. Students having various cultural backgrounds may feel alienated in classroom activities and find it difficult to follow current classroom teaching. School leaders in Norway are also familiar with these increasing heterogeneous cultural issues and thus have began accepting and implementing culturally-relevant changes in their respective school systems (Jacobson, Johnson, Ylimaki, & Jacobson, 2013).

The LOCUMS (Local Cultures for Understanding Mathematics and Science) project aims at finding out how students' engagement in mathematics and science gets affected when they themselves are asked to influence the starting point of teaching-learning process. Initiating their education process by first asking the students to provide relevant input about *their own culture*, for example, likes, interests and leisure activities to the teachers and researchers, they are assumed to get an autonomy, control and a part of responsibility of what *they want* to learn. Their desires will plausibly serve as an inspiration to the educators for designing the teaching-learning activities, and also as a possibility for the pupils to bring forward their own cultural identity in the class. Ascribed to the fact that commencement of teaching-learning situation would be derived by students' interests and activities they want to learn more about, we consciously use the term *culturally-inspired mathematics and science education* to describe the attention of this project. This notion allows us to bring in culturally-responsive mathematics and science teaching in the form of interactive cooperation between teacher and students in Norwegian multicultural classrooms.

## Theoretical framework

The aim of my project is to study changes happening in the knowledge gaining process of pupils as a result of engaging them in culturally-inspired activities surrounded by intercultural context (students work in groups). Therefore, we find socio-cultural and cultural-historical activity theories to be relevant. In addition, we will draw on research related to ethnomathematics, culturally-relevant pedagogy and instruction (Ladson-Billings, 1994; Rajagopal, 2011), and culturally-responsive teaching (Gay, 2010), as they suggest an educational approach that advocates valuing students' cultural background and prior experiences in the same way as socio-cultural theory. These themes favor cherishing cultural diversity present in the class to enrich the socio-cultural surroundings of

diverse students so that they can learn effectively. Nevertheless, it does not mean that the teacher should teach in a “black” or “asian” way, but the level of educational activities should be reachable from and meaningful for students’ personal level of understanding. Simultaneously, involving their interests in planning the lessons can motivate them to learn using their own culture. Therefore, we believe that this literature would enrich and facilitate our project to enhance the learning experiences of diverse children in Norwegian classrooms.

## Methodology

Being a problem driven pragmatic and empirical research, the aims to be fulfilled during the course of this project are justified by using a combination of design-based and action-based research methodology. The first student projects were designed and finalised with the cooperation of teachers, school leaders and students and, as the participators would be the practitioners as well, it shapes itself as action research. An iterative design cycle (3 repetitions) would be employed for each of the three planned student projects we plan to work out throughout the project. Until now, we have collected data from the first iteration of our initial student project.

## Plan of action

Some of the classroom interventions are planned to be executed in a multicultural school in Trondheim. In the first trial, pupils’ input on their aspirations was collected through questionnaires. Accordingly, teachers and researchers planned and implemented the new teaching-learning strategies. The classroom activities were audio and video recorded. Teachers and researchers will now review, analyze and reflect those recordings to find and correct up eventual shortcomings in the first attempt. Further, two following iterations would adopt similar pattern as the first one and each part of data collected would be observed both before and after each student project to capture the changes in students’ engagement, participation and learning. Data analysis will be carried out in the light of socio-cultural and activity theories.

## Introduction

The debate on visual culture raises questions that have been stressed in the educational research, such as the role of the image in the process of subject-formation and the visuality as a form of knowledge. Visual Culture is an interdisciplinary field that combines arts, philosophy, anthropology, and cultural studies. The main point of this field is the question of visuality, which means focusing on the relationship between the seen and the seer. In short, the target of Visual Culture Studies is not an object at all, but it “consists of things we can see or whose existence is motivated by their visibility; things that have a particular visuality or visual quality that addresses the social constituencies interacting with them” (Bal, 2003). Thus, the term of visuality has become an important keyword for this field (Mirzoeff, 2006), because it refers to the vision and visuality are both socially and historically constructed.

With regards to mathematics education research, Flores (2012) has proposed this perspective of visuality to investigate how images, particularly paintings, affect and are affected by Cartesian perspectivalism visual practices, as well as to grasp the fabrication of a certain mathematical rationality to look and to think within the realms of culture. The author has considered

the term ‘visuality’ instead of ‘visualization’, because the former leads to a deconstruction of the founding principles of sense of vision and perception. In contrast, visualization is understood as a process of construction and transformation of mental images, whereas visuality is the sum of discourses that inform how we see. Thus, while the latter is concerned with learning geometry’s concepts and visual skills, visuality discusses visual practices in the context of history and culture. (p. 7060).

Thus, at stake is a kind of mathematical thinking presents in contemporary school practices and that is provoked notably itself through images of arts (Flores, 2016).

## Going through infinity

In response to this, we have been examining historically the artistic practices of infinity considering, particularly, those involving the discussions of perspective in renaissance painting. Furthermore, we have analysed modern paintings exhibiting characteristics of a classical system of visuality, which means using concepts of harmony, symmetry, parallelism and perspective. On a whole, we have found not only that our way of looking is shaped within an already built field of techniques and discourses, but also that mathematics ideas play an important role in the constitution of how we think.

## Being in the diversity

In the methodological path of cartography, Schuck (2015) has developed an intervention plan with alcohol and drugs dependents in treatment on a Psychosocial Care Center in Florianópolis, Brazil, in 2014. Four workshops were conducted and each one was centered on images suggesting the infinity idea. By focusing on discourse analyses, interpreting multi-faceted narrative, looks and affections by the subjects involved, it was possible to highlight the effects of looking at infinity rather than ‘truth’ *per se*. For instance, seen from the perspective of the people involved, the ways of looking at infinity deal with reflections situated between the mystical and the emotional experiences such as nothingness, emptiness, freedom. In this regard, we call attention to two points: “mathematical mind-set” is not the sole result of a schooling regime; and subject’s visual subjectivities emerge in the entanglement of the individual in discursive formations. In order to discuss this, we, in the poster, displayed some information concerning on the visualization and visuality, the cartography as research methodology, the workshops itself, and the discourses about infinity staged by the people involved in the intervention mentioned above.

Following Foucault’s assumptions, we consider that by a better understanding of how a certain kind of mathematical visualization has been constituted within the sociocultural practices might contribute not only teacher education but also mathematics learning practices. In sum, we bring under our attention that both mathematical rationality and visualization are staged and configured within the diverse sociocultural practices.

# TWG11: Comparative studies in mathematics education

## **Introduction to the papers of TWG11: Comparative studies in mathematics education**

Paul Andrews, Eva Jablonka, Mirosława Sajka and Constantinos Xenofontos

As with earlier CERMEs, TWG 11 adopted an eclectic perspective in its interpretation of comparison as referring to any study that documents, analyses, contrasts or juxtaposes cross-cultural or cross-contextual similarities and differences across all aspects and levels of mathematics education. In this way the TWG aimed to encourage critical but supportive discussions around a number of predetermined and emergent themes.

A recurrent but very productive aspect of this working group has been the relatively small number of paper presentations. This year ten papers and three posters created space not only for colleagues to share their research in detail but allowed participants to engage in lengthy and inclusive discussions on the nature of comparative mathematics education research and the means by which it can be meaningfully and rigorously undertaken. As is shown below, the different paper contributions fell naturally into four themes, each reflecting significant substantive and methodological variation.

Firstly, two papers, with very different foci and methodological conceptualisations, framed a discussion on the importance of identifying an appropriate unit of analysis. This issue, while of importance in all research, is particularly foregrounded in comparative research. One of the two papers, Sajka's eye-tracking examination of different response groups' visual attention to the statement of a mathematical problem showed that such groups respond in culturally conditioned ways. The second of these two papers, Clarke, Mesiti, Cao and Novotna's study of the culturally-located variation in the vocabulary of the typical school mathematics classroom, foregrounded the importance of understanding that much mathematic didactics vocabulary may be culturally unique. Importantly, both studies exposed hitherto unconsidered demands with respect to what is actually being analysed.

A second theme could be found in the three papers construed as having a tacit focus on beliefs. Firstly, Andrews and Xenofontos presented a quantitative analysis of Cypriot and Greek initial teacher education students' understanding of a hypothetical solution to a non-arithmetical linear equation. They found considerable emphases on rote solution methods although Cypriot students were more articulate on the matter than their Greek colleague. Secondly, Koljonen's case study of one Swedish teacher's deployment of the teacher guide associated with a translated Finnish textbook showed how teachers' responses to such materials, irrespective of any instructional material they contain, are interpreted by culturally-determined expectations of what is appropriate. Thirdly, Nosrati and Andrews interviewed Norwegian and Swedish upper secondary students about their experiences of school mathematics and found a dominant perception that the purpose of school mathematics is to prepare students for a successful economic engagement with the world. All three studies highlighted well the extent to which mathematics classroom participants' perspectives are informed by culturally-located beliefs.

A third theme, also reflected in three papers, concerned mathematics teacher knowledge. In the first of these, Kingji-Kastrati, Sajka and Vula used an extant test to examine Kosovar and Polish teacher education students' knowledge of fractions. In the second, Tchoshanov, Quinones, Shakirova,

Ibragimova and Shakirova used a battery of TIMSS-derived test items to examine differences in US and Russian lower secondary teachers' content knowledge. Both studies highlighted substantial differences in the content knowledge of the groups under scrutiny. Finally, Xeonfontos and Andrews examined Cypriot and Greek students' didactical explanations of the same hypothetical solution to a non-arithmetical linear equation as discussed above. In this case, Cypriot students' explanations were more didactically robust than their Greek colleagues. All three papers confirmed the extent to which mathematics content knowledge is not the culturally independent body of knowledge assumed by international studies of student knowledge.

The fourth theme drew on two papers framed by the anthropological theory of didactics (ATD). Firstly, Modeste and Rafalska's drew on ATD's of didactical transposition, or the transformation of academic knowledge to that knowledge taught, to highlight differences and similarities in the presentation of algorithmics in the curriculum materials of Ukraine and France. Secondly, Asami-Johansson, Attorps and Laine exploited ATD's concept of praxeology, which provides the methods for solving a domain of problems (praxis) and a structure (logos) on the discourse those methods, to compare the practices of case study teacher educators in Japan, Finland and Sweden. The two studies, in addition to highlighting substantial differences between the cultural groups under scrutiny, showed how different elements of ATD can be productively employed in cross-cultural studies.

Finally, three posters, each with different foci and methodologies, were presented. Haara, Bolstad and Jenssen, as preparation for a later Norwegian study, presented a research review on mathematical literacy in school. Istúriz, González-Ruiz, Diego-Mantecón, Recio, Búa, Blanco, González and Polo reported on an Erasmus project in which students in different countries develop activities to integrate art into STEM activities. Finally, Tesfamichael, Botten and Lundebj presented a comparative analysis of Norwegian and Ethiopian textbooks presentation of relations and functions.

Overall, the papers and posters presented to the group reflected not only cultural diversity but also methodological pluralism. For example, studies included those that were informed by a priori theoretical assertions and those that were not. There were equal numbers of qualitative and quantitative studies focused on a range of aspects of children's and teacher education students' learning of mathematics. All studies confirmed the extent to which mathematics and its teaching and learning are culturally normative.

# Beginning teachers' perspectives on linear equations: A pilot quantitative comparison of Greek and Cypriot students

Paul Andrews<sup>1</sup> and Constantinos Xenofontos<sup>2</sup>

<sup>1</sup>Stockholm University, Sweden; [paul.andrews@mnd.su.se](mailto:paul.andrews@mnd.su.se)

<sup>2</sup>University of Nicosia, Cyprus; [xenofontos.c@unic.ac.cy](mailto:xenofontos.c@unic.ac.cy)

*In this paper we examine aspects of beginning primary teachers' understanding of linear equations. First-year teacher education students on a programme in Cyprus (12 Greek and 21 Cypriot) were shown a solution to the equation  $x + 5 = 4x - 1$  comprising four rows of mathematically correct algebra but no commentary. They were asked to explain, in writing, the solution to a friend who had missed the lesson in which such equation solving processes had been taught. Analyses found almost all students, irrespective of nationality, writing about knowns and unknowns before offering a 'change the side and change the sign' rule. However, a major difference was that Cypriot students' accounts typically included an objective for the equation solving process, which the Greek students' did not.*

*Keywords: Linear equations, comparative research, Cyprus, Greece, teacher education.*

## Introduction

The topic of linear equations occupies an important position in students' learning. It "stands on the border between mathematics as concrete and inductive and mathematics as abstract and deductive", offering "one of the first authentic opportunities for them to connect their understanding of arithmetic to the symbolism of mathematics" (Andrews & Sayers, 2012, p.476). Yet, it is a difficult topic to teach well, because when learning arithmetic, learners typically come to see the equals sign as an instruction to operate (Kaput et al., 2007). This operational perspective (McNeil & Alibali, 2005) creates few problems with respect to arithmetical equations, with the unknown in one expression, because it supports a process of operation reversal (Herscovics & Linchevski, 1994; Kieran, 1992). However, non-arithmetical equations - the unknown in both expressions - requires a relational (Kieran, 1992) understanding of the equals sign as an assertion of equality between two expressions (Alibali et al., 2007; Filloy & Rojano, 1989) in order that they can operate on the unknown as an entity. In short, students find equation solving problematic because operational perspectives on expressions like  $3x+1$  prevent their being construed as objects subject to, in relational terms, operations themselves (Kieran, 2004). Furthermore, to compound students' difficulties, teachers' practices frequently collude in the maintenance of an operational perspective on the equals sign (Haimès, 1996; Harel et al., 2008; Stephens, 2008), highlighting a need to evaluate the equations-related understandings that beginning teachers bring to their courses. This reflects the aim of this pilot study and an atypical approach, which is described below.

## Perspectives on the teaching and learning of linear equations

Typically, research on equation solving has focused on approaches to the solution of non-arithmetical equations, not least because their solution poses few conceptual difficulties. In this respect, the most widely criticised is redistribution, a rote-learned, *change the side, change the sign* procedure (Nogueira de Lima & Tall, 2008), focused on transposing the equation so that the

unknown finishes on the left-hand side and a value on the right (Filloy & Rojano, 1989). The unknown's arbitrary leftwards movement perpetuates operational conceptions of the equals sign and fails to support students' understanding that such movement does not change the equation's equality (Capraro & Joffrion, 2006). Other approaches, like trial and improvement, support an understanding of the relational nature of the equals sign and the role of the unknown in context (Knuth et al., 2005). However, while it may be an appropriate initial strategy in a teaching sequence, it is inefficient and does not support the learning of general equation solving strategies (Filloy & Rojano, 1989). Other approaches (see Dickinson and Eade, 2004; Fong & Chong, 1995), present the equation as two rows of mathematical objects, one laid on top of the other, as in the representation of  $2x + 10 = 4x + 2$  shown in Figure 1. Here, the authors claim, students can see easily how it reduces to  $2x + 2 = 10$ ; an equation is amenable to an operation reversal procedure.

$x$	$x$	10		
$x$	$x$	$x$	$x$	2

**Figure 1: A representation of  $2x + 10 = 4x + 2$**

However, while such approaches be procedurally helpful and support students' understanding of equations as manipulable objects, they may hinder students' understanding of the invariance of the solution. Moreover, despite Dickinson and Eade's (2004) optimistic arguments otherwise, they remain problematic with respect to negative coefficients (Marschall & Andrews, 2015).

Finally, in studies of teachers' unprompted approaches to equation solving, the balance scale has been the most widely reported, being the approach of choice in case studies from, for example, Canada (Haimes, 1996), Finland, Flanders and Hungary (Andrews & Sayers, 2012), New Zealand (Anthony & Burgess, 2014) and Poland (Marschall & Andrews, 2015). Here the solver manipulates, through addition or subtraction, weights on scale pans, while keeping the scales in balance. Its advocates argue that it helps students see the equation as a whole and not an instruction to operate (Warren & Cooper, 2005). Moreover, it supports an understanding of the need to do the same to both sides (Anthony & Burgess, 2014) and underpins the symbolic foundations of later algebraic formalisms (Andrews, 2003). Systematic attempts to evaluate the balance's efficacy have shown that it helps students to understand the principles of equations, solve non-arithmetical equations with understanding, particularly from the perspective of doing the same thing to both sides (Araya et al., 2010; Warren & Cooper, 2005) and facilitates students' acquisition of an appropriate vocabulary (Vlassis, 2002). Its critics argue that it cannot represent negatives in anything but a contrived way (Pirie & Martin, 1997), a criticism supported studies showing teachers simulating the tying of helium filled balloons to scales to counter the weight of objects in the scale pans (Anthony & Burgess, 2014).

In this paper we explore how students following an initial primary teacher education programme in Cyprus construe non-arithmetical linear equations. Due to Greek being the language of instruction, the programme includes both Cypriot and a high proportion of Greek students.

## Methods

Shortly after the start of their course and before they had been exposed to university mathematics teaching, students were shown a solution to the equation  $x + 5 = 4x - 1$  and asked to write a short

account of how they would explain it to someone who had missed the lesson in which it was introduced. The solution, with no additional narrative, was presented as follows

$$\begin{aligned}x + 5 &= 4x - 1 \\5 &= 3x - 1 \\6 &= 3x \\2 &= x\end{aligned}$$

A non-arithmetical equation was used for several reasons. Firstly, it could not be solved by means of a reversal of operations. Secondly, it should expose, in ways that an arithmetical equation could not, the underlying equations-related conceptions students bring to their courses. Thirdly, it would uncover the extent and depth of their equations-related procedural knowledge as, at each step, they would need not only to interpret and explain the solver's hidden thinking but decide what would need to be made explicit to the unknown learner. It was believed that this would be a more effective means of uncovering students' familiarity and understanding of the topic than a conventional test item and expose any pedagogical predisposition they bring to their course, as a result of their previous schooling.

## Analysis

Students' transcripts were subjected to a constant comparison analysis (Fram, 2013), whereby a transcript was read and re-read to identify different equations-related understandings. This was followed by the next transcript being read and re-read in order to find further evidence of the original codes and any new ones not seen in the first. If new categories were found then the earlier transcript was re-read in case they had been previously missed. This process continued for all 33 transcripts, a number typically thought sufficient to achieve categorical saturation, and yielded seven categories of understanding, which can be seen in Table 1.

With respect to demonstrating the emergence of these categories, we turn to Ekaterini, a female Cypriot student, who wrote that

To solve this exercise we have to first set apart the known from the unknown numbers. The known numbers are the ones that don't include a letter, as for example, 5 and -1. Unknown numbers are the letters or the numbers that are accompanied by a letter, for example,  $4x$  and  $x$ .

Ekaterini's comment about separating the known from the unknown implies an implicit objective for equation solving; in essence, solving an equation entails precisely that. In the same sentence can also be seen evidence of her awareness of the unknown and its role in equation solving. In the second and third sentences she goes further and defines an unknown. She then wrote (her parentheses):

To separate the two, the known numbers should be on one side of the equation, for example, on the left side, as we solved it in the class, while the unknown numbers should be on the other side. Later, I added  $5 + 1$  (whose sign has changed because it moved to the other side of the equation) and subtracted  $4x - x$  (again the sign changed because  $x$  has moved to the other side of the equation and when there is  $x$  or  $y$  alone this means  $1x$  or  $1y$ ). Finally, I reached  $6=3x$  and so I divided 6 by 3 so that  $x$  is equal to 2.

Throughout this paragraph runs a rote procedure for equation solving invoking two simple instructions. The first is that knowns must be moved to one side of the equation and unknowns to the other. The second is that when an object moves from one side of an equation to the other its sign changes. Finally, having achieved this objective, an understanding of the role of inverse operations is invoked to divide the total of the knowns by the coefficient of the unknowns. Within this procedure, as with many of the students' suggestions, is evidence of flexibility in that it does not matter to which side of the equation which type of object travels, implying that it may be a matter of convenience.

Articulating an awareness of the unknown	31
Defining what is meant by an unknown	15
Offering an implicit objective for equation solving	18
Offering an explicit objective for equation solving	1
Offering a rote procedure for equation solving	29
Articulating an understanding of the role of inverse operations	26
Offering an unspecified process for equation solving	4

**Table 1: The seven categories of understanding elicited from the data**

With respect to the remaining two categories, only one student offered an explicit objective for equation solving. In this case, Irene, a Cypriot female, wrote that the “question in this equation is to find ‘x’ and what value it has”. Finally, four students wrote of an unspecified procedure. For example, Moira, a Greek female wrote, “I would tell the student that we separate the known from the unknown numbers and then make the calculations”. From her comment we inferred three perspectives on equation solving; an implicit objective tied to separating the known from the unknown, an awareness of the unknown and an unspecified procedure. The seven categories of response, along with their respective frequencies, can be seen in Table 1.

## Results

The figures of Tables 2 and 3 show which of the seven categories identified by the constant comparison analysis were found in the accounts of the Greek and Cypriot students respectively. From these can be inferred both similarities and differences. With respect to the former, several similarities were identified. Firstly, with a single exception in each country, students' explanations showed an explicit awareness of the unknown. Secondly, a very high proportion of students from both countries - only four students did not - offered a rote procedure for solving the equation and of these, all focused on the mantra, change the side change the sign. Thirdly, only five students did not write in ways indicative of their understanding inverse operations, although this was typically seen with respect to explaining how the solution is reached from the point where  $6=3x$ , as in Chloe's comment that “after reaching  $6=3x$ , we divided 6 by 3 so that x will be by itself”. Fourthly, around half of all students in each group defined what they meant by an unknown

Greek student	A	B	C	D	E	F	G	H	I	J	K	L	12
Aware of unknowns	1	1	1	1	1	1	1	1	1		1	1	11
Defines unknowns		1			1	1			1		1	1	6
Implicit objectives						1					1		2
Rote procedure	1	1	1		1	1			1	1	1	1	9
Inverse operations		1	1		1	1	1			1		1	7
Unspecified process				1			1	1					3
Explicit objectives													0
	2	4	3	2	4	5	3	2	3	2	4	4	3.17

**Table 2: Distribution of Greek students' equations-related insights**

With respect to differences, only two Greek students offered any sense of objective, albeit implicit, for the equation solving process compared with 17 of the Cypriot, of which only one, student F, offered an explicit goal.

Cypriot student	A	B	C	D	E	F	G	H	I	J	K	L	M	N	O	P	Q	R	S	T	U	21
Aware of unknowns	1	1	1	1	1	1	1	1		1	1	1	1	1	1	1	1	1	1	1	1	20
Defines unknowns	1		1	1				1							1	1	1		1		1	9
Implicit objectives	1	1	1	1				1	1		1	1	1	1	1		1	1	1	1	1	16
Rote procedure	1	1	1		1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	20
Inverse operations	1	1		1	1	1	1	1	1	1	1		1	1	1	1	1	1	1	1	1	19
Unspecified process				1																		1
Explicit objectives						1																1
	5	4	4	5	3	4	3	5	3	3	4	3	4	4	5	4	5	4	5	4	5	4.1

**Table 3: Distribution of Cypriot students' equations-related insights**

The figures of Tables 2 and 3 show also that Greek students' data yielded fewer codes per student, 3.17, than their Cypriot counterparts mean of 4.10. Indeed, at the upper end of the spectrum the accounts of seven Cypriot students, A, D, H, O, Q, S and U, yielded five categories of response, compared with that of just one, F, Greek student. At the lower end, the accounts of four Greek students, A, D, H and J, yielded only two categories each, compared with zero Cypriot students. These differences were statistically significant in two ways. Firstly, a t-test showed differences in the mean number of codes were unlikely to be due to chance ( $t = 2.95$ ,  $p = 0.006$ ). Secondly, a chi-square test performed on the data in Table 4 confirmed that variation in the number of codes yielded by each of the Greek students and Cypriot students respectively were unlikely to be due to chance ( $\chi^2 = 9.15$ ,  $df = 3$ ,  $p = 0.027$ ). This difference in the codes, we argue is likely to be a consequence of differences in how the two systems introduced their students to linear equations; a possibility warranted by, for example, evidence that Cypriot students tended to specify objectives in their accounts in ways that their Greek colleagues typically did not. Finally, of the eight students whose accounts yielded five codes, seven yielded the same five. That is, they indicated an awareness of and defined the unknown; they offered implicit objectives and a rote procedure alongside an awareness of inverse operations related to division. In short, the most complete responses were typically the same.

	Number of codes per student				
	2	3	4	5	
Greek	4	3	4	1	12
Cypriot	0	5	9	7	21
	4	8	13	8	33

**Table 5: Distribution of total number of codes per student per country**

## Discussion

The aim of this pilot study, the quantitative analyses for which are presented in this paper, was to explore the equations-related understanding primary teacher education students bring to their courses and, in so doing, evaluate the effectiveness of a simple to implement tool for later comparative use. In this instance comparison was made possible by the fact that courses in Cyprus are taught in Greek, making them accessible to Greek students. The results are methodologically encouraging but, acknowledging the fact that all respondents were prospective teachers, mathematically worrying, albeit with some qualifying strengths.

Methodological encouragement stems from the evidence that students responded positively to the invitation and produced written accounts sufficient to expose their perspectives on or conceptions of linear equations. It was also encouraging that the tool was able to discriminate between the two cultural groups in its highlighting similarities and differences in students' accounts that, we infer, reflect systemic differences in the ways in which linear equations had been experienced by these two sets of students as learners of school mathematics. In short, the tool proved fit-for-purpose.

The mathematical disappointment derives in part from the lack of any evidence of students holding a relational (Kieran, 1992) conception of the equals sign, in that nothing said by any student indicated an understanding of the equals sign as an assertion of equality between two expressions (Alibali et al., 2007; Filloy & Rojano, 1989). Mathematical disappointment also derives from the very high proportion of students in both countries who seemed to construe equation solving as a rote process of 'change the side and change the sign'. That is, the majority of students appeared to have a procedural rather than a conceptual perspective on equations in which symbols are moved around "with a kind of additional 'magic' to get the correct solution" (Nogueira de Lima & Tall, 2008, p.4). Indeed, even those students whose accounts yielded the most categories of response presented procedural perspectives with implicit objectives and rote procedures. However, in contrast with international research showing the balance as teachers' preferred representation (Andrews & Sayers, 2012; Anthony & Burgess, 2014; Haimes, 1996; Marschall & Andrews, 2015), no reference to the balance was made by any student. Indeed, with the exception of their implicit awareness of inverse operations, which we discuss below, nothing written by any student indicated a narrative based on performing the same action to both sides of the equation.

Despite the negatives, there were some interesting positives. The majority of students, particularly the Cypriot, indicated an awareness of the role of inverse operations. In every case this occurred at the point in the solution where the step connecting  $6=3x$  to  $2=x$  was discussed. Here, students indicated, albeit implicitly, an awareness that division was the inverse operation to invoke, insights that seem to confound the mechanical procedure of 'change the side, change the sign'. Also, despite the highly procedural nature of their accounts, only two students, one from each country, did not

demonstrate an awareness of the unknown. That is, students not only used an appropriate vocabulary but were generally aware of the function of the unknown in the equation solving process. Indeed, around half of all students from both groups offered a definition, typically implicitly, of the unknown, as in Carissa's account in which she wrote, "I separated the known from the unknown numbers. Unknown  $x + 5$  (known) = unknown  $4x - 1$  (known)".

Finally, Cypriot students' accounts yielded more response categories than their Greek colleagues, typically due to their tendency to offer objectives, again implicit, which their Greek colleagues did not. We speculate that such a difference may reflect cultural teaching norms; while the evidence of these students' accounts indicates the outcome of procedural teaching this particular finding suggests that Cypriot teachers may warrant their procedural approaches to a topic in ways that their Greek colleagues may not. In sum, the responses from both sets of students indicated deep-set procedural perspectives on linear equations. It was clear that they had understood the task in that all their explanations were valid but, with both the Cypriot and the Greek curricula advocating that students learn a relational mathematics, the implications of this study for teacher education are profound.

# Comparing the practices of primary school mathematics teacher education

## Case studies from Japan, Finland and Sweden

Yukiko Asami-Johansson<sup>1</sup>, Iiris Attorps<sup>1</sup> and Anu Laine<sup>2</sup>

<sup>1</sup>University of Gävle, Sweden; [yuoasn@hig.se](mailto:yuoasn@hig.se), [ias@hig.se](mailto:ias@hig.se)

<sup>2</sup>University of Helsinki, Finland; [anu.laine@helsinki.fi](mailto:anu.laine@helsinki.fi)

*In this study, we have observed three different teacher educators' lessons, concerning area determination of polygons in primary school teacher training courses in Japan, Finland and Sweden. The aim of this paper is to investigate the main elements of the lessons and to compare the differences between the countries. We focus on how the teacher educators relate the didactic construction of the lessons for prospective teachers to the school mathematical and didactical organisations by applying Chevallard's anthropological theory of the didactic (ATD). The analysis shows how the curricula and the different traditions of teaching practice in each country influence the mathematical and didactical construction of the lessons.*

## Introduction

The notion of *didactic divide* is introduced by Bergsten and Grevholm (2004) to illuminate the problematics within the teacher education in Sweden. They refer to Kilpatrick, Swafford and Findell (2001) stating that teacher education needs to provide opportunities for prospective teachers to *connect* different kind of knowledge, and if such connection is not realized, one may say there is a didactic divide between disciplinary and pedagogical knowledge of mathematics. Bergsten and Grevholm also illustrate the point of issue in teacher education citing Ball and Bass's argument; "teacher education across the 20th century has consistently been severed by a persistent divide between subject matter knowledge and pedagogy", a gap that "fragments teacher education by fragmenting teaching" (Ball and Bass, 2000 in Bergsten and Grevholm, 2004, pp. 125-126).

As an attempt to elucidate the phenomenon above within the teacher education in Sweden, we studied the lesson structures of mathematics education at the primary school teacher education programs, using a comparative study. For comparison, we chose Finland which had significantly high result in mathematical literacy among Scandinavian countries (OECD, 2013); and Japan, where teaching culture in mathematics seems to be more shared, compared to the US and Europe (Winsløw, 2012).

The aim of this study is to investigate and compare lessons of three countries' teacher education programs, type of teaching methods courses concerning area determination for teaching in school.

## Theoretical framework and research questions

Chevallard proposed to study the mathematical knowledge in an institutional context; learning mathematics is extended to any other human activity and gives rise to the anthropological theory of

the didactic (ATD). There, mathematics learning is modelled as the construction of praxeologies (Bosch & Gascón, 2007) within social institutions. A praxeology provides both methods for the solution of a domain of problems (praxis) and a structure (the logos) for the discourse regarding the methods and their relations to broader settings. Hence the praxis part includes *types of tasks* (**T**) and a *technique* (**τ**) to solve the task type and the logos part includes a *technology* (**θ**) which justifies the techniques and a *theory* (**Θ**), which further justifies the technology. The form of a praxeology is determined by a mutual interaction of a mathematical organisation (MO) and a didactical organisation (DO). The MO describes mathematical activities of the praxeology, and the DO describes the activities to support the learning or teaching of the MO.

In the case of lessons of a teaching methods course in teacher education, types of tasks of the DO are usually to make prospective teachers (PTs) to learn the content knowledge and its teaching approaches. Teacher educators' DOs promote the PTs to learn how to construct the praxeologies (the MO and DO) of their future lessons. We call the didactical praxeology of teacher education as the  $DO_{TE}$  and school mathematical and didactical praxeologies encapsulated under the  $DO_{TE}$  as  $MO_{SCH}$  and  $DO_{SCH}$ .

The praxeologies ( $MO_{SCH} \leftrightarrow DO_{SCH}$ ) demonstrated in the lessons are thus *encapsulated* in the teacher educators'  $DO_{TE}$ .

To realize the aim of this paper, we addressed three research questions: 1. What are the main elements of each teacher educator's didactical praxeologies in their lessons? In particular, (how) do they relate the didactic praxeologies of the lessons to school mathematical and didactical praxeologies relation to the area determination? 2. What are the main differences between the three lessons, concerning the research question 1? 3. What could be the wider explanations for those differences?

In order to find out the answers to the research questions 1 and 2, it was necessary to identify the components of both the praxis and logos of the school praxeology ( $MO_{SCH} \leftrightarrow DO_{SCH}$ ) presented in the lessons. Subsequently, we describe how the teacher educators'  $DO_{TE}$ s encapsulate the ( $MO_{SCH} \leftrightarrow DO_{SCH}$ ) in their lessons.

To identify mainly the praxis part of the  $DO_{TE}$  and the part of the encapsulated school praxeologies, video recordings were made; "Quantity and Measurement" by Mr. Matsui (Japan, with 53 PTs), "Area of Polygons" by Mrs. Laine (Finland, with 34 PTs) and "Area and Perimeter" by Mrs. Nilsson (Sweden, with 20 PTs). The teacher educator in Finland is the third author of this paper. The names of the educators in Japan and Sweden are pseudonyms.

The questionnaire consists of eight questions and we consider that some of the questions may support to identify different components of the  $DO_{TE}$  and ( $MO_{SCH} \leftrightarrow DO_{SCH}$ ). For instance, Q1: "What do you intend the prospective teachers (PTs) to learn on this content (e.g. area of polygons)?" is related to identify the components of the logos part of the  $MO_{SCH}$  and what is prioritized in the  $DO_{TE}$ . Also, Q4: "Which kind of difficulties connected with teaching the content" and Question as

Q7: “What are your teaching procedures and particular reasons for using these to engage your teaching?” gives an indication to identify the technology ( $\theta$ ) and the theory ( $\Theta$ ) of the  $DO_{TE}$ . Studying the answers to those questions is also relevant to the research question 3, since the Q4 and Q 7 particularly may give us the picture of what kind of conditions and constraints in each context *form* the praxeologies in each country.

Further, we studied each country’s curricula and textbooks concerning the chapter of measurement to reinforce the investigation concerning the research question 3. We selected the chapters concerning measurement, since the lessons in all three countries more or less deal with the introducing the area determination of rectangles using arbitrary objects

## Results and analysis

### Curriculum concerning measurement in each country

In the Japanese guideline for the curriculum for grades one to six (MEXT, 2008), the determination of length, area and volume is described in an own chapter *Quantity and Measurements*, between the chapters of *Arithmetic* and *Geometry*. The contents for each grade are described in detail with concrete teaching proposals. As guidelines for teaching methods, it is stressed to build on pupils’ previously learned knowledge and their various ways of solving problems. The introduction of the chapter consists of four phases; direct comparison, indirect comparison, comparison using arbitrary objects, comparison using standard units. This order is clearly followed by Japanese textbooks (Miyakawa, 2010).

The content regarding quantities, units and measurement are shortly described in the chapter *Geometry and Measurements* in the Finnish curriculum (Finnish National Agency for Education, 2014) and in the chapter *Geometry* in the Swedish curriculum (Skolverket, 2011). These curricula do not give any practical guidelines for teaching the contents. In Sweden, textbooks are not controlled by the ministry. The presentations of those contents in the textbooks for grades 1-3 are often placed in sections covering Arithmetic (e.g. Brorsson, 2013), although the Swedish curriculum introduces them in Geometry. Unlike the Japanese curriculum, the four phases of the introduction of the concept of measurements are not known in Sweden, some textbooks introduce direct comparison and comparison using standard units at the same time (ibid.). Also, the problem that corresponds to the indirect comparison is not addressed in most textbooks<sup>1</sup>. Comparing these two contexts, we might state that the Japanese curriculum does not give much space for different interpretations of its contents. It provides a suggestion of a uniform teaching approach for textbook authors and the users. We assume the reason that many Swedish textbook authors locate the section of measurements in the domain of arithmetic, is to enable a natural connection between area calculations and the basic arithmetical operations. It indicates that different textbooks provide different teaching approaches in Sweden.

### Lesson observation “Quantity and Measurement” in Japan

Mr. Matsui is the lecturer of the course “Arithmetic Education” in a state university located in the middle part of Japan. He has worked as a mathematics teacher in lower secondary school for 14

---

<sup>1</sup> We have not completed the investigation of Finnish textbooks yet.

years and as teacher educator at universities for 12 years. He explains the four phases in the process of pupils learning about measurement by referring to the curriculum guidelines and clarifies those different comparison methods for the class. Thereafter, he discusses how the above mentioned four phases are treated in digital textbooks for grades one to five. The second half of the class is spent to experience the structured problem solving approach. This approach emphasises learner's active participation in mathematical activities, challenging problems and collective reflections (Stigler & Hiebert, 1999). Mr. Matsui lets the PTs find out several different methods for the determination of the area of parallelograms aiming to teach pupils of grade five. Four PTs draw pictures and explain their different solutions on the blackboard (see Figure 1). Mr. Matsui points out the different kinds of “shifts” used by the PTs, and categorises them in: using the sum of the squares (Figure 1 in the middle), “*parallel translation*” (top left), “*rotation*” (bottom left), “*same area transformation*” (top left and bottom left) and “*double area transformation*” (top right). Then, he explains the formula for the area of parallelogram as height times length since the geometric transformations shows that the width (or height) and length of the parallelograms corresponds to those of rectangles. In the same way, he gives a final problem to find out methods for determining the area of trapezoids, using same didactical approach, and concludes the formula for the area of trapezoid;  $(a + b) h/2$ .

**Figure 1: The solutions of the prospective teachers**

**Findings:** The (T) of the  $DO_{TE}$  in this episode is to let the PTs experience what the  $MO_{SCH}$  and the  $DO_{SCH}$  of “determination of area of a parallelogram and trapezoid” can look like. There, (T) of the  $DO_{SCH}$  is to encourage the pupils to find out different solving methods of determination of area of a parallelogram and trapezoid to lead to establish the formula. To anticipate how pupils in grade five would solve area determination, Mr. Matsui makes the PTs participate in an exemplary lesson using the structured problem solving approach. He let them follow up one of the ( $\tau$ ) of the  $DO_{SCH}$  – whole-class discussions, where the ( $\theta$ ) of the  $DO_{SCH}$  – applying the statement of pupils’ previous experienced  $MO_{SCHS}$  – is demonstrated. Those components of the  $DO_{SCH}$  promote to construct a praxeology where several local  $MO_{SCHS}$  from the previous to the forthcoming grades are connected. The Guidelines is both the technique ( $\tau$ ) and the technology ( $\theta$ ) of the  $DO_{TE}$ , since it suggests different kind of fundamental didactical approaches; e.g. using pupils’ previous knowledge from grades one to six, and the use of divers didactical terms of the measurements (direct, indirect, arbitrary comparisons, standard units) and area determination (e.g. “same area transformation”).

### **Lesson observation “Area of Polygons” in Finland**

The observed lesson is a workshop using manipulatives in the course “Didactics of Mathematics” for prospective teachers for grades one to six in a state university located in southern Finland. Mrs. Laine, the lecturer of the course, has worked as mathematics teacher in primary and lower secondary school for 5 years, thereafter, as teacher educator for 16 years. Previously she explained

classification of mathematical figures (e.g. set of squares belong to set of rectangles, and set of rectangles belong to set of parallelograms...), line symmetry and rotational symmetry, perimeter and the area of polygons, property of circle, concept of scale. Today, the PTs move between six different tables to work practically with above mentioned concepts. The PTs work in groups using a compendium giving them instructions how to demonstrate those mathematical concepts practically for pupils. The compendium is written by Mrs. Laine and she also moves between the tables to give advices to the PTs on to how solve the tasks the compendium suggests. In this paper, we focus on the workshops “Area of Polygons” and “Area and perimeter”.

In accordance with the description in the compendium, one PT in a group plays the “teacher role”. As it is prescribed in the compendium, the “teacher” explains how to calculate the area of rectangles by using grid paper with squares of  $1\text{cm}^2$ . PT1 reads the text in the compendium and explains that the sum of the squares is equal to the area of the rectangle. In the compendium, it is emphasised that teachers shall promote pupils to use an inductive way of working/learning. It means, letting pupils experience how to calculate the area of different types of rectangles, and have them find out the formula “height times length”. The next task is to find out the formula for the area of a parallelogram. The compendium describes the method of parallel translation (however, these didactical terms like *parallel translation* and *same area transformation* were not observed in the lesson) and explains that the same formula as for rectangles can be applied. PT2 explains this method by drawing the figures for their colleagues. In the same way, the PTs explain to each other the method of area determination of triangles, by reflecting the instruction in the compendium: “make a parallelogram by drawing two similar triangles and let pupils notice that area of the one of the triangle is the area of the half parallelogram”.

The next task “Area and perimeter” is to make different kinds of quadrangles with area  $12\text{ cm}^2$ . Ms. Laine encourages the PTs to make even irregular quadrangles with the same area. The PTs test to make several different shapes of quadrangles and eventually notice that the perimeter do not need to be the same even the area is same. Ms. Laine then asks the group that how a figure does look like in order to have big perimeter. PT3 makes a long slim rectangle and shows it to others. Then PT4 wonders and asks Mrs. Laine, “why does it work in that way? Are there any rules to be able to describe?” then Mrs. Laine answers, “it has to do with the inductive way of working in lower grades. We can derive understanding toward this phenomenon by working with many single cases in the lower grades. That is good enough on these levels (lower grades)”.

**Findings:** In the first episode, the task (T) of the  $\text{DO}_{\text{TE}}$  is to let the prospective teachers learn “inductive way of teaching/learning” to make school pupils find out the formula of area of a rectangle. There, the description from the compendium with exercises (workshop) and role-play are the  $\text{DO}_{\text{TE}}$  ( $\tau$ ) to let the PTs to experience the praxeology of the school lessons ( $\text{MO}_{\text{SCH}} \leftrightarrow \text{DO}_{\text{SCH}}$ ). Using the compendium and the statement of (not mathematical) induction is the  $\text{DO}_{\text{TE}}$  ( $\theta$ ) to justify the praxis of the  $\text{DO}_{\text{TE}}$ . The compendium describes directly ( $\text{MO}_{\text{SCH}} \leftrightarrow \text{DO}_{\text{SCH}}$ ) where e.g. the  $\text{MO}_{\text{SCH}}$  ( $\tau$ ) is figures, counting of the grids and multiplication, also the ( $\theta$ ) are standard units and commutative property of multiplication. Consequently, the  $\text{DO}_{\text{SCH}}$  ( $\tau$ ) is to let pupils try to count different kind of rectangles’ area to find out the formula by their own. Here, the use of the inductive way of thinking is an essential element of the didactic technology of both the  $\text{DO}_{\text{TE}}$  and  $\text{DO}_{\text{SCH}}$  about the teaching of concept of area determination.

In the last episode, PT4 wants to know the theory level of the  $MO_{SCH}$  regarding the area and perimeter. However, Mrs. Laine's  $DO_{TE}$  ( $\tau$ ) consistently aims to inform the prospective teachers the ( $\theta$ ) of the  $DO_{SCH}$  – “derive the understanding toward this phenomenon through many single cases” and do not aim to create a technological discourse of the  $MO_{SCH}$ .

### Lesson observation “Area and Perimeter” in Sweden

The course Mathematics and Learning for Primary School, Grades 4-6 Teachers II, Geometry, in a state university located in middle of Sweden, treats the knowledge in mathematics and mathematical education in relation to the current Swedish curriculum. The lecturer Mrs. Nilsson has worked as a mathematics teacher in grades 4-7 in 13 years and as teacher educator in 12 years. To begin with the lesson, she asks the PTs to write down what are their “own perceptions of the area”. Then she gives five group-exercises concerning area and perimeter. The sixth exercise consists of determining the area of different polygons by using Geo-board. Mrs. Nilsson demonstrates a method for area-determination of an isosceles triangle by using a rubber band around the triangle. She divides the rectangle into two squares which are in turn divided into two halves. Half of the area of the squares is subtracted from the each side. Now, the PTs ponder the method for area-determination of another isosceles triangle in groups.

**Figure 2a: an isosceles triangle. 2b: with an auxiliary line. 2c: PT6's figure**

Mrs. Nilsson then demonstrates PT5's solution where the same method is applied as the one she explained. (See Figures 2a & 2b).  $4 - 1 - 1 - \frac{1}{2} = 1\frac{1}{2}$  (area units). Then PT6 asks if he can apply the formula of the area determination for a triangle. He explains; first, dividing the original triangle into two triangles with the base of 1.5 length units (see Figure 2c), and then adding the area of the two triangles. This gives the area,  $(1.5 \cdot 1)/2 + (1.5 \cdot 1)/2 = 0.75 + 0.75 = 1.5$  (area units). Some of the PTs express that they do not grasp directly how it works. Then Mrs. Nilsson comments “one (a pupil) can understand (this method) if he/she has more mathematical skills”.

**Findings:** The ( $T$ ) of the  $DO_{TE}$  is making the PTs to learn a teaching method regarding area determination of isosceles triangles with manipulatives, where the  $MO_{SCH}$  ( $\tau$ ) is the division of figures and subtraction of area. However, the  $DO_{TE}$  ( $\tau$ ) and  $DO_{SCH}$  ( $\tau$ ) – using Geo-board – ensures actually several another mathematical techniques than Mrs. Nilsson has planned to apply. This caused a breaking of a didactical contract (Brousseau, 1999) when the PT6 proposed another technique. Mrs. Nilsson's intention was to train the PTs' algorithmic skills with one technique. She let PT6 explain his alternative technique, nevertheless, did not validate it. Her intention was not to discuss the viability of different mathematical techniques for the grade five class but to establish a certain technique which is possible for all prospective teachers to manage. The didactic theory of the  $DO_{TE}$  is difficult to identify from the observation.

### The summarized answers to the questionnaires

Mr. Matsui states that the PTs should learn area of polygons can be determined in various ways by using pupil's previously learned knowledge. He stresses also that the prospective teachers should be

able to use some mathematical terms; the terms describe the various methods for area determination. He mentions also that the PTs should know the flow of the problem solving closely.

Ms. Laine's intention in this lesson is, each method of area determination of polygons area is related to each other; the area of parallelogram is based on rectangles, and the area of triangles is based on parallelograms. She emphasizes the importance of the application of inductive ways of working to find a general result, by examining a number of specific examples. She describes her PTs' fragmental knowledge of the formulas for area determination. During her lesson, she often discusses pupils' misconceptions of area and perimeter to let the PTs realise their own misconceptions of this content.

Mrs. Nilsson remarks her PTs' difficulties and limitations concerning geometrical figures. Some of them have learnt formula for area determination superficially and sometimes incorrectly. Also their perception, "geometry is a difficult subject" blocks their learning process. Furthermore, the PTs have not developed mathematical terms that allow them to explain their solutions. To deal with these difficulties, she uses manipulatives to give them concrete ideas of different mathematical concepts and train to establish their own interpretation of the concepts. To train their mathematical communication skills, she uses group discussions with workshops.

## Final discussion

The detailed Japanese curriculum with sufficient specifications about the teaching approach, the tradition of the structured problem solving and the textbooks adopting the same teaching approaches – all these factors contribute to give practical hints about how to design the lessons with epistemologically connected praxeologies to a Japanese teacher educator. It becomes explicit for the prospective teachers how to construct mathematics lessons in which alternative techniques are assessed and a technological discourse is taking place. Also, as it is described in Mr. Matsui's answer to the questionnaire, a didactical terminology that describes mathematical techniques such as "same area transformation" is *collectively* used. It leads to the knowledge of the  $MO_{SCH} \leftrightarrow DO_{SCH}$  being institutionalized in the community of teacher educators and prospective teachers.

In Finland, the explicit didactical theory of the  $DO_{TE}$  (the compendium applying the inductive way of thinking) supports the PTs to learn the knowledge of the  $MO_{SCH} \leftrightarrow DO_{SCH}$ . However, the analysis from the lesson observation indicates a limitation of the compendium as the (•) of the  $DO_{TE}$  to mediate the theory level of the  $MO_{SCH} \leftrightarrow DO_{SCH}$ . Even though the prospective teachers are interested in learning more about the theory level of the MO, the workshop with the compendium lacks a function to give them a space for the discussions to institutionalize the theory block of the praxeology. According to the questionnaire, Mrs. Laine's  $DO_{TE}$  aims to stimulate prospective teachers' cognitive learning. Hence we might state that the institutional conditions which forms her  $DO_{TE}$  are actually originated from a pedagogical level. Thus the compendium gives single techniques in the  $MO_{SCH}$  to let the PTs to *visit* the praxeology of the school lessons.

In the case of Sweden, a didactical theory of the  $DO_{TE}$  is not clearly distinguished neither from the observation nor the results from the questionnaire. The lack of shared knowledge of the  $DO_{TE}$  indicates that praxis part of the  $DO_{TE}$  – presentation of how to construct the  $MO_{SCH} \leftrightarrow DO_{SCH}$  is *individually* designed by teacher educators in Sweden. The result from the questionnaire shows that Mrs. Nilsson's focus is definitely on the pedagogy. The PTs' fragmented mathematical knowledge

and their anxiety for applying mathematics strongly influence her teaching strategies. Similarly to the Finnish case, neither the Swedish curriculum nor the customs of the lessons with manipulatives help the teacher educators to encapsulate the lesson sequences with complex praxeologies.

*Use of English as the international language of educational research can mask the nuanced meanings of constructs that researchers working in languages other than English originally employed in framing their practice and their theories. Cross-cultural comparisons are framed in terms of constructs expressed in the language of publication, usually English. Attention has been drawn to the significance of the resulting validity-comparability compromise (Clarke, 2013). The Lexicon Project investigates the pedagogical naming systems used by educators in nine countries (eight languages). Drawing on examples from the Australian, Chinese and Czech lexicons, this paper outlines the project's research design and addresses the implications of distinctive lexical features for comparative classroom research between communities employing different lexicons to describe the phenomena of middle school mathematics classrooms.*

*Keywords: Professional language, mathematics education, international comparison.*

## Introduction

The Lexicon Project involves research teams from Australia, Chile, China, Czech Republic, Finland, France, Germany, Japan and the USA. The project aims to document the naming systems (lexicons) employed by different communities speaking different languages to describe the phenomena of the mathematics classroom. Such lexicons consist of words of locally agreed meaning in a single language that collectively accord to lexical norms and conventions characteristic of the language community (mathematics educators) of the particular country.

The theoretical position adopted by this project is that our experience of the world, our engagement in socio-cultural practices, and our reflection on those experiences and practices are mediated and shaped by available language. The Sapir-Whorf hypothesis suggests that our lived experience is mediated significantly by our capacity to name and categorize our world.

We see and hear . . . very largely as we do because the language habits of our community predispose certain choices of interpretation (Sapir, 1949, p. 162).

Marton and Tsui (2004) suggest that categories “not only express the social structure but also create the need for people to conform to the behavior associated with these categories” (p. 28). In this project we examine this normative role of language in relation to classroom practice and research.

While a professional language of teaching practice seems lacking in the USA (Lampert, 2000), such a language seems to be well-established among educators in China and Japan (Fan et al., 2004;

Fernandez & Yoshida, 2004). Our interactions with classroom settings, whether as learners, teachers, or researchers, are significantly mediated by our capacity to name what we see and experience (Clarke et al., 2016). Speakers of one language have access to terms, and therefore to perceptive possibilities, that may not be available to speakers of another language. This has implications for international comparative research.

Any claim that researchers speaking different languages are analyzing “the same classroom,” even when working from the same video records, can be usefully contested. In two published translations of Vygotsky, we find the Russian term, “obuchenie,” represented as “instruction” in one translation and “learning” in another. This is not merely a problem of mistranslation. The term refers to an activity in which teachers and students are jointly participant for which there is *no equivalent term* in English. The term offers a conceptualisation of classroom practice with profound implications for the theorization of classroom teaching/learning. Recognition of these implications is not afforded in English. Educational research increasingly employs English as the primary language through which theory is developed and disseminated. It is essential to recognise the constructs that other cultures have employed in conceptualising their practice and examine the consequences for research and for theory of those distinctive terms (and the designated constructs) that might otherwise be ignored by an international community restricted to communication in English.

## Research design

In the Lexicon Project, local teams of researchers and experienced teachers in all nine countries viewed a common set of video records of one eighth-grade mathematics lesson from each participating country. Specific lessons were selected by each country team for the diversity of activities displayed rather than for their representativeness. The purpose of this activity was to stimulate identification of those terms in the local language of each team that constituted the national pedagogical lexicon with respect to the teaching of middle school mathematics (ages 11 to 14). It is via the medium of these terms that teachers plan, engage with, discuss, and reflect upon the mathematics classroom. It was assumed that the vocabulary available to researchers in each country included most terms employed by teachers, but that the researchers’ vocabulary would include other terms not necessarily locally derived, being translations or literal appropriations of terms generated by other educational communities. For that reason, because of the focus on the local language, it was the teachers’ lexicon that was the principal focus of investigation in each country.

The key prompt used by all teams was: “What do you see that you can name?” Once a term was identified and endorsed by the local team, a consensus description was constructed of the specific classroom phenomenon to which the term referred and examples and non-examples identified to maximize effective communication of the term’s meaning and classroom referent. These descriptions, examples and non-examples were crucial to the communication between teams of the meanings of terms that originated in the local (predominantly non-English) language.

But teams were not restricted to only those phenomena visible in the video material. For example, where observation of one type of classroom activity reminded the observer/s of another activity type not evident in any of the video material, that term was included in the lexicon, together with a description, examples and non-examples. It was anticipated that these terms would describe classroom practices, both structures (such as organizational patterns or activity sequences) as well as

specific activities observable in the middle school mathematics classroom. The function of the video material was fundamentally catalytic, stimulating recall of the names of classroom phenomena present and absent in the classrooms filmed. However, the video material also assisted communication within and between the different teams, clarifying the meaning of terms.

Local team consensus was required for the inclusion of a term in the lexicon and in problematic cases authority was accorded to classroom experience and the team members' capacity to argue that the term was in current use by teachers. The essential point was to record single words or short phrases that were consistently and widely used by teachers within that country with a consistent and agreed meaning. Subsequently, a process of local and then national validation was pursued to refine and ratify each lexicon. The means by which this validation process was undertaken varied from country to country, but basically involved inviting a national cross section of mathematics educators to comment on the adequacy, accuracy, and clarity of the constructed lexicon for that country.

Of course, such lexicons are continually evolving and a process of regular updating is anticipated. The international project team takes particular interest in the studying the connections between terms within a given lexicon and the consequent clusters of related terms that provide the structure for each country's lexicon. Both teachers and researchers were involved in the identification of these connections. The Chinese example below illustrates one approach to the identification of such structures. Comparison of the emphases evident within each country's lexicon reveals distinctive features of the different countries' mathematics pedagogy and priorities of classroom practice.

### **Lexicon selection for the purposes of comparison and contrast**

In this paper, one English speaking and two non-English speaking communities have been chosen to provide contrasting examples of the language that educators in Australia, China and the Czech Republic employ to describe the objects and events of the middle school mathematics classrooms in their countries. Structural aspects of the lexicons suggest underlying pedagogical principles or associations that shape the ways in which middle school mathematics teachers function and interact within the mathematics classrooms of that country. The lexicons also offer insight into the language available to researchers in each country, by which they study, classify, analyze, conjecture and theorize about the practices and the affordances of the mathematics classrooms of their country.

The project identified both similarities and differences in the national lexicons, revealing significant differences in the way teachers and researchers from each country perceive the classrooms that are the focus of their professional activity. These differences raise the question of the extent to which the international community of mathematics teachers and researchers can meaningfully and productively share the wisdom of long-established pedagogical traditions of practice, where these are encrypted in the naming systems by which each community identifies those classroom activities that it considers to be significant. Discussion is provided of: (i) the implications for comparison of the lexicons, and (ii) the implications of the lexicons for other comparative classroom research. These two purposes are conceptually distinct but connected.

In this paper, English is used to describe the content and structure of both the Chinese and Czech lexicons. This reflects the underlying purpose and challenge of the Lexicon Project: to identify and make accessible to the international community the pedagogical principles and distinctions encrypted in different lexicons. Examples from the original language are cited for purposes of clarification. For

example, some terms can be approximated in English (e.g., “Teacher Feedback” adequately names 教师反馈 which is “jiào shī fǎn kuì” in Chinese pinyin<sup>1</sup>) but there are those that have no simple equivalent English term or phrase but can only be represented in pinyin and an extended English description (e.g., 课堂生成 which in pinyin is “kè táng shēng chéng” and which refers to “when the teacher makes full instructional use of an unexpected event beyond the intended plan for the lesson”). Similarly, the Czech term “S cílem objevit” (literally, “with the aim to discover”) refers to the occasion when “by solving the problem students discover something new.” Examples are used, if needed, in the discussion that follows. The three lexicons: Australian, Chinese and Czech are used to illustrate respectively the methodological processes of Lexicon Identification, Structure and Interpretation.

### **The Australian lexicon: Generic rather than discipline-specific terms**

The Australian National Lexicon consists of 63 terms that are familiar and in widespread use (e.g., *Assigning Homework*, *Rephrasing*, *Worked Example*). A description was constructed for each term, together with both examples and non-examples of the use of the term. Because of the role of video in stimulating the recognition of terms, many terms can also be illustrated with video examples.

In consultation with practicing teachers, the lexical items were organized in five categories: Administration (8 terms); Assessment (11 terms); Classroom Management (6 terms), Learning Strategies (27 terms) and Teaching Strategies (50 terms). A lexical item appeared in more than one category if the Australian team decided on the basis of teacher advice that there was a strong association with each category.

One feature of the Australian National Lexicon is that none of the 63 terms identifies a practice unique to the mathematics classroom. The terms all refer to general pedagogical practices. Also worthy of note is the prevalence of ‘gerunds’ (a verb form that also functions as a noun; “teaching” and “learning” are relevant examples) in the Australian National Lexicon. This duality provides both advantage and disadvantage: “learning” as a noun is explicitly the product of the activity of “learning” in a way that objectified “knowledge” is not, but this duality can also result in less precise communication due to the inherent ambiguity over what is being referred to: process or product. The duality of simultaneously invoking both object and activity is not available in some languages, highlighting the affordances of particular languages and the difficulties of translation.

The generic character of the Australian Lexicon content suggests that the lexicon might also be applicable to other school settings besides the mathematics classroom.

### **Integrating forms of connection to structure the Chinese lexicon**

In the Chinese Lexicon, 126 terms were identified as being used by Chinese middle school mathematics teachers in describing their classrooms. Within the lexicon, every term is related to some other terms, which makes the teacher’s language an organic entirety. The challenge for the Chinese

---

<sup>1</sup> Pinyin is a phonetic rendering of Chinese characters using the Latin alphabet employed in English and four basic tonal annotations.

team was to clarify the structure of teacher's pedagogical language as encompassed in these 126 terms. A two-step process was employed by the Chinese team to do this.

**Step One:** Three types of connections were identified between lexical items: Hierarchical, Coincident and Sequential.

### *Hierarchical*

Level One: In the first level, the terms can be divided according to whether the term referred to Teachers, Students or to Teacher-student Interactions.

Level Two: Terms within the category “Teachers” could be divided into: Classroom Management, Demonstration, Questioning, Feedback, Summarizing, Explanation, and Tutoring.

The category “Students” included: Classroom Management, Demonstration, Questioning, Feedback, Summarizing, Doing Exercise, Collaborative Studying, Self-learning and Listening.

The category “Teacher-student Interaction” had no sub-structure at this level.

Level Three (only one example can be shown for reasons of space): “Classroom Management” included: Teaching Affairs Management and Order Management.

Apart from the hierarchical links, it was clear that some activities can happen at the same time while others occur in a sequence. This provided two additional mechanisms for the clustering of terms.

### *Coincident*

This category refers to terms used in a teacher's pedagogical language that refer to activities that can happen at the same time. For example, Group Report and Student Listening — when a group is reporting their findings or answers, the other students must be listening carefully in the class.

### *Sequential*

Teacher Questioning and Student Answering are an example of a pair of tasks that are intrinsically sequential — when the teacher asks a question of the class, this action is typically followed by an individual answering or the class answering together.

**Step Two:** Using the three types of connections, it was possible to organize the terms in the Chinese Lexicon into a structured array. Experienced teachers were recruited from high achieving schools in different parts of China to identify the connections. In this way, regional variations in interpretation and association could be identified. This illustrates the value of the lexicon in helping to identify regional pedagogical variations in a country as large as China, while also highlighting common pedagogical elements.

## **Differences between professional language communities: Teachers and researchers in the Czech Republic**

As for all the country lexicons, the Czech lexicon does more than simply describe the current pedagogical vocabulary of practising Czech mathematics teachers. It should also be considered as a way to understand the Czech “culture of education” by providing examples that illustrate how it is possible to think about education. The use of pedagogical terms varies according to the groups of users (authors in different fields of pedagogy, teachers, etc.). One purpose of the Czech lexicon at the national level is to provide teacher education with a tool for triggering and framing discussion among pre-service students and practising teachers to facilitate better understanding of lesson structure and classroom practice.

The terms of the Czech Lexicon were classified using the following categories: Classroom Management; Introductory Communication; Explanation of New Topic; Revision of Previously Taught Topic; Solving of a Problem; Checking Individual Work; Institutionalisation; Summary; Non-mathematical Social Interaction; Assessment; Concluding the Lesson; Individual Consultation with a Pupil. The Czech lexicon is highly stratified. There are several sub-categories in each of these themes. One distinctive feature is the prevalence of student-oriented terms that reflect the importance attached within Czech education to the teacher-student relationship. For example, “shrnují na pokyn učitele” (student invited to recapitulate teacher’s instruction) and “vysvětlují na pokyn učitele” (student invited to explain teacher’s instruction) are distinctively student actions.

When constructing the Czech lexicon, the research team identified particular characteristics. One characteristic concerned the difference between how the language was used and understood by different target groups. Practising teachers used few technical pedagogical terms and communicated mostly using words from the language of everyday life. Pre- and in-service teachers were more likely to make use of terms drawn from their lessons on mathematical didactics. For example, “Heuristický rozhovor” is an academic term meaning “heuristic dialogue,” but a practising teacher would be more likely to say, “řízená diskuse” meaning “guided discussion” to refer to the same classroom phenomenon. The Czech team’s concern was how to combine the two ways of using the Czech lexicon – as a tool describing the structure of Czech lessons and highlighting important parts of lessons and as a tool to facilitate discussion between different groups. This dilemma is accentuated by the relative paucity of Czech technical terms not only in the domain of didactics of mathematics but also in pedagogy. The Czech example illustrates the different uses of the lexicon for teachers, student-teachers and educational researchers and identifies the potential for the Czech lexicon to serve as a catalytic focus for discussion between these different communities.

## **Discussion: Implications for comparison**

The key steps in lexicon construction of Identification, Structure and Interpretation have been illustrated with examples from the Australian, Chinese and Czech lexicons respectively. Each step offers insights into the pedagogical history encrypted in each lexicon and the potential value of the lexicon to the teaching and research communities in each country. In this section, we explore the question of comparison. Two forms of comparison warrant discussion: within-project comparison of the separate lexicons for the purpose of gaining insight into the pedagogical principles of each language community encrypted in the professional lexicon of middle school mathematics teachers; and, second, the broader implications for international comparative classroom research of the documented differences in how the phenomena of the middle school mathematics classroom are conceptualized within each language community. Each of these is discussed separately below.

### **Comparing lexicons: Constructs as boundary objects**

The primary consideration in making comparison between any two lexicons is the mediating construct that forms the basis of comparison (Clarke, 2015). For example, comparison might be made between the *agency* accorded in one lexicon to the teacher or to the students. That is, what proportion of lexical terms refer to teacher actions and what to student actions (cf “Level One” in the Chinese lexicon), and what is the nature of the actions in each case: initiating or reactive (for example). The Australian lexicon makes a comparable distinction between Teaching Strategies and Learning

Strategies. In this case, “agency” provides the boundary object by which the two lexicons might be compared. Clearly, “agency” need not be a term situated in either lexicon. Instead, it represents an organizing construct with comparable conceptual legitimacy within each lexicon. As such, it constitutes an acceptable boundary object for the purposes of comparison of the lexicons. Other boundary objects might name categories of lexical items, such as: *assessment* or *management*. The requirement for legitimate comparison would be that the organizing construct (say, assessment) has local validity within each lexicon as designating a cluster of lexical terms and cross-lexicon validity in characterizing conceptually the same shared attribute for each lexical cluster being compared. Comparison of the Australian and Czech lexicons is possible on this basis, with respect to either of the mediating constructs: agency or assessment.

### **Comparative research: Validity-comparability compromise**

The documentation of the separate lexicons has the potential to heighten the legitimacy of comparative classroom research being undertaken across two communities. For example, application of a measure of *participation* to the comparative analysis of classroom data from two countries is problematic, unless it can be demonstrated that “participation” has the same cultural relevance within the pedagogical practices of each community. However, if participation is treated not as the basis for an imposed metric, but as a boundary object, then the question can be asked, “What forms of participation are legitimized within the lexicons of the two countries whose classrooms are being compared?” Analysis of the separate lexicons to identify those terms that characterize forms of participation in classroom practices would reveal both similar and different types of participatory activity. For example, choral response has been documented as a frequent form of participatory activity in mathematics classrooms in China and Korea, but not in classrooms in Australia and Japan. Reciprocally, student-student talk is a common form of participatory activity in mathematics classrooms in Australia and Japan but not in China and Korea (Clarke, Xu & Wan, 2013). Any comparison of student participation in classroom activity in these four countries can be undertaken with much greater validity, where attention is given to important distinctions between forms of participation as these are facilitated and named by teachers in each of the countries whose classroom practices are being compared. Utilization of the lexicons from each country to identify legitimate points of comparison would heighten both validity and comparability (Clarke, 2013).

### **Conclusion**

The construction of national lexicons representing the naming systems employed by educators using different languages to “name what they see” in the middle school mathematics classroom represents the starting point for the deconstruction of pedagogical histories and norms of practice enshrined in the languages by which classroom phenomena are described, studied and theorized in different countries. The documentation of these lexicons has significant practical value to each participating community and to the international community of mathematics education practitioners and teacher educators. The focus of this paper, however, has been on the implications of such lexicons for the legitimacy of international comparative research and on the use of any named construct as a boundary object for the purposes of comparative research analyses. It is intended that the lexicons serve as tools to interrogate, enhance and advance comparative classroom research internationally.

# A comparison of Kosovar and Polish pre-service teachers' knowledge of fractions

Jeta Kingji-Kastrati<sup>1</sup>, Mirosława Sajka<sup>2</sup> and Eda Vula<sup>3</sup>

<sup>1</sup>University of Ljubljana, Faculty of Education, Slovenia; [jetakin@gmail.com](mailto:jetakin@gmail.com)

<sup>2</sup>Pedagogical University of Cracow, Faculty of Mathematics, Physics and Technical Science, Poland; [msajka@up.krakow.pl](mailto:msajka@up.krakow.pl)

<sup>3</sup>University of Pristina, Faculty of Education, Kosovo; [eda.vula@uni-pr.edu](mailto:eda.vula@uni-pr.edu)

*The aim of this study was to examine Kosovar and Polish pre-service teachers' knowledge of fractions. Thirty-three Kosovar and thirty-five Polish pre-service teachers participated in the study. They were asked to complete a fractions knowledge test, which was adapted from Cramer, Post, and del Mas's (2002) study. The results identified substantial differences between Kosovar and Polish pre-service teachers' knowledge of fractions. The differences between these two groups of preservice teachers' knowledge of fractions appeared to be a consequence of the number of courses related to mathematics, the number of hours of lectures in mathematics during their studies and the structures of the programmes in both universities.*

**Keywords:** Pre-service teachers, fractions, mathematical knowledge.

## Introduction

Fractions present one of the most important and, at the same time, most complex mathematical concepts of the elementary school curriculum (Behr, Post, Harel, & Lesh, 1993; Charalambous & Pitta-Pantazi, 2007) with applications to many other areas of mathematics. Researchers internationally have shown that in the context of primary school education, fractions are one of the most problematic concepts for both pupils and teachers (Cramer, Behr, Post & Lesh, 1997; Carpenter, Corbitt, Kepner, Lindquist, & Reys, 1981). The NCTM (2000) points out that secondary school students should possess an in-depth knowledge of fractions and be able to use them appropriately in the process of problem solving. Misconceptions that students have about fractions, both in terms of fractions (as numbers) and how to operate with fractions, relate particularly to the way fractions are represented and how they are taught (Barmby, Harries, Higgins, & Suggate, 2009). These difficulties begin in elementary school (Empson & Levi, 2011; Moss & Case, 1999), continue through secondary school (Smith, 2002) and high school and very often even at the level of higher education (Orpwood, Schollen, Leek, Marinelli-Henriques, & Assiri, 2011).

There are few doubts that a deep understanding of fractions, both conceptually and procedurally, and the skills to solve word problems with fractions are necessary for mathematics teachers to teach effectively. They should not only experts from the point of view of mathematical content knowledge but they also need to know how to teach this content, considering their position as experts from a pedagogical content knowledge point of view.

However, many studies have shown that teachers also have difficulties in understanding fractions and operations with them (Ball, 1990) and have stressed that teachers' knowledge was not satisfactory (Charalambous & Pitta-Pantazi, 2007; Lin, Becker, Byun, & Ko, 2013). Therefore,

closer attention must be paid to the future teachers, in order to help them improve children's procedural and conceptual knowledge generally and fractions specifically. Such gaps in knowledge directly influence the learning of fractions by students (Charalambous & Hill, 2012; Hill, Rowan, & Ball, 2005). When working with fractions they encounter difficulties with respect to both teaching and explaining them, which poses a constant challenge for the teaching community of mathematical education. Therefore, it is important to pay closer attention to the subject matter knowledge of pre-service teachers (Wilson, 2010), as well as pre-service teachers training concerning the issue. In this study, therefore, we focus on Kosovar and Polish pre-service teachers' knowledge of fractions. We tested their conceptual and procedural knowledge of fractions, and their ability to explain their solution strategies to a variety of tasks, both standard and word problem.

## **Theoretical background of the study**

The concept of fractions has been examined and discussed by many authors. Many of them have identified and discussed different ways of presenting the fractions (Behr et al., 1993; Kieren, 1976). Different theoretical models have been proposed for understanding of fractions (Behr et al., 1993; Charalambous & Pitta-Pantazi, 2007). Kieren (1976) was the first to propose that fractions should not appear only as a single concept model, recommending that they should be conceptualized as a set of interrelated sub-constructs: part-whole, ratio, operator, quotient, and measure. The presentation of fractions as part of a whole refers to division of an amount or a group of discrete objects into equal parts and comparing these pieces with the total value of quantity (Vula et al., 2015). The ratio sub-construct represents the interconnection between two quantities and usually appears as  $a:b$  or  $a/b$ . This way of presenting the fractions expresses a relationship between the two quantities. The operator is a function that transforms segments, figures or numbers (Behr et al., 1993). Fractions as a quotient appear as a result of division of two integers and measure construct identifies fractions as numbers or associating fractions with the measure assigned to some interval (Kieren, 1976). To be able to teach fractions successfully, teachers require a comprehensive understanding of these different conceptualizations, the interconnection between them and a battery of teaching approaches (Behr et al., 1993).

## **Purpose and research questions**

The main purpose of the research was to compare Kosovar and Polish pre-service elementary teacher's knowledge of fractions. In so doing the study aimed to (a) assess and compare pre-service teacher's knowledge of the different fractions' concepts and their didactical representations and (b) analyze the ways in which pre-service teachers from both countries explain their rationale for a procedure.

1. What are the main differences between Kosovar and Polish pre-service teacher's knowledge of fractions?
2. Are there differences in strategies used by Kosovar and Polish pre-service teachers?

## Method

### Participants

The data were collected from 68 pre-service elementary teachers from the University of Pristina in Kosovo (N=33) and the Pedagogical University of Cracow in Poland (N=35). In Kosovo, elementary school teachers for grades 1-5 are generalist teachers. Consequently, all pre-service elementary teachers are trained in all school subjects, including mathematics. The elementary Bachelor's degree program is a 4-year qualification. Three courses of elementary mathematics are taught in the first and second year of study (in total 514 hours) and the course on teaching mathematics (in total 178 hour) is taught in the last year of the study program.

Teachers in Poland are generalist only for grades 1-3 of elementary school, and to teach for the next three grades they must specialize in a chosen subject. In order to teach mathematics from grades 4 through 6 they should achieve Bachelor's degree in mathematics with a teaching specialization (3 years). They attend many theoretical courses in pure mathematics (in total 1239 hours) as well as courses designed for the teaching specialization (in total 893 hours) and others. Although, there is no subject like elementary mathematics, its main themes are discussed and practiced within the course named Didactics of Mathematics.

### Procedure

Participants were asked to complete the fractions' knowledge test, developed and administrated to measure their performance of fractions' knowledge. The items of the test were used in previous studies (Cramer et. al. 2002; Charalambous and Pitta-Pantazi 2007; Lin, et al. 2013). The test was divided in three subsets of tasks and time for its completion was not limited.

### Methodology

The first subset of tasks, drawing on Kieren's (1976) model, includes fraction-related problems focused on pre-service teachers understanding of fractions as parts of a part-whole (tasks 1-2), ratio (task 3), quotient (task 4), operator (task 5) and measure (tasks 6-7). The second subset addresses how pre-service teachers explain the process of solving fractions problems. The third subset focused on fractions-related word problems and analyzed according to Vula's (2006) model.

## Results

First research question: What are the main differences between Kosovar and Polish pre-service teacher's knowledge of fractions?

Figure 1 shows the success rates, as percentages, of the two groups of pre-service teachers on each of task, with the Kosovar results being shown in the left-hand column and the Polish results in the right-hand column for each task. It can be seen, for example, that 100% of the Polish participants solved task 5 correctly (all with justification), while only 60.61% of the Kosovo participants solved this task correctly (although only 14 gave the justification). We also found notable differences on tasks 11, 13, 14. More than 60% of the Kosovar pre-service teachers failed to solve task 11, while 66% of the Polish participants solved it correctly. Similar differences were identified on tasks 13 and 14. In particular, the most significant differences were found with respect to tasks 7 (measure)

and 15 (solving word problem with 3 steps). While more than half of all Polish students solved them correctly, 65.70% and 54.30% respectively, not one Kosovar students solved either.

**Figure 1: General success rate results**

Second research question: Are there differences in strategies used by Kosovar and Polish pre-service teachers?

The figures of Table 1 show the number of participants who answered the different tasks correctly with justification, without justification or incorrectly.

Kind of answer (Kosovo; Poland)	Whole-part (Task 1)	Whole-part discrete (Task 2)	Ratio (Task 3)	Quotient (Task 4)	Operator (Task 5)	Measure (Task 6)	Measure (Task 7)
Correct with justification	(15; 28)	(26;30)	(23; 34)	(31; 34)	(14; 35)	(23; 34)	(0, 23)
Without justification	(10; 3)	(4; 4)	(6; 0)	(0; 0)	(12; 0)	-	(0, 0)
Incorrect	(8; 4)	(3; 1)	(4; 1)	(2; 1)	(7; 0)	(10; 1)	(33, 12)

**Table 1: Number of answers in both groups respectively in pairs (Kosovo, Poland)**

The majority of participants from both countries provided the correct answer to task 1, although 8 students from Kosovo (Figure 2) and 4 from Poland (Figure 3) provided incorrect answers when asked to present a fraction as a part of an ‘irregular’ unit, assuming that the ‘whole’ would be a circle (the examples presented are chosen randomly).

1. Kjo është tërësia.

Me çfarë thyese paraqitet kjo pjesë?

*Kjo është  $\frac{1}{4}$  e tërësisë*

Arsyetoni përgjigjen:

*Tërësia është e ndarë në 4 pjesë të barabarta dhe kemi marrë një pjesë të saj pra ndaloj themi se kemi marrë 1 pjesë nga të katër pjesët në 1 të tërësisë dhe e quajmë  $\frac{1}{4}$  e thyesës.*

This is the unit.

What fraction represents this piece?

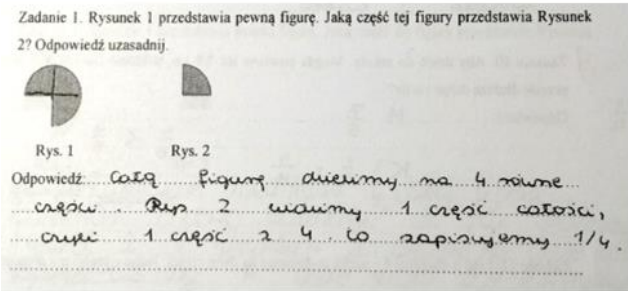

*This is  $\frac{1}{4}$  of the whole.*

Explain how you determined your answer.

*The unit is divide into four equal pieces and we took one piece from it therefore we say that we took one piece from all four pieces that unit has and we present it as  $\frac{1}{4}$  of the whole.*

**Figure 2: Task 1 sample answer, Kosovo**

Zadanie 1. Rysunek 1 przedstawia pewną figurę. Jaką część tej figury przedstawia Rysunek 2? Odpowiedź uzasadnij.

Explain how you determined your answer.

We divide a whole figure into 4 equal pieces. In Fig. 2 we can see one piece of the whole, so 1 piece out of 4. We write this as  $\frac{1}{4}$ .

Figure 3: Task 1 sample answer, Poland

For solving task 4 (quotient), different strategies were used by Kosovar and Polish pre-service teachers. Almost all Kosovar participants who completed the task correctly, converted fractions to decimal numbers or used “butterfly method” (cross multiplication) and explained which fraction is bigger. The Figure 4 provides an example how 1 student used two strategies for solving the task. In the first part it is shown the cross multiplication strategy and then explained why the second fraction is bigger. The second strategy used by this student is by converting fractions to decimal numbers.

4. Cila prej këtyre dy thyesave është më e madhe? Pse?

$\frac{6}{14}$  dhe  $\frac{5}{9}$

$6 \cdot 9 = 54$  dhe  $5 \cdot 14 = 70$

$6 : 14 = 0.42$  dhe  $5 : 9 = 0.55$

Thyesa e dytë është më e madhe sepse kur shumëzojmë numërat e thyesës përkatëse me emuesin e thyesës tjetër fitojmë numër më të madhë numër 70 që është më i madhë se numër 54 që përfaqëson thyesën e parë.

Which fraction is larger? Why?

$\frac{6}{14}$  and  $\frac{5}{9}$

We also have different ways of comparing i.e.  $6 : 14 = 0.42$   
 $5 : 9 = 0.55$

Second fraction is larger because when we multiply the numerators of the fractions with denominators we get 70 that is larger than 54 that represent the first fraction.

Figure 4: Task 4 sample answer, Kosovo

The majority of Polish participants, 27 people, found a correct solution using the strategy of transferring given fractions into a common counter (3 people, common counter: 30) or common denominator (24 people), which was 126 (12 people) or 63 (11 people) and one person only described the method (without calculation). The second strategy used by 6 people was comparing the given fractions to  $\frac{1}{2}$  and noticing that the first is smaller and the second bigger than  $\frac{1}{2}$ . Only two people used the method of solving the task by converting fractions to decimal numbers, and one of them only described the method but did not apply this (getting 0 points for that task).

Strategies in group	Common denominator	Estimation (decimals)	Estimation (comparing to $\frac{1}{2}$ )
Kosovo	2	24	0
Poland	33	3	1

Table 2: Distribution between strategies used

For solving task 5 three strategies were used from participants: strategy of common denominator, estimation strategy in the form of decimals and strategy of the comparison to half. Two participants from Kosovo and the great majority of 33 participants from Poland solved the task using a common

denominator strategy, while 24 participants from Kosovo and 3 participants from Poland used an estimation strategy in the form of decimals. Table 2 shows the distribution of the strategies used by both groups. Two Polish participants used two strategies, providing apart from common denominator the estimation strategy - one in decimal form and the other comparing to  $\frac{1}{2}$ .

While in Poland only 2 students did not answer task 7, all of Kosovo students failed to solve given task (Figure 5). 23 Polish students calculated the distance between adjacent points marked on the number line (Figure 6).

Figure 5: Task 7 sample answer, Kosovo

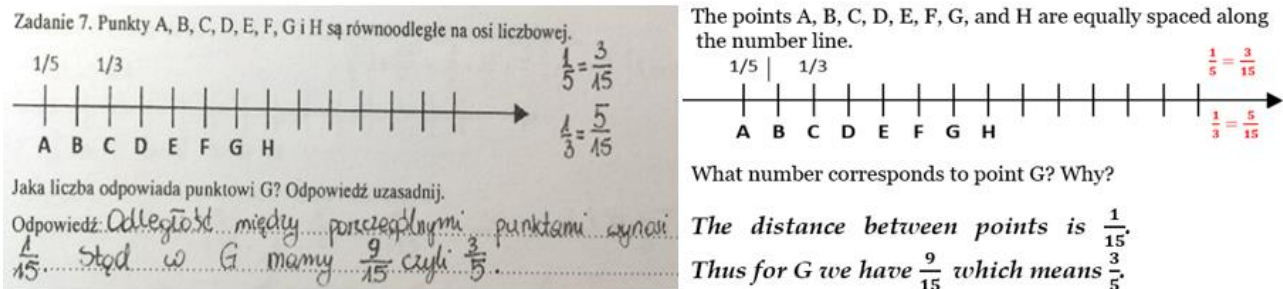

Figure 6: Task 7 sample answer, Poland

## Discussion

The purpose of this study was to (a) assess and compare Kosovar and Polish pre-service teacher's knowledge of fractions and their representations and (b) analyze how they explain the process of solving fractions. To answer these questions, we analyzed test tasks completed by pre-service teachers from the two countries. In so doing, we identified substantial differences between Kosovar and Polish pre-service teachers' knowledge of fractions, with Polish students being more procedurally successful on every task and typically able to offer better explanations. These differences were found across all fraction conceptualizations as discussed by Kieren (1976).

There may to be several reasons for these differences. For example, the number of hours that students receive in mathematics courses and teaching methods in mathematics are much higher in Poland than in Kosovo. Also, because pre-service teachers in Kosovo are being trained to be generalist teachers from grade 1 to 5, they may not receive sufficient hours dedicated to mathematics and didactics in order to fulfill their needs for mathematics knowledge of pre-service teachers (Wilson, 2010). In addition, differences in the curricula and the ways in which fractions are represented in elementary mathematics textbooks (Vula et al., 2015), both sources on which pre-service teachers draw during teaching practice, and their own previous learning as school students

may also explain why Kosovar students performed less satisfactorily than their Polish colleagues. Therefore, the findings of this study should act as a springboard for further research into and discussion of how elementary teachers are prepared for their professional responsibilities. In this respect we argue that it is important for the instructors of pre-service teachers' mathematics courses to provide adequate opportunities for their students to develop a knowledge of fractions that better prepares them for their future roles as teachers of children.

In light of the above, our future aims are to investigate further not only Kosovar and Polish pre-service teachers' knowledge of fractions but also those of pre-service elementary teachers in other European countries.

# **Finnish teaching materials in the hands of a Swedish teacher:**

## **The telling case of Cecilia**

Tuula Koljonen

Mälardalen University, Sweden; [tuula.koljonen@mdh.se](mailto:tuula.koljonen@mdh.se).

*A common perception in Sweden is that the best teachers do not rely on ready-made teaching materials. The position taken in this paper, building on socio-cultural theory, assumes that teacher materials can support teachers. Although there is an emerging body of research focusing on teachers' use of teaching materials, cross-cultural studies on this are scarce. The current study addresses this gap by offering unique insight into how a Swedish teacher makes use of teaching materials originally from Finland but slightly adapted to the Swedish context. Based on teacher interviews and classroom observations, I studied how the teacher planned for and enacted lessons. Findings indicate that she fits the material to her pre-existing practice and, thus, does not follow the material's original intentions. The results are compared with previous results on materials and their use, and finally some implications for Swedish mathematics education are presented.*

*Keywords: Cultural scripts, educational context, primary school, teaching materials, telling case.*

### **Introduction**

Finland is known as a country with good learning outcomes in mathematics (e.g. OECD, 2013). Furthermore, since the 1980s the country has had a tradition of producing exhaustive teacher guides (TGs) in collaboration with teachers, teacher educators and other experts (Niemi, 2012). These two factors have likely increased the interest in applying commercially produced Finnish teaching materials, such as textbooks and TGs, in Sweden as well as other countries, such as Italy. Applying new teaching material from Finland in Sweden could be achievable, as there are many similarities between the school systems in the two countries – for instance, the inclusive nine-year compulsory basic education with no special tracking, and the national core curriculum that provides an overall outline for school education. In addition, primary school teachers in both countries often teach all subjects, and are free to choose which teaching materials to use. There are also differences between the countries' educational systems; e.g., Swedish teachers at primary school level are seldom subject specialists while Finnish teachers are well educated, but also the widespread negative talk in Sweden concerning the use of ready-made teaching materials (Bergqvist et al., 2010), which does not occur in Finland. Swedish teachers' orientation toward ready-made teaching materials most certainly affects how they engage with and use them (cf. Stein, Remillard & Smith, 2007).

Swedish teachers seldom use TGs in planning and enacting mathematical instruction (Jablonka & Johansson, 2010). Instead, they rely mostly on the student textbook as their main source, a common feature of teachers in many parts of the world (Remillard, 2005; Stein et al., 2007). Also, Swedish compulsory school teachers have for the last two decades often organized individualized teaching, whereby students work individually in different areas and at their own pace (Bergqvist et al., 2010; Remillard, Van Steenbrugge & Bergqvist, 2016). The fact that students are taught largely according to the structure of their textbook has also resulted in less variation in teaching (Jablonka & Johansson, 2010). However, Finnish teachers, especially primary school teachers in mathematics, trust and use

commercially produced TGs extensively, and there are indications that Finnish teachers often organize whole-class teaching and use teaching methods other than individual seatwork. This has consequently led to a classroom practice that is different from the Swedish one (Jablonka & Johansson, 2010; Pehkonen, Ahtee & Lavonen, 2007). While there is growing interest in adopting and implementing mathematics materials in a new educational context, we know little about how imported mathematics materials are used or how they may influence classroom practice.

Therefore, in this paper I aim to investigate the interplay between a Swedish teacher and the written curriculum as represented in the suggested lesson plans in a TG – *Favorit Matematik (FM)*, originally from Finland. Moreover, I intend to show how this interplay may impact on enacted teaching. Teaching is viewed as a cultural activity, and cultural activities are represented in cultural scripts (cf. Stigler & Hiebert, 1999) and are consistent with the stable web of beliefs and assumptions within a cultural group. Scripts provide a background for interpreting behaviors; however, they do not describe, determine or predict the behavior of individual teachers (Stigler & Hiebert, 1999). Both teacher and teaching materials are significant participants and are situated in a socio-cultural context, a specific educational context. Through this, they both play a role in mediating that interplay, which is shaped by historical, social and cultural factors (Brown, 2009; Remillard, 2005). Since cultural scripts are deeply rooted in practices and are hard to see from within a given culture, I opted for a case study approach, allowing for a deep analysis. I therefore anticipate that a study on the use of teaching material from one culture by a teacher from another culture will advance our understanding of the cultural scripts in both cultures, and of the participatory relationship between teacher and teaching material.

I have previously analyzed TGs from four Finnish textbook series in mathematics, and found that their structure, form and content were relatively homogeneous (Koljonen, 2014). In Koljonen, Ryve and Hemmi (under review), we captured what kind of mathematics classroom the Finnish guides promote. Recurrent cultural scripts of the classroom practices were found, comprising: keeping the class around a specific topic; keeping the teachers and students active; clear lesson goals are vital features; different recurrent activities; concrete material; and embedded differentiation. Due to these findings and the different classroom practices in Sweden and Finland, it is of interest to investigate a Swedish teacher's interplay with Finnish teaching material as a way to compare the written and the enacted curricula grounded in two different cultural platforms. The research questions guiding this study are: 1) *How does a Swedish primary school teacher, locally regarded as competent, interact with a Finnish teacher guide while planning and implementing teaching?* 2) *How does this interaction influence the classroom practice?*

## Methodology

This study is part of a larger cross-cultural project examining the interplay between Swedish and Finnish teachers using the same mathematics teaching materials. The data for this project are comprised of semi-structured interviews with four primary mathematics teachers from each country. The interview questions cover seven themes: teacher's education; teacher's experience; school settings; classroom culture; beliefs about mathematics and its teaching; TGs; and planning of lessons. Additionally, three consecutive mathematics lessons per teacher were videotaped. When videotaping during the lessons, I used two cameras: one teacher camera that captured the teacher's actions and talk, and one whole-class camera focused on the students' actions and talk. I conducted and

transcribed the audio-recorded interviews (50-110 minutes) and the videotaped lessons (40-60 minutes). *FM* (Asikainen, Nyrhinen, Rokka & Vehmas, 2015) includes references to the Swedish national core curriculum (Lgr 11), but does not describe how the lesson goals actually serve to prepare students to meet the curriculum goals. Earlier studies (Koljonen, 2014) revealed that *FM* lacks educative support (cf. Brown, 2009) for teachers as well. For example, the rationales behind its suggested lesson activities are rarely explicitly discussed, which is a critical component in teacher learning. Each lesson (4 pages) in *FM* has a similar structure, both visually and content-related; for instance, clear recurrent headings located in the same place on every page, and a variety of optional activities presented for each lesson. The activities are all linked to the central content and the lesson objectives, from which the teacher is to choose appropriate activities for their practice.

As a starting point in the larger cross-cultural project, I selected one of the Swedish teachers, Cecilia (fictitious name), to exemplify a single case as this approach offers possibilities for deeper theoretical insights that would otherwise go unseen (Andrews, In press). Cecilia graduated in 2010 as a compulsory school teacher (F-6), and was prepared to teach all other subjects besides mathematics as well. Thus, she is not a mathematical subject specialist. However, one of the criteria for selecting the teachers was that they were regarded as locally competent (cf. Clarke, 2006). Among the other teachers, Cecilia is recognized and esteemed for her locally defined ‘teaching competence’ and has been nominated by the school’s principal and the municipality and is thus regarded as a local subject specialist. At the time this study was conducted, Cecilia was in her third year of teaching with *FM*. She teaches children in Grade 3; her 24 students come from a constrained socio-economic area, with mostly non-native speaking families. Cecilia volunteered to participate, knowing the study was on *FM* and its use.

### **Data analysis**

Teaching is viewed as a cultural activity (Stigler & Hiebert, 1999) and a design activity, whereby teachers craft instruction, and do so with different degrees of artifact appropriation: offloading, adapting and improvising (Brown, 2009). Cecilia’s interaction with TGs is characterized through these three analytical constructs. *Offloading* emerges when a teacher follows material and assigns a great degree of authority to the teaching material. That is, the agency for the delivery of content lies in the material. *Adapting*, on the other hand, occurs when a teacher reflects when elaborating with the material. Here the agency is embedded in both the material and the teacher. *Improvising*, finally, relates to when a teacher does not closely follow the material. That is, the agency lies with the teacher as she relies on her own strategies for instruction, with minimal reliance on the material. The relationship is further characterized as participatory or non-participatory (cf. Remillard, 2005). When the teacher regularly and deliberately uses the material, and also looks at it critically, this provides an intimacy between teacher and material and is thus categorized as a *participatory relationship*. Meanwhile, if the teacher’s use of the material is more tacit and sporadic, it will lack intimacy and is thus categorized as a *non-participatory relationship*. My intention is to characterize Cecilia’s interaction with the material in use (*FM*) and to compare the written curriculum in *FM* and Cecilia’s enacted curriculum. I do not intend to evaluate which degree of interaction (offloading, adapting or improvising) or the relationship (participatory or not) is better than the other. However, I acknowledge that comparison and evaluation are intertwined (cf. Jablonka, 2015). Below, I present

Cecilia as the telling case through some merged snapshots of from both interview and classroom recordings.

## The telling case of Cecilia

During her interview Cecilia said that it is a waste of time making a written plan, because “if a lot of the students don’t understand today’s lesson, we would have to repeat it tomorrow and then my intended plan would crash if I’d written it down” (Cecilia, 9 Nov 2015). On the one hand, such comments indicate that Cecilia, as a locally competent teacher, trusts her ability to deliver the mathematical content with appropriate strategies for instruction. On the other hand, it can also be due to a lack of time that she does not write her plans, as she stressed that the ongoing national professional development program, Matematiklyftet, takes time away from all the things she has to do. Cecilia stated that she starts her planning for the introduction phase not by using the TG but the student textbook:

I turn to the current page in the textbook and see that the next passage is about multiplication by 9. Immediately, I have an idea about which strategies I want the students to know, and notice that the book is using the same strategy as me... but I prefer to create my own [instructions] using my own language. (Cecilia, 9 Nov 2015)

Cecilia’s prospective mental plan is partially consistent with the textbook’s plan. However, here the agency stays with Cecilia, since she claims to have her own mental plan. Her use of and interaction with the textbook could be understood through the Swedish teachers’ context, in which they are not accustomed to using TGs in planning and teaching. In addition, the minimal support provided for how TGs may be used may compel Swedish teachers to turn to the textbooks instead. This and several other similar excerpts led me to infer that Cecilia is influenced by Swedish culture, as she states that she “prefers to create her own instructions”, reflecting a generally held perception of Swedish teacher competence. During the interview, Cecilia mentioned, due to lack of time, that she occasionally glances at the TG to get a skeleton plan for the lesson. She then looks at its “introduction box”, which suggests how to introduce the lesson’s topic on the board. Hence, from the interview I infer that she perceives the material as worth having in the classroom but not necessary for planning. I infer that she improvises when planning, and that the agency lies with her. I further infer that she has a more tacit than close relationship with the material, especially since she seldom uses the TG and hardly ever reflects on the material or its impact on the context.

The video data reveal that, while mobilizing the teaching, Cecilia sequenced her lessons into four distinct episodes. The allocated lesson time of her lessons consists of: the introduction phase, taking approximately 22% (~10 min) of the lesson time; what to work on in the student textbook; the students’ individual seatwork, taking approximately 56% (~25 min) of the lesson time; and the closure of the lesson. Cecilia always starts her lessons by showing a strategy or method in the introduction phase that is applicable to that day’s pages in the student textbook, and by referring to textbook: “Hey, listen! Last Thursday we went over page 90 in the textbook, as we used these hands [pointing to the cut-out hands in fabric on the blackboard] as one strategy for multiplying by 9. Today we’ll revise it” (Cecilia’s L1, 9 Nov 2015). Here, Cecilia is simultaneously showing the textbook pages they have been working with. This revision is not included in the TG’s suggested lesson plan, and no elaboration or reflection is revealed. But this could also be due to the evaluation at the last

lesson closure. Hence, I infer that Cecilia is improvising. Nevertheless, the video data frequently show that the delivery of the content is based on the material, as she offloads the agency to the textbook as she follows the textbook pages, lesson by lesson. Cecilia is very firm during the interview that the cut-out fingers she refers to are not from the TG but were instead an idea that simply came to her. During Lesson 1, she first shows two examples of the old strategy before introducing a new strategy for multiplying by 9: “Hey guys, listen! At the top of page 91, it says ‘Multiply and write in the table’... This is a different strategy... So, let’s try this too! Ehh, *they want us to think like this...* Can you give me a multiplication from the 9 table, Ali?” (Cecilia’s L1, 9 Nov 2015). This extract illustrates Cecilia turning to a rather close offloading to the student textbook – especially when she says *they want us to think like this*. The textbook lacks a description of how to deal with this task, and the fact that Cecilia does not explain to the students how “to think” indicates that she has not elaborated on this task beforehand. I infer that she shows this task since it is included on that day’s lesson pages in order to prepare the students for their individual seatwork. However, the TG offers some explanation, and recommends that they fill in this table together in the whole-class setting, which Cecilia has missed since she does not read the TG carefully or regularly. This displays that her relationship with the TG is rather tacit. The video data further reveal that after the introduction Cecilia always tells the students which pages to work with during the individual seatwork. She does this through the material’s website and the SmartBoard, where she shows the students the pages. She also writes the pages on the whiteboard. This procedure is not stated in the material, which confirms that Cecilia is improvising and maintaining the agency. The following is an example of how she transitions the students into their individual textbook work: “I think most of you managed to do both pages 90 and 91, and possibly also 92 or 93. On page 94 it says ‘We rehearse’, and these two pages are the goal of today’s lesson” (Cecilia’s L1, 9 Nov 2015). This extract additionally confirms that Cecilia is closely offloading to the textbook, as she assigns a great degree of authority to it. At no time does she present the lesson objectives, which are clearly visible in the TG. Instead, she mentions that the lesson goal is to do pages 94 and 95. Neither does she use the different recurrent activities or concrete materials included in the TG during any of these lessons.

The video data further reveal that, during the individual seatwork, some students are working on other pages than the ones Cecilia had announced before they started working individually, and some are even working in a textbook for Grade 2. This is not in line with the material’s intention, as it offers embedded differentiation instead. As shown in the video data, Cecilia always closes the lessons with a blind evaluation to determine whether she can move on or if rehearsal is necessary.

Now, close your eyes and answer YES to my question by raising your hand. If your answer to my question is NO ... leave your hand on the table [...] ‘I feel confident about the strategy of using my fingers to multiply by 9’ Okay, those of you who have your hands up can put them down. ‘I still think it feels a little hard to use this strategy, using my fingers to multiply by 9’ Thanks! ... ‘I feel pleased with what I did during the mathematics lesson today’ Great! (Cecilia’s L1, 9 Nov 2015)

This extract confirms that Cecilia does not just say she wants all her students to be *on track* but that she also checks this before ending the lesson. In so doing, she is checking their understanding of the “old” strategy for multiplying by 9, but not whether they understand the “new” strategy she has introduced, or the objectives displayed in the guide. Two of the questions are related to the

mathematics, whereas the last is connected to students' individual seatwork. There is no support in the material for how to end the lessons, so Cecilia trusts to experience and improvises the evaluation. Hence, from the video data I deem that she uses the textbook for support for the students' individual seatwork but not for her actions or events when mobilizing the teaching. The video data show that Cecilia improvises, but does not critically reflect on the material or its impact on the educational context, or make any changes in relation to the material. In addition, at several points, the interview and video data show collectively that Cecilia largely offloads the agency to the textbook and uses it on an ad hoc basis. Cecilia's use of the TG is minimal. Thus, this settles her weak interaction with the material; i.e., having a non-participatory relationship with it.

## Discussion and conclusion

In this paper, I present the telling case of Cecilia, a Swedish teacher, locally regarded as competent. The aim is to reveal her interaction with an imported TG from Finland when placed in her specific context. Thus, the material is sited in a new educational context. In the analysis I compare the written Finnish TG with Cecilia's actual classroom practice. The analysis is therefore combined with in-depth descriptions and snapshots of events, and is thus in line with the telling case (cf. Andrews, In press) as an attempt to make visible how she interacts with the Finnish material and how this interaction may have affected her classroom practice.

*First, how does Cecilia interact with the Finnish material?* My analysis revealed that Cecilia uses the student textbook when teaching, and that she offloads agency to the textbook. This interaction is categorized as non-participatory since it lacks intimacy. Her interaction with the TG is even weaker, and more sporadic and tacit than with the textbook, and is thus also non-participatory. When she trusts in her own knowledge and experience, improvising occurs, especially in regard to the repetition at the beginning of the introduction phase and the closure of the lesson with the blind evaluation. No adaptation was observed, since no equally embedded agency was found. Cecilia says she creates her lesson plans mentally. However, her focus is not on the entire lesson, since she only prepares the introduction phase. Even though she has chosen *FM* due to her judgment of its overall good quality, she does not seek support for teacher learning or to enhance the variety in her lessons through its recurrent activities. *Second, is Cecilia's classroom practice affected by her interaction with the Finnish material?* My analysis revealed that Cecilia's enacted classroom practice mirrors the "typical Swedish" practice, with short introductions and then individual seatwork most of the time (cf., e.g., Remillard et al., 2016). Cecilia does not keep the students together around a specific mathematical topic by using the embedded differentiation, and no concrete materials are used during these three lessons. No objectives are stated, either. These are all important parts of the cultural scripts found in Finnish TGs (Koljonen et al., under review). Thus, Cecilia's classroom practice is in contrast to those promoted by the Finnish TG. I deem that Cecilia's practice is marginally affected by her relationship with the material. This may be because it does not offer enough support for how to use it, or explain its intentions, therefore forcing Cecilia to follow the common norms of Swedish classroom practice; as well as the fact that it is challenging for teachers to change their teaching (Stein et al., 2007; Stigler & Hiebert, 1999). Further studies are needed to capture the essence of the Swedish classroom practice when using imported material.

My conclusion is that the use of the originally Finnish material has not had the intended impact on the practices as promoted by the guides. Instead, Cecilia uses and confirms her preexisting culture

rather than the intended one as in the Finnish TG (cf. Davis, Janssen & Van Driel, 2016; Stein et al., 2007; Stigler & Hiebert, 1999). One possible implication of this is that it may be hard to implement material from other educational contexts, even if it is quite similar and is assumed to change or even improve the quality of teaching. Yet without targeted support for how to use new material it is hard, even if a teacher is regarded as competent, to independently conduct changed or improved teaching and simultaneously maintain or gain pedagogical autonomy. This is especially important since the Finnish material lacks educative support and, thus, is not regarded as educative material (Hemmi, Krzywacki & Koljonen, 2017; Koljonen, 2014). I argue that this requires that teacher materials be included in professional development programs, as previously argued for by Ball and Cohen (1996), in order to proficiently convey and highlight the principles of the materials and adjust them to the new context that is underpinned by the social and cultural practice. It remains to be seen whether subsequent case studies of the other teachers in the larger project reveal whether the above-mentioned tentative conclusions hold for the larger data set.

# Algorithmics in secondary school: A comparative study between Ukraine And France

Simon Modeste<sup>1</sup> and Maryna Rafalska<sup>2</sup>

<sup>1</sup>Université de Montpellier, IMAG – UMR CNRS 5149; [simon.modeste@umontpellier.fr](mailto:simon.modeste@umontpellier.fr)

<sup>2</sup>National Pedagogical Dragomanov University; [m.v.rafalska@npu.edu.ua](mailto:m.v.rafalska@npu.edu.ua)

*This article is focused on the teaching and learning of Algorithmics, a discipline at the intersection of Informatics and Mathematics. We focus on the didactic transposition of Algorithmics in secondary school in France and Ukraine. Based on epistemological and didactical frameworks, we identify the general characteristics of the approaches in the two countries, taking into account the organization of the content and the national contexts (in the course of Mathematics in France and in the course of Informatics in Ukraine). Our results give perspectives on understanding the place that Algorithmics can hold in the teaching and learning of Mathematics and Informatics.*

*Keywords: Algorithm, algorithmics, didactic transposition, curricula comparison, France, Ukraine.*

## Introduction

Mathematics and Informatics<sup>1</sup>, as disciplines, have strong links. On one hand, Mathematics gives theoretical basis and instruments to Informatics, and on the other hand, Informatics enriches Mathematics with new objects and problems, and brought some changes in the mathematical activity. Many disciplines (Discrete Mathematics, Algorithmics, etc.) developed at their interface. Nowadays, there is an international movement towards including Informatics and these subjects in secondary education. Algorithmics is more and more present in secondary school in many countries. It can be involved in programs of Mathematics (as in France) or Informatics (as in Ukraine). This situation questions the goals of teaching and learning Algorithmics in secondary school, the contents of the curricula as well as the approaches and activities proposed to pupils. To contribute to the study of these issues, we propose a comparative study regarding the concept of algorithm and the contents of Algorithmics in secondary school in France and Ukraine.

Algorithm is a central notion in Mathematics and Informatics. Algorithm in “classic” Mathematics is generally used with the meaning of a general effective procedure for solving problems. Since the origins of Mathematics, algorithms have been designed and used for solving problems (arithmetic operations with decimal numbers, solving equations, etc.). The use of computers and programming languages brought a new point of view on the notion of *algorithm* referring to the formalization of procedures, the automation of computations and the problem of data treatment. In this context, the notions of finiteness, iteration and recurrence play an important role (Chabert, 1999, pp. 6–7).

As a reference, we retained the following definition of an algorithm given by Modeste (2012, p. 25) and based on the academic literature on the subject: “a procedure for solving a problem which, in a finite number of constructive, effective, not ambiguous steps, gives a result for any instance of the

---

<sup>1</sup> We will use the term “Informatics”, a more faithful translation from the French and Ukrainian than Computer Science.

problem". We will delimit the discipline Algorithmics as the field that deals with algorithms, the problems they can solve, their design, their use, their analysis and their comparison.

### Research questions, theoretical framework and methodology

To formalize our problematic, we have formulated the following research questions:

- What is the place of Algorithmics in secondary school in France and Ukraine?
- In what way the learning contents related to Algorithmics are organized?
- What types of activities in Algorithmics are proposed to pupils in both countries?
- What common points and differences appear? How can they be interpreted?

Our study is based on the concept of didactic transposition (Chevallard, 1985) developed in the Anthropological Theory of the Didactic (Bosch & Gascón, 2014). The didactic transposition describes the processes of transformation between academic knowledge, the knowledge to be taught and the taught knowledge. It takes a step back from the curriculum and the content actually taught, to understand the role and the influence of the different institutions involved in these processes.

In order to analyse the content devoted to Algorithmics in the curricula, to measure their distance to the academic knowledge, and to develop our comparative study, we lean on an epistemological framework, in accordance with a classical methodology in Didactics of Sciences and Mathematics (Artigue, 1990). Concerning the concept of algorithm and Algorithmics we used the epistemological framework developed by Modeste (2012; Modeste & Ouvrier-Buffet, 2011). The epistemological model distinguishes five fundamental aspects of the concept of algorithm: **problem** aspect (the fact that an algorithm is a tool to solve all instances of a problem, the notions of input and output); **effectiveness** aspect (all elements referring to the fact that an algorithm solves problems effectively: the notion of operator; the finiteness of instructions and executions, etc.); **complexity** aspect (all elements referring to the notion of complexity of algorithms and problems); **proof** aspect (referring to the links between algorithm and proof); **theoretical models** aspect (referring to the theoretical works in Logic and Informatics concerning the concept of algorithm). Among these aspects, *problem* and *effectiveness* refer to algorithm as a tool, whereas *proof*, *complexity* and *theoretical models* refer to algorithm as an object. This tool-object dialectic of the concept of algorithm will be useful to understand the points of view in different institutions.

In this study, we analysed the official instructions, the official resources for teachers and particular textbooks (we focused on the knowledge to be taught, but our analysis of textbooks also informs about the taught knowledge). For this purpose (addressing the didactic transposition in a given institution), it is not sufficient to study the discourse about algorithms: it is essential to examine the algorithms selected by the institution, their representations and the activities involving these algorithms: this can reveal differences (and even contradictions) with the general discourse. To do this, for each resource, we answered to the following questions:

- What kind of definition of algorithm is proposed?
- What algorithms (or types of algorithms) have been selected?
- What representations of algorithm are used?
- What tasks (or types of tasks) in Algorithmics are proposed?

Answering these questions brings elements that permit to address our principal question:

- What aspects of algorithm are presented (according to the five fundamental aspects)? Do this aspect relate to algorithm as a tool or as an object?

Our corpus of resources is described in Table 1. In the following, we present the results of our analyses and the answers to the research questions. As we cannot provide all details in this paper, we present only the main results of the comparison. Before that, it is necessary to give an overview of the situation in France and Ukraine, regarding the teaching of Algorithmics.

Resources	France	Ukraine
Official instructions and documents	Official program of Mathematics for middle school; Official curricula of Mathematics for high school: grade 10, grades 11 and 12 (all paths); Official accompanying resources in Algorithmics for grade 10; Official program for the ISN option.	Official program of Informatics for middle school (5-9 grades); Official programs of Informatics for high school (grades 10 and 11): standard, academic, professional and advanced levels.
Textbooks	Three collections of Mathematics textbooks (Indice, Bordas ; Math'x, Didier ; Transmath, Nathan) for grades 10, 11 and 12 (scientific, economic and humanities paths) ; Textbooks for middle school are not available yet.	One collection of textbooks in Informatics (Ryvkind J.Ya. et al., 2011) for grade 11, standard and academic levels, part 'Algorithmics'; two collections of textbooks in Informatics (Morze N.V. et al., 2014, 2015, Ryvkind J.Ya. et al., 2014, 2015) for grades 6 and 7, part 'Algorithmics'.

**Table 1: Analysed resources.**

## **Presentation of the contexts and evolutions of curricula in Ukraine and France**

### **Situation in Ukraine (organization, history and recent evolutions)**

The Ukrainian school system consists of primary school (grades 1-4, age of pupils – 6-9 years), middle school (grades 5-9, 10-15 years) and high school (grades 10-11, 16-17 years). In high school pupils make a choice between general or professional-oriented paths. Informatics has been taught since 1985 in secondary school in USSR. From the beginning, Algorithmics was a part of it. At that time, the course was mainly dedicated to writing algorithms in pseudo-code and executing them manually. Only two programming languages were used: Rapira (especially elaborated in USSR for teaching) and Basic. The major part of the first manual of Informatics in USSR is devoted to solving algorithmic problems. An algorithm is defined as “a clear and precise instruction destined to an operator to carry out a sequence of actions in order to reach a goal or solve a problem”. In this manual, the notion of *operator* plays a central role. It is also underlined that an operator executes an algorithm formally, i.e. it can carry out operations one by one in defined order without understanding the goal. A *scheme for solving a problem with a computer* is presented: in brief, it consists of modelling the problem, constructing an algorithm, writing it in a programming language, executing it, and analysing the results. Many tasks require constructing algorithms for solving mathematical and physical problems with a computer, such as Horner's method or the approximation of the area under the graph of a positive function.

Since 1985, Informatics has always been a mandatory subject in high school. In the programs published in 2008, Informatics can be taught at the following levels: standard (for general and humanitarian paths), academic (for science path), professional and advanced (for informatics and mathematics paths). The difference is the number of hours of Informatics per week (between 1 and

5) and the contents. As a part of the subject, Algorithmics is studied at every level with a total amount of hours that varies a lot: Standard (5), Academic (28), Professional (175), Advanced (191). In 2013, Informatics also became a mandatory subject in primary (from grade 2) and middle school. Thus, at the moment, Algorithmics is also present in middle school (from grade 6).

### **Situation in France (organization, history and recent evolutions)**

The secondary French school system consists of middle school (*collège*, grades 6-9, 11-15 years) and high school (*lycée*, grades 10-12, 16-18 years). In high school, professional, technical and general orientations are proposed, and the general orientation is divided into humanities, economic and scientific paths<sup>2</sup>. In this study, we will concentrate on the general orientation. Recently, many reforms happened in the French curricula, the last one was in 2016 and concerned middle school. Gueudet, Bueno-Ravel, Modeste and Trouche (to appear) give more details about the evolution of French mathematics curricula, including Algorithmics. Informatics appeared for the first time in the French curricula in the 1980's (Baron & Bruillard, 2011), with an introduction to Programming and Algorithmics in high school. It disappeared in the 1990's, replaced by the use of computer tools and new technologies. Recently, Informatics came back in secondary school. In 2012, an optional course was created in grade 12 in the scientific path (ISN: "Informatics and digital sciences", 2h/week), and in 2015, an optional course appeared in grade 10 ("Informatics and Digital Creation", 1h30/week). Starting from 2016, Informatics will also be taught in middle school (principally in grades 7-9) in the mathematics and technology classes. Few years before that (from 2009 for grade 10 to 2012 for grade 12), some contents of Algorithmics were introduced in the curricula of Mathematics in high school (Modeste & Ouvrier-Buffet, 2011).

### **Comparison at high school level (grades 10-12, ages 15-18)**

#### **Algorithmics in high school in Ukraine**

Through all grades and levels, a common approach to Algorithmics can be identified. It includes the presentation of *the steps for solving problems using a computer* and the role of algorithms in this process, distinguishing algorithms from programs, with an emphasis on the notion of *operator*. The activities involve various representations of algorithms (common language, flowchart and program). In the analysed textbooks the term *algorithm* is defined as a finite sequence of instructions that determines what operations and in which order to carry out for obtaining a goal. In this definition, as well as in the description of the properties of an algorithm (discreteness, certitude, feasibility, finiteness, effectiveness) given explicitly at all levels, we can identify the aspect *effectiveness*. The *problem* aspect is expressed in the property of "generality" of an algorithm, which says that an algorithm applies to a set of similar problems, which have the same question and solving procedure and differs only by the values of initial data. At the same time, the specific term "instance algorithm" is used in the textbooks to define an algorithm that solves only one case of a problem. Most part of the proposed instance algorithms are: algorithms of daily life (e.g., preparing meal), algorithms from others disciplines (e.g., geometrical constructions), algorithms implementing a

---

<sup>2</sup> For details about French system: <http://eduscol.education.fr/cid66998/eduscol-the-portal-for-education-players.html>

strategy (e.g., the wolf, goat, and cabbage problem). The expected competence is to represent the solution of a problem in an algorithmic way (as a sequence of instructions) rather than to solve it.

At **standard level**, many tasks concern the construction of algorithms for a given operator. The activity is centred on identifying the system of commands of an operator and writing an algorithm using only these commands. Although, most of the problems are quite easy and the goal of the tasks is to find the best strategy and present it in the required form. This concerns principally instance algorithms and refers to the *effectiveness* aspect. Generic algorithms (algorithms with many instances) mostly relate to solving mathematical problems (solving equations, evaluating the area of a polygons.) and computations (evaluation of simple expression). Pupils construct algorithms, describe them in the requested form (principally flowcharts) and execute them manually.

At **academic level**, Algorithmics is based on Delphi, an object-oriented programming language: pupils get accustomed to Algorithmics by learning the instructions of Delphi. 65% of the tasks are about writing programs, executing and modifying them, 19% of tasks are devoted to object-oriented programming. Algorithms are mostly verified by testing the programs. *Generic algorithms* are more present than *instance algorithms*. Most of them concern computations (e.g., evaluation of simple expressions) (33 %) and solving mathematical problems (e.g., solving equations, primality test) (31%). A bit less tasks concern the computation of sequences, products, sums (11%) and data treatment (e.g., sorting, searching in an array) (17 %). The textbook includes many tasks where an algorithm is only used for formulating a procedure before programming it. One can also found tasks where algorithms plays the role of *tool* for problem solving (e.g., finding the divisors of an integer). In this case, the focus is more on the construction of algorithms than on writing and debugging programs. Although we found many generic algorithms, only the *effectiveness* and *problem* aspects are strongly present. The *complexity* aspect is only evoked concerning the binary search algorithm.

At **professional and advanced levels**, an algorithm is presented not only as *tool* but also as an *object*. At **professional** level we found many “rich” algorithms, such as recursive algorithms, algorithms on graphs, algorithms of treatment of stacks and lists, etc. Expected competences for pupils are not only to understand some algorithms and write programs, but also to analyse algorithms’ efficiency and compare them. The *complexity* aspect is also evoked. At **advanced** level the *theoretical models* aspect is present (e.g., NP-complete problems). Expected competences concern the abilities to choose an algorithm appropriate to a problem, to compare algorithms according to their complexity, to analyse and compare algorithms. Algorithm is present as an object.

### Algorithmics in high school in France

**Programs of Mathematics** for high school, for all levels, contain the same Algorithmics part, with a list of expectations for the end of high school: pupils must be able to “describe algorithms in natural and symbolic languages”, to “carry out some of them using a spreadsheet or a small program written in a calculator or a software” and “interpret more complex algorithms”. It is mentioned that “algorithmics has a natural place in all the mathematical subjects”. Pupils must learn elementary instructions, conditional instructions and loops. At each level, few specific algorithms are mandatory, e.g. plotting a curve (grade 10); solving equations of the type  $f(x)=0$ ; simulating random experiments (grade 12, scientific path). Most of the algorithms in the programs deal with sequences, numerical methods and simulations in probability and statistics. Algebra and geometry are just

mentioned as fields for algorithmic activities. Discrete Mathematics have a very little presence. The priority seems to be given to the implementation of algorithms in a programming language.

The **accompanying resource for grade 10** – that seems to have driven the approach to Algorithmics in high school (Modeste, 2012) – does not define the term *algorithm*, and does not even distinguish it from the term *program*. The activities are focused on language and rigorous expression of operations, and often aim at writing programs. It results in a confusion between *program* and *algorithm* that indicates a focus on the *effectiveness* aspect. A specific language to describe algorithms is implicitly developed, mixing pseudo-code and technical programming constraints – that we called *paper-program* (Modeste, 2012). Many instance algorithms are present, which confirms a confusion between writing algorithms and describing step-by-step operations.

In the studied textbooks for all levels, we can see the strong influence of this accompanying resource. Most algorithms are described as “paper-programs” before being implemented (generally as immediate translation). Many exercises deal with interpreting, writing or translating algorithms in a given language. Algorithm is only shown as a tool, even the problem aspect has little presence. In the program for the **ISN** option, the approach differs. The program explicitly defines the notion of algorithm and mentions that it must be distinguished from the notion of program. Algorithmics is presented as a branch of Informatics and algorithms are not restricted to programming. The concept of algorithm appears as a tool and as an object (*complexity* and *proof* aspects are present).

### Comparison in high school

In Ukraine as in France, the effectiveness aspect is central. In all levels, algorithm is used as a tool, but the *problem* aspect is more developed in Ukraine. Algorithm is treated as an *object* only at professional and advanced levels in Ukraine, and in the ISN option in France. We could have expected them to appear in the French scientific paths but it is not the case. In Ukraine, the approach to Algorithmics seems to be guided by the development of algorithmic thinking whereas in France the focus is on the programming and language skills. It appears clearly in the textbooks: in Ukraine, the concept of algorithm is defined and a list of its properties is given, whereas, in France, an algorithm is defined by the language that describe it. Although in France, Algorithmics is taught in the Mathematics class, the focus on programming seems to be stronger than in Ukraine for standard level, where programming is not required and the focus is on elementary algorithmic thinking. In Ukraine, two features can be highlighted, probably inherited from historical context of teaching of Informatics in USSR: significant role of the scheme of problem solving (presumably influenced by the problem-solving theories) and the emphasis put on the notion of operator. In France, in Mathematics, algorithms are used to solve mathematical problems and are considered as a mean to deal with the mathematical concepts. The important presence of programs for simulations in probability or for embodying properties of mathematical objects attests to this point of view. The approach developed in ISN, in France, is close to the approach proposed at professional and advanced levels in Ukraine. They involve advanced concepts and aim at developing advanced algorithmic thinking, but we suspect a difference between the programs and the taught knowledge.

## Comparison at middle school level (grades 6-9, ages 11-15)

### Algorithmics in middle school in Ukraine

In the programs for grades 6 and 7, the part devoted to Algorithmics is similar to the program for standard level of high school. Although the program declares programming as one of the pupils' activities, it does not specify any programming language to use. In the textbooks for grades 6 and 7, an algorithm is defined as a finite sequence of instructions to be carried out for solving a problem. As we can see, in the given definition the effectiveness and problem aspects are on the first plan. At the same time, the fact that an algorithm solves all instances of a problem is not presented. The main part of proposed problems concerns the construction of instance algorithms for different operators. Both textbooks propose to program in Scratch. Pupils' activity is focused on developing programs and projects, using this programming environment. In grades 8 and 9, the Algorithmics part of the program is devoted to object-oriented programming. In grade 8, the notion of variable and different types of data are introduced. In grade 9, search algorithms in arrays are studied. The expected competences of pupils refer mostly to writing, modifying and debugging programs. The aspects related to algorithm as an object are not present.

### Algorithmics in middle school in France

In 2016, Informatics appeared in middle school. Algorithmics contents essentially appeared in the Mathematics course, in the cycle 4 (grades 7-9), in the theme "Algorithmics and Programming". Textbooks for this reform were not available at the time of the study, so we only analysed the programs. One general competence guides the program: "write, elaborate and execute a simple program". Then, more specific competences are listed (decomposing a problem into sub-problems, designing a program to solve a problem; writing programs driven by events; and writing parallel programs) and contents are specified: notions of algorithm and program; variables in Informatics; event-driven action, sequence of instructions, loops, conditional instructions; exchanged messages between objects. These contents are strongly oriented towards programming and, even if it is not declared, the software Scratch must be used to teach these notions. The chosen approach implies developing projects and games (in order to develop pupils' reasoning) and does not focus only on mathematical concepts. Effectiveness aspect of algorithm is present and problem aspect is more notable than in the high school curricula. Contrary to the approach proposed in Mathematics in high school, Algorithmics is introduced by programming (independently from mathematical contents).

### Comparison in middle school

In France and in Ukraine, in middle school, algorithm is presented as a tool. The *effectiveness* aspect is dominant. Although the *problem* aspect is mentioned, the role of algorithms for problem solving and the place for generic algorithms are not clear. At this level, the *complexity* and *proof* aspects are not proposed. Contrary to the curricula for high school, there are more similarities between the two curricula for middle school. Particularly, the notions of algorithm and program are distinguished; the introduction to Algorithmics includes event-driven programming in Scratch, and objects and variables are introduced later. The approach is based on solving concrete problems and developing projects in Informatics and in other disciplines. This could be explained by the influence of an international movement towards the teaching of Informatics in primary and middle school. Nevertheless, there are also important differences. In France, the most part of the proposed projects

are in Mathematics (maybe because it will be taught by Mathematics teachers, not well trained yet in Informatics), and there is a strong focus on programming (in a different way from high school). In Ukraine, the notion of *operator* is still highlighted, representations of algorithms with schemes and flowcharts are requested and many examples of algorithms are taken from everyday life. This is directly inherited from the didactic transposition proposed in the 1980's and today in high school.

## Conclusions and perspectives

On the one hand, this comparative analysis of the didactic transposition of the concept of algorithm and Algorithmics in secondary school in France and Ukraine brings out differences that reveal the impact of institutions, traditions and historical contexts on the curricula. The comparison of two contexts where Algorithmics is not a part of the same course (Mathematics versus Informatics) shows the influence of these disciplines on the contents, on the points of view on Algorithmics and on the algorithmic activity. On the other hand, in the two countries, we see general orientations in middle school that seem to be part of an international movement towards the teaching and learning of Informatics. This study contributes to understand and improve curricula, by taking into account the points of view of Mathematics and Informatics on Algorithmics. It gives perspectives to study the development of algorithmic thinking, and the teaching and learning of Algorithmics' concepts.

*In this paper we investigate Norwegian and Swedish upper secondary students' perspectives on the purpose of school mathematics. Students were group interviewed in various schools in both Norway and Sweden and the video recordings of those interviews fully transcribed. In each country transcriptions were subjected to a constant comparison analytical process that, coincidentally, yielded the same two dominant themes that we report here. Firstly, all students spoke about how learning mathematics facilitates being able to manage shopping, personal finances and other functional aspects of the real-world. Secondly, students spoke about how learning mathematics would facilitate their getting a job, including some Swedish students who saw mathematical success as a high status qualification preferred by employers.*

*Keywords: Purpose of school mathematics, Norway, Sweden, student perspectives.*

## Introduction

Despite evidence that large scale assessments of mathematics achievement like the Organisation for Economic Cooperation and Development's (OECD) Programme of International Student Assessment (PISA) have prompted curricular changes in many OECD member countries (Breakspear, 2012), the nature of school mathematics is not an unproblematic given and varies considerably cross-culturally (Andrews, 2016). Indeed, all curricula, which are based on a culture's conception of an ideal person (Cummings, 1999), are rooted in substantially more than what can be inferred from official documents. Consequently, the ways in which teachers conceptualise and present mathematics varies from one cultural context to another, inevitably influencing the beliefs that students form about mathematics and its purpose (Cobb, 1985).

Students' beliefs about mathematics and its teaching have been the focus of much research for more than four decades, following Erlwanger's (1973) case study of Benny, a twelve year-old student who had come to see mathematics as invented rules, each for a particular type of problem, that work like magic. Benny's beliefs about mathematics effectively laid the ground for the field, not only from the perspective of what students believe about mathematics and its teaching but also the ways in which teachers' beliefs and practices are implicated in the construction of such beliefs. In short, the significance of this work draws on the premise that students' beliefs are informed by, and inform how they respond to, their mathematics-related learning opportunities (Erlwanger, 1973; Callejo and Vila 2009). In this regard, "beliefs constitute, for the believer, current knowledge about the world" (Cobb, 1986, p.4).

Over the succeeding years, research into students' mathematics-related beliefs has addressed a variety of themes, which have been well summarised by Op 't Eynde and his colleagues (Op 't Eynde et al., 2002; 2006), which they present under three broad headings; beliefs about mathematics

education, beliefs about the self as a mathematician and beliefs about the mathematics class context. Within these three broad headings, which space prevents us from discussing in depth, are located most aspects of mainstream beliefs-related research. However, a strand that has received less explicit attention the literature, particularly in the Scandinavian context, has been the beliefs students hold about why they are compelled to learn mathematics for so many years.

### **The purpose of school mathematics**

In general terms, the reasons why children spend so many years studying mathematics are not always clear, although typically they seem to be tied to ensuring either the social, economic and political mobility of the individual citizen or the nation's economic growth through preparing the next generation of employees (Schoenfeld & Pearson, 2009). Such perspectives are philosophically rooted in either personal emancipation or the reproduction of the existing social order respectively. That being said, while much philosophical research has addressed the general aims of education, "very little sustained work of this kind appears to have been carried out in mathematics education", to the extent that "there is sufficient disagreement, lack of clarity and modesty to warrant further enquiry" (Huckstep, 2000, p. 8). It is on this that we next focus, confirming Huckstep's concerns.

Various scholars have considered the purpose of school mathematics. For example, Niss (1996) discusses the justification and the goals of mathematics education from both theoretical and historical perspectives. Davis (2001) adopts a largely philosophical standpoint in suggesting three distinct purposes, which he describes as the teacherly, the rhetorical and the hermeneutic. The teacherly purpose for teaching mathematics derives from a set of largely forgotten reasons tied to the belief that "knowledge of mathematics is necessary for every citizen of today's world" (p. 18). The rhetorical purpose derives from an "explanatory fantasy that is currently preferred to organize and structure experience" (p. 19). The hermeneutic purpose lies in beliefs that "there are moral and ethical imperatives that operate in the human and in the more-than-human realms" (p. 21). In a slightly more prosaic manner, Noyes (2007) writes of six broad purposes; mathematics for the academy, for employment, for general education, for citizenship, for the information age and, finally, critical mathematics education. Ernest (2016), in a not unrelated manner, describes seven purposes; functional numeracy, work-related knowledge, advanced specialist knowledge, problem posing and solving, mathematical confidence, social empowerment through mathematics and, finally, appreciation of mathematics itself. Finally, Watson (2004), in a manner that seems to summarise both Ernest and Noyes and mirror Davis (2001), proposes three broad purposes; mathematics as a set of useful skills and procedures, a support for the burgeoning mathematics-related professional, and a tool that facilitates successful societal participation. In sum, as Huckstep (2000) indicated, mathematics is taught for various reasons tied to cultural norms and values.

Interestingly, despite research discussing the purpose of mathematics from an outsider perspective, few studies have engaged with the insider; what do recipients of mathematics teaching think is the purpose of what they are taught? In this respect, it is salient to note that Brown, McNamara, Hanley and Jones (1999), when investigating beginning primary teachers' understanding of mathematics and its teaching, found that "a sense of bafflement about the purpose of school mathematics permeated many accounts" (Brown et al., 1999, p. 305). That is, these students had completed school and still had no idea as to the purpose of school mathematics. In the light of such uncertainty and acknowledging the lack of research in the field, particularly in the context of Scandinavia, we

examine the beliefs about the purpose of school mathematics of both Norwegian and Swedish upper secondary students. As in Brown et al.'s (1999) study, these students are close to the end of their school careers and should have formed clear ideas as to the purpose of mathematics.

## **The study and its methods**

The data on which this paper is based derive from a comparative interview study of upper secondary students in Norway and Sweden. In broad terms the study set out to explore students' perspectives on their many years of school mathematics. Students were interviewed in pairs or threes, and the interviews were structured around the following four questions, with follow-up questions where appropriate:

1. How would you describe a typical mathematics lesson at school?
2. What do you think is the purpose of compulsory school mathematics?
3. What do you think mathematics as a subject has to offer to those who engage with it?
4. If you could say something about the nature of mathematics education to those in charge of the educational system, what would it be?

It is the answers to question 2 that we will be focusing on in this paper.

The Norwegian data derived from 17 interviews involving 42 students from three schools. Two schools, one in Oslo and one in Trondheim, were high-achieving academic schools, while the third was a relatively low-achieving vocational school in Oslo. The Swedish data derived from 18 interviews involving 50 students from four schools. These schools, from various parts of Stockholm, all offered a range of vocational and academic tracks. Consequently, we make no claims about schools' representativeness nor do we seek to generalise. All participants were fully aware of the purpose of the research and of their rights to withdrawal.

Interviews, undertaken at a time chosen by the students, were video recorded on laptop computers, a decision justified in four ways. Firstly, video, especially when participants talk over each other, simplifies transcriptions. Secondly, video captures non-verbal communication. Thirdly, due to their classroom ubiquity, laptops were expected to create less disruption than tripod-mounted video cameras. Fourthly, laptops record data directly to their hard-drives, simplifying data storage and analysis. All interviews were transcribed and, in each country, subjected to a constant comparison analysis whereby each transcript was read and categories of response identified. With each new category, previously read episodes were re-read to determine whether the new category applied to them also. The two data sets were analysed separately to ensure the cultural integrity of the findings.

## **Results**

The data from both countries yielded a variety of themes. However, two closely related themes dominated the analyses in both contexts and it is these we turn to in this paper. These were related to being able to function in the real world and getting a job, and were present in every single interview in one form or other. Below we give a more detailed description of the two themes as well as exemplifying interview extracts from both academic (A) and vocational (V) students. Other

themes, relating to mental training, appreciation, and uselessness were also present in the data (though much less so). However, it is beyond the scope of this paper to discuss those here.

### **Mathematics enables one to function in the real world: Norway**

A large number of students emphasised the importance of mathematics in daily life, which typically seemed to consist of going to the supermarket or calculating one's salary and taxes. In respect of the former, Line's (A) comment was typical; "maths is a lot about everyday life... you wouldn't be able to go to the store and buy goods if you didn't have some maths". Similarly, Robin (V) commented that "when you are going to buy food and stuff, you need to know how much things cost and stuff".

With respect to both shopping and income, Tania's (A) comments were not atypical. She said that

You need it in daily life and... you're in the shop, you want to buy something, and then you must add... sum the price of the things you buy and stuff... like if you work, and if you want to know how much you earn and you want to know your net income... if you know it yourself you can double check if the person who does it has done it right and stuff.

While Ruben (V) added that "you can calculate numbers and stuff... it helps you on in life... if you work you can calculate your salary and stuff", before adding that "there is a lot of maths that you don't need, but you need at least a part of it". Others offered less specific statements regarding 'daily life'. For example, Amalie (A) commented that she hadn't "thought that much about it" before adding that "you do at least have to know some maths... like in daily life, then maths is useful". Interestingly, she then offered the observation that "when we are at high-school level then I don't exactly think that all the maths I learn will be useful".

In sum, the Norwegian students were confident that knowing mathematics would support their functioning in the real world, although there were occasions when the manner of this support was vague and imprecise. It was also interesting to see Amalie's and Ruben's comments that while mathematics was a real-world support, much of what they learned was unnecessary in this respect.

### **Mathematics enables one to function in the real world: Sweden**

In every Swedish interview students spoke about how they saw mathematics as preparing them to face a world beyond school, mathematics as supporting their real-world functionality. Within this utilitarian strand two major themes were identified. The first concerned personal finance and the management of money. Here, almost all students spoke about understanding interest, as with Jacob's (V) comment that "percentages in terms of interest and loans and things like... that's very good to know because you might not really figure out in your head how much you can spend". In similar vein Pedram (A) said that "amortization..., interest rates, interest costs, to be able to figure it out, it is important". Others spoke more generally about the management of personal finances. For example, Mark (V) commented about the need to manage "larger sums, as well as your salary", while Kenneth, in the same vocational track interview, added that "it becomes much easier to make financial plans... if one has several years of mathematics". Finally, several students spoke of the need to avoid overextension, as in Göte's (A) concerns with respect to "SMS loans and stuff, there are many who do not know how much you lose there" and Omar's (A) worries that "there are too many adults today who do not really understand interest and how it works".

The second major theme relating to being able to function in the real world related to the mundane world of everyday shopping. Comments typical of others were like those of Alice (A), who said that “it's something you use in everyday life, it's typical when you go shopping, it's just the basics”, or Mark (V), who said that “it's always good to have a base in maths. So, if you go shopping and have a hundred, then you cannot buy for more than a hundred”. Others offered a slightly different perspective. For example, Hanna (A) raised the overall mathematical expectation of such transactions by commenting that “if you've gone shopping and there is a discount and know how to do that or how to pay what you're gonna pay in. It is like useful to use maths like this”, while André (V) added that “you always look at the prices and compare them to the prices in another store”.

### **Knowing mathematics enables one to get a job: Norway**

A number of students spoke about how they saw their learning of mathematics in relation to their future careers. In most cases students spoke hypothetically as few seemed to have considered their own particular career aspirations. For example, Sarah (A) said that

I think that maybe we need to spend as much time on maths as we do because we don't know who ends up as engineers or who maybe works with something that you maybe don't need a lot of maths for... you can't know in advance, so everyone has to learn everything... so that you can be what you want.

In similar vein, Kristine (A) commented, after acknowledging “that is a bit of a difficult question”, that

it depends a lot on what you plan to do after high school... if you have planned to take a fairly high education then it is clear that there is a lot of maths; if you, for example, are going to be a chemist or a physicist or... medical studies too... or generally medicine, if you are to calculate dosages for a pain killer it is a bit bad to get a really huge dose... but if you plan to work at Mc Donalds for example, then it is not so important.

The comments of both students indicate an understanding that different professions will require different levels of mathematical competence. However, neither of them sees mathematics as an important component of education for everyone for its own sake. However, having observed that working in McDonalds does not require much by way of mathematical competence, Kristine added that “but how do we know from the start who will be a physicist and who will work at McDonalds?”

Other students noted that they do mathematics for as long as they do because it is a formal entry requirement for higher education (even if that higher education is unrelated to mathematics). In this respect, Andreas (V), in a comment typical of others, noted that “actually it is an entrance requirement for the college I plan to go to later... but apart from that I don't see any reason to know such advanced maths”. In such a comment, and those of Sarah and Kristine, lies a tacit concession that everyone has to spend twelve years learning mathematics *just in case* it might be useful, a conclusion summarised well by Gina (A), who said, “I think maybe you don't notice the importance until later”.

In a related manner, Malin (A) spoke of how mathematics supports the learning of other subjects. She commented that

you need to use maths a lot in other subjects, so you have it in chemistry and physics and stuff... so maths is a very important tool... so it is not... if you look at the maths as a subject... just a subject, then it can be a lot of numbers and a bit like... but if you put it in the context of other science subjects, then it is the most important tool you have.

### **Knowing mathematics enables one to get a job: Sweden**

Very few students did not, during the course of their interviews, refer to the ways in which learning mathematics would enhance their employment prospects. Within the Swedish data two major subthemes were identified. The first of these concerned students' beliefs about the generic ways in which mathematical knowledge would prepare them for work. At its most basic, according to Andreas (V), "any job requires quite some math knowledge, in all cases, plus or minus, often times. ... and that applies to the majority of all jobs". More specifically, as in the comments of Thomas (V), "you get better chance of getting a better job with like higher level of mathematics", while Alice (A) believed that "when one has read maths, one can study further and get ... more opportunities for the future, one can say, more career choices". Others still, saw beyond their first job, as with Kenneth's (V) comment that "even when you think you have found out what you want to be, you might want to switch careers later and then maybe you need more knowledge in maths". From the perspective of particular career routes, Dennis (V) commented that "as an electrician you need so this current, voltage, and everything like that, it requires maths for", while Roxana (A) suggested that "if you're going to become an engineer for example you're gonna read a lot of mathematics".

The second, slightly cynical, theme found students discussing how being mathematically qualified gave them an advantage over those who were not. For example, Ted (V) commented that "I think that many who have not read maths will not get a job, for the employer will not hire those who cannot work in the same way", while Jacob felt that the mathematically qualified "is more knowledgeable, that way he can solve the problem the less skilled cannot; he can see the big picture of things better". Hanna's (A) view was that such advantages stemmed from the fact that

it might be like easy for that (mathematically well-qualified) person to think logically, to think outside the box and that kind of stuff. And the other (less well-qualified) person might have a few more problems with that, maybe... and probably it's easier for the person that's really good at math to excel in whatever they want to do... which is harder for the other person

Most Swedish interviews also contained some reference to the ways in which mathematics was seen as a service tool to other forms of activity. Typically, these focused on the natural sciences, as in the comments of Adam (V), who said, "you use math well in other subjects like physics", Mikaela (A), who believed that "I know ... in chemistry or physics ... I need maths. So I think to learn the physics or those things you need to learn, to know the maths first. So you can build on it" and Julio (V), who argued that "maths is the grounding for several subjects, so if you remove maths, it's not just maths skills that will be worse, but then it is physics, chemistry and yes science subjects just disappear, so maths is an important part". Others' comments were more general, as in Winston's comment that mathematics "works well with other subjects that also need the maths, like they complement each other", while Max commented that "sports is a subject where you use it (mathematics)".

## Discussion

In this paper we set out to uncover what Norwegian and Swedish upper secondary students believed was the purpose of school mathematics, particularly as it has been an ever-present compulsory part of their school careers. The results seem much removed from mathematics as a problem posing and solving discipline (Ernest, 2016) for which teaching aims to “lead students to appreciate the power and beauty of mathematical thought (Dreyfus and Eisenberg, 1986, p.2). Indeed, the two dominant themes, mathematics as a support for functioning in the real world and mathematics as an entry into employment, are as utilitarian as it is possible to be, showing no connection to mathematics as a cultural artefact to be appreciated as would be art, music or literature. Moreover, the themes were not utilitarian in the sense that students saw themselves as having been educated for citizenship (Noyes, 2007), made socially empowered (Ernest, 2016) or inducted into societal participation (Watson, 2004). They were utilitarian solely from the perspective of personal advancement. There was no evidence that these students, many of whom were expecting to go to university and study mathematics-related subjects, saw mathematics as part of the “moral and ethical imperatives that operate in the human and in the more-than-human realms” (Davis, 2001, p. 21).

While such findings may be disappointing, we acknowledge that these students’ perspectives have not emerged by chance but from individually unique experiences of mathematics. These ten- and eleven-year experiences, located in different countries and schools, will necessarily have influenced the formation of individuals’ beliefs about the nature of mathematics and its purpose (Cobb, 1985), and yet their collective voice was close on deafening. So, are there any explanations? Well, the literature is not particularly expansive on such matters, although a recent case study may offer some insight. In their study of largely disaffected Swedish upper secondary school students, Andersson, Valero and Meaney (2015) motivated their students by means of tasks involving, inter alia, percentages related to personal economics. This approach, which was received positively by the students concerned, raises at least two important questions. The first is whether such an approach legitimates students’ perception that school mathematics is about preparing them for the real world. The second is whether students’ positive reactions were a consequence of the task meeting their expectations of school mathematics. In short, which came first, the chicken or the egg?

# **Visual attention while reading a multiple choice task by academics and students: A comparative eye-tracking approach**

Mirosława Sajka

Institute of Mathematics; Pedagogical University of Cracow, Poland; [msajka@up.krakow.pl](mailto:msajka@up.krakow.pl)

*This study exploited eye-tracking technology to analyse the visual attention, while engaging with a multiple-choice mathematical task, of 103 participants with different levels of expertise and experience, including academics, university students and secondary school students. The majority of participants, irrespective of experience or prior knowledge, skipped or did not process all the information provided by the task. Important differences were discerned between how the academics and the two student groups attended to the different areas of the task's presentation, highlighting the different problem-solving approaches of the experienced and the inexperienced. Moreover, a 'hit ratio' parameter allowed the identification of those participants who did not look at these important areas of the task. The research highlights methodological advantages and disadvantages of using eye-tracking and different ways of data analysis.*

*Keywords: Eye-tracking, multiple choice task, comparative study.*

## **Introduction**

The use of eye-tracking for research in mathematics education is an emergent field, albeit still relatively rare. For example, during the ICME-13 congress, only 4 of 1952 papers and 533 posters, contained the phrase eye-tracking or its variants in their title. Most mathematical education-related eye-tracking research has been undertaken in laboratories, with classroom-based studies using head-mounted eye-tracking device are rare (e.g. Garcia & Hannula, 2015; Hannula 2016). Examining visual attention not only shows where and how gaze is directed, but also constitutes a basis for further analysis of problem solving, reasoning, attention and mental images. (Just & Carpenter, 1976; Zelinsky & Sheinberg, 1995; Ball et al. 2003; Yoon & Narayanan, 2004). The measurement of the eyes' fixations can provide reliable and sensitive insights into otherwise unavailable cognitive processes (e.g. Sosnowski, 1993).

From the perspective of mathematical problem solving, researchers have used eye-tracking to distinguish between the behaviors of experts and novices with respect to the solving of linear equations (Susac et al., 2014), geometry problems (Epelboim & Suppes, 2001) and their interpretation of mathematical representations (Andrà et al., 2009), interpreting graphs (Wcisło et al., 2014), perception of Cartesian coordinates (Krichevets et al., 2014) as well as perception of a number line (Shvarts et al., 2015).

Students need to learn how to read mathematical problems. Thus, in-depth knowledge of strategies for reading mathematical problems has important didactical consequences, although more needs to be known about how participants of different levels of education approach unfamiliar problems. In this paper I report an eye-tracking study of approaches to the reading and solving of a multiple choice graphical problem concerning motion. The relatively large sample of the current study, more than 100 participants, is novel as the majority of previous eye-tracking studies in mathematics education have been case studies with small samples of fewer than 20 people.

## Methods

The primary aim of the study was to use eye-tracking to investigate whether different groups of participants' visual attention while reading and analyzing a mathematical problem varied with experience and problem-solving expertise. The first group, academics (A), comprised one professor of physics and three academics in mathematics, physics and computer science respectively. The second group, university students (U), comprised 75 university students at different stages of their courses in computer science, physics, mathematics and biology. The third group comprised 24 high-achieving school students (ages 17-18 years) (S) who attended a so-called *university class* with an extended curriculum in mathematics and physics. Thus, study participants included people with widely differing experiences of mathematics. All participants were guaranteed anonymity and could withdraw from the study at any time.

### Task and apparatus

Respondents were invited to solve a multiple-choice mathematical task (proposed by Prof. W. Blasiak) concerning the interpretation of a motion graph. The Polish mathematics curriculum introduces the interpretation of graphs of functions to students in grade seven (lower secondary school). Later, students aged 14-15 years old learn the concept of a function and use its representations. During both mathematics and physics classes they also learn the relationships between average speed, displacement and time as well as constant acceleration. Thus, the mathematical subject matter knowledge of every participant should have been sufficient to solve the problem. However, the task, shown in Figure 1, is complex, caused mainly by the simultaneous presentation of two time-velocity graphs. In addition, participants were asked to identify incorrect statement(s), what is not a standard request. Academics were invited to identify any incorrect statements, of which there were two, A and E. For the other participants the task was simplified to one incorrect statement A.

Statement A is incorrect due to its assumption that the graphs represent trajectories. Statements B, C, D are correct. Answer B (and E) concerns the distance driven by the vehicles. Statement B can be verified in an elementary way, based only on the analysis of speed values: vehicle (I) moves in the time span 0-10 min. with higher speed than vehicle (II), so its displacement is greater. Statement C concerns only the interpretation of values of the functions for the argument  $t = 10$  min. Statement D essentially requires a basic understanding of acceleration, although knowledge of the monotonicity of linear functions would be sufficient. Statement E is the most sophisticated, being true only at  $t = 10$  min. One can notice it comparing the area of respective figures: rectangle and triangle bounded by the graphs of the functions and  $x$ -axis (graphical interpretation of the distance at the motion graph). Concerning version for academics (see Fig. 1) for all positive  $t \neq 10$  statement E is incorrect, thus the general statement is also incorrect. The difficulty connected with statement E was specifically included to make a more challenging task for the academics. Other participants were asked to verify the statement for  $t = 10$  minutes, therefore statement E for them was correct.

To record participants' eye movements, the Eyetracker Hi-Speed 1250 with iView X™ was used. The sampling rate was set to 500 Hz, monocular. The movements of the left eyeball were examined for every participant and the data obtained processed by the BeGaze software. The 13-point calibrations were accepted with an angular accuracy of less than  $0.5^\circ$ . All respondents sat at a distance

of 50 cm from a 22-inch monitor. The duration of the experiment was not limited. Participants' eye movement data, question responses and mouse clicking were recorded by Experiment Center 3.1. Additionally, respondents were asked to orally confirm their selected answers.

Figure 1: The task translated from Polish

## Results

The analyses were undertaken in several stages.

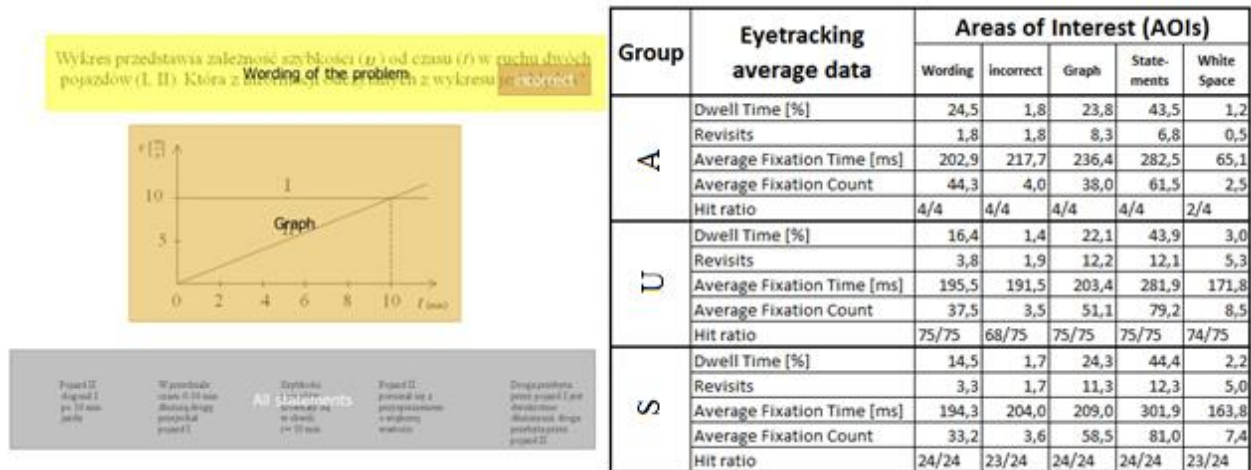

Firstly, the figures of Figure 2 show the problem solving results for each group. It is interesting to note that while both the university and school students were not particularly successful, identifying many correct statements as wrong and not identifying the incorrect statement, the academics, with their amended statement E, failed to identify it as incorrect.

Selected answers	A	B	C	D	E
A (4)	4	0	0	0	0
U (75)	24 (32%)	19 (25%)	8 (11%)	9 (12%)	15 (20%)
S (24)	8 (33%)	5 (21%)	3 (13%)	0 (0%)	8 (33%)

Figure 2: Results of the task for each group

Secondly, with respect to the eye-tracking analyses, participants' eye movements were studied initially by five broad areas of interest (AOIs), as shown in the left hand side of Figure 3. These were the words comprising the task formulation (Wording), the key word within that text (Incorrect), the graphical diagram (Graph), the statements A – E (Statements) and, finally, the remainder of the slide (White Space). The right hand side of Figure 3 (right) shows the average data for each AOI for each

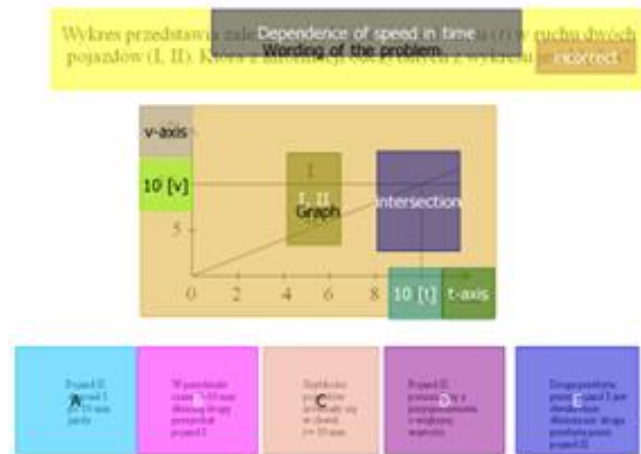

group: the percentage *dwell time*, number of *revisits*, *fixation* time, *fixation count* and so called *hit ratio*, which informs how many participants looked at the AOI.

**Figure 3: Definitions of broad AOIs (left) and their eye-tracking data in defined groups (right)**

The data presented in Figure 3 (and Figure 5) should be viewed with caution because of the calculation of average data. That said, some interesting differences can be discerned between the academics and the two student group. Firstly, academics responded to ‘Wording’ differently from the two students groups. They spent 24.5% of their total time on task dwelling on the words of the problem, in comparison to 14.5% (S) and 16.4% (U). Academics achieved a greater number of fixations (44,3) on ‘Wording’ than the student groups (33.2 (S), 37.5 (U)), indicating that the academics’ attended more to the words of the problem than students’ in either group. Academics addressed ‘Wording’ more attentively than did the students because their average number of revisits, 1.8, was around half of that of the two students’ groups (3.3 (S) and 3.8 (U) respectively). Secondly, the reverse seemed to be true for ‘Graph’; the average number of fixations for academics was lower (38) than for in either group (58.5 (S) and 51.1 (U)). Thirdly, Academics’ attention to ‘Statements’ was lower than that of the students (61.5 (A), 81 (S) and 79.5 (U)). Fourthly, academics’ dwell time was uniformly distributed between ‘Wording’ and ‘Graph’ (24.5% and 23.8% respectively) which was not the case for students. Fifthly, students revisited ‘Statements’ twice as many times as the academics. Sixthly, students made more than ten times as many revisits as the academics to ‘White Space’ and spent three times as much time on it, indicating that their visual attention was more located outside the defined parts of the slide. Finally, the *hit ratio* for showed that eight students (1 S and 7 U) failed to look at the AOI “incorrect”, prompting one to ask, what question were they answering?

In sum, academics not only spent a higher proportion of their time on the wording of the task than the participants of either student group but also made fewer revisits. It can also be seen that the academics made fewer fixations on and made fewer revisits to the graphs, the statements and the white space than did the participants of either of the other two groups, indicating that the time they spent on the words benefitted their problem solving.

**Figure 4: Detailed definitions of AOIs**

The third stage of the analysis was to examine more specific AOIs, which are shown in Figure 4. Ten additional areas were associated with task those characteristics that should be analyzed for the problem to be solved. These concerned the phrase “dependence of speed in time” (Dependence), the two axes (v-axis, t-axis), the graphs’ labels (I, II), the intersection of the graphs (Intersection) and the Statement A – E, separately. The chosen average eye-tracking data are presented in Figure 5.

	A	U	S	A	U	S	A	U	S	A	U	S	A	U	S
	Dependence			v-axis			10[v]			t-axis			10[t]		
Dwell time[%] (average)	5,4	5,9	5,3	3,2	1,8	2,1	1,5	1,3	1,3	0,7	1,4	1,2	0,9	1,3	1,5
Hit ratio	4/4	73/75	23/24	4/4	66/75	23/24	4/4	64/75	22/24	4/4	73/75	21/24	4/4	65/75	23/24
Revisits (average)	2,8	3,5	3,3	2,8	2,6	2,8	2,8	2,6	3	6,8	4,4	1,9	1,8	2,6	3,3
Revisitors	4/4	69/73	20/23	4/4	54/66	19/23	3/4	52/64	20/22	4/4	71/73	13/21	4/4	53/65	17/23
Average fixation [ms]	210,7	193,5	180,7	315,8	232,7	262,8	254,5	176,4	159,6	230,9	222,7	211,2	141,2	155,3	165,4
Fixation count (average)	14	13,5	13	6,3	3,9	4,6	4,3	3,4	4,1	8,8	6,4	2,8	3,5	3,6	4,7
	Statement A			Statement B			Statement C			Statement D			Statement E		
Dwell time[%] (average)	11	10,3	11,4	11,4	10,6	11,5	7,3	7,1	6,3	9,7	7,1	5,9	9,4	7,6	8,5
Hit ratio	4/4	74/75	24/24	4/4	74/75	23/24	4/4	74/75	23/24	4/4	71/75	23/24	4/4	65/75	19/24
Revisits (average)	3,3	3,7	3,4	3,8	4,8	4,3	2,5	3,7	3	2	3,6	2,9	1,3	2,7	3,5
Revisitors	4/4	68/74	24/24	4/4	71/74	22/23	4/4	64/74	17/23	3/4	64/71	21/23	4/4	46/65	17/19
Average fixation [ms]	329,6	297,8	328,9	233,3	252,7	261,5	292,3	266	284,6	317,2	272,3	278,8	284,8	231,9	219,8
Fixation count (average)	18,5	16,2	17,4	27	20,6	22,7	14,8	13,7	12,2	17,3	13,5	11,2	18,5	14,9	17,5

**Figure 5: Eye-tracking average data in groups for chosen detailed AOIs presented in Figure 4.**

The figures of Figure 5 show both similarities and differences. It is interesting to note, for example, that the times spent by all three groups on the five statements were similar. However, the academics focused proportionally more time on the v-axis and less on the t-axis than either student group, which is interesting as their number of revisits to the v-axis was comparable to the students but much greater with respect to the t-axis. It is also interesting to note that academics, despite their failure to identify the incorrectness of the statement, made fewer revisits to statement E than either student group. In such an instance, it is possible that the academics had drawn an over-confident conclusion. Finally, the hit ratio shows that while all the academics attended to all ten AOIs, students’ attention was complete only one occasion, when all school students fixed on statement A.

## Discussion and summary

In general, the data indicate that academics were better focused on the task formulation than either group of students. Not only did they spend a higher proportion of their time on the wording of the task but made fewer revisits. They read each word carefully and did not revisit the same places as often as students. Academics also made fewer fixations on and made fewer revisits to the graphs, the

statements and the white space than the participants of either of the other two groups, indicating that the time they spent on understanding and interpreting the problem benefitted their problem solving. Unsurprisingly, being academics, they understood what they read and knew where to look to analyse a problem. They were more competent than students in their graphical interpretation, being able to understand the key elements of the graph. In related vein, their visual attention was distributed uniformly across both the problem statement and the graph, and they were not distracted by irrelevant parts of the slide. Thus, while the conclusions are not surprising, the data highlight well differences in the ways in which experts and novices address mathematical problems.

**Figure 6: Sequence charts for all academics and two students per group**

As indicated above, the data presented here are the averages for each group on each AOI. Individually, there was an interesting variation within each group of participants. For example, Figure 6 shows the complete sequence of eye-tracking activity with respect to the broad AOIs for all four academics and the two extremes, the longest and the shortest, from each student group. It can be seen clearly that there was a tendency towards an academic homogeneity, particularly the first three who spent considerable amounts of time on the task wording. However, the variation within each student group was considerable. Indeed, the academics typically spent around a minute on the task, while university students' time on task ranged from around seven seconds to two minutes and 40 seconds. In sum, while the study above has been helpful in showing some differences between expert and novice problem solvers, individual variation has highlighted the need for further research into how eye-tracking can support our understanding of effective problem solving strategies.

This paper has offered one analysis, based on average behaviours, focused on how eye-tracking data can support our understanding of the problem solving process. However, this averaging process with the atypically large numbers of participants may have masked individual differences, which themselves may prove insightful. Thus, focusing on individuals may be a fruitful direction as it may identify different factor implicated in either problem solving success or failure. For example, Figure 7 shows the variety of the participants' visual attention, presenting so called *scan paths* for an academic (left), a U student (middle) and an S student (right) respectively.

**Figure 7: Scan paths of a chosen participant from each groups: A (a), U (b) and S (c).**

Finally, it was interesting that none of academics questioned the correctness of Statement E. Here we faced the limitation of pure eye-tracking methodology – mixed methods with interviews or written questionnaires may have exposed the reasons. Thus, several months after the research, academics were asked to think again and solve the task, without eye-tracking. While solving the task again they confirmed answer A, read again all the other statements and eliminated them, treating again as correct. When asked why statement E is correct, they answered that the displacement can be counted as the area under the graph. They indicated  $t=10$  min. After further questions they were surprised that “ $t=10$  min” was not written explicitly in the statement. The previous statements for  $t=10$  min together with the graph and dashed line indicating the point (10, 10) caused their certainty that the statement E was also formulated for  $t=10$  min. That was their tacit assumption, which could be provoked by the three factors. One of academics mentioned about the routine of solving multiple choice tasks, usually with the only one correct answer, therefore his inquiring mind was asleep after finding the correct answer A.

### Acknowledgment

The study was run within scientific activities of Interdisciplinary Group of Cognitive Didactics at Pedagogical University of Cracow, of which I am a member. I would like to offer my thanks to the previous head of that group Professor Władysław Błasiak and the present leader Professor Roman Rosiek for the possibility to work on the data; to Dr. Anna Stolińska for the permission to use the device; as well as to all members of the group, especially to Dr. Dariusz Weisło, for their help.

*This study presents a quantitative analysis of middle school mathematics teachers' content knowledge in two countries. The sample comprises lower secondary mathematics teachers from the US (grades 6-9, N=102) and Russia (grades 5-9, N=97). The instrument was designed to assess teacher content knowledge based on the cognitive domains of knowing, applying, and reasoning, as well as addressing the lower secondary mathematics topics of number, algebra, geometry, data and chance. Results indicate significant differences in teacher knowledge between the countries in content as well as in cognitive domains. The study results may inform the field on priorities placed on lower secondary mathematics teachers' knowledge in USA and Russia.*

*Keywords: Comparative studies, teacher knowledge, lower secondary mathematics.*

## Introduction

The motivation for the study is based on the 8th-grade mathematics portion of the TIMSS-2011 results (Mullis et al. 2012). We identified two countries ranked closely to each other: Russia - in the 6th position and the USA – in the 9th position. At the same time, a difference in the US and Russian students' performance was revealing: the average score of Russian students in the content domain was 539 and of the US students 509, with Russian students gaining higher scores on Number (534 vs. 514), Algebra (556 vs. 512) and Geometry (533 vs. 485) whereas US students outscored Russian students in the domain of Data and Chance (527 vs. 511). Russian students also outperformed the US students in each cognitive domain: Knowing (548 vs. 519) Applying (538 vs. 503), and Reasoning (531 vs. 503). These data triggered the following question: to what extent does US and Russian lower secondary mathematics teachers' knowledge differ by content and cognitive domains?

## Cross-national studies of teacher knowledge

Conducting cross-national studies allow comparing, sharing, and learning about issues in an international context which in turn helps researchers understand their own context, teaching practice, teacher knowledge, and student learning (Stigler & Perry, 1988). During the last decade, the number of cross-national studies on teacher education is increasing in order to understand differences in student performance on international tests such as TIMSS, PISA (Wang & Lin, 2005). Scholars have addressed these differences focusing on characteristics such as teachers' perceptions of effective mathematics teaching (Cai, Ding, & Wang, 2013), teacher knowledge (Tatto & Senk, 2011; Tchoshanov et al., 2017), among others.

Few cross-national studies focused on teacher knowledge. A large-scale study conducted by the University of Michigan examined the mathematical content and pedagogical content knowledge of pre-service teachers from 17 countries including USA and Russia (Tatto & Senk, 2011). The nature of mathematics teacher knowledge, conceptual representation, and curriculum materials were examined by Ma (1999) to explain differences in students' performance in the U.S. and China. An, Kulm, and Wu (2004) studied the PCK of middle school teachers in the U.S. and China. They found that mathematical PCK differs among the countries since Chinese teachers emphasize developing procedural and conceptual knowledge through traditional teaching practices while their counterparts in the U.S. focus on promoting creativity and inquiry through activities designed to develop students' understanding of mathematical concepts. Sorto et al. (2009) administered a survey that measured teachers' content knowledge in Costa Rica and Panama and found that teachers in both countries focus more on knowing rules and procedures than on making connections and reasoning.

In the last several decades, the field of mathematics education is expanding its knowledge-base in understanding the role of teacher characteristics in student learning and achievement. The major shift in the field had happened with Shulman's (1986) work on teacher knowledge that proposed an alternative approach to the educational production function perspective, which was concerned with examining proxies of teacher knowledge such as coursework/certification and its impact on student achievement (Charalambous & Pitta-Pantazi, 2016). Research on teacher knowledge initiated by work of Shulman (1986) has focused on teacher knowledge as a major predictor of student learning and achievement. Recently, the field benefited from numerous studies (Hill, Ball, & Schilling, 2008; Baumert et al., 2010) that substantially advanced the conceptualization of teacher knowledge and its association with student performance.

Following up on this conceptualization, some scholars (Izsak, Jacobson, & de Araujo, 2012) examined different facets of teacher knowledge without explicitly emphasizing its connection to student learning. Other scholars stressed the importance of the kind of knowledge a teacher possesses because it impacts his/her teaching (Steinberg, Haymore, and Marks, 1985). Another line of research (e.g., Baumert et al, 2010; Hill, Ball, & Schilling, 2008; Tchoshanov, 2011) specifically targets the effects of different types of teachers' knowledge on student achievement. Additionally, scholars have advanced the field by examining teacher knowledge in variety of domains including Number Sense (Ma, 1999; Izsak, Jacobson, & de Araujo, 2012), Algebra (McCrory et al., 2012), Geometry and Measurement (Nason, Chalmers, & Yeh, 2012), and Statistics (Groth & Bergner, 2006). However, the field lacks cross-national research that provides a comprehensive analysis of the various facets of teacher knowledge (including content and cognitive domains) and its connection to student performance.

## **Methodology**

The proposed study is based on the assessment framework used by TIMSS (Mullis et al. 2012). In this section, we will describe the study participants, the instrument as well as data collection and data analysis procedures.

### **Participants**

The sample of this study consisted of lower secondary mathematics teachers from the US (grades 6-9, N=102) and Russia (grades 5-9, N=97). The US teacher-participants were selected from urban

public middle schools in the Southwestern part of the country. Teacher sample demographic information was self-reported by participating teachers. In terms of gender distribution, 55% of teacher participants were females and 45% - males. Most of the US participants (64%) had 1-5 years of teaching experience. Additionally, 62% of the teacher sample received their teaching certificate through traditional teacher preparation programs and 38% of participating teachers were certified through alternative programs. The Russian teacher-participants were selected from urban public secondary schools in the Volga region. Russian participating teachers had attained a secondary mathematics teacher preparation Specialist's degree, which allowed them to teach in secondary schools (grades 5-11). The majority of participating teachers were females (89%). The sample was composed of 78% of teachers who have more than 10 years of teaching experience.

### Instrument

The instrument used in this study was the Teacher Content Knowledge Survey which was developed using TIMSS framework (Mullis et al. 2012). It was designed to assess teacher content knowledge based on the three cognitive domains: Knowing, Applying, and Reasoning. The TCKS survey consisted of 33 multiple-choice items addressing main objectives of lower secondary mathematics curriculum: Number, Algebra, Geometry, Data and Chance. The instrument was piloted for construct and content validity as well as checked for the reliability. The alpha coefficient technique was utilized to evaluate the reliability of the teacher content knowledge survey. "The value of the coefficient of .839 suggests that the items comprising the TCKS are internally consistent" (Tchoshanov, 2011, p. 148). Examples of the TCKS items in Algebra domain across different cognitive types (Knowing, Applying, and Reasoning) are presented below.

**Figure 1. Diagram to the TCKS item in Algebra domain**

Use the diagram above (see Figure 1) to answer the questions that follow.

#### 1. Knowing

Which of the following equations best describes the function  $y_3$ ?

- A.  $y = ax^2 + bx + c$
- B.  $y = ax^2 + bx + 1$
- C.  $y = ax^2 + 1$
- D.  $y = x^2 + 1.$

#### 2. Applying

The function  $y_3$  is translated 4 units left and 7 units down. Which of the following equations best describes the new function?

- A.  $y = ax^2 + 11x + 28$
- B.  $y = ax^2 + 4x + 7$
- C.  $y = ax^2 + 8ax + c$
- D.  $y = x^2 + 28x + 11.$

### 3. Reasoning

The diagram shows a family of functions in the form  $y = ax^2 + bx + c$ . Which of the following statements best describes the changes in the values of the coefficients as the graphs transform from  $y_1$ , to  $y_2$ , to  $y_3$ ?

- A.  $a$  is increasing,  $b = 0$ , and  $c$  is increasing
- B.  $a$  is increasing,  $b = 0$ , and  $c$  is decreasing
- C.  $a$  is decreasing,  $b$  is increasing, and  $c = 0$
- D.  $a$  is decreasing,  $b$  is decreasing, and  $c = 0$ .

### Data Collection and analysis

Each teacher was given 90 min to complete the survey. In correspondence with the research question, data analysis was performed using non-parametric techniques (chi-square). This statistic was selected to measure the variance between independent groups of the same (not normal) distribution with arbitrary sample sizes of each group. The selection of this test was also based on the ranked nature of data for content and cognitive domains of teacher knowledge and student performance.

### Results

In this section, we first analyze teacher knowledge data by content domain, then we examine teacher data by cognitive domain, and finally we discuss parallels between student and teacher performance within and between countries.

Content Domain	Mean	SE	SD	Conf. level (95%)
Number	623	20.3129	205.1512	40.296
Algebra	563	23.2356	234.6679	46.093
Geometry	514	25.4349	256.8802	50.456
Data and Chance	593	20.9738	211.8252	41.606

**Table 1. US teachers' means scores by content domain**

The results reported on teacher content knowledge show that the US teachers' highest mean score was obtained on Number domain – 623 and lowest on Geometry domain - 514 (see Table 1).

Russian teachers' highest mean score was obtained on Algebra domain – 728 and lowest on Data and Chance domain – 387 (see Table 2).

Content Domain	Mean	SE	SD	Conf. Level (95%)
Number	656	106.5819	319.7456	23.873
Algebra	728	82.8841	248.6523	30.648
Geometry	586	72.7004	218.1013	45.505
Data and Chance	387	125.0891	306.4044	35.844

**Table 2. Russian teachers' means scores by content domain**

Moreover, we found that in the cognitive domain the US teachers' highest mean score was obtained, as expected, on Knowing – 734 and lowest on Reasoning - 495 (see Table 3).

Cognitive Domain	Mean	SE	SD	Conf. level (95%)
Knowing	734	19.7673	197.6733	39.2226
Applying	505	20.7101	207.1015	41.0934
Reasoning	495	23.8130	238.1303	47.2502

**Table 3. US teachers' means scores by cognitive domain**

Russian teachers' highest mean score was obtained, as expected, on Knowing domain – 760 and lowest, unexpectedly, on Applying domain - 504 (see Table 4).

Cognitive Domain	Mean	SE	SD	Conf. level (95%)
Knowing	760	14.2486	135.1745	28.3117
Applying	504	12.7961	121.3950	25.4257
Reasoning	593	17.7406	168.3028	35.2503

**Table 4. Russian teachers' means scores by cognitive domain**

Moreover, we identified that there is no significant difference between Russian and US teachers' knowledge on Number and Geometry domains (Chi-square 0.347  $p > .05$  and Chi-square 1.293  $p > .05$ ) (see Table 5).

Content Domain	Number	Algebra	Geometry	Data and Chance
Russia	656	728	586	387
USA	623	563	514	593
Chi-square (df=1)	0.347	6.311*	1.293	8.003**

**Table 5. Russian and US teachers' knowledge by content domain (\*  $p < .05$ , \*\* $p < .01$ )**

However, there is a statistically significant difference between Russian and US teachers' knowledge on Algebra domain (in favor of Russian teachers; Chi-square 6.311  $p < .05$ ) and Data and Chance domain (in favor of US teachers; Chi-square 8.003  $p < .05$ ) (see Table 5). This finding closely parallels the US and Russian students' performance on TIMSS on Algebra domain (in favor of Russian students) and Data and Chance domain (in favor of US students).

Also, this study reported that there is no significant difference between Russian and US teachers' knowledge on Knowing and Applying cognitive domains (Chi-square 1.707  $p > .05$  and Chi-square 0.008  $p > .05$ ) whereas there is a statistically significant difference on Reasoning domain (in favor of Russian teachers; Chi-square 19.117  $p < .05$ ) (see Table 6).

Cognitive Domain	Knowing	Applying	Reasoning
Russia	760	504	593
USA	734	505	495
Chi-square (df=1)	1.707	0.008	19.117**

**Table 6. Russian and US teachers' knowledge by cognitive domain (\*  $p < .05$ , \*\* $p < .01$ )**

This finding parallels the US and Russian students' performance on TIMSS' cognitive domain.

## Discussion and conclusion

This study confirms the differences between Russian and the U.S. lower secondary in-service teachers' knowledge in the content domain as it was reported by the TEDS-M study that was focused on pre-service teachers (Tatto & Senk, 2011). At the same time, this study expands the examination of in-service teachers' knowledge to the cognitive domain.

Teacher preparation could be considered as the main factor contributing to the differences between Russian and US teachers' knowledge. Overall, there is a tangible difference in secondary teacher preparation curriculum between the two countries: in average, Russia offers about 240 credit hours in teacher preparation programs compare to 120 credits in the USA. Furthermore, cross-national curriculum analysis shows that Russian lower secondary mathematics teachers have more extensive content preparation compare to their American counterparts. A number of contact hours for mathematical content knowledge, as well as pedagogical content knowledge and specialized mathematics knowledge offered at selected teacher preparation programs (e.g., the University of Texas at El Paso, USA and Kazan Federal University, Russia) in two countries, are presented in table 7.

Country	Mathematics Content Knowledge	Pedagogical Content Knowledge	Specialized Mathematics Knowledge
Russia	1857	278	380
United States	442	72	87

**Table 7. Contact hours in Mathematics related disciplines in teacher education programs in Russia and United States**

Numbers depicted in the table are compatible with the findings of the TEDS-M study (Tatto & Senk, 2011). Close examination of secondary teacher preparation curriculum in Russia shows that more emphasis is placed on an analytic and algebraic component of mathematics curriculum and less emphasis - on statistic and probability component compare to the US curriculum. Moreover, item analysis of standardized tests for the lower secondary schools in USA and Russia revealed the difference in selection and composition of algebra problems as well as problems related to data and chance in the test: while in Russia more emphasis is placed on algebraic problems and less emphasis on data and chance problems, in the USA – the emphasis is equally distributed among algebraic problems and data and chance problems. We observed another noticeable difference in the role of

proof in the academic mathematics component of the teacher preparation program which could explain the difference in the reasoning domain of the teacher knowledge: Russian curriculum places a heavy emphasis on proof across the mathematics coursework including school mathematics whereas the US curriculum uses proof in selected mathematics courses primarily in academic mathematics coursework.

We are cognizant of the limitations concerning the convenient sampling technique that influences generalizability of the study results. Moreover, there is no cluster matching between teachers participating in the study and students tested in TIMSS. However, the study main results suggest that student performance on international tests could be explained by teacher knowledge. The study also presents opportunities for comparing, sharing, and learning about issues in cross-national context in US and Russian teacher education, training, and development. Moreover, the reported cross-national study on teacher knowledge may inform the field on priorities placed on lower secondary mathematics teachers' knowledge in USA and Russia by content and cognitive domains.

# Explanations as tools for evaluating content knowledge for teaching: A cross-national pilot study in Cyprus and Greece

Constantinos Xenofontos<sup>1</sup> and Paul Andrews<sup>2</sup>

<sup>1</sup>University of Nicosia, Cyprus; [xenofontos.c@unic.ac.cy](mailto:xenofontos.c@unic.ac.cy)

<sup>2</sup>Stockholm University, Sweden; [paul.andrews@mnd.su.se](mailto:paul.andrews@mnd.su.se)

*In this paper, as a proxy for their mathematical knowledge for teaching, we examine Greek-Cypriot (n=21) and Greek (n=12) first-year undergraduate teacher education students' written explanations regarding a linear equations-related scenario. Qualitative analyses identified four broad themes permeating most accounts, irrespective of nationality, which were interpretable as either disciplinary explanations or instructional explanations. The themes concerned (a) definition of unknowns, (b) inverse operations, (c) presentation of objectives, and (d) rote procedure. The analyses indicated the weakness of students' explanation, whether from a disciplinary or an instructional perspective, which was independent of their country of origin.*

*Keywords: Mathematical knowledge for teaching, instructional explanations, disciplinary explanations, prospective teachers.*

## Introduction

The question regarding what kind of knowledge is needed to teach mathematics has preoccupied a number of scholars, while, at the same time, the association of mathematics teacher knowledge with instructional quality and student learning is considered to be complex (Charalambous & Pitta-Pantazi, 2016). Over the last years, several conceptualizations of this kind of knowledge have been proposed. Drawing upon Shulman's (1986) seven tentative categories for teacher knowledge, Ball, Thames, and Phelps (2008), for instance, developed the *mathematics knowledge for teaching* framework, which divides *subject matter knowledge* and *pedagogical content knowledge* into three further sub-categories each. From a different perspective, grounded in data-driven analyses of video-taped lessons by prospective elementary teachers, Rowland, Huckstep, and Thwaites (2005) proposed the *knowledge quartet*, a framework comprising four units, namely, foundation, transformation, connection, and contingency. These units, the authors claim, can be found in every mathematics lesson and can be used for evaluating teacher knowledge during the course of teaching. More recently, Davis and Renert (2013) have written on *profound understanding of emergent mathematics*, arguing that teachers' knowledge could be productively interpreted as a complex evolving form which is tacit and is better understood as a learnable disposition than a domain to be mastered.

Several of scholars (i.e. Copur-Gencturk & Lubienski, 2013; Phelps & Howell, 2016; Hill, Schilling, & Ball, 2004) have urged for the development of effective measures of the knowledge required for teaching mathematics. Various approaches to this task have been undertaken (Charalambous & Pitta-Pantazi, 2016), including, paper-and-pencil tests, the use of lesson videos inviting teachers to critique and/or predict, as well as inviting post-instruction reflections on both lesson plans and the actual realization of the plan. Adaptations of such approaches, however, should be carried out with careful sensitivity to the cultural context, as teacher knowledge, of both in-service (Andrews & Sayers, 2012) and pre-service teachers (Xenofontos, 2014), is conditioned by

cultural expectations with respect to what mathematics is valued and how it is presented. For example, Andrews (2003) has highlighted how some cultures construe competent mathematics teachers as those who ensure their students complete a large number of tasks every lesson, while others see competence in the completion of a few.

An important element of a teacher's didactical repertoire is the explanation. Explanations, which typically draw on students' prior knowledge (Leinhardt & Steele 2005), are manifestations of teachers' depth of content knowledge (Inoue, 2009). Of Leinhardt's (2001) four classifications of explanation, two are particularly relevant here; disciplinary explanations are domain specific and conform to the epistemological expectations of the relevant discourse, and instructional explanations, which are intended to teach some aspect of a particular subject matter to others, are "jointly built through a coherent discourse surrounding a task or text that involves the whole class and the teacher working together" (Leinhardt, 2001, 340). Therefore, in accordance with prior research that explanations may be a useful tool for measuring prospective teachers' knowledge (see, for example, Charalambous, Hill, & Ball, 2011; Inoue, 2009), we present the results of a pilot study focused on the use of a single task as a means of evaluating Greek and Cypriot beginning teachers' didactically-related mathematical understanding. The extent to which we consider our tool as effective is discussed in another paper of this TWG (see Andrews & Xenofontos, 2017). Here, we focus on the identification of similarities and/or differences between the two cohorts' written explanations, which, we believe could offer better insights into the mathematical knowledge beginner teachers bring to teacher education and how we, as teacher educators, could build on or deconstruct this knowledge.

## The study

Participants were first-year undergraduate students reading for a degree in elementary education at a private university in Cyprus. With Greek being the language of instruction, the programme includes both Greek-Cypriot and Greek students. Data collection took place before students had experienced any university instruction and involved 21 Greek-Cypriot and 12 Greek students. Students were shown, with no additional text, the solution to the equation presented below, and asked to write a short account indicating how they would explain it to someone who had missed the lesson in which it had been taught. Such a task has the advantage that it allows for both disciplinary and instructional explanations (Leinhardt, 2001).

$$x + 5 = 4x - 1$$

$$5 = 3x - 1$$

$$6 = 3x$$

$$2 = x$$

Data were analysed as single set by means of a *constant comparison process* (Fram, 2013). These analyses, as reported in Andrews and Xenofontos (2017, TWG11), yielded seven themes with respect to how participants explained the solution. Of these seven, four themes were present in most accounts and are here considered in depth. In the following, we present the results of this process, discussing each theme in relation to first the Cypriot and then the Greek students. All names are pseudonyms.

## Results

### Definition of unknowns

A number of Cypriot students wrote statements interpreted as explicit definitions of the unknown. For example, Ekaterini wrote that the “known numbers are the ones that don’t include a letter, as for example, 5 and -1. Unknown numbers are the letters or the numbers that are accompanied by a letter, for example,  $4x$  and  $x$ ”. In similar vein, Carissa wrote, “I separated the known from the unknown numbers: Unknown  $x + 5$  (known) = unknown  $4x - 1$  (known)”. Both comments, we argue, are structurally equivalent in their assertions that unknowns are represented by letters and the knowns by numbers. Other students’ definitions tended to the implicit. For example, Hermione wrote that “the first thing to do is to separate  $x$  from the numbers. In other words, to set apart the known from the unknown so that we can find what  $x$  is”. Likewise, Alexandra commented that their teacher had given “two expressions, each with an unknown ( $x$ ) and which are equal to each other. She asked us to find out what the value of  $x$  is”. While neither student explained explicitly what they meant by the unknown, their comments present a tacit understanding of the unknown as the number represented by the letter  $x$  that has to be found.

In ways similar to their Cypriot colleagues, Greek students offered either explicit or implicit definitions of the unknown. With respect to the former, Nina wrote that “we separate the known from the unknown numbers: known: 5, -1 and unknown:  $x$ ,  $4x$ ”, while, in a slightly more fluid manner, Paraskevi commented that “I separate the known from the unknown. The known numbers are all numbers, unknown is whatever is a letter, for example,  $x$ ,  $y$ ,  $z$ ,  $w$ ”. Students explicitly distinguished between  $x$ , as a representation of the missing number, and numerical values separated from the unknowns. With respect to the latter, Callisto, having written of the need to separate knowns from unknowns, wrote that “all the ‘ $x$ ’ are taken to the right and whenever ‘ $x$ ’ is on the left part of the equation, you change the sign. On the left part, the known numbers enter while the unknown enter the right”. Similarly, Daphne commented that “the first unknown  $x$  is moved to the second part of the equation but instead of a plus we make it a minus”. In both cases, students offer instructions in which the  $x$  terms are afforded a treatment that distinguishes them from numerical terms in ways that indicate their understanding of the nature of the unknown and its significance in the equation solving process.

### Presentation of objectives

The accounts of almost all Cypriot students included some statement regarding the objectives of equation solving. In most cases this was implicit and typically represented in statements concerning the separation of knowns from unknowns. The briefest such statements were as in Carissa’s “I separated the known from the unknown numbers” and Ioanna’s “we set apart the known and unknown numbers”. In such statements can be seen an understanding that the identification of the unknown was the objective. Even when such students wrote longer statements, the message was the same, as in Chloe’s “we separated known and unknown numbers, that is, 5 and 1 and  $4x$  and  $x$ ”. Here, the distinction between Chloe’s and the other two students’ statements is that she incorporated an implicit definition of the unknown, but offered no more than them with respect to her objectives. Other Cypriot students offered accounts with a slightly less implicit objective in that they also discussed the separating of the knowns from the unknowns but in so doing explicitly mentioned the

role of  $x$ , which Chloe did not. For example, Medea wrote that the “first step is to set apart the known and the unknown numbers, that is, to bring ‘ $x$ ’ to one side and the numbers to the other”, while Stamatia commented that “we separated the known from the unknown numbers, that is, the ‘ $x$ ’ and the ‘simple’ numbers.

Four students wrote statements indicative of an explicit objective. Two of these were brief, as in Stefania’s “the aim is to find which number equals  $x$ ” and Irene’s “the question in this equation is to find ‘ $x$ ’ and what value it has”. The other two students wrote longer statements, as with Hermione’s “the first thing to do is to separate  $x$  from the numbers. In other words, to set apart the known from the unknown so that we can find what  $x$  is”. In all three statements, albeit expressed differently, can be seen an expression concerning the identification of the unknown,  $x$ . Finally, of the four students who offered an explicit objective, Alexandra’s statement also offered the only evidence of a relational understanding of the equals sign. She wrote that “the teacher gave us two expressions, each with an unknown ( $x$ ) and which are equal to each other. She asked us to find out what the value of  $x$  is”.

For the Greek students, the same three categories of response were identified. For example, with respect to implicit goals embedded in statements about separating the knowns from the unknowns, Pantelis wrote that “we part the known from unknown numbers”, while Moira wrote that “I would tell the student that we separate the known from the unknown numbers and then make the calculations”. As far as the second category is concerned, whereby students offered implicit objectives alongside an explicit mention of the role of  $x$ , Callisto commented that “we separate the known from the unknown numbers. For assistance, you can underline the ‘ $x$ ’ from the numbers”, while Paraskevi wrote that “I separate the known from the unknown. The known numbers are all numbers, unknown is whatever is a letter, for example,  $x$ ,  $y$ ,  $x$ ,  $w$ ”. Finally, one Greek student offered an explicit objective. In this respect Panorea wrote that she “would explain to the student that it’s an equation whereby we are trying to find the unknown  $x$ . The data we have are the numbers. After, I would explain how to find  $x$ ”.

### **Rote procedure**

Few Cypriot students did not offer a rote rule for solving the equation and of those that did all alluded, either explicitly or implicitly, to the redistributive ‘change the side and change the sign’. With respect to those who discussed the rule explicitly, one of the more detailed accounts was offered by Irene, who wrote that

Whatever moves to the other side changes ‘sign’. The ‘sign’ is (+) or (-). We have  $x + 5 = 4x - 1$  and want to separate ‘ $x$ ’ from the numbers, so we have to say  $5 = 3x - 1$ . Why?  $1x$  went to the right part and changed signs becoming  $-1x$  (since  $x$  is now  $1x$ ) therefore  $4x - 1x = 3x$  ( $4 - 1 = 3$ ). ‘ $x$ ’ in common. Now we have to justify  $6 = 3x$ . We have  $5 = 3x - 1$ . Since  $(-1)$  is a number, it must shift to the left part of the equation and become plus, that is  $5+1=6$ . (It was  $-1$  and since crossing over the  $=$  it becomes plus). So  $6 = 3x$ .

These, and other, students seemed both confident and clear as to the process involved in solving the equation. They offered rules whereby objects were moved from one side of the equals sign to the other along with a change of sign. Of course, the direction of such movement was determined by the solution presented to them but in no case did students offer any justification for the changing of the

sign. Interestingly, and unique among students, Elina offered a no less unwarranted but general account. She wrote that

At first we get an equation with letters and numbers. The first thing to do is to move all numbers to one side and all letters on the other. If a number has a minus (-) sign or plus (+) once they are moved to the other side their sign changes; in other words, from minus (-) it becomes plus (+). That's how we deal with similar calculations.

Several Cypriot students offered accounts, typically short, in which the movement and the changing of signs were implicit. For example, Hermione wrote that “[a]s you can see  $x$  and  $4x$  have been joined and the same is true of 5 and 1. Therefore,  $x$  has become  $3x$  and then  $5 + 1$  is 6”. In these, and other, cases neither the movement across the equals sign nor the changing of the sign were made explicit. Our interpretation is that students were familiar with the process and saw such properties as givens rather than something in need of either explanation or warrant.

As with their Cypriot colleagues, Greek students typically offered a ‘change the side change the sign’ rule. Also, as before, the extent to which this was presented explicitly varied. For example, with respect to an explicit account, Daphne wrote that

Since we have two unknowns on both parts of the equation, the first unknown  $x$  is moved to the second part of the equation but instead of a plus we make it a minus. Then we subtract it from  $4x$  to get  $3x$ . After getting -5 in the second part, we move it to the first, therefore 1 is not a minus but plus. Then we add 5 and 1 to get 6.

In their accounts can be seen an understanding of the ‘change the side change the sign’ rule for solving equations. In neither case, however, can be seen evidence of a relational understanding of the equals sign as would be represented in statements justifying the described actions. There was no sense, for example, that students saw these actions as a consequence of adding or subtracting equivalent amounts from each side. In addition, as with the Cypriot students, one student offered a generalised account of the same process. In this respect, Callisto wrote that “[a]ll the ‘ $x$ ’ are taken to the right and whenever ‘ $x$ ’ is on the left part of the equation, you change the sign. On the left part, the known numbers enter while the unknown enter the right. Afterwards, we add the known to the known and the unknown with the unknown”.

However, the majority of Greek students offered implicit summaries of the solution with which they had been presented. Typical of others, Panorea wrote that she would “shift the given numbers to one side and the unknown,  $x$  (or  $3x$ ) on the other side (e.g.,  $3x$ ) and that way I would find the unknown  $x$ ”. Similarly, Paraskevi wrote that “[a]t this stage, we carefully observe when to change (+) or (-). When they move from the 1<sup>st</sup> part to the 2<sup>nd</sup>, the sign changes from let's say (+) to (-) and vice versa. Once we reach this point  $6=3x$ ”. In such statements can be seen different but equally incomplete accounts of the rote rule. For example, Panoreas's account highlighted the bringing together of the knowns and unknowns respectively, leaving the reader to infer the changing of the sign, while Paraskevi's emphasised the changing of the signs at the expense of her detailing the changing of the sides of like objects. In other words, both left significant elements for their readers to infer.

## The inverse operation

In almost all cases, having articulated some sense of a rote rule, students from both countries invoked an operation reversal to explain the final line of the solution, whereby  $6 = 3x$  became  $2 = x$ . In this respect, eleven of the 21 Cypriot students offered, albeit implicitly, an understanding of the inverse operation necessary to transform the line  $6 = 3x$  to  $2 = x$ . Typical of these were the comments of Chloe, who wrote that “after reaching  $6 = 3x$ , we divided 6 by 3 so that  $x$  will be by itself. I found  $x$  to be 2” and Hermione, who wrote “then I divide 6 by 3 and  $x$  is equal to 2”. Of these eleven students, two students offered more extended but no less implicit suggestions, as in Stamatia’s comment that “we take number 6 and equate it ‘=’ with  $3x$ . Then we divide 6 by 3, i.e.  $6/3$  equal to  $x$ 1, “ $6/3 = x$ .  $6/3$  makes 2 and so  $x$ 1 is equal to 2, ‘ $x = 2$ ’ ”. In these cases, students’ comments about dividing by three seemed to us to reflect, at least implicitly, a recognition of the structural significance of the unknown’s coefficient that necessitated division.

A further seven students offered accounts indicative of a better developed understanding of the role of the coefficient and its function with respect to inverse operations. For some this could be seen in the ways they reiterated earlier comments about isolating the unknown. This was seen in, for example, the writing of Perikles, who added that “arriving at  $6 = 3x$  I divided  $3x$  by 3 to get  $x$  alone, and 6 on the other side with the 3 before the unknown. So the answer is  $x = 2$ . Others in this group were more explicitly aware of the coefficient and its significance, as in Medea’s comments that “once the basic calculation was made, we divide both parts by the unknown’s coefficient and then get the result” or Vassiliki’s “I take the number in front of the  $x$  and divide both sides of the equation by it”. In such comments, focused on the coefficient of the unknown, can be seen.

The Greek students’ comments could be categorised similarly, although a smaller proportion, three of the eleven, offered entirely implicit statements. Of these, typical was Crino’s “we have reached  $6 = 3x$  and consequently, we divide 6 by 3 to get the result”. Seven students, also a higher proportion than with the Cypriot cohort, presented accounts with an explicit reference to the coefficient, as with Ivy’s comment that he (the invisible teacher) “divided by the coefficient of the unknown 3 to get  $2 = x$ ” and Paraskevi’s note that “once we reach this point  $6 = 3x$ , I must divide by the coefficient of the unknown to see what the value of  $x$  is, that is to say, to divide both the 1<sup>st</sup> part and the 2<sup>nd</sup> by 3”.

Interestingly, two of these seven students offered accounts, albeit whose intentions were clear, that employed an incorrect vocabulary, as with Daphne’s “finally, we divide 3 by the fraction” or Nikoleta’s “we divide it by the denominator of  $x$ , namely, 3 and we arrive at the final result that  $2 = x$ ”. In such cases students’ intended meaning was clear.

## Discussion

Our analyses provide substantial insights, both encouraging and discouraging, into the conceptualisation of mathematics these beginning teachers bring to their teacher education programme. In this respect, both sets of students appeared procedurally competent, recognising the equation for what it is and typically understanding how it had been solved. However, from a disciplinary perspective (Leinhardt, 2001), students’ explanations showed very little awareness of the epistemological underpinning of mathematical knowledge, almost without exception warranting their chosen procedures on the basis of their personal authority as teachers. Moreover, from the perspective of research on the solving of equations, students indicated no relational understanding

of the equals sign, a prerequisite for learners confident solving of equations of the form above with the unknown on both sides (Alibali et al., 2007; Filloy & Rojano, 1989). From an instructional perspective (Leinhardt, 2001), students' explanations typically alluded to a presentation of objectives and the importance of the unknown and its role in equation solving. However, the presentation of such a rule would typically allow little opportunity for learners to understand the reasoning behind it. Interestingly, although their rote rules never alluded to operations performed on both sides, many students were aware of inverse operations in relation to the unknown's coefficient. In sum, and drawing on Skemp's (1976) distinctions, our data showed that both Cypriot and Greek students were locked into an instrumental rather than relational understanding of mathematics, perspectives which their respective curricular traditions would not have encouraged. Finally, when framed against the mathematical knowledge for teaching literature, it seems that at this stage of their careers both sets of students showed evidence of Rowland et al.'s (2005) foundation knowledge, albeit problematic, but, as yet, none of transformation, connection or contingency. Moreover, if the goal of teacher education is to facilitate beginning teachers' profound understanding of emergent mathematics (Davis & Renert, 2013) then much is still to be done.

## Research on mathematical literacy in schools - Aim, approach and attention

Frode Olav Haara<sup>1</sup>, Oda Heidi Bolstad<sup>1</sup> and Eirik S. Jenssen<sup>1</sup>

<sup>1</sup>Western Norway University of Applied Sciences, Faculty of Teacher Education and Sports,  
Sogndal, Norway;

[frode.olav.haara@hvl.no](mailto:frode.olav.haara@hvl.no), [oda.heidi.bolstad@hvl.no](mailto:oda.heidi.bolstad@hvl.no), [eirik.jenssen@hvl.no](mailto:eirik.jenssen@hvl.no)

*Keywords: Mathematical literacy, review, empirical research.*

Research in mathematical literacy has different emphases; whether the teaching and learning of mathematical literacy or the synthesis of results from worldwide studies that emphasises mathematical literacy (e.g. the PISA 2003 studies) to focus on the curricular implications. However, a comprehensive review of the current empirical research on the area is missing. The poster presentation focuses on what research brings attention to in empirical studies where mathematical literacy is highlighted. These are both quantitative and qualitative based projects, and include for instance articles with data collection where mathematical literacy is emphasised in the development of tools for the data collection or in what is being measured, and articles focusing more on teachers' implementation of mathematical literacy in teaching and learning. The poster also focuses on what research finds to be implications for teaching and future research on mathematical literacy.

The poster is based on our work on a review article, submitted to an international journal, that aims to address the research on mathematical literacy in primary and lower secondary school, by bringing together, comparing and synthesizing the diverse body of current research, emphasise implications for research on the area, and point to necessary areas for research to come. Through the poster we aim to inform about our review on research on mathematical literacy in school. The poster is used to present a systematic review of recent empirical studies through comparing, analysing, and discussing the body of articles in relation to the following key questions:

1. *What methodologies have been used to examine emphasis on mathematical literacy in primary and lower secondary school?*
2. *How is mathematical literacy conceptualised?*
3. *What is the focus of attention in research on mathematical literacy?*
4. *What are the implications for primary and lower secondary school teaching, and recommendations for future research on mathematical literacy?*

We have applied methods well-known for review articles that aim to identify a state of the art within a field of research on school related issues, and to make suggestions for further research within the area at hand (e.g., Beltman, Mansfield & Price, 2011). This counts for the identification of parameters for the review, search in data bases based on the identified parameters, and selection of publications to form the basis of the review and analysis. The body of articles for the review consists of 28 articles that fulfil the selection criteria used. The studies were conducted worldwide, but with a clear majority of European and Asian contributions.

Our findings show that the research is dominated by quantitative approaches, and do not focus on what goes on in the classroom. It focuses on the outcome of what goes on in school. The lack of identified attention to qualitative research on teaching for mathematical literacy seems to be due to four main reasons. The decision to apply existing data from PISA studies for more quantitative analyses on mathematical literacy related areas, application or even exploitation of the mathematical literacy concept in studies that are not directly focused on mathematical literacy, and tension between policy documents and practice in school on one hand, and tension between learning achievements and mathematical literacy on the other hand. This leads to lack of attention to best-practice projects. Hence, it seems that research in the future to a larger extent might report research based results on what schools and teachers ought to do in order to teach for mathematical literacy. Several of the articles use data from PISA test results, and are therefore obliged to acknowledge the prevailing OECD definition at the time of testing, because the attention to mathematical literacy in the PISA tests is based on this definition. In addition, some of the articles reviewed connect subject matter theories within mathematics education with the concept of mathematical literacy. A common factor for these articles is their interest regarding the teaching of mathematical literacy in school. Regarding implications for primary and lower secondary school teaching and further research on mathematical literacy, three main challenges were identified: both researchers and teachers are uncertain about how to develop students' mathematical literacy, specific attempts to work directly with mathematical literacy through mathematics alone have not been successful, and teaching for mathematical literacy appears to require non-traditional methods for teaching mathematics.

Furthermore, the subject of mathematical literacy is given extensive attention both at political and societal levels (OECD, 2009) and within mathematics education research. In fact, Sfard (2014, p. 141) urges the research community to address this issue: "The question of how to teach for mathematical literacy must be theoretically and empirically studied. When we consider the urgency of the issue, we should make sure that such research is given high priority." The approach to such a quest seems to be through increased emphasis on qualitative research, for instance, through studies of best-practice and research projects involving practising teachers. Therefore, the research community's attention needs to shift from nurturing data and findings that highlight student results on mathematical literacy tests to research on what to do in order to improve the students' opportunities to develop mathematical literacy. A starting point for such a shift in focus could be to examine how mathematical literacy is understood, facilitated and experienced in schools.

### STEAM

STEM (Science, Technology, Engineering and Mathematics) is an educational approach based on the interdisciplinarity and applicability of scientific and mathematical knowledge to technology and engineering. STEAM integrates Art into STEM in order to promote children's creativity (Fenyvesi, Téglási and Szilágyi, 2014). In many European countries, the number of graduates in science, maths, technology and engineering areas is clearly insufficient for the needs of their companies and industries. To stimulate students' interest in these areas and art, the European Union has dedicated a lot of resources and effort, developing a large number of projects for pre-university classrooms. For a review, see Rocard, Csermely, Walberg-Henriksson and Hemmo (2007).

### KIKS project

KIKS, Kids Inspiring Kids for STEAM is a European Erasmus+ Project, which involves four European institutions: Metropolitan University of Budapest (Hungary), STEM Team East (Cambridge, United Kingdom), University of Jyväskylä (Finland) and University of Cantabria (Spain). The project started in March 2016 and its main aim is to promote secondary education students' interest on the STEAM areas, by developing activities and presenting them to other students locally and internationally. Many students and teachers do not enjoy or have confidence in maths and STEM: they have anxiety even maths/technophobia and drop it as soon as they can. So we seek to promote the creativity and motivation for learning of these less confident students, working interdisciplinary, using technology, and fostering communication and the transfer of ideas/knowledge across cultures. From a research point of view, KIKS aims to compare cross-culturally the elaboration and resolution of STEAM activities at secondary education level.

### Development of activities

Students, in teams of fives and led by at least one teacher, are asked to elaborate STEAM activities or projects under the following approach: How would you get your schoolmate to love Maths? The activities or projects can emerge from a teacher, a pupil, or a KIKS coordinator's idea. Once the idea emerges, it is developed into an activity or project. It should involve different STEAM areas, but its duration and degree of difficulty can vary according to teams' availability. Once an activity is elaborated, the team presents it to their local homologous (in face to face events) and to their international homologous (through video conferences). Schools from different countries are invited

to participate in the project, at the moment we have more than 25 participant schools from different countries and backgrounds.

### **Products to be developed by the students**

Each participant team has to elaborate a written document, an explanatory video, and a presentation of its work. (1) The written document (Word Doc or Power Point) has to include a presentation of the team members, and a description of the activity with the main results and the material used. (2) The edition of the video has to include the practical or technical aspects of activity, which are difficult to explain on paper. For example, the manipulative construction of objects, the use of measurement tools, etc. All the products have to be developed in the English language. The limited scope of this paper does not allow us to include here examples of the activities already developed by our teams, but they can be found at our website (<http://www.kiks.unican.es/en/actividades/>).

### **KIKS support**

KIKS provides support to the teams through different platforms including Goggle Drive, YouTube, Facebook and a Website ([www.kiks.unican.es](http://www.kiks.unican.es)). The Google Drive and Facebook platforms function as storages of information— where teachers and coordinators can exchange ideas— as well as repositories of documents elaborated by the teams. The YouTube Canal works as repository of videos, and the Website provides different and meaningful information about the ongoing process of the project. Apart from the above, KIKS provides support to the teams proposing activities, helping in aspects related to the English language, and furnishing technical support for video edition, online connections, etc.

### **Evaluation**

Parallel to practical work of the project, we are undertaken a research study aiming to evaluate the strengths and weakness of KIKS. Firstly, this research aims to assess cross-culturally teachers' and students' perceptions about STEAM. Secondly, we aim to characterise the STEAM activities elaborated by the teams, according to the cognitive (competences, capacities, skills) and motivational (attitudes, emotions) dimensions they may develop in the learners. In short we seek to evaluate the impact of STEAM activities in the learning process. Tools for evaluating these two dimensions are currently under construction.

# The teaching and learning of relations and functions: A comparative study of Norwegian and Ethiopian textbooks

Solomon A. Tesfamicael and Geir H. Botten and Øyvind A. Lundebby

Faculty of Teacher and Interpreter Education (FLT), Norwegian University of Science and Technology (NTNU), Norway; [Solomon.a.tesfamicael@ntnu.no](mailto:Solomon.a.tesfamicael@ntnu.no); [geir.h.botten@ntnu.no](mailto:geir.h.botten@ntnu.no)  
[Øyvind.a.lundebby@ntnu.no](mailto:Øyvind.a.lundebby@ntnu.no)

*Keywords: Relations, functions, textbooks, comparative studies.*

## Introduction

Comparative studies in mathematics include studies that document, analyze, contrast or juxtapose similarities and differences across all aspects and levels of mathematics education (Jablonka and Andrews, 2012). In this project, which is in an early phase, we intend to carry out such a study at the cross-national level. The rationale behind it is to identify similarities and differences between mathematics education in Norway and Ethiopia, to reflect on their practices in the light of international wisdom (Clarke, 2003), and to lay down grounds for further intervention studies, for example for the Norwegian NORHED project that will start in 2017. (<https://www.norad.no/en/front/funding/norhed/news/>).

We have started comparing textbooks, since textbooks are the main resources used in mathematics classrooms (Pepin, 2010) in many countries including Ethiopia and Norway. Textbooks are tools, or instruments, that facilitate the daily work of teachers. They also contribute to the field of mathematics by preserving and transmitting skills and knowledge (Rezat, 2008a). In general, Mathematics is a subject that has long been associated with textbooks and curriculum materials (Remillard, 2005). Therefore, it is important to look at textbooks as a source of comparison.

At this stage, emphasis is given to the teaching and learning of relations and functions as presented in the textbooks, partly due to students' difficulties with learning these topics (Denbel, 2015). As teacher educators working with students preparing to work in primary and middle school in Norway, we have also observed that many student teachers struggle to grasp these concepts and hence to teach them.

## Method

In this study we selected six textbooks in Norway and the one textbook from Ethiopia from lower secondary level which covers the concepts of relation and function. At this early phase of the study, definitions, examples, representations, exercises and problems, activities, group works, contexts and level of abstractions in the textbooks are being identified and compared.

## Findings

As mentioned above, the purpose of this poster is to communicate the beginning of our project, which will enable constructive sharing of knowledge and experience about the teaching and learning of mathematics between the two countries, and we hope with the international mathematics education community in the coming years. We report our findings to date as follows.

Among the selected textbooks, only two of them (one text from Norway and the textbook from Ethiopia) address the concept of relations directly by providing definitions, domain and range of relations and different representations, examples and exercises, without including the topic of function. The other Norwegian textbooks deal with the topic of function by taking for granted that students understand the concept of ‘relation’ in mathematics. Most of the books follow the teaching of functions by giving context-based definitions and examples, beginning with proportional relationships of variables, building to linear and then quadratic functions.

In The Ethiopian textbook (M9) the definitions of relations and functions are provided in terms of subsets of a Cartesian product of two sets. Examples and problems are consistently abstract and unrelated to any real context. In contrast, we find no single definition and representation in the respective Norwegian textbooks. In addition, the Norwegian textbooks include many real life related contexts that are accessible by the students, and they are full of different representations (graphs, symbols, words, tables and physical figures) for both concepts. With reference to this topic, the textbook M9 has a higher level of abstraction than its Norwegian counterpart. Symbolic and graphic representations are present in M9, but it is devoid of contexts and real life related examples and problems.

# TWG12: History in mathematics education

## **Introduction to the papers of TWG12:**

### **History in mathematics education**

Renaud Chorlay<sup>1</sup>; Kathy Clark<sup>2</sup>; Katalin Gosztonyi<sup>3</sup>; Snezana Lawrence<sup>4</sup>

<sup>1</sup>Uni. Paris Diderot & ESPE de l'Académie de Paris, France; [renaud.chorlay@espe-paris.fr](mailto:renaud.chorlay@espe-paris.fr)

<sup>2</sup>Florida State University, USA

<sup>3</sup>Eötvös Loránd University, Budapest, Hungary

<sup>4</sup>Anglia Ruskin University, UK

History of mathematics in mathematics education continues to receive much attention. However, empirical research and coherent theoretical/conceptual frameworks within this area have emerged relatively recently. The purpose of this TWG is to provide a forum to approach mathematics education in connection with history and epistemology dedicated primarily to theory and research on all aspects of the role, effect, and efficacy of history and epistemology as elements in mathematics education.

TWG12 welcomes both empirical and theoretical research papers, and poster proposals related to one or more of the following issues:

1. Design and/or assessment of teaching/learning materials using the history of mathematics, preferably with conclusions based on empirical data; all levels can be considered, from early-age mathematics to tertiary education and teacher training.
2. Surveys on the existing uses of history or epistemology in curricula, textbooks, and/or classrooms in primary, secondary, and tertiary levels;
3. History of mathematics education;
4. Relationships between, on the one hand frameworks for and empirical studies on history in mathematics education and, on the other hand, theories, frameworks and studies in other parts of mathematics education research.

Even though the creation of this TWG is fairly recent – it started in CERME6 (2009) – it has deeper institutional roots within the maths education research community. Indeed, the *HPM* study-group (*History and Pedagogy of Mathematics*) was created at the 1972 ICME conference; it has been organizing satellite conferences to the ICME meetings since 1984, and has several active regional branches (HPM-Americas, European Summer Universities). In CERME10, 16 papers and 2 posters were presented in TWG12, for a total of 23 participants affiliated to this group, covering a large range of European countries (from Ireland to Russia) and beyond (Brazil, Mexico, the U.S.). A short survey showed this TWG attracts newcomers to the CERME community from the HPM community, since 9 participants were CERME first-timers, yet only two had never attended any HPM-related event.

Before going into any details, it should be stressed that this TWG has four general but distinctive features which give these meetings their specific flavour. Firstly, its topic lies at the intersection of

different fields of research – maths education research and history of mathematics – which requires versatility and methodological vigilance (Fried, 2001; Chorlay & Hosson, 2016). Secondly, the strength of the historical and the HPM community varies greatly among countries, and these meetings play a crucial role for researchers working in relative isolation, and with difficult access to resources in the field. Thirdly, the scope of TWG covers both history *in* mathematics education and history *of* mathematics education, which are two significantly different research topics (TSG 24 and 25 in ICME13); connecting the two lines of investigations is a constant challenge. Fourthly, since the topic of TWG12 is neither specific to one level of the educational system (from primary education to teacher-training) nor to any single mathematical topic (be it fraction concepts, algebra, proof, etc.), the work in TWG12 intersects that of most other TWGs. This time, intersection with TWG1 (Proof and argumentation), TWG18 (Teacher education), and TWG22 (Resources and task design) was significant. It should be noted that, for this edition, there was little intersection with what was covered in TWG8 (Affects and mathematical thinking), TWG10 (Diversity and maths education), in spite of the fact that it is not uncommon for outsiders of the HPM research community – among which most policy-makers and curriculum-designers – to ascribe such goals to the historical perspective in teaching.

These four features made this meeting not only useful but also challenging and exciting. As the final discussion made clear, the general feeling among the participants was that one of the main outcomes of this meeting is that we actually *learned* a lot from the one another, both from their papers and from the lively discussions. Let us now highlight some of the significant feature of the 2017 conference.

For quite some time it has been stressed that more attention should be paid to the actual effects of the use of historical sources, either in the classroom or in teacher training (Chorlay, 2016; Jankvist, 2009). This year, at least two papers contributed to this line of research. For example, the *Transforming Instruction in Undergraduate Mathematics via Primary Historical Sources* (TRIUMPHS) project is a five-year project funded by the National Science Foundation in the United States, which will create and test 25 full-length Primary Source Projects (PSPs) and 30 one-day “mini-PSPs.” Each PSP is designed to cover its topic in about the same number of course days as mathematics classes would otherwise. With PSPs, rather than learning a set of ideas, definitions, and theorems from a modern textbook, students learn directly from the original work of mathematicians such as Leonhard Euler, Augustin-Louis Cauchy, or Georg Cantor. The project includes an extensive “research with evaluation” study, which will seek to address several evaluation and research questions and enable both formative and summative evaluation of the project activities. Data sources to inform the research are pre- and post-course surveys (of both students and instructors), post-PSP surveys, student interviews, student PSP work samples, video captures of selected classroom instruction and audio captures of selected small group student work, and instructor post-implementation reports. By the end of the project it is expected that some 50 instructors and over 1000 students will participate in undergraduate mathematics classrooms where PSPs are used.

On a smaller scale, Areti Panaoura studies the manifold difficulties faced by an “ordinary” teacher attempting to use a textbook activity on Egyptian multiplication. It raises many questions for our research community to investigate further: as to the level and nature – mathematical, didactical,

historical – of expertise required from the teacher; as to our (as researchers and teacher-trainers) criteria for assessing such teaching sessions; as to the relevant theoretical frameworks for the description and analysis of teacher-practice (in particular the use of pedagogical documents). Along with these questions, it shows the importance of leaving our comfort-zone, a zone in which the teaching sessions are implemented by the researcher who designed them or by teachers with a significant experience in the field.

As is customary in HPM-related meetings, a large number of papers carry out detailed content analysis. Let us restrict ourselves to those dealing with numbers and early-algebra: Antonio Oller-Marcén and Vicente Meavilla describe forms of argumentation about equations of the  $ax^n = bx^m$  type in a 16<sup>th</sup> century Spanish treatise, and endeavour to make sense of what we would consider to be errors or flaws; Chorlay studies arguments justifying the rule for fraction multiplication in a Chinese treatise from the Han dynasty and compares them with arguments found in today's textbooks; Maria Sanz and Bernardo Gómez devise a structural classification of sharing problems on the basis of a large historical sample, and complement this classification by showing the variety of methods – both arithmetic and algebraic – for solving them. Coming from a perspective of history of education, Rui Candeias discusses in details a pedagogical approach to operation on decimals, in a context which combines proportionality and magnitudes. Although this line of investigation may seem to be very content-oriented, its connections to didactical questions – be they theoretical or more applied – are manifold. First, it is hardly necessary to say that content-analysis is a central part of *a priori* analysis, and that – on a par with a purely mathematical analysis – investigations into the history of mathematical knowledge and mathematical practices provide key background data. Second, the work presented in some of papers is explicitly described as a first phase in a larger research project focusing either on learners (Sanz-Gómez) or teachers (Chorlay). Third, the content-analyses presented in these papers contribute to the general theoretical discussion on some important didactical concepts, such as “epistemological obstacle” (Oller-Marcén) or “generic example” (Chorlay).

As far as history of education is concerned, let us highlight the contribution of Katalin Gostonyi. Her comparative study of the works of mathematics educators T. Varga (in Hungary) and G. Brousseau (in France) shed light on the origins of theoretical frameworks which are still very much alive in mathematics education research.

Finally, the paper of Liz de Freitas contributes to the ongoing work in the HPM community from a new perspective. Being a philosopher of mathematics, she draws on both her personal research – in the continental tradition of the philosophy of mathematics and mathematical practice – and her experience in the training of maths teachers to suggest a large number of research questions which are relevant for the historian and the maths education researcher alike. Here, we briefly mention two such issues which we feel would be worth investigating further. A first series of questions bears on diagrams: the way they are drawn and read; their cognitive impact and their epistemological significance; the historical evolution of the meta-rules governing the use of diagrams, in themselves and in their relations to other elements of mathematical texts. A second series of questions bears on the image of mathematics maths teachers have, its impact on their teaching, and the way teacher-training modules may impact this image. Investigating this second series of questions could bridge the gap between the maths education community and the science education community, a

community in which research on the Nature of Science (NOS) is a central research topic (see for instance Abd-El-Khalick, 2013).

# Arithmetical problems in primary school: Ideas that circulated in São Paulo/Brazil in the end of the 19<sup>th</sup> century

Luciane de Fatima Bertini<sup>1</sup> and Andreia Fernandes de Souza<sup>2</sup>

<sup>1</sup>Universidade Federal de São Paulo, Brazil; [lfbertini@gmail.com](mailto:lfbertini@gmail.com)

<sup>2</sup>Universidade Federal de São Paulo, Brazil; [deianandes@hotmail.com](mailto:deianandes@hotmail.com)

*This article aims to analyze teaching programs, textbooks and journals of education in order to better understand the ideas that circulated in São Paulo, Brazil, at the end of the 19<sup>th</sup> century about the conceptualization and the utilization of problems for the teaching of mathematics in these documents. The research was conducted through a culture-historical approach (Chartier, 2002), which compels the researcher to have a questioning attitude towards the object of study. Thus, it was possible to observe that both the teaching program and the textbook valued the utilization of problems because both connect the concept of problem with activities presented through narratives in order for students to apply previous knowledge. On the other hand, the theme did not have the same value in the journal of education because it discussed that topic in only one article, which introduced the concept of problem as a synonym for a type of exercise related to calculations.*

*Keywords: Arithmetical problems, primary school, intuitive method.*

## Introduction

In the state of São Paulo, Brazil, the end of the 19<sup>th</sup> century was marked by events that would bring significant changes to primary school over the next decades and that would also be a reference for other states. In the last decade of that century the foundations of school organization – time, space and curriculum structuring - were established. In addition, *grupos escolares*, which represented the idea of a modern and quality urban school, began to be introduced in the state of São Paulo in 1893 (Souza, 2009).

Since that was a period whose proposals and determination impacted primary school nationwide over the next decades, research on the history of mathematics education has great interest in understanding the ideas that circulated in that period regarding the teaching of mathematics.

This paper aims to contribute to such understanding as it intends to analyze proposals for the utilization of problems in the teaching of mathematics by using textbooks<sup>1</sup>, journals of education<sup>2</sup> and teaching programs<sup>3</sup> from that period as sources.

---

<sup>1</sup> Choppin (2009) observed the existence of several expressions to name school books. Names vary according to context, use or style. In this paper the expression “textbooks” is used to name all publications written in order to be used in Brazilian primary school classrooms.

<sup>2</sup> Publications that compiled articles written by intellectuals and teachers on themes related to teaching.

<sup>3</sup> Publications that provided guidance on school organization, content and methodology.

Previous research done by the authors of this paper (Bertini, 2016a; Bertini, 2016b; Souza, 2016a; Souza, 2016b) shows the presence of arithmetical problems, or of proposals for their application, in several documents from different periods and with different goals. In this paper, the authors aim to conduct an analysis of these documents in order to better understand the ideas that circulated in São Paulo, Brazil, in the end of the 19<sup>th</sup> century about the use of problems for the teaching of arithmetic.

In this study, the definition of *problem* is not presented a priori because that term is understood in different ways according to the historical period in question. Thus, one of the objectives of this research work is to identify what concept of *problem* the documents contain.

## Methodological and theoretical framework

To develop the historical production in this study, all analyses took into account the historical moments and spaces in which the documents were produced as well as the interests involved in this production. Thus, we take a culture-historical approach as proposed by Chartier (2002), which not only encourages researchers to carry out descriptive work, but also compels them to raise questions about the documents studied in order to identify how a specific reality arises and establishes itself according to the place and time in which it emerges. According to De Certeau (2001, p. 35), a historian's work is more connected to finding *meaning* and *purpose* than to simply *narrating* facts.

From that perspective, the notion of *appropriation* is crucial for a significant historical production because it proposes the existence of creative invention in the process of reception (Chartier, 2002, p. 136). Teaching programs, textbooks and journals of education will be analyzed based on that notion because, although in different manners, they all *appropriated* the ideas and determinations that circulated about the utilization of problems to teach arithmetic. Besides, throughout the process of creative invention, the authors will work to understand which ideas and determinations are produced in the documents about this utilization.

Moreover, the notion of purpose, presented by Chervel (1990), will be harnessed once it is related to the options made for teaching. The historical study that involves the use of arithmetical problems in primary school will encompass the understanding of the purposes of their use. The authors will be guided by two questions when studying the documents: How were problems harnessed in these sources? Why were they suggested that way?

It is important to emphasize that, according to Valdemarin (2004), in the 19<sup>th</sup> century the Brazilian educational context was influenced by ideas which arose from the intuitive method. She sustains that proposals for school activities included presenting a variety of objects to the senses so that ideas would be formed as a result of a rational, concrete and active teaching style. Two ideas are presented as paramount in the proposals that followed the intuitive method: first, the notion that observation leads to reasoning; second, the belief that work prepares individuals for the future (Valdemarin, 2001).

The proposal for educational renewal opposed the abstract and little useful character that teaching had had so far and comprised a new teaching method (the intuitive method). It started to be introduced

in Europe, through Pestalozzi's<sup>4</sup> e Fröbel's<sup>5</sup> elaborations, and in the USA, where the work "Primary object lessons", by Calkins,<sup>6</sup> was first published, in 1861. Brazil was inserted in this refreshing effort in the 1880's, when the country began to adopt the new intuitive teaching method. That movement was influenced by foreign ideas but it was also an attempt to meet political demands in the country due to the end of the Empire (Valdemarin, 2001, p.159).

Dialogues with these productions on the History of Brazilian Education are considered necessary for harnessing the theoretical concepts here presented as an option for the construction of a historical narrative because it will contribute to the understanding of the context in which the documents were produced.

## Teaching programs, journals of education and textbooks

The first teaching program in the state of São Paulo, as determined in Decree 248 of July 26<sup>th</sup> 1894, provided school management guidance and teaching instructions such as school organization, materials, students' attendance, reports, disciplinary procedures, school-year calendar, curricular content and methodology. The Decree was signed by Bernardino de Campos and Cesário Motta Junior, who were respectively the President of the State of São Paulo and Secretary of the Interior.

Nevertheless, besides being determined by law, all those instructions needed to be spread among both active teachers and future teachers. In that sense, journals of education were presumably a tool to transmit models of work that would help teachers appropriate the new educational proposals. In the last decade of the 19<sup>th</sup> century, the *paulista* journal "A Eschola Pública" was sponsored by the government and its editorial staff was composed of teachers, principals and school inspectors.

In addition to teaching programs and journals of education, textbooks were another tool used to guide teachers' work because they presented proposals of activities to be done by students in the classroom, as well as proposals for school organization (ordering of contents, quantity and style of activities).

Finally, in this analysis we will articulate these different documents in order to generate understanding of the ideas that circulated in São Paulo, Brazil, in the end of the 19<sup>th</sup> century regarding the utilization of problems for the teaching of arithmetic.

- **The program of 1894**

Teaching programs are part of the norms that integrate school culture and help us understand it. However, we know that changes and innovations proposed by governments are the result of political disputes, which prevents them from happening naturally and passively (Souza, 2009, p.83- 84).

In the *paulista* program of 1894 there is guidance on choosing a methodology:

Article 9 – Lessons on subjects of any course year need be more empirical and concrete than theoretical and abstract, and should be conducted in order for children's faculties to be developed

---

<sup>4</sup> Johann Heinrich Pestalozzi (1746-1827), Swiss educator.

<sup>5</sup> Friedrich Wilhelm August Fröbel (1782-1852), German educator.

<sup>6</sup> Norman Alisson Calkins (1822-1885), American educator. This work was translated/adapted to Portuguese by Rui Barbosa in 1886.

in a gradual and harmonic manner. Article 10 – The teacher need aim, especially, to develop the faculty of observation by applying intuitive processes for this purpose. (São Paulo, 1894)

The expressions “lessons... more empirical and concrete” and “intuitive processes” remind us of the educational trend that was disseminated at that time, i.e., the intuitive method.

It is possible to notice that in the program some subjects are not present in every school year. Arithmetic, however, remains in all grades/years, with contents that are graded according to their difficulty level.

Besides providing the list of subjects, the program included “more and more detailed prescriptions coming from teaching administration departments”. The 1894 program was extensive, according to testimonials by inspectors and principals of *grupos escolares*. Contents related to reading, writing, calligraphy and arithmetic were considered essential by teachers. On the other hand, the ones related to geography, history and science were of secondary importance (Souza, 2009, p. 84).

For the teaching of arithmetic, the term *problem* appears in the content list in the following expressions: “Supplementary studies: problems and practical questions”, “Easy problems”, “Problems”, “Supplementary assignments: problems, practical questions”.

It is important to emphasize that the term *problem* is present from the second year on, always in the end of the list of contents. As years/grades advance, the words “easy” and “practical questions” join the term *problem* in expressions.

- **Journal “A Eschola Pública”**

Journals of education are extremely rich and varied sources (Monarcha, 2004). The author reveals a chronological list of journals of education of São Paulo, which includes three titles that were published in the last decade of the 19<sup>th</sup> century. Out of those three publications, the UFSC Digital Repository<sup>7</sup> has two: “Revista do Jardim da Infância” and “A Eschola Pública”, respectively *Kindergarten Journal* and *Public School*, in free translation. As this paper aims to analyze primary school, we will focus on articles published in “A Eschola Pública”. This journal of education was first published in 1893. Its early stage, which lasted until 1894, comprises eleven issues. The second publishing stage started in 1896, with its final issue published in the following year.

This journal is the result of a council formed by people who had graduated at Escola Normal da Capital<sup>8</sup> (*Capital's Normal School*, in free translation) and actively took part in political and cultural movements at the time. After that publishing period, many of its council members held important offices in the government, for example Oscar Thompson, who was named General Manager of State Public Education (*Diretor Geral da Instrução Pública do Estado*), and Arnaldo Oliveira Barreto, who was a teacher at *Escola-Modelo do Carmo* (Carmo Model School, in free translation), in 1894, and the inspector of the associated schools of São Paulo.

---

<sup>7</sup> Database fed by GHEMAT researchers, where theses, dissertations, articles, textbooks, education journals and students' notebooks are available. Available in <https://repositorio.ufsc.br/handle/123456789/1769>

<sup>8</sup> First Normal School in the state of São Paulo, called Caetano de Campos today. It was founded in 1894 and prepared future teachers.

According to Monarcha (2004), the publication had 21 issues. Nevertheless, only 18 issues are available at the UFSC Repository, whose digital database is fed by the GHEMAT researchers. All over the 18 issues, only 15 articles feature the teaching of arithmetic and only one, which was written by Arnaldo Oliveira Barreto in 1897, referred to the term *problem*.

In addition to being a teacher at Escola-Modelo do Carmo, the first *grupo escolar* in São Paulo, in 1894, Arnaldo Oliveira Barreto (1869-1925) reorganized Grupo Escolar de Lorena, São Paulo. In the period between 1902 and 1904, he was editor-in-chief of *Revista de Ensino (Journal of Teaching)*, in free translation). He was also part of Sociedade de Educação de São Paulo (*Education Society of São Paulo*). Throughout his career, he produced several books, articles and guidebooks.

In an article published in March 1897<sup>9</sup>, the author provides suggestions regarding the order of the work a teacher needs to perform in the classroom: “write the exercises”, “students with their arms crossed”, “distribute all necessary material”, “ring the bell for work to start”, “divide your board” and copy “all problems and then do them” (Barreto, 1897, p.38).

In this article, the author talks about the utilization of calculations involving all four fundamental operations whose results are not higher than 20. Some examples of calculations presented in the article are as follows:  $3 + 2 =$ ,  $4 + 3 =$ ,  $6 \div 3 =$ ,  $4 - 2 =$ ,  $6 \times 2 =$  (p. 40). He also suggests two different correction procedures: individual and collective. For the collective correction, he recommends that each student reads his/her problem:

- Three plus two makes five.
- Four plus three makes seven.
- Two and two are four.
- A six has two threes, etc. (Barreto, 1897, p.39)

To refer to the proposed calculations, the author alternates between the term “exercise” and the term “problems”, as we can observe in the final part of his article: “provide daily variation in the exercises, which is most convenient, and I emphasize that the problems should always be about the four fundamental operations” (Barreto, 1897, p. 39).

#### • “School arithmetic”

In the period between the end of the 19th century and the beginning of the 20th century there was a “close relation between the public primary expansion and the publishing expansion in the state of São Paulo” (Razzini, 2004, p. 1), which was originated with the establishment of the Republic in 1889. The textbook was set as one of the necessary aspects for implementing the proposal of *grupos escolares*.

Costa (2011), in a study about arithmetic textbooks in *grupos escolares* in São Paulo, states that Ramon Roca Dordal’s work titled “Arithmetica escolar – exercícios e problemas para escolas primárias, famílias e collegios” (*School Arithmetic – exercises and problems for primary schools, families and other schools*, in free translation), which is composed of six books, circulated in public schools in the state of São Paulo in the end of the 19<sup>th</sup> century and beginning of the 20<sup>th</sup> century. The

---

<sup>9</sup> Available in <https://repositorio.ufsc.br/xmlui/handle/123456789/126750>

first four parts of his work were analyzed in this paper. However, after an extensive search, the two final parts could not be obtained.

In addition to the title, a highlight to the fact that the work is composed of exercises and problems is also present in the introduction done by the author himself. Although there is no clear indication of what is understood by “exercise” or “problem”, the order of the activities featured in each lesson is pretty similar and seems to focus on the following: introduction of the rule, exercises and problems. Therefore, the term “problems” seems to be associated with a narrative of a daily life situation.

Lesson XI from the second book, for example, introduces the rule “When the sum does not provide exact tens, one should write the exceeding units in the sum and the tens should join the following order” (p. 11), followed by operations (Figure 1).

1.º	2.º	3.º	4.º
18	23	21	18
+ 36	+ 18	+ 15	+ 36
+ 11	+ 27	+ 32	+ 22

**Figure 1: Operations featured in Lesson XI of the second book.**

Finally, problems are presented as a final part of each lesson:

5th – A traveler has covered 25 leagues on a train, 14 leagues on a horse and 44 by ship; how many leagues has he covered?

6th – From Santos to São Paulo there are 16 leagues, from São Paulo to Jundiaí there are 12 and from Jundiaí to Campinas there are 9; how many leagues are there between Santos and Campinas?

Another point that Roca Dordal highlighted about the use of problems was that it was necessary to use easy problems, which should compose short lessons, so that children would remain interested and attentive, which is paramount for the success of the teaching process.

The first three books feature all problems that involve the addition operation and the fourth contains problems which are all related to subtraction. The situations featured in the problems have as backgrounds mostly children’s everyday life situations (school, shopping, etc) and also adult life situations (distance between two cities, populations, etc).

## **Conclusion: Ideas that circulated**

From observing the three sources selected for this study, it is possible to characterize some ideas that circulated in the state of São Paulo, Brazil, in the end of the 19<sup>th</sup> century about the use of problems in the teaching of arithmetic.

In that historical period the use of problems in classrooms to teach arithmetic was highly valued, which is characterized by the presence of problems in almost every teaching program for primary school (except for the first year/grade) and also by the presence of the term *problems* on the cover of Ramon Roca Dordal’s work. Textbook covers somehow try to introduce some of the work contained inside so that it is more likely to be bought, adopted or used. Therefore, the presence of the term *problem* on the cover seems to endorse the notion that it was valued by those who would make use of it or recommend it (institutions or teachers).

Despite the high regard observed in the teaching program and in the textbook under analysis, discussions over the utilization of problems do not seem to have been a serious debate topic in the

articles featured in the journal that circulated in São Paulo at that time. The teaching of arithmetic was the theme of fifteen journal articles but the term *problem* was referred to in only one of them. Still that one article did not discuss effectively the understanding of what a problem actually is. In that article, the term *problem* was applied as a synonym for exercise and referred to the calculations proposed using numbers and operation signs.

Nevertheless, a different understanding is expressed both in the teaching program and in the textbook. In these two documents, even though there is no clear exposition of what a problem is, they seem to be more related to proposals of activities based on narratives, which somehow approach daily life topics, just like the situations contained in the textbooks by Ramon Roca Dordal. The use of the expression “practical questions” alongside the term *problem* in the teaching program may also be related to everyday life or to the utilization of objects to be presented to the senses for the formation of ideas, once the program represents ideas based on the intuitive method.

The recommendation to use easy problems is one more idea which is highlighted both in the teaching program and in Ramon Roca Dordal’s textbook. This aspect is clearly revealed in the way that the documents are written and also in how their utilization is suggested. In the teaching program, for example, there is no proposal for the use of problems in the first year/grade, which suggests that first children need to acquire knowledge of the four operations, know their signs and be able to perform calculations with objects or numbers before being able to make use of this knowledge to solve problems. Likewise, in the book by Ramon Roca Dordal, problems are introduced only in some of the lessons, which happens after children have exercised their knowledge of the operations. One needs to have knowledge of how an operation is done to be able to apply that knowledge in problem solving, which points to a suggestion that the purpose of the problems was the application of previously acquired knowledge. This interpretation is reinforced when we observe that all problems featured in the book are related to the topics contained in the lesson in which the problems are shown or in previous lessons.

# Mathematics in the initial pre-service education of primary school teachers in Portugal: Analysis of Gabriel Gonçalves proposal for the concept of unit and its application in solving problems with decimals

Rui Candeias

Agrupamento de Escolas Terras de Larus, UIED/FCT Portugal; [rp.candeias@campus.fct.unl.pt](mailto:rp.candeias@campus.fct.unl.pt)

*This study aims to analyze Gabriel Gonçalves didactic proposal for the initial approach of rational numbers in primary education, published in the 1974 edition of Didactic of Calculation (Didática do Cálculo). At a time where modern mathematical ideas began to influence mathematics education in the early years, it is important to understand how mathematics was addressed in the pre-service education of teachers of this school level. Among the themes approached in this textbook, the choice of rational numbers was due to the many difficulties that primary students usually have with this subject matter, as well as the teachers in teaching them. The study was conducted with a historical perspective based on documents analysis. The proposal of Gabriel Gonçalves emphasizes the initiation of rational numbers through decimals instead of fractions and the different types of problems that should be presented to students in the initiation to decimals.*

*Keywords: History of mathematics education, elementary school mathematics, decimals*

## Introduction

This paper is part of a broader work that aims to characterize, in a historical perspective, mathematics in the initial pre-service education of primary school teachers in Portugal. On the one hand, from the point of view of the centrally issued legislation, on the other hand from the analysis of textbooks for teachers, which constitute a point of view closer to the practices. This is a pioneering study that will focus the analysis of the teacher training textbooks on their approach to non-negative rational numbers. It is intended to select a set of representative authors from different periods, between 1844 and 1986, and examine how the proposed initiation to non-negative rational numbers in the early years of schooling evolved. In this article, I selected a representative author of the beginning of the 1970s, whose proposal of approach to rational numbers will be described.

This paper analyzes the didactic proposal of Gabriel Gonçalves, former teacher of the Primary Teacher Training School of Porto (Escola do Magistério Primário do Porto), for the initial approach to rational numbers presented in the textbook for teachers of the Special Didactic (Didática Especial) discipline of initial pre-service education of primary school teachers, entitled Didactic of Calculation, 1974. The main questions in this paper are: What is the initial proposal for the teaching of non-negative rational numbers presented by this author? What kind of representations are privileged? What kind of teaching materials are referred to? What importance does this author give to the definition of unity? What are the most used contexts for the display of decimal numbers? What kind of problems does the author propose to students?

According to Chartier (1990), the pedagogy textbooks for teachers constitute a source for the history of teacher professionalization, and are a sample of what constitutes teachers professional knowledge. Pintassilgo (2006) considers these textbooks for teachers a major instrument of innovation and

control, legitimizing certain ideas and practices, and simultaneously withdrawing this legitimacy to others. Moreover they are important resources in building a school culture and as guides in classroom and students management, as well as in the professional teacher development.

The importance of research in the context of the history of mathematics teaching is not limited to the knowledge of the past. Chervel (1990) points out that, through the historical observation, we can bring this disciplinary models and operating rules whose knowledge and exploitation may be useful in discussions about teaching today. In this sense, Matos (2007) states that knowledge of the past may allow an action more grounded in the present. In this perspective, it is important to see how it was done the training of primary school teachers, in a mathematical topic as the rational numbers, at a moment when the Modern Mathematics Movement begins to emerge, favorable to an active construction of knowledge and the use of structured materials in mathematics teaching. The operationalization of the analysis of the work of this author was conducted as an historical study based on the collection and selection of sources as defined by McCullough (2004). At this stage of the work, the document was analyzed essentially in a descriptive way, trying to organize a scheme with the topics to be analyzed (Creswell, 2012).

### **Pre-service education of primary school teachers during the New State regime (Estado Novo)**

In Portugal, the military dictatorship implanted in 1926, and later the New State regime that followed, changed the pre-service education of primary school teachers (Pintassilgo, 2012). In 1930, still in the transition from military dictatorship to the New State regime, the Normal Primary Schools (Escolas Normais Primárias) were replaced by Primary Teachers Training Schools (Escolas do Magistério Primário) involving a radical change in school organization, the curriculum framework and, later on the syllabi, in 1943.

With the restructuring of the course in 1942, and the syllabi published in 1943, the mathematical content of the programs of the Primary Teachers Training Schools came to be centered on teaching and methodological dimensions of the primary content. In these 1943 syllabi, did not exist any discipline with mathematical content. The reformulation of syllabi in 1960 reinforced the discussion on teaching methodologies. These syllabi had no disciplines with mathematical scientific content, situation that remained until 1975 syllabi. It is in the context of these 1960 syllabi that the Didactic of Calculation, analyzed in this paper, was published.

### **Decimal numbers in the teachers textbook of pre-service education of primary school teachers: Gabriel Gonçalves' approach in *Didática do Cálculo***

Didactics of Calculation (Didática do Cálculo), composed of two volumes published in 1972 and in 1974 by Porto Editora, is part of a set of textbooks for teachers written from the 1960s to serve as a support to the discipline of Special Didactics B of the courses of pre-service education of primary school teachers. According to the author, Gabriel Gonçalves, former professor of the Primary Teachers Training School of Porto and inspector-advisor at the time of the edition of the manual, Didactics of Calculation was mainly intended for students-masters of the Primary Teachers Training Schools although it could also be used by all of those who were interested in education issues.

From chapter VII to chapter XIII of the second volume of Didactic of Calculation, Gonçalves (1974) addresses the teaching of decimals. Due to space limitations, this article will not address the entirety

of this author's proposal. This paper focuses on chapter VII which deals with general aspects of the teaching of decimals and chapter XIII dedicated to the concept of unit and its application to problems, which are important aspects of the teaching of these numbers.

The chapter VII, entitled "Preparation of the study of decimals; measurements with linear units already known. Writing and reading of representative numbers of these measurements; using the decimal point" is organized into three main sections: 1) Goals; 2) General considerations and 3) Direction of Learning. In the goals, the author begins by pointing out that the aim is that the child expands his knowledge of decimal number system, extending it to tenths, hundredths and thousandths. These concepts would appear as an extension of the base ten numbering system.

Gonçalves (1974) presents subsequently some general considerations about the teaching of decimals and fractions, starting by putting the question if the teaching of rational numbers should be done with decimals instead of common fractions. On this issue, Gonçalves (1974) presents two opposing trends. On the one hand, quotes methodologists<sup>1</sup> that, according to Gonçalves (1974), claim that one should start with decimal fractions in its decimal representation, because it would be "as a continuation of the study of decimal number system, but with numbers lower than the unit "(p. 38). He presents the submultiples of length measurements, capacity and weight, as examples stating that:

Each of these units contains ten units of the next lower order. So, we can operate in the written calculation as if they were natural numbers. And as the calculation with decimal is much easier than with fractions, it will be with the decimal fractions, in the form of decimal representation, which should start. "(Gonçalves, 1974, p. 38).

On the other hand, he presents the opinion of methodologists<sup>2</sup> who claim that we should begin the study by the common fractions, of which the decimal fractions would be only a case. Then he forwards the arguments of these authors, stating that:

The calculation becomes more intuitive and rational: the half, third, fourth, ..., are easier to understand than the tenth, the hundredth, ... The calculation of common fractions prepare better for the decimal than the contrary. (Gonçalves, 1974, p. 38).

Given these two divergent trends, Gonçalves (1974) refers that he will follow the first, as it was prescribed in primary syllabi at the time<sup>3</sup> that is, starting with decimals representation. In section 3 of this chapter, called the Direction of learning, Gonçalves (1974) shows what stood as the teaching of decimals in the primary education syllabi of the time. This topic was considered "the greatest obstacle to overcome in the 3rd grade" (p. 39). According to the primary syllabi, the approach to decimals should be made from the length measurements, placing students in situations that were necessary to measure with meter and decimeter. These measurements would express numbers in what was called mixed decimals, numbers with a whole part, that after a decimal point had a decimal part. After working with these mixed decimals, students should verify that the rules used with whole numbers also applied to decimal numbers, "the numbers continue to have an absolute value and a position

<sup>1</sup> On this subject, Gonçalves (1974) quotes methodologists like Büttner, Tank or Pikel, but does not identify the works of reference of these authors.

<sup>2</sup> On this subject, Gonçalves (1974) quotes methodologists like Böhme or Hentshel, but does not identify the works of reference of these authors.

<sup>3</sup> At the time were in effect the syllabi approved in Decree No. 23,485, Government Daily, 167, 16.07.1968, 1019-36.

value." (p. 39). After performing this work, situations that could lead them from mixed decimals for simple decimal numbers should be offered to students.

Gonçalves (1974) establishes a relationship between the perspective in the previous two chapters of his manual, which addressed the metric system, with measurements only with positive integers, in the final part of his general considerations. In this chapter, he proposes to address measurements, using the decimal notation, with the decimal point.

Gonçalves (1974) continues the chapter with section 3. Direction of Learning, with the suggestion of some techniques and activities for the introduction of the concept of the tenth, starting from decimeter, and the notion of the hundredth and thousandth, from notions of centimeter and millimeter. The author proposes the introduction of the tenth in eleven steps (table 1):

1) Measurements, in which the meter is used a whole number of times;	2) Measurement expressed a whole number of times in meters and decimeters (ex.: the picture measures 1 m and 2 dm);
3) In the measurements, identification of the entire unit, the meter, and the tenth of the entire unit, the decimeter. Representation in conventional manner, with the decimal point and the identification of the position value.	4) Identification that the rule that governed the whole numbers also apply in decimal numbers: "In a number, any digit at the right of other is order units ten times smaller than the first one" (p. 30);
5) Measurements that result in mixed decimal representation. Registration in tables;	6) Measurements that result just with decimal part. Lead students to understand that the zero to the left of the decimal point is the absence of whole units;
7) Exercise that does not exceed the unit Ex.: $3 \text{ dm} + 2 \text{ dm} = 5 \text{ dm}$ $0,3 \text{ m} + 0,2 \text{ m} = 0,5 \text{ m}$	8) Exercises which form exactly the unit Ex.: $5 \text{ dm} + 5 \text{ dm} = 10 \text{ dm}$ $0,5 \text{ m} + 0,5 \text{ m} = 1,0 \text{ m} = 1 \text{ m}$
9) Exercises that exceed the unit Ex.: $4 \text{ dm} + 5 \text{ dm} + 3 \text{ dm} = 12 \text{ dm}$ $0,4 \text{ m} + 0,5 \text{ m} + 0,3 \text{ m} = 1,2 \text{ m} = 1 \text{ m} + 0,2 \text{ m}$	10) Exercises Ex.: $0,4 \text{ m} = 0,1 \text{ m} + 0,1 \text{ m} + 0,1 \text{ m} + 0,1 \text{ m}$ $= 0,2 \text{ m} + 0,2 \text{ m} =$ $= 0,3 \text{ m} + 0,1 \text{ m}$
11) Application and verification exercises.	

**Table 1. Proposal for an approach to decimal (Gonçalves, 1974)**

Chapter XIII, titled the "Expansion of the Unit Concept. Its application to solve problems with decimals" is divided into two sections: 1. Goals and general considerations and 2. Preparatory exercises. In a footnote at the beginning of this chapter, Gonçalves (1974) draws attention to the possible application in problems with common fractions<sup>4</sup>. The first section provides some general

<sup>4</sup> The footnote with reference to common fractions is placed in the text by the author, because in later chapters, when it comes to addressing the common fractions, will present the same kind of problems. However, we will not address common fractions in this paper.

considerations about the unit and its nature. Gonçalves (1974) begins by distinguishing the single units of the 1st or 2nd order units, such as ten or hundred, or units designated as decimals, as 0.1; 0.01. Also distinguishes other composite units as the dozen or the quarter of a hundred or other sets as a basket of oranges that can be considered as a whole. For Gonçalves (1974), this expansion of the concept of unit "is the basis of an important branch, allowing you to easily solve questions that otherwise would be too complex" (p. 79) and therefore should be developed in children. Gonçalves (1974) points out that many problems with decimals have the following expressions: "the amount corresponding to the unit; the fraction<sup>5</sup>; the amount corresponding to that fraction or else their counterparts, the value of the unit (the whole); the fraction; the value of the part corresponding to the fraction" (p. 79). He points out that being given two of the above items is always possible to find the third, and stresses that this implies the possibility of formulating three groups of problems: 1) given the amount corresponding to the whole and the fraction, find the value of the part corresponding to that fraction; 2) given the fraction and the amount corresponding to that fraction, find the value of the whole; 3) given the value of the whole and the value of a part of the unit, find the fraction which corresponds to that part.

The author presented several examples considered similar, for the first group of problems. The first problem, with a context of capacity measures, is to find the amount corresponding to the respective unit. For this type of problem is presented a resolution, first find the value of the decimal unit 0.1, and then multiplying by the number of times it is repeated, in this case, multiplying by three.

- 1) Each liter of olive oil costs 18\$00. How much will cost 0.3l of that olive oil?

The problem can be solved, first finding the decimal value of each unit ( $18\$00:10 = 1\$80$ ) and then multiplying it by number of decimal units ( $1\$80 \times 3 = 5\$40$ ). (Gonçalves, 1974, p. 79)

Soon afterwards a second example is shown. It is also an iterative situation that leads to the meaning of multiplication and can be considered a counterpart of the first: "2) Each liter of olive oil costs 18\$00. How much will cost 3 l of the same olive oil" (p. 80). The resolution is the multiplication of 18\$00 by 3,  $18\$00 \times 3 = 54\$00$ . Gonçalves (1974) believes that after children observe the resolution of the second problem they will eventually realize that the action in the first problem is also multiplicative, noting that multiplying by 0.3 is the same as dividing by 10 and multiply the result by 3. He points out that the child will also conclude that "given the value of the unit, to know the amount (whether higher or lower than the unit), the action is multiplicative." (p. 80, italics in original). For this first group of problems are still presented other examples. According to Gonçalves (1974), the intention is to extend the concept of unit, to the concept of the whole.

<sup>5</sup> Gonçalves (1974) uses the term "fraction", in the sense of part of a whole and not in the sense of fraction representation of the rational number.

In the second group of problems titled “given the fraction and the amount corresponding to that fraction, find the value of the whole” several problems are presented. The first two are in the context of capacity measures and the author intended that should be solved by analogy.

1) They bought three liters of olive oil for 54\$00. How much did cost one liter?

2) Were purchased three deciliters (0.3 l) of olive oil for 5\$40. How much did cost one liter? The meaning of the first problem is clearly partitive ( $54\$00:3=18\$00$ ). (Gonçalves, 1974, p. 80)

The first problem is associated with a partitive situation and the solution involves a division,  $54\$00:3=18\$00$ . From this, the student should recognize that the second problem presents a similar situation, inferring that if you know the value of a certain amount, to know the unit, the meaning is to divide. For the second problem, another kind of solution is suggested: first determine the price of each tenth and then multiplying this result by 3. Other examples of similar problems are then presented.

In the third group of problems, “given the value of the whole and the value of a part of the unit, find the fraction which corresponds to that part”, are initially presented two problems.

1) With 54\$00, which portion of olive oil can we buy, whose price is 18\$00 per liter?

2) With 5\$40, which portion of olive oil can we buy, whose price is 18\$00 per liter?

(Gonçalves, 1974, p. 82)

The first problem is considered to be the division quotative meaning, and the resolution proposed is  $54\$00:18\$00=3$ . The second problem is also framed in a similar reasoning and therefore should be solved similarly  $5\$40:18\$00=0.3$ . To Gonçalves (1974), these two problems comprise the quotative meaning. Gonçalves (1974) points out that “*the fraction is given to us by the relationship (or ratio) between the value of the quantity and value of the unit.*” (p. 82, italics in original). It points out that learning these problems should not only be supported by the memorization of rules, or repetition, without be a prior understanding. Gonçalves (1974) considers that this understanding of work was previously done when they worked multiplication and division of decimals as a generalization of the basic rules of these operations with whole numbers.

In section two of this chapter, entitled preparatory exercises, are suggested three different types of problems, 1. Recognize (or find) the fraction; 2. Find the value of the fraction; 3. Find the value of the unit (or the whole) which corresponds to the sorts of problems previously shown. Gonçalves (1974) begins by highlighting that for the understanding of the basics for learning problem solving, should be practiced some sensory exercises, called concrete phase, such as manipulation, paper folding, drawing, of which the preparatory exercises were examples.

## Concluding remarks

In chapter VII of the manual in analysis, the first dedicated to the teaching of decimals, Gonçalves (1974) starts by discussing where to begin the study of rational numbers, by the decimals or by

fractions. In his work, Gonçalves (1974) follows the indication of the primary school official syllabi of that time and primarily addresses the rational numbers by its decimal representation. Gonçalves (1974) also refers to arguments of different authors. Regarding the teaching of rational numbers, Brousseau, Brousseau and Warfield (2007) also present a discussion on the best way to introduce them to students considering that it is not necessary to know fractions to learn decimals. Rather, decimals can be understood at once as a decimal number, supported by the decimal measuring system, allowing that all practical measurement problems can be solved more easily. They consider that this solution has many advantages for teaching, especially in countries where children are already familiar to the use of metric measurements.

The different syllabi of mathematics discipline for primary education in Portugal also seem to reflect this discussion. In the 1960s two syllabi to this level were in force. In both cases the rational numbers were discussed in the third grade from decimal numerals, with the use of linear measurements. The fractions were worked only in the fourth grade, but only the concept of fraction. In the syllabi for the school year 1974/1975 the introduction of rational numbers was still made with decimal representation and working with fractions was no longer part of the primary syllabi, happening the same in 1975 syllabi. However, in the 1978 syllabi, the chapter devoted to rational numbers deals first with the fractions and then the decimal representation. In the 1980 syllabi, rational numbers were again addressed exclusively by decimal representation. In 1990, the official syllabi for primary education began the work with rational numbers in the second grade, with the fractions, but only had an applied operator to a discrete set. Afterwards and until 5<sup>th</sup> grade rational numbers were worked out just with decimal representation.

Gonçalves (1974) distinguishes different types of units, referred to as units of "various kinds". He defines the single unit, but ten and hundred are first and second order units, that means they are composed units. Other composite units are also presented, called set-unit as the dozen or a quarter of a hundred. Monteiro and Pinto (2009) highlighted the different types of unit as one of a major difficulty in the study of fractions in the early years.

This unit concept is considered by Gonçalves (1974) as essential for solving problems with decimals, because of that definition results the possibility of grouping the problems into three distinct groups: 1) find the value corresponding to a part of the designated fraction; 2) find the value of the whole giving a part; 3) find the part of a whole.

In the presenting of the problems, Gonçalves (1974) emphasizes the symbolic representation, but also presents some problems, and the respective resolutions, illustrated with pictorial models. However, in the second section of chapter XIII, he highlights the importance of concrete phase, suggesting the use of sensory exercises using the manipulation, paper folding and drawing. However, no structured didactic materials are referred.

Synthesizing, in this proposal of Gonçalves the importance attributed to the work with the decimals stands out by the affinity with the calculation with the natural numbers that the students previously worked. This option is based on the curriculum that was in force in Portugal at the time, but methodologists from other countries who support this option were also mentioned. As the works of the mentioned methodologists are not mentioned, it is not possible at this moment to attest to the influence they had on the proposal of this portuguese author. This is a discussion that continues today

as it is possible to see in the works of Brousseau et al. (2007) and the successive changes in the approach to rational numbers presented in the portuguese curricula.

The work with different units and the importance given to the definition of the unit it is also relevant in Gonçalves work. This definition of unit allows Gonçalves to systematize the type of problems to be presented to the students in the beginning of the learning of this numerical set. The most used contexts in these problems are those of measurement (length, weight).

## Introduction

We will endeavour to show that some historical documents which are probably too difficult to be used in the classroom can nevertheless be fruitfully used in teacher-training, in order to provide teachers with tools for the analysis of informal or semi-formal justifications. We will analyze an extract from the *Nine Chapters*, so as to spell out tool for the analysis of three school documents bearing on the multiplication of decimal or general fractions.

## A historical example: Multiplying fractions in the *Nine Chapters*

The *Nine Chapters on the Mathematical Art* (九章算術) is a Classic that was compiled during the Han Dynasty (206 BC – 220 AD). It contains an organized list of problems with general procedures to solve them, yet with no attempts at justification. In 263 AD, scholar Liu Hui wrote an extensive commentary in which endeavoured to justify all the procedures, and identify key subprocedures of general scope. We will comment on the passage in chapter one which deals with the multiplication of fractions, on the basis of the critical edition and French translation (Chemla & Shuchun, 2004)<sup>1</sup>.

Problem 1.19. Now given a [rectangular] field,  $\frac{4}{7}$  *bu* in breadth and  $\frac{3}{5}$  *bu* in length. Tell: what is the area? Answer:  $\frac{12}{35}$  *bu*.

(...)<sup>2</sup> Procedure for the multiplication of parts: multiply the denominators to make up the divisor; multiply the numerators to make up the dividend. Divide the dividend by the divisor.

(...) [Liu Hui]: In all cases when a dividend does not fill a divisor, then they are called denominator and numerator. If there are parts, expand the corresponding dividend by multiplication, then, when the divisor is filled, the division yields an integer. If, moreover, one multiplies something by the numerator, the denominator must therefore divide in return [*baochu*]. To divide in return is to “divide the dividend by the divisor”. Now, “the numerators are multiplied one by the other”, hence both

<sup>1</sup> An independent English translation is also available (Crossley, Lun & Shen, 1999). As far as this passage is concerned, the two translations differ significantly; our interpretation is based on Chemla's translation and interpretation.

<sup>2</sup> I edited out two similar examples (with proper fractions), as well as Li Chunfeng's commentary.

denominators have to divide in return. Whence the multiplication of the two denominators, and the division at one go [by their product].

The mere length and width of a rectangular field leave no room for a general explanation. Let someone ask: “20 horses are valued at 12 *jin* of gold. Now 20 horses are sold and the proceeds are shared by 35 persons. How much does each one get?” The answer is  $12/35$  *jin*. To solve this by the procedure for dividing into parts, take 12 *jin* of gold as dividend, and 35 persons as divisor. Now, change [the problem] to: “5 horses are valued at 3 *jin* of gold; now 4 horses are sold, and [the proceeds] are shared by 7 persons. How much does each one get?” Answer: each one gets  $12/35$  of *jin*. To solve this, you need to homogenize these quantities (*shu*) of people and of gold; it is then completely similar to the first problem, that of dividing into parts. If so, “multiply the numerators to make up the dividend” does homogenize this quantity of gold; “multiply the numerators to make up the dividend” does homogenize this quantity of people. Equalizing the denominators yields 20, but that plays no part: we just need the homogenized. Moreover, when 5 horses are valued at 3 *jin* of gold, these are the *liu* in whole numbers. If we express them with parts, 1 horse is valued at  $3/5$  *jin* of gold. Let 7 people sell 4 horses, 1 person does sell  $4/7$  of a horse. (...) As far as expression is concerned, that’s different; yet as far as quantities are concerned, the three procedures boil down to the same.

**Figure 1: (Chemla & Shuchun, 2004, 169-171). Free translation: R. Chorlay**

Even if the procedure is quite easy to understand – and familiar to the reader – Liu Hui’s commentary is probably hard to decipher. Even without a clear understanding of the details, one can probably see at least two things: the goal of Liu is to justify the general procedure of the classic; he gives two different justifications, one which does not rely on a semantic context nor on specific numbers, and one which does.

Let us first focus on the first justification. Liu first distinguishes between two cases: a basic case in which the fractions represent whole numbers; in this case, the procedure for multiplication is already known. Of course, the goal is here to justify the new procedure – in the case where the divisions have non-zero remainders – on the basis of the basic procedure. The word “procedure” is important, since what is to be justified is the validity of an algorithm. More precisely, two sequences of calculations are to be compared:

Sequence 1: divide  $a$  by  $b$ ; divide  $c$  by  $d$ ; *multiply* the two quotients.

Sequence 2: multiply  $a$  by  $c$ ; multiply  $b$  by  $d$ ; divide the first product by the second product.

If the two sequences relied on operations defined previously and independently, the goal would have been to prove the universal equivalence of these two algorithms (that is, same entries yield the same output). However, if one is not to beg the question, the first sequence actually contains the undefined operation *multiply*, since the final multiplication may involve a multiplication of fractions<sup>3</sup>. So the goal here is rather to justify that sequence 2 (which involves only well defined operations on integers)

---

<sup>3</sup> When the remainder in the Euclidean division is non-zero, the quotient, the remainder and the dividend were read as a mixed number. For instance, the division of 7 by 3 has quotient 2 and remainder 1, so its result is 2 and  $1/3$ .

should be universally equivalent to sequence 1, thereby implicitly defining “multiply” in terms of “multiply.”

To perform this, Liu uses terms which are specific to the commentary: whereas the Classic uses “divide” and “multiply”, Liu uses “expand by multiplication”, and “divide in return” (*baochu*); these terms point to the role of these operations. However, it is important to know that throughout the *Nine Chapters*, “*baochu*” denotes a division whose role is to compensate for a multiplication by the same number, so that these two steps of the procedure do not affect the final output of the sequence of operations. On this basis, one can see that Liu’s justification involves a third sequence of operations:

Sequence 3:

1. multiply  $a$  by  $b$ , so that the first factor becomes  $ab / b$ , which is equal to  $a$
2. multiply  $c$  by  $d$ , so that the second factor becomes  $cd / d$ , which is equal to  $c$
3. multiply the two factors, which yields  $ac$
4. divide by  $bd$ , which is the product of the two denominators

This sequence is not to be *actually* performed, it is mentioned for justificatory purposes only. Since step 4 is a *baochu*-division, it compensates steps 1 and 2. The line of argumentation can thus be reconstructed as: sequence 1 (which is yet undefined) should be universally equivalent to sequence 3, and sequence 3 boils down to sequence 2.

This line of argumentation may seem far-fetched. However, it is quite close to the following contemporary proof of the following theorem: the only map  $f$  from  $\mathbb{Q} \times \mathbb{Q}^*$  which is  $\mathbb{Z}$ -bilinear and which is a prolongation of integer multiplication (i.e. if  $m$  and  $n$  are integers, then  $f(m, n) = m \times n$ ), is  $f\left(\frac{a}{b}, \frac{c}{d}\right) = \frac{a \times c}{b \times d}$  (where  $a, b, c, d$  denote integers, with  $bd \neq 0$ ). The proof goes as follows:

$$\begin{aligned} (b \times d) \times f\left(\frac{a}{b}, \frac{c}{d}\right) &= f\left(b \times \frac{a}{b}, d \times \frac{c}{d}\right) \text{ by } \mathbb{Z}\text{-bilinearity} \\ &= f(a, c) \text{ by a Lemma}^4 \text{ which relies only on addition in } \mathbb{Q} \\ &= (a \times c) \quad (\text{prolongation requirement}) \end{aligned}$$

Diving both sides by  $(bd)$  completes the proof. One could argue that, although Liu Hui states the prolongation requirement quite explicitly, never does he say anything resembling the bilinearity requirement. Even if this requirement is not explicit, it should be stressed that the bilinearity of the operation being defined (i.e. *multiply*) can be rephrased as follows: multiplying either of the two factors by an integer  $n$  should multiply the product by  $n$ ; which is exactly the property which justifies the role of the *baochu* division.

The second part of Liu Hui’s commentary clearly follows another line of argumentation. The first part does not rely on a semantic context of interpretation, nor does it use specific numbers. The second part, however, depends on a semantic context which Liu Hui introduces out of the blue after dismissing the context provided by the Classic (rectangular areas), and uses the numbers from Problem 19.

In the second part, several in-context problems are mentioned, and their relationships discussed.

---

<sup>4</sup>  $b \times \frac{a}{b} = \frac{a}{b} + \dots + \frac{a}{b}$  (with  $b$  terms)  $= \frac{ba}{b} = a$  (assuming  $b \in \mathbb{N}^*$ ).

Pb. 1: 20 horses are valued at 12 *jin* of gold [for all 20 horses]. Now 20 horses are sold and the proceeds are shared by 35 persons. How much does each one get?

Pb. 2: 5 horses are valued at 3 *jin* of gold [for all 5]. Now 4 horses are sold and [the proceeds] are shared by 7 persons. How much does each one get?

Problems 1 and 2 can be connected by a series of problems. Starting from Problem 2, one can consider:

Pb. 2': 5x4 horses are valued at 3x4 *jin* of gold. Now 4 horses are sold and [the proceeds] are shared by 7 persons. How much does each one get?

Although Pb2 and 2' differ from a semantic viewpoint, they are equivalent in the following sense: the numerical answers to Pb 2 and 2' are equal, since the second parts are the same, and the answers depends only on the ratio between horses and *jin* of gold. The argument would hold for any factor, it so happens that "4" is more relevant than others for what follows<sup>5</sup>. This is quite explicit in the text, since throughout the *Nine Chapters* the technical term *lǜ* denotes either a ratio, or numbers which are to be considered up to multiplication by a common factor. The relationship between Pb2 and Pb 2' is the same as that between Pb2' and Pb2'':

Pb. 2'': 5x4 horses are valued at 3x4 *jin* of gold. Now 4x5 horses are sold and [the proceeds] are shared by 7x5 persons. How much does each one get?

Now, Pb 2'' is the same as Pb 1, so their numerical answers are the same: 12/35.

But there is another way to solve Pb 2. The numerical answer to Pb 2 is the same as that of

Pb 2''': 1 horse is valued at 3/5 *jin* of gold. Now 4/7 horses are sold and [the proceeds] are shared by 1 person. How much does this person one get?

We want to define multiplication of fractions so that the following property of integer multiplication remains valid: total value = unit value times quantity. As a consequence, the product  $\frac{3}{5} \times \frac{4}{7}$  should be the numerical answer to Pb 2''', hence to Pb 2 just as well, hence equal to 12/35.

A more formal summary would go as follows (we use  $\otimes$  to denote to multiplication of fractions, to be defined here in terms of  $\times$ ):

$$\frac{3}{5} \otimes \frac{4}{7} = \frac{3 \times 4}{5 \times 4} \otimes \frac{4 \times 5}{7 \times 5} = \frac{3 \times 4}{\cancel{5 \times 4}} \otimes \frac{\cancel{4 \times 5}}{7 \times 5} = \frac{3 \times 4}{7 \times 5}$$

As for the extra-steps mentioned in the first argument, none of these intermediary operations are to be performed when actually multiplying fractions; they are here for justificatory purposes only. This formal summary does not do justice to the nature of the argumentation, since it is the context only which justifies the equalities: dependence on ratios only (first equality); then reduction to a problem involving only two integer data instead of four, and which can be solved by ordinary division. Just as well, the fact that any given fraction can be freely replaced by any equivalent fraction can be justified

---

<sup>5</sup> We will not comment on the use of technical terms such as "equalizing" and "homogenizing", which Liu Hui introduced in the context of the addition of fractions:  $\frac{a}{b} + \frac{c}{d} = \frac{(ad) + (bc)}{(bd)}$  ← this is what you get by "homogenizing".  
 ← this is what you get by "equalizing"

by the context; for instance, the unit price depends only on the ratio between the number of horses and their total value.

## Tools for the analysis of arguments in today's textbooks

### Reflecting on the *Nine Chapters* from a teacher-training perspective

The obscurity of the Chinese text probably makes it impossible to use in the classroom. In this paper, we would like to show how the mathematical analysis of this text that we carried out in the first part can help raise the awareness of prospective teachers as to several general features of argumentation in rather informal contexts (this is our Hypothesis #1); and even supply them with tools which are useful in everyday teaching, when they are to decide how to (somehow) justify some mathematical definition or property (this is our Hypothesis #2)<sup>6</sup>.

The analysis of the *Nine Chapters* drew our attention to several facts, some of which bear specifically on fraction multiplication, and some of which are of a more general scope:

- There are several ways to justify the rule for the multiplication of fractions.
- The use of letters is not the only way to express a general line of argumentation, as Liu Hui's first argument illustrates.
- The rule for fraction multiplication is not only an equality between *formulae*; it can also be seen as the equivalence of two different algorithms (one with two divisions followed by a multiplication, and one with two multiplications followed by a division). This equivalence of algorithm can be established using general arguments within the algorithmic framework (i.e. arguments *about* algorithms), as opposed to the rewriting of formulae within an algebraic framework.
- Argumentation is not limited to properties or theorems: the choice of a definition (here: for the multiplication fractions) can also be justified. With fraction multiplication we are dealing with a case domain extension: some notion was already defined for a given class of objects; the to-be-defined notion has to apply to a class of objects that encompasses the first class, and to coincide with the former notion on the first class. In our case, a very weak form of justification would be: this definition of fraction multiplication boils down to ordinary multiplication (of integers) should the fractions denote integers (this could be called the *control case*). The *Nine Chapters* suggests a stronger kind of justification: the extended definition of “multiply” should preserve some structural properties of the former definition, properties that we value. For instance: bilinearity; or the validity of the formula “total value = unit value times quantity”. On the other hand, we are ready to give up on some properties, such as: the product of two numbers is greater than or equal to either of them. To some extent, when justify the choice of a definition, these required properties play the part that hypotheses play in the proof of a theorem.
- In some cases, from a mathematical viewpoint, these requirements completely characterize the new notion. In these cases, whether or not this uniqueness property should be proved in

---

<sup>6</sup> The decisions as to *how* to justify a given definition or property is closely related to the decision as to whether or not it *should* be, and to the knowledge of ways to justify it (*can* it be defined, or not, in a given mathematical context?). We will not have time to discuss the interplay of these three aspects in this short paper.

the classroom calls for another decision. Even if the teacher thinks the uniqueness aspect cannot / need not be made explicit, the *Nine Chapters* suggest another lead. Making explicit the properties that we want to extend also has a *heuristic* value, suggesting the path to a definition of the extended notion.

- Liu Hui's second line of argumentation also suggests many fruitful leads, which we can only mention in passing for lack of space:
  - A rather unusual form of argument: proving that two formulae or two algorithms are universally equal / equivalent by exhibiting a class of in-context problems for which the answer is unique – for any given set of initial data –, and for which – for reasons that can be spelled out – both formulae or algorithms work out the solution. Of course, this form of argumentation – that can be called *semantic immersion* – raises questions as to the context-dependence of the argument. For instance, multiplication plays a part in the context of commercial transactions and in the context of area calculation, and nothing proves that the fact that the relevant operations coincide in both contexts when the data are integers will still hold with all rational data.
  - Liu Hui's second argument is not only in-context (a horse-deal), it is also an arguments which clearly claims full generality while dwelling on a single specific case, that of  $\frac{3}{5}$  times  $\frac{4}{7}$ . This raises the well-known but deep questions pertaining to the notion of *generic* example (Balacheff, 1987, 157). Let us mention two such questions: (1) from a mathematical viewpoint, which conditions guarantee the minimal level of non-specificity that an example should enjoy to be potentially seen as generic (for instance: dealing with  $\frac{1}{5}$ ,  $\frac{7}{5}$ , or  $\frac{15}{5}$  instead of  $\frac{3}{5}$  would probably make this case less generic)? (2) The *genericity* of a case is not a mathematical property but is a multilayered property of the relationship between it and the students; it involves pragmatic aspects (students should be able to *adapt* the reasoning to other cases), and epistemological aspects (students should *regard* this case as a mere representative of all cases, thus providing some form a general argument); what are the general conditions for a didactical genesis of this relationship?

## Field-work

We shall end with some applied work. The following three documents are extracts from contemporary French textbooks or standard teacher-training documents, for students in the second year of middle-school (Figures 2 and 3) or in the last year of primary school (Figure 4). In cases 2 and 3 they are meant for students who are somewhat familiar with fractions and their addition, but with no knowledge of multiplication. As to Figure 4, students are familiar with integer multiplication, and with multiplication and division of decimals by powers of 10. These extracts are what most French textbooks call “introductory activities”, in which students are to experience a new notion from a hands-on, guided but non-dogmatic approach. We suggest these documents be analyzed in TWG12 in order to test Hypotheses #1 and #2.

Figure 2: Two ways to work out a rectangular area (Malaval, 2014, 69)

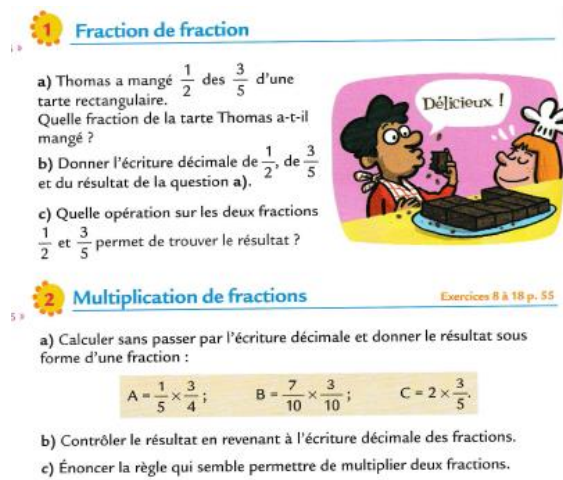

Figure 3: A justification in terms of combination of operators, and a conjecture relying on the control-case of decimal fractions (Mante, 2006, 50)

Multiplication	Technique opératoire
Multiplication de nombres décimaux	
Calcul de $12,7 \times 35,2$	
$  \begin{array}{r}  12,7 \\  \times \\  35,2 \\  \hline  254 \quad \leftarrow 2 \times 127 \\  6350 \quad \leftarrow 50 \times 127 \\  38100 \quad \leftarrow 300 \times 127 \\  \hline  447,04  \end{array}  $	<p>Tout se déroule comme dans l'exemple précédent. Je fais l'opération sans tenir compte de la virgule et je la positionne au résultat.</p> <p>En fait, je vais multiplier 12,7 et 35,2 par 10</p> <p>Le résultat doit donc être divisé par <math>10 \times 10 = 100</math></p>

Figure 4: Generalizing multiplication from integers to decimals using bilinearity<sup>7</sup>

## Conclusion

The goal of this short paper was to contribute to the ongoing reflection on the use of original historical sources in the classroom or in teacher-training; a reflection which bears both on the goals of this use, and on the relevant ways to use such documents.

Within this general field of research, the main features of this specific contribution are: we dealt with teacher-training only, since we do not think this excerpt from the *Nine Chapters* can be used with

<sup>7</sup> Document retrieved from a teacher-training slideshow: <http://docslide.fr/documents/techniques-operatoires-cycles-2-et-3-multiplication-jean-luc-despretz-cpc-landivisiau-avril-2010-lacquisition-des-mecanismes-en-mathematiques-est-toujours.html> (slide 22). Accessed September 14, 2016.

students who learn to multiply fractions; we endeavoured to show that even for such documents, they can be used in teacher-training for other purposes than simply teaching some history of mathematics, or enriching teacher's image of mathematics. As teachers, it is or will be part of their everyday work to analyze/assess teaching documents and make decisions on the basis of this analysis/assessment. Among these documents, some will be of an argumentative nature: sometimes in the form of pretty formal and academic proofs; more often than not, these documents will explicitly display or rather implicitly point to other forms of argumentation. We think the conceptual analysis – an analysis which has a mathematical component and an epistemological component, and which is to be distinguished from both the historical analysis and the didactical analysis – of some historical documents can give teacher-trainers opportunities to make explicit some tools which can be of constant use in the analysis and assessment of argumentative documents.

In this paper, we dealt with pretty informal arguments and elementary mathematics. However, we do not think this general scheme is specific to such contexts, since this work is a continuation of our CERME8 paper (Chorlay, 2013), in which a similar approach was used in a formal and rather advanced mathematical context (proof of the relationship between the variations of a function and the sign of its derivative).

*Transforming Instruction in Undergraduate Mathematics via Primary Historical Sources (TRIUMPHS) is a five-year, seven-institution collaborative project funded by the US National Science Foundation to design, develop, test and evaluate curricular materials for teaching standard topics in the undergraduate mathematics curriculum in the United States via the use of primary historical sources. Three short projects designed for use in a topology course are described, together with elements of a pilot study that collected data from students in the course to evaluate changes in attitudes toward mathematics and its study.*

*Keywords: Instructional materials, primary historical sources, topology, worldviews.*

## Introduction

There are numerous motivations and benefits for incorporating the use of primary sources into undergraduate mathematics teaching. Primary among the cited motivations is that providing students experience with reading texts in which the genetic development of a topic is presented gives them an opportunity to expand their mathematical education in such a way that includes both traditional and modern methods of the discipline (Fried, 2014; Laubenbacher et al., 1994). Another motivation is that using original sources in the teaching of mathematics makes it possible to contextualize the mathematics in ways that many textbook treatments do not afford. That is, original sources place particular mathematical ideas in the context and setting of the investigations in which the author was engaged at the time. As a result, the problems with which the author was struggling, and the motivations for solving them, are often more clearly and naturally described, and more compelling than traditional textbook expositions. Exposing the original motivations behind the development of esoteric mathematical concepts may be especially critical for placing the subject “within the larger mathematical world,” in the hope of making it more accessible to students (Scoville, 2012). Furthermore, primary texts seldom contain the specialized vocabulary that comes with later formalism, promoting access to the ideas by students with a wider range of backgrounds than is achieved with more standard presentations.

Many mathematics instructors interested in bringing the history of mathematics to the classroom question the use of primary historical sources in light of the increased availability of high quality secondary historical sources (e.g., Katz, 2009). Such resources may suffice to help students reap some of the benefits of original works; however, they carry their own difficulties. For example, there is a risk of placing too much emphasis on the history of mathematics per se, as opposed to using that history to support the learning of mathematics. Other key differences between using primary and secondary sources are described by Jankvist (2009):

When using secondary sources, the students are exposed to a given historian's presentation and, possibly, interpretation of history, and they must make their choices based on this (Furinghetti, 2007, p. 136). When reading original sources, the students must, on the other hand, perform their own interpretation of what actually took place, why a certain mathematician developed a theory in one way or another, whether or not what is written is true, what internal and/or external forces drove the development of the work, etc. ... The extent to which original sources are being used does, of course, have an impact on what the students learn: what students may gain from just "sniffing" at a few picks from an original source and what they might learn from being exposed to systematic readings of original sources are immensely different things. (p. 250)

In this final statement, regarding "what students may gain from just 'sniffing' at" selections from an original source, Jankvist points to the primary focus of the *Transforming Instruction in Undergraduate Mathematics via Primary Historical Sources* (TRIUMPHS) project.

### **The TRIUMPHS project**

In 2015, a seven-institution collaborative project to design, test, and evaluate curricular materials for teaching standard topics in the university mathematics curriculum in the United States via the use of primary historical sources was funded by the National Science Foundation. The TRIUMPHS project seeks to help students learn and develop a deeper interest in, and appreciation and understanding of, these mathematical concepts by crafting educational materials in the form of Primary Source Projects (PSPs) based on original historical sources written by mathematicians involved in the discovery and development of the topics being studied. These PSPs contain excerpts from one or several historical sources, a discussion of the mathematical significance of each selection, and student exercises designed to illuminate the mathematical concepts that form the focus of the sources. PSPs are meant to guide students in their explorations of these original texts in order to promote their own understanding of those ideas. TRIUMPHS plans to work with mathematics faculty and graduate students from over forty institutions in the United States who will participate in the development and testing process of these PSPs. As part of this five-year project, impacts of the materials and approaches to implementing them will be investigated in terms of teaching, student learning, and departmental and institutional change.

### **Organization of the paper**

The remainder of the paper is organized into four sections. First, we describe the three "mini-PSPs" implemented by the third author during his topology course in spring of 2016. Next, we present a broad overview of one of the components of research we are conducting during the five-year project, and then discuss a small subset of the data collected from five student participants. The paper concludes with a discussion of the implications from this small data set from the pilot year of the project, and a review of next directions planned for the research.

### **Primary source projects in topology: The case of three mini-projects**

The third author developed and implemented three "mini-PSPs" during the Spring 2016 semester at Ursinus College, a small liberal arts school outside Philadelphia, Pennsylvania. His experience using primary source materials in the classroom began in 2012 when he introduced them into a discrete mathematics course. His current interest in using primary sources in the classroom involves teaching topology. Three "mini-PSPs," each taking up two 50-minute class periods, were written for use in an

Introduction to Point-Set Topology course, an upper-division elective course for mathematics majors and a designated “capstone” course intended to provide an experience for mathematics students to test and apply previously acquired mathematical knowledge and skills. The author taught this course twice before in a standard lecture-based style. A short description of each of the three projects is provided below.

The course was introduced with a mini-PSP titled “Topology from Analysis” that investigates a paper by Georg Cantor (1872) in which he considered a problem in Fourier series, namely, if a function has a Fourier series expansion, when is such an expansion uniquely determined? Cantor proved in a previous paper that two convergent trigonometric series with equal sums have the same coefficients (uniqueness theorem), even if – for a finite number of values of the variable – the series either fail to converge, or converge toward different sums. Could this theorem be extended to certain infinite sets of points? After reading Cantor’s statement of the problem, the students explore simple examples of infinite sets where such an extension is possible. They investigate what properties these examples have that allow for such an extension. The desirable properties ultimately prompted Cantor to define concepts like limit points, derived sets, point sets, and iterated derived sets. The students were then able to use these concepts to prove a more general theorem. Even though these concepts were used to prove a result in analysis concerning Fourier series, they are naturally topological concepts. Hence the project helped to connect analysis and topology, thereby motivating new definitions through the need to clarify concepts, rather than introducing them as standard jargon.

The second mini-PSP focused on the topological concept of connectedness. It again considers a work of Cantor (1883) and his study of the continuum. Students follow Cantor’s musings concerning the best way to define such a concept. After he defined a perfect point set based on derived sets, he investigated whether the property of perfectness is sufficient to characterize a continuum. The students wrestle with this question, and eventually observe that such a definition will not suffice. Cantor then proposed an additional property, connectedness, which he defined using a metric. After reading Cantor’s definition of connectedness, students examine a work of Jordan (1883, pp. 24-27) which viewed connectedness in terms of separation of point sets into components. This introduces the students to a new conceptual perspective for the same notion considered by Cantor. Next, students read from a paper by Schoenflies (1904, pp. 209) in which it was proven that connectedness is a topological invariant. To do this, Schoenflies required a definition of connectedness that does not appeal to a metric, and is therefore purely topological. Finally, students read from a work of Lennes (1911, pp. 287, 303) in which he attempted to give a proof of the Jordan Curve Theorem and gave yet another definition of connectedness. Students are then asked to show that Lennes’ definition is equivalent to the definition used today.

The final mini-PSP used in the course studies excerpts from a paper of John Henry Smith (1874) on discontinuous but integrable functions. Smith intended to provide a counterexample to a “theorem” of Henkel. He constructed an integrable function that is “very badly” discontinuous. Students are led through Smith’s work involving the definition of the concept of nowhere dense set in order to construct such functions. As in the first mini-PSP, students examine a problem that motivates the need for a new mathematical concept by abstracting the essence of particular examples in order to capture the essential properties that a set must satisfy to prove a result. Ultimately, this project

culminates in Smith's construction of a generalized Cantor set. A function that is continuous except on a generalized Cantor set is then seen to provide a counterexample to Henkel's claim.

A major benefit of these mini-PSPs is that they naturally induce sophisticated discussions about the mathematics by students. During classroom implementation, students were observed to be carefully and thoughtfully working to understand concepts, answer questions, and pose their own questions and conjectures. One such instance occurred when students began to question Schoenflies' definition of connectedness, without prompting from the instructor. The question was raised as to what Schoenflies meant by the phrase "... can be decomposed ...". One student suggested that he meant a partition, but it was soon realized that such an interpretation would be too general. Others then began to modify the partition idea to make it work. This sort of high-level engagement had not occurred in any previous topology course taught by the instructor.

## **Description of the research**

The TRIUMPHS project includes an evaluation-with-research (EwR) study, designed to provide both formative and summative evaluation of the key project activities and defined goals for each. In the original EwR study design, we designated three project components for which we would conduct extensive research and evaluation, and designated these as "student change," "faculty expertise," and "development cycle." Here we only describe a small piece of the "student change" component of the study.

### **Rationale and research questions**

For decades much of the research literature on the impact of the history of mathematics on students, particularly at the secondary level or post-secondary level, was focused on students' attitudes (e.g., Marshall, 2000; McBride & Rollins, 1977). There was scant focus on the use of primary sources as a classroom tool in the early work in the field of history in mathematics education. However, more recent work on the use of primary sources has been done in countries such as Denmark (e.g., Kjeldsen & Blomhøj, 2012) and Brazil (e.g., Bernardes & Roque, 2016), while such research has not yet been conducted with student populations in the United States. Thus, we are committed to investigating the ways in which mathematics students respond to concepts within the undergraduate curriculum that are taught via primary sources. To this end, we developed several research questions, of which we provide a subset here:

1. As a result of students' work with or study of a PSP, what changes do students report in their attitudes and beliefs about learning mathematics?
2. As a result of engaging with PSPs, what do students report as challenges and benefits of learning from primary sources?
3. What is the dominant mathematical worldview reported by students on pre- and post-course surveys? And, does academic major (or gender, or race or other attribute) make a difference in the reported worldviews?

### **Pilot study: The case of a topology course**

This work took place in the first year (pilot year) of the project, which was focused on developing instruments and refining the questions that were formulated in the original grant proposal. The only

data sources available for analysis were student pre- and post-course surveys, student work samples (from the three mini-PSPs), and instructor surveys and post-implementation reports. Data were collected from four undergraduate mathematics courses during the pilot year of the TRIUMPHS project: two courses in Fall 2015 (geometry; analysis) and two in Spring 2016 (abstract algebra; topology). In the topology course, the three mini-PSPs described above were implemented and tested for the first time by the third author. In this paper we report data that inform the first, second, and fourth research questions listed above for the five of eight students enrolled in that course who consented to participate in the research and for whom we obtained a complete set of data.

### **Exploring student responses: Research questions 1 and 2**

Our initial pre- and post-course surveys (to which students responded before instruction on any PSP occurred and again at the end of the course) only contained one pair of open-ended questions asking students to identify what they enjoyed most and least about studying mathematics:

What do you enjoy most about studying mathematics. (Explain briefly.)

What do you enjoy least about studying mathematics. (Explain briefly.)

For this small group of students, pre- and post-course responses were mostly stable for this pair of questions. This could be a function of the fact that all five students were in the final two years of their undergraduate program. However, we discuss two interesting pre-/post-course survey pairs of responses below.

First, in response to the second prompt, Student 2 stated on the pre-course survey that she was “not fond of professors/texts that state a definition/theorem/idea without giving any hint to how that conclusion was derived, either historically or through proof/explanation.” By the end of the course, however, her response no longer referred to lacking historical grounding or a thorough proof or explanation. Instead, her response focused on the fact that “it is very easy to go through math classes and fall behind. If you don’t understand one topic, the class often moves on without you...”

A similar change in identifying what he enjoyed least about studying mathematics occurred with Student 3. On the pre-course survey, Student 3 stated that he least enjoyed “how everything is given to you but never comes with an explanation of where the math is coming from.” However, in response to the same item on the post-course survey, Student 3 only commented that he disliked having to remember definitions and equations. It is possible that for Students 2 and 3 that the historical sources related directly to the formal content of the course satisfied their initial “sore spot” with regard to what they previously enjoyed least about studying mathematics. Since there was no effort in the pilot year to ask for student clarification (e.g., via follow up interviews), we cannot link the change in the sample responses presented here as resulting from students’ engagement with the PSPs. However, the responses signal potential interesting outcomes and we have modified our pre- and post-course surveys and have added post-PSP surveys to further investigate this potential influence.

We also asked students to describe their experience using the mini-PSPs in the topology course, as a way to explore the benefits and obstacles they identified. The student responses were encouraging, and in important ways their responses point to the underlying effect of engaging with materials that provide an opportunity to understand the evolution of a mathematical concept. Here, we provide a sample of three of the students’ descriptions:

Student 1 (Mathematics major): “We used these sources to learn about topics such as connectedness as we thought about origins of the idea and read about how the definitions changed the longer it was studied.”

Student 2 (Computer Science major): “Each PSP was an interesting addition to class, and it was unique to be able to see the process of mathematical ideals through the eyes of the various mathematicians.”

Student 5 (Physics & Mathematics major): “I enjoyed the document on definitions of connectedness, because it showed how mathematics is really done and how it takes time to accurately articulate an idea. I also liked the first document because it helped motivate topological ideas and illustrate the connection between topology and analysis.”

### Exploring student responses: Research question 3

To address the third research question, we included a subset of 20 items from Törner (1998) on the pre- and post-course surveys. Törner and his colleagues surveyed 310 German secondary mathematics teachers in order to identify attitudes about mathematics that captured “the essence of mathematics,” where they defined “mathematics as a field and not as a subject taught in school” (p. 119). In doing so, they identified attitudes relating to four aspects of a mathematical worldview: scheme, formalism, process, and application. Tables 1 and 2 report the pre- and post-survey means of students’ responses for these items. Item responses ranged from 1 to 5, where higher values indicate stronger association with that particular worldview. The predominant worldview (in bold in tables 1 and 2) of the Spring 2016 topology students on both the pre- and post-course survey was the process view.<sup>1</sup>

Mathematical worldview	Student 1 (female; 4 <sup>th</sup> year <sup>2</sup> )	Student 2 (female; 4 <sup>th</sup> year)	Student 3 (male; 3 <sup>rd</sup> year)	Student 4 (male; 3 <sup>rd</sup> year)	Student 5 (male; 4 <sup>th</sup> year)
Schema	3.4	3.2	3.4	<b>4.2</b>	1.6
Formal	3.8	3.4	3.8	4	4.4
Process	<b>4</b>	<b>4.6</b>	<b>5</b>	3.6	<b>4.8</b>
Application	3.6	3.4	3.6	3.4	3.4

**Table 1: Mathematical worldview of Topology students, Spring 2016 sample (pre-survey)**

Mathematical worldview	Student 1	Student 2	Student 3	Student 4	Student 5
Schema	3.4	2.6	4.2	3.6	1.4
Formal	<b>4.8</b>	3.4	4	3.8	4
Process	4.2	<b>4.4</b>	<b>5</b>	<b>4</b>	<b>4.4</b>
Application	3.8	3.4	4.4	3.8	3.4

**Table 2: Mathematical worldview of Topology students, Spring 2016 sample (post-survey)**

<sup>1</sup> Törner (1998) described each of the four aspects. For example, the process aspect characterizes mathematics “as a process and as an activity in thinking about problems and gaining knowledge” (p. 122); whereas the schema aspect represents a view of mathematics as “a “tool-box and bundle of formulas” and an idea oriented with algorithm and schemes” (p. 123).

<sup>2</sup> In the college and university system in the United States, typical undergraduate degrees are four years in duration.

Törner (1998) reported on the relations among these four aspects, stating, “the formalism and schem[a] scale represent both aspects of the static view of mathematics as a system and intercorrelate highly” (p. 125). However, these two aspects of a static paradigm “correlate with the process scale in a significantly negative way” (p. 125), which is a finding that appears to hold for several students in our sample. For example, where there are lower means on the scheme and formal aspects (e.g., Student 2 pre/post; Student 3 post; Student 4 post), higher mean values occurred on the process aspect.

## Discussion

This paper highlights the promise of robust investigations and implications that may result from the EwR efforts of the TRIUMPHS project. The project’s pilot year enabled us to trial student and instructor survey instruments and data collection procedures. We chose the topology course as a case because of the particular nature of the PSPs (“mini” as opposed to full-length), the students’ mathematical maturity (juniors and seniors), and the expectation that many of the courses participating in TRIUMPHS will also likely have small enrollments. As a result of the pilot year, we have significantly modified our survey instruments and research questions, and our aggregate student population has now increased. As we move forward, our research plans include conducting multiple analyses to identify trends in students’ mathematical worldviews (within courses, across courses, and disaggregated by other demographic characteristics). We have also developed and incorporated post-PSP surveys and are currently developing and piloting multiple interview protocols.

# A course in the philosophy of mathematics for future high school mathematics teachers

Elizabeth de Freitas

Manchester Metropolitan University, Manchester, UK, [l.de-freitas@mmu.ac.uk](mailto:l.de-freitas@mmu.ac.uk)

*In this paper, I discuss a course in the philosophy of mathematics designed to help future high school mathematics teachers develop an understanding of philosophical questions about mathematics. Throughout the course, our discussions link core philosophical questions to particular theories of mathematics teaching and learning. Thus the course mixes traditional philosophy of mathematics with the study of everyday embodied mathematical habits, offering a kind of descriptive and synthetic approach more often associated with continental traditions of philosophy. This paper describes some of the key theoretical themes and issues, and argues that such courses offer future teachers important insights into the nature of mathematics.*

*Keywords: Philosophy of mathematics, ontology, epistemology, teacher education.*

## Introduction

Philosophical questions about mathematics open up discussions about why we have the mathematics we have, inviting consideration of how mathematics is embodied in particular material practices. This paper discusses a course designed for pre-service mathematics teachers with the aim of diversifying their image of mathematics, and enhancing their skills at philosophically analyzing mathematical behavior. Throughout the course, our discussions link core philosophical questions to historical developments in mathematics (and philosophy) and to particular pedagogical approaches to mathematics education. Thus the course mixes historical perspectives with traditional philosophy of mathematics and with the study of everyday embodied mathematical habits. The focus on embodied material practices in mathematics – past and present – is more often associated with phenomenology and other continental traditions of philosophy, rather than the analytic tradition one typically finds in the philosophy of mathematics. Such a mixture of analytic and continental philosophy is extremely challenging, in part because analytic approaches have been typically concerned with foundational questions that do not always translate into studies of everyday mathematical practice. The course is modeled on what Corfield (2003) calls *descriptive epistemology* insofar as it entails interpreting mathematical activity for how it reflects certain philosophical assumptions about the nature of mathematics, following earlier efforts by authors such as Lakatos and Kitcher to remake the philosophy of mathematics into the study of mathematical practice, while incorporating and expanding approaches to the foundational concerns.

Students enroll in the course often not knowing anything about philosophy, let alone the philosophy of mathematics. They are usually in their fifth year of a combined bachelor degree in mathematics and master's degree in education, and are just beginning to visit high school mathematics classrooms and practice-teach. I open the course with a set of statements that Brown (2008) calls the common “image” of mathematics. Students are then exposed to the following set of core questions. These core questions drive many of the discussions and course assignments.

1. Can a diagram function as a mathematical proof?

2. What is the nature of proof? How has mathematical proof changed over history?
3. Is there such a thing as mathematical intuition? Where is it? Is it innate?
4. Is mathematics indispensable to science? Could science work without math?
5. What should be the relationship between logic and mathematics?
6. What is the status of axioms? Are they grounded in reality?
7. Are mathematical propositions *necessarily* true (or false) (rather than culturally or contingently true/false)?
8. Is mathematics a language (a system of symbolic signs that are immaterial and not part of the physical world)?
9. Can we speak about actual infinity (or just potential infinity)? How has the concept of infinity influenced the development of mathematics?
10. What is the role of the body in doing mathematics? How is mathematical knowledge embodied?
11. Is mathematics discovered or invented? What are the ontological implications of your answer?
12. Is mathematics objective and certain (rather than subjective and open to revision)?

It's absolutely essential that before tackling these questions, we unpack the difference between epistemological and ontological concerns (knowing versus being). Of course the two concerns are always entangled, but students need to identify the distinctive contribution of each. The need to keep these two concerns separate while understanding their relationship helps considerably as they go on to formulate arguments to support their positions on the core questions. Perhaps because these are education students, they seem more at home with epistemological questions (How do we come to know the concept of number?) and are initially baffled by ontological questions (What is number?). I have learned to motivate the latter by suggesting that such questions will be of huge interest to their future students. I suggest they treat the typical student query "how is this relevant?" as a philosophical question, and that they consider these queries akin to the very questions posed by philosophers of mathematics. Indeed, these bored students are asking, in their own way, the philosophical question: "Why mathematics?". Rather than offer the usual unconvincing answer, such as "because you can use it to do ...." teachers might explore with their students the various schools of thought that developed as a means of answering this very question. They could, I suggest, introduce one of the core questions into their lessons, as a motivator for all those astute students who have raised this central concern about the relevance of mathematics. In other words, rather than dwelling on the pragmatic nature of mathematics, I suggest we direct attention to the more *speculative* aspect of mathematical activity.

The course uses historical case studies to help students diversify their image of mathematics. Pairs of students research and present a 10-minute slideshow on a discussion topic each week, focusing on what are deemed controversies. Sample topics are: Zeno's paradoxes and the parallel postulate. As the instructor, I introduce links between the topics and the core philosophical questions that structure the course. For instance, a presentation about the parallel postulate might simply recount attempts to prove it and mention developments of non-Euclidean geometry without linking these developments to our readings about Kant and his claims about the *a priori* synthetic nature of geometry. Further links need to be raised that help the students grasp how this topic is related to questions about the certainty and objectivity of mathematics, and its relation to science. With little to no training in history or philosophy, these students tend to present their topics without consideration of social context or

cultural ramifications. These brief presentations feed into their later more substantial assignment to compose a philosophical paper, arguing in support of a position on one of the key questions listed above. It has always intrigued me that these students, despite being immersed in mathematics, a field known for its careful deductive methods, struggle so much in composing a formal philosophical argument. Many of these students confess to having selected mathematics because they don't enjoy reading and writing. However, I feel strongly that, as future teachers, they need to become excellent communicators, and I treat the course as an opportunity to build that skill as well. I have designed guidelines to help them structure their assignments, and I work with various draft versions of their papers to help them improve this skill.

### **General philosophical themes**

The distinction between ontology and epistemology helps us narrow in on students' assumptions about mathematical activity, as we discuss how Platonism and other schools of thought consist of an ontological claim *and* an epistemological claim. In this we follow Bostock (2009) who effectively differentiates these kinds of claims for different schools of thought. The ontological questions are the most difficult for the students to comprehend. We ask: In what sense can universals (redness or beauty or triangles or numbers) be said to "exist"? This, as Bostock reminds us, is a question about the ontological status of universals. Most students don't quite know how to engage with this question, although they are more than ready to grant universality (generality) to geometric figures or arithmetic entities like numbers. They tend to think of this generality as cross-cultural, and confuse it with the question of truth value. My task is to tease out questions about truth from metaphysical questions about being. I offer them some choices: If universals do exist, do they exist outside the mind, or simply as mental entities? If they exist outside the mind, are they corporeal or incorporeal? If they exist outside the mind, do they exist in the things that are perceptible by the senses or are they separate (or independent) from them? To further support and scaffold their exploration of these questions, I offer three schools of thought, each with a different answer to these questions, and I ask the students to decide who they most identify with. I am really forcing their hand in this, in that I hope to show them that these three responses do not actually exhaust the possible answers to the ontological question. In the next section, I discuss how new directions in the philosophy of mathematics offer different choices. But the choices first given, drawn from those used by Bostock (2009), are simplifications so that they can begin to engage in debate. As in all such sorting and labeling, we can query whether a particular mathematician or philosopher is a good example of a particular philosophical paradigm (for instance Hilbert is egregiously characterized as a nominalist in this list), and I am careful to tell the students that they will debate these issues later, after reading more primary texts:

- The *realist* (Plato, Frege, Godel) claims that universals exist outside the mind and are independent of all human thought.
- The *conceptualist* (Descartes, Kant) claims that they exist in the mind and that they are created by the mind. Some claim that we create these universals based on sense perception and some say they are innate and do not require perceptual stimulation.

•The *nominalist* (Hilbert, Field) claims that they do not exist outside of language. Some claim that the words and symbols we use are mere shorthand for longer ways of expressing the same idea and some claim that statements with such terms are simply untrue in the sense that they refer to nothing.

The assignment of the names to the schools is imperfect, but it works as a starting point. One of the difficulties in starting with the main schools of thought, and then trying to tease out the subtle differences and ways in which these philosophers' claims are not perfectly aligned with the school, is that the students are not yet ready to delve deeply into these historical subtleties. For instance, it might seem a travesty to put Descartes and Kant together, since Kant pushed past Descartes' claim that mathematical truths are innate, clear, and distinct ideas, so that he might attend to the synthetic nature of mathematical judgment. According to Kant, space and time are the mind's contribution to experience. Space and time are the "form" of experience, a form imposed by us on the raw data of experience. Historians of philosophy usually oppose Descartes (the rationalist) against Locke and Hume (empiricists), and posit Kant as the reconciler. Bostock (2009), however, claims that Locke, Hume and Descartes, despite their differences, share the same beliefs about the ontological status of mathematical objects (they are ideas or mental entities), and differ in how they think we acquire these mathematical ideas. One might then associate Kant with this approach as well, since, as Brown (2008) suggests, according to Kant, "Our *a priori* knowledge of geometric truths stems from the fact that space is our own creation." (p.119) Similarly, arithmetic for Kant is connected to time and the fact that time is also a form we impose on the world. This conceptualist approach seems to have saturated many of the later treatments of the philosophy of mathematics, seeping into the realist and nominalist camps as well. Brown indicates that Frege (a Platonist) embraced Kant's view on geometry, Hilbert (the formalist or nominalist) embraced Kant's view on arithmetic, and even Russell (the logicist) can be characterized as Kantian. One might also argue that the conceptualist approach has saturated theories of learning, and has become full-fledged in cognitive psychology and its dominant image of learning. This image assumes that learning entails an acquiring of a set of cognitive 'schemas' and assumes that brains are the seat of reason. Pre-service teachers need to be aware of this history so that they might become empowered to identify and critique the theories of learning that structure the curriculum policy they are meant to adopt in their classrooms.

## Diagrams and the body

Questions about the status of diagrams in proofs are easy for students to connect with, and link directly to the opening readings by and about Plato. Students are drawn to the compelling distinction that Plato draws between the physical world and the realm of mathematics. We discuss the theory of ideal forms, and how Plato was motivated by the gap between the ideas we can conceive and the physical world around us. Some students see in the proposal of an ideal realm a way of reconciling their belief in the universality of mathematics with the messiness of learning, but more often than not they are drawn to a conceptualist approach, perhaps Kantian, whereby mathematics is considered a cognitive invention that aligns with the physical universe. Thus they tend to ascribe to the human mind a consciousness or intuition or faculty that is capable of bringing together the ideal forms (triangles, numbers, etc) that are unchanging and eternal (the realm of being or essence) with the physical realm (the realm of becoming or change). We discuss how there is a strong dualism (between mind and body) at work in this approach, and how this dualism plays out in different pedagogies. The vast majority of pre-service teachers split mind from body, arguing that we grasp the ideal forms only

through mental reflection, while we understand the physical world through the senses, just as Plato might say. Most of the contemporary philosophy of mathematics we read in the course questions the validity of this dualism, and we discuss the main criticisms of Platonism that were formulated centuries ago.

Diagrams figure prominently in this discussion, as they have, since Plato, if not before, bridged the dualism in ways that trouble its claim to a clean distinction (de Freitas, 2012). In small groups, the students are given a set of visual proofs, and asked “What does this diagram prove?” I use this question to provoke debate, as it gets to the heart of concerns about what constitutes a legitimate proof in mathematics. We discuss to what extent the diagram might function as a proof of an arithmetic statement.

We situate the question historically, by discussing readings by Plato (Meno, Theatetus, Republic). Although the students tend to find Socrates overbearing in the Meno, they begin to grasp how the Socratic method emerges from a particular set of philosophical assumptions about the nature of mathematical diagrams and concepts. We compare this method to the kind of questioning sequences they see in their observations in classrooms. For Plato, geometrical knowledge is obtained by pure thought and divorced from sensory observation, which seems to go against what many of the students experience in mathematics classrooms. This is when they become somewhat unhappy with their Platonism. As Brown (2008) explains, Plato considered the diagram as merely a heuristic to help us “access” the pure forms of mathematics. Plato is critical of the geometers who work with diagrams and are led astray by the visual *images* of mathematical ideals. Plato is rather disparaging of all this talk of diagrams and gestures and activity, chiding the geometers for using material verbs to talk about mathematical actions:

Don’t you also know that they use visible forms besides and make their arguments about them, not thinking about them but about those others that they are like? They make the arguments for the sake of the square itself and the diagonal itself, not for the sake of the diagonal they draw, and likewise with the rest. These things themselves that they mold and draw, of which there are shadows and images in water, they now use as images, seeking to see those things themselves, that one can see in no other way than with thought. (Plato, Book VI, 510d, p. 191)

Here, true apprehension is achieved only through rational discernment (“thought”), rather than empirical investigation or what Kant will call synthetic reason. For Plato, geometers use diagrams and visual forms to speak about *ideal* forms, “seeking to see those things themselves” when only “thought” in its pure disembodied capacity can access such ideal forms. In the course, we discuss the consequences of Platonist and conceptualist approaches that deny or demote the significance of the material activity of doing mathematics and prize instead only the mental or cognitive reasoning faculty. We begin to read contemporary theories of embodied cognition that attack this approach philosophically (Lakoff, G. and Núñez, R., 2000; Nemirovsky et al, 2009; Roth 2010). The students begin to grasp how diagramming (and other embodied activities) are not merely heuristic but rather necessary for thinking mathematically. We discuss what it might mean for thinking to occur in and through this activity rather than independent of it.

The readings in this section of the course range across phenomenology, focusing on the role of the body in learning mathematics. We begin to consider how recent work in embodied mathematics might

engender a new philosophy of mathematics. Although the work of Lakoff and Núñez is still ‘conceptualist’ in how it treats the body as the container of the mind (a dualism inherent to their approach), there are other scholars who attempt to move even further into a monist philosophy of mathematics (Nemirovsky & Ferrara, 2009; Roth, 2010; Stevens, 2012). For instance, de Freitas and Sinclair (2014) push past the phenomenology framework, seeking a more post-humanist approach that attends more generally to the diverse material forces at work, and less exclusively on the human body’s individuated capacities.

## The ontological turn

The pre-service teachers are shown how much of the philosophy of mathematics since the nineteenth century has been contending with the Kantian assertion that mathematical truths are *a priori* and *synthetic*. Kant claimed that if a proposition is thought as (1) necessary and (2) universal then it is an *a priori* truth; and if a judgment of truth requires one to engage with the phenomenal world in some fashion, it is a *synthetic* judgment rather than an analytic one. Mathematical truth, according to Kant, is both synthetic and *a priori*. How can such knowledge be possible? This is a perennial question in the philosophy of mathematics, the question as to how *pure* mathematics is possible as an activity in this messy world (Hacking, 2013). In other words, how can we grasp universal and necessary truths by using our material bodies to determine whether they are true? Hacking claims that one has to look closely at applications of mathematics if one is to address – or contest – this question of purity.

Corfield (2003) argues that the philosophy of mathematics has spent far too much time on the foundational ideas of the 1880-1930 period, and neglected the thinking and doing of “real” mathematicians both before and after that period. Corfield believes that a philosophy of mathematics should “concern itself with what leading mathematicians of their day have achieved, how their styles of reasoning evolve, how they justify the course along which they steer their programmes, what constitute obstacles to these programmes, how they come to view a domain as worthy of study and how their ideas shape and are shaped by the concerns of physicists and other scientists.”(p.10) He names this approach *descriptive epistemology* and defines it as the “philosophical analysis of the workings of a knowledge-acquiring practice.” (p. 233) Imre Lakatos (1976) is often taken as inspiration in this kind of approach to the philosophy of mathematics. He examined the process of meaning-making in mathematics, by studying the historical evolution of concepts and procedures, and offering insight into the form of deliberation that characterized creativity in the work of mathematicians. He was interested less in the so-called foundational issues in mathematics, and more in the empirical and material making of mathematics, an approach he called “critical fallibilism”:

It will take more than the paradoxes and Gödel’s results to prompt philosophers to take the empirical aspects of mathematics seriously, and to elaborate a philosophy of critical fallibilism, which takes inspiration not from the so-called foundations but from the growth of mathematical knowledge. (Lakatos, 1978, p. 42)

Hersh (1997) characterizes Lakatos as a philosopher of mathematics who was committed to studying the social and “humanist” aspects of doing mathematics. For Hersh, Lakatos was a humanist because he celebrated the specificity of informal reasoning found in the work of mathematicians, rather than or in addition to the generality of its truth claims. For Lakatos, these examples of informal reasoning are not simply unfinished formal proofs, in which the pertinent axioms and logical rules of inference

are suppressed, but rather a significantly different mode of inquiry, a non-axiomatic argument that has its own trajectory and its own becoming.

Despite the significance of this more humanist perspective on the philosophy of mathematics, which values the study of informal and unfinished mathematical activity by experts, we still lack philosophical insight into the experiences of those who, for the most part, do mathematics from an outsider or fringe position, like most students. Although recent moves in the philosophy of mathematics – like Corfield – have insisted that we look more closely at the *practice* of contemporary mathematics to build a philosophy of mathematics, these scholars are still entirely focused on extremely accomplished mathematicians, and remain focused on the epistemological dimension of that activity. In other words, *they are still concerned with how mathematicians determine the truth of their mathematical propositions*. But this is not the only issue! Despite the more expansive study of mathematical activity, Corfield’s approach of “descriptive epistemology” is, as the name suggests, directed at mathematician’s epistemology or theory of knowledge production.

A focus on *knowledge production* confines one to attend to particular aspects of activity – indeed, this focus explains why scholars like Corfield look exclusively at accomplished mathematics. In order to grapple philosophically with mathematical activity more broadly – be it expert or novice, animal or human, revolutionary or controlling, conceptual or algorithmic – one needs to consider mathematics not merely as a knowledge production activity. Contemporary philosophers like Zalamea (2014) and Châtelet (2000) and Deleuze (1994) lend support in this venture, as they grant mathematics more ontological import, although continuing the focus on high-stakes achievement. These scholars track how mathematics operates in the world as both an expression of human cultures (perhaps as knowledge), but also as a kind of *worlding* in itself. In other words, mathematics is an activity both pragmatic and speculative that makes and mutates possible worlds. As part of what many have called the “ontological turn” in the humanities, this speculative work (“worlding”) informs a contemporary shift in the philosophy of mathematics, towards an emphasis on “mathematics as ontology”, the latter refrain capturing Alain Badiou’s attempt to position mathematics *within* philosophy, but not merely as logic in drag.

The ontological turn and related developments in philosophy are reshaping the way we think about all material-cultural practices, let alone mathematics. The course aims to move students through conventional idealism (best formulated in Plato) through conceptualism (best formulated in Kant) through phenomenology (best formulated in Merleau-Ponty) to a more post-humanist perspective that dethrones the human subject as the central orchestrator of his/her mathematical participation. It is near impossible to move students through these radical shifts in one course, but one can begin to problematize the landscape and trouble assumptions about mathematics.

## Conclusion

This course aims to help pre-service teachers develop a nuanced appreciation for the philosophy of mathematics, so that they might begin to critique the intellectualist and conceptualist model of mathematics teaching and learning.

# Variational strategies on the study of the existence and uniqueness theorem for ordinary differential equations

Rodolfo Fallas-Soto<sup>1</sup> and Ricardo Cantoral<sup>2</sup>

<sup>1</sup>Cinvestav, Mathematics Education Department, México City, Mexico; [rfallass@cinvestav.mx](mailto:rfallass@cinvestav.mx)

<sup>2</sup> Cinvestav, Mathematics Education Department, México City, Mexico; [rcantor@cinvestav.mx](mailto:rcantor@cinvestav.mx)

*In this paper, we study historical proofs of the existence and uniqueness theorem for the differential equation  $y' = f(x, y)$ . We analyze original works that played a part in the problematization of this concept, thus offering a rational reconstruction of its genesis which sheds light on its meaning. We will use results from the socioepistemologic theory to show that variational strategies are efficient in the analysis of the proof. We believe this epistemological analysis may help in the future for pedagogical designs.*

*Keywords: Socioepistemology, variation, existence, uniqueness, differential equation.*

## Introduction

We present the results of an ongoing research on the existence and uniqueness theorem for first order ordinary differential equations. The socioepistemological theory, theoretical basis of the research, faces, from a systemic view, a possible reconstruction of its meaning due to the variational strategies in its development, without limiting itself to a chronological reproduction of the contributions of the mathematical works, nor a reinterpretation of what we actually know of the theorem.

Variational strategies involved the construction of the mathematical notions related to the theorem mentioned above are analyzed. These strategies are part of a study program called “Variational Thinking and Language” that the socioepistemological program develops. From the study a different use of the actual knowledge is recognized, that is considered a potential element to start changing the relation with said knowledge from the objects to the actual practices (Fallas-Soto, 2015).

This notion of “from the objects to the actual practices” talks about constructing a new interpretation of the object (the theorem in this case) based on practices (Cantoral, 2013), with the notion of starting with the *problematization of knowledge*, from the Socioepistemology, finding the meanings of said knowledge at the moment of actual use. Then, the problematization from this view, consists in performing a double study whose elements, *historize* (historical reconstruction of knowledge) and *dialectize* (coordination of mathematical notions, examples, counterexamples and conceptions and misconceptions), are the base to study the evolution of the theorem throughout history and thus to analyze how its associated mathematical notions plays in order to construct the theorem from the point of what is known today.

Therefore, the research problem is linked to the *meaning* in mathematics, this because the way how the existence and uniqueness theorem is presented on textbooks does not appears to be deduced from the practices properly, nor also from the mathematization. Then, the problem, which are the principles that give meaning to the notions of existence and uniqueness as specific characteristics of the solution's nature? The hypothesis of this research work is to assume that the construction of the theorem can be a prediction model with the study of variation. It can be said that there's a common

thread that organizes the conditions for the existence and uniqueness, and is connected with the prediction idea that was the basis for the theorem along with its hypothesis.

The research focus for this research was to *mean the existence and uniqueness theorem* from a particular problematization of mathematical knowledge.

## Methodology

The phases that describe the research are briefly described below: we study the textbooks used in the teaching of Differential Equations, particularly we analyze the demonstration. By showing that there is no problematization of this mathematical knowledge and only remains as a test of hypothesis, it is decided to study the genesis of this knowledge and its evolution. We offer a rational reconstruction of the main arguments used by mathematicians and in the part of conclusions we make a comparison of the origin of the theorem with the current didactic treatment.

A rational reconstruction for the existence and uniqueness for differential equations, in a first stage, a bibliographical research is presented with some of the mathematical works of the time that helped on the construction of this knowledge. These are:

- (Cauchy & Moigno, 1844), *“Leçons de Calcul Différentiel et de Calcul Intégral”*
- (Lipschitz, 1880), *“Lehrbuch der Analysis”*
- (Lipschitz, 1868) *“Disamina della possibilità d' integrare completamente un dato sistema di equazioni differenziali ordinarie”*
- (Peano, 1973 – new-edition) *“Sull' integrabilità delle equazioni differenziali di primo ordine”*.
- (Picard, 1886) *“Cours d' Analyse”*

This proposal there will be reported the results obtained in the analysis of Cauchy & Moigno (1844) and Lipschitz (1880) papers, all of them for the study of the variational strategies. These five books were chosen because of Picard and Peano appear in the current textbooks contributing to the theorem. Then Picard (1886) in his work refers to Cauchy and Moigno in addition to Lipschitz.

On a second stage, a documental analysis, the elements used on the mathematical works for the study of the existence and uniqueness theorem are reconstructed. This gives contributions to generate implementation strategies that propitiate the construction of the theorem based on a pragmatic evolution of the practices. To obtain the conclusions of tis work, we perform a confrontation between the mathematical works (also used for teaching) that arose at the end of the XIX century and at the beginning of the XX century, with ideas from the textbooks of XX century and nowadays.

With respect to the variational strategies presents on this theorem, we are based on the PylVar (That its acronym in Spanish means Thinking and Variational Language) program that has been used throughout the years by some authors (Caballero, 2012), (Cabrera, 2009), (Cantoral, 2004; 2013a), (Cantoral & Farfan, 1998). This approach seeks to show the construction of mathematical knowledge from the study of motion, change and the variation of physical or natural phenomena. Our research work does not mention the modeling of phenomena related to the theorem of existence and uniqueness, however in the study of change is how the differential equations are born and we continue to deepen in current research. These works have permitted to explicit the variational strategies (practices on the study of change) that the Pylvar program describes, and that are discussed in Caballero (2012):

- Comparison: Associated to the action of establishing differences between states.
- Serialization: It is associated with the action of establishing relations between successive states. To study the changes to determine a certain pattern.
- Estimation: Starting from other knowledge of changing states, proposing states for a short term.
- Prediction: The action of being able to determinate after analyzing some states to deduct posterior states. It means to anticipate to a certain rational state.

## Results

We do not offer a mathematical proof but to show arguments that helped the mathematicians in formalizing this mathematical knowledge.

Cauchy & Moigno (1844) consider the differential equation  $y' = f(x, y)$  with the hypothesis that  $f(x, y)$  and  $\frac{\partial f}{\partial y}$  are continuous functions with the initial condition  $(x_0, y_0)$ . The authors prove the convergence of the sequence of points obtained by the fractions method.

386 CALCUL INTÉGRAL.

$n$  valeurs correspondantes de  $y, y_1, \dots, y_{n-1}, Y$ , à l'aide  
des équations

$$\begin{aligned} y_1 - y_0 &= (x_1 - x_0)f(x_0, y_0), \\ y_2 - y_1 &= (x_2 - x_1)f(x_1, y_1), \\ &\dots\dots\dots \\ Y - y_{n-1} &= (X - x_{n-1})f(x_{n-1}, y_{n-1}), \end{aligned}$$

en éliminant  $y_1, y_2, \dots, y_{n-1}$ , on obtiendra une valeur de  
Y de la forme

$$Y = F(x_0, x_1, x_2, \dots, x_{n-1}, X, y_0),$$

Figure 1: Fractions method utilized by Cauchy & Moingo, page 386 of the lesson 26 of the work  
Leçons de Calcul Différentiel et de Calcul Intégral.

This method (this method of approximation was expounded by Euler in 1768 in his *Institutionum Calculi Integralis*) consists on determining successive states that depend on the preceding state parting on the study of the linearity and small variations that can be taken with the differential equation (as the rate of change that determines the slope of the line) and the initial condition (point by which the line passes). This procedure is shown in the following figures.

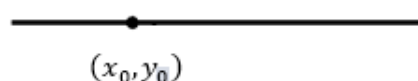

$$y_1 - y_0 = (x_1 - x_0)f(x_0, y_0)$$

Figure 2: First iteration of the fractions method.

$$y_2 - y_0 = (x_1 - x_0)f(x_0, y_0) + (x_2 - x_1)f(x_1, y_0 + (x_1 - x_0)f(x_0, y_0))$$

**Figure 3: Second iteration of the fractions method**

Therefore, the process is generalized and it is approximated that  $y - y_0 = \pm \theta A(x_n - x_0)$  where  $A$  is an average of the  $f(x_n, y_n)$  and  $\theta$  a value between 0 and 1. Then, the authors generalize the process and stating that  $y_n$  is equal to

$$y_n = y_0 + (x_n - x_0)f(x_0 + \theta(x_n - x_0), y_0 \pm \theta A(x_n - x_0))$$

**Figure 4: N-th iteration obtaining a numerical approximation of the solution.**

From which  $y_n$  corresponds, practically, to the same value that  $y_0$  if the difference  $x_n - x_0$  is small. In other words, if  $x_n \rightarrow x_0$  then  $y_n \rightarrow y_0$ .

Besides, convergence is studied in the following form as part of a stability of the system. If a small increment  $\zeta_0$  is added to  $y_0$ , then  $y_n$  will have an increment  $\zeta_n$ . In order for it to converge, this last increment has to be as small as  $\zeta_0$ . This seeks the stability of the function  $y$  to guarantee the existence. Again, the small variation plays a fundamental role to compare states and thus determine a local prediction on each iteration to determine a final global prediction (estimation) of the system.

**Figure 5: Case where the increment of  $y_n$  changes considerably with respect to the increment of  $y_0$ .**

This result is studied even further by Lipchitz (1880) when working with systems of equations and the uniqueness of the solution. By looking at figure 05, what is really happening is that from the first

iteration two tangent lines are obtained that correspond, respectively, to each of the solutions. Because of this, on the point  $(x_1, y_1)$ , and another one close to it, say  $(x_1, \eta_1)$ , with  $\eta_1 = y_1 + \theta_1$  such that  $\eta_1 - y_1$  is close to zero, two tangent lines are determined, given by

$$y - y_1 = (x - x_1)f(x_1, y_1)$$

and

$$y - \eta_1 = (x - x_1)f(x_1, \eta_1)$$

Which are depicted in the following representation

**Figure 6: The existence of two solutions for the equation.**

Then, if we study the difference between these two lines, we see that is the same that subtracting their two respective slopes, this because  $\eta_1$  is a value that is close to  $y_1$ . Notice that the distance between the two lines is determined by

$$|f(x_1, \eta_1) - f(x_1, y_1)|$$

That is why the Lipschitz condition plays a very important role, due to the fact that this difference would be bounded by

$$|f(x_1, \eta_1) - f(x_1, y_1)| < M|\eta_1 - y_1|$$

where the constant  $M$  is the bound of  $\frac{\partial f}{\partial y}$  that not necessarily is a continuous function. Therefore, if this condition holds, we would have that  $|f(x_1, \eta_1) - f(x_1, y_1)| = 0$ , being a unique solution to the equation. If the Lipschitz condition does not hold, we cannot guarantee uniqueness, it can or cannot exist.

## Conclusions

This study, from the socioepistemological point of view, broadens the knowledge on the Existence and Uniqueness Theorem for Ordinary Differential Equations, but most of all it shows the kind of practices (variational strategies) that play a role in the justification of both existence and uniqueness. The fractions method, absent in most textbooks on Differential Equations, is present in textbooks on numerical methods. This is the second time this phenomenon arises. A similar situation arose in the prediction based on Taylor series. This findings, are worth mentioning, are derived from an appropriate problematization of the mathematical knowledge. Two things that gave genesis to this problem were the looking for a formalization on the proof of the theorem and also the determination of the minimum quantity of hypothesis that guarantee the existence and uniqueness of the solution.

Additionally, the initial questions referred to the inverse tangent problem and the different examples present in the mathematical discourse for school were answered, but these time with the support different resources: variational, numerical, analytical and visual. All these was obtained thanks to a

documental analysis that was based on original mathematical works. On the other hand, it was possible to discuss other constructs, such as convergence, the Lipschitz condition and the continuity of the functions  $f(x, y)$  and  $\frac{\partial f}{\partial y}$ , with respect to  $y$ .

Besides, the variational strategies on the construction of this theorem were:

- Comparison: The states that correspond to the numerical solution of the differential equation are compared. Besides, the solution is compared before and after of the small variation to determine its uniqueness.
- Serialization: When finding a relation between a state and another, starting with the initial conditions, in a lot of cases are possible to obtain an analytical solution to the equation, while in other cases it is only possible to predict the value that the solution will take in the next state (numerical solution), both cases with the support of the study of the patterns between one state and the other.
- Estimation: When knowing the initial values and unknowing the next value that determines the numerical solution of the equation, is when the linear approximation enters to determine the next value or state.
- Prediction: This theorem corresponds to a predictive model, it is utilized to predict the existence of the solution, and with the small variation we are certain of the convergence and uniqueness of the solution.

When performing a study such as this one, it is possible to study the rupture between most contemporary textbooks against the works reported on the mathematical studies of the past. Besides, it can be observed that some rationalities arise that will help to design teaching and learning activities by means of the use of teaching variables or control variables to modify, keeping in mind the present construction of these meanings. Reconstructing these meanings helped us to understand other problems related with differential equations, such as the stability of a system of differential equations, and to construct other visual interpretations.

# Understanding didactical conceptions through their history: A comparison of Brousseau's and Varga's experimentations

Katalin Gosztonyi

Eötvös Loránd University, Budapest, Hungary; [katalin.gosztonyi@gmail.com](mailto:katalin.gosztonyi@gmail.com)

*In this article, I compare two experimental projects led in the 1960s and 1970s by Tamás Varga in Hungary and by Guy Brousseau in France, concerning the teaching of combinatorics and probabilities. I attempt to show that this comparison can contribute to a better understanding of their theoretical reflection on the teaching of mathematics and the dependence of their didactical conceptions on the particular historical context in which these reflections were realized.*

*Keywords: History of mathematics education, didactical theories, New Math, probability teaching, abstraction.*

## Introduction

In the Hungarian mathematics education community, the “complex mathematics education” reform led by Tamás Varga during the 1960s and 1970s is considered as one of the most important milestones of the history of mathematics education in Hungary. Varga's conception is viewed as a representative of the so called “discovery based” tradition of mathematics education. However, this conception was never developed in a theoretical level: it can be understood from the documents of the reform (as the curriculum, the textbooks, teacher's handbooks etc.) and from some articles of Varga, but most of the time, these texts present his approach on very concrete examples and give only limited, indirect access to the conceptual basis of his didactical conception.

The research presented in this article is part of a more complex work, aiming to analyse Varga's conception with a combined, historical and didactical approach, and in comparison with the French reforms and mathematics educational movements of the same period (Gosztonyi, 2015a). This analysis contains three levels: the study of the historical context, of the epistemological background (the conceptions about the nature of the mathematics in the background of both reforms) and a didactical analysis of the reforms' documents.<sup>1</sup> For this third part, French didactical theories were used, Brousseau's *Theory of Didactical Situations* (TDS) (Brousseau, 1998) among others. The TDS proved to be an expedient theory to reveal characteristics of Varga's conception; however, some difficulties of the analysis let to think there were also some important differences between Varga's and Brousseau's didactical approach.

These theoretical questions led to consider Brousseau's work not only as a theoretical framework for my research, but also as a *research object*: actually, Brousseau himself was one of the actors of the French math education scene of the 1960s and 1970s. He led experimentations during this period, and he developed his didactical theory in relationship with these experimentations, in the very particular historical context of the French reform movement. So, a historical analysis of Brousseau's projects

---

<sup>1</sup> (Gosztonyi, 2016b) gives a short summary of this work, showing how the difference of the epistemological background, represented by influent groups of mathematicians in both of these countries, can explain, at least partly, the differences of the two reforms.

of the period could contribute to the comparison of the two countries' reform movements and to the understanding of Varga's project.

One more reason explains my interest for Brousseau's experimentations. One of the main domains of Varga's activity concerns the teaching of combinatorics and probability: so I was interested to do comparative analysis partly on these domains. At the same time, these domains are missing from the French obligatory education of the period which makes the comparison obviously difficult between the two countries. However, during the 1970s, these subjects appear in France in certain experimental projects, and one of the most developed examples is Brousseau's experiment on teaching probabilities, described in a retrospective article (Brousseau, Brousseau & Warfield, 2002).

In the following, I will resume the comparison of Brousseau's experiment with Varga's teaching projects and experiments, and I attempt to show how this comparison helps to understand the authors' didactical conceptions.

### **Some elements of the historical context**

The international discourse on mathematics education during the 1960s and 1970s is dominated by the New Math movement and the debates following the introduction of New Math related reforms in several countries. France is one of the leading countries of the international reform movement, with the "mathématiques modernes" reform introduced in 1969/70. Varga declares also being influenced by the international movement: he starts his experimentations in 1963, inspired by Z. P. Dienes' lectures in Hungary in 1960 and a UNESCO conference organized in Budapest in 1962, and follows the reforms of several countries during the following decades. His experimentations concerning the primary and later also the middle-school are progressively spread in the country, and give the basis of a new official curriculum in 1978.

Although Brousseau is not among the main actors of the French curricular reform movement, his early experiments can also be interpreted in the context of the reform. In France, various experimentations on primary and secondary school mathematics education were encouraged and supported during the 1960s and 1970s. For example the system of the IREMs<sup>2</sup> was progressively created from 1968, with the mission to form in-service teachers to the implementation of the reform, but also to continue experimentations. During the 1970s, the IREMs became also centers of critical debates on the reform, and principal sources of the emergence of didactical research in France. Brousseau's early work fits clearly in this context: he led experiences since the 1960s, and his projects led in the Jules Michelet experimental primary school from the beginning of the 1970s became the basis of the development of his later theory. The experimentations on the teaching of probability described in his retrospective article were also led in 1973 and 1974 in this school.<sup>3</sup>

### **Brousseau's and Varga's teaching projects and experimentations**

#### **The reasons to teach combinatorics and probability**

In France and Hungary, combinatorics and probability are not present in primary and middle-school curricula before the New Math period. So, the experiments concerning these domains attempt to

---

<sup>2</sup> Insittut de Recherche sur l'Enseignement des Mathématiques

<sup>3</sup> For more details and references on the historical background of the two projects, see (Gosztonyi, 2015a, part I.)

introduce new elements of curricula or introduce them much earlier than in precedent cases. Varga explains in several papers why he found important to introduce these domains very early during mathematics education. According to him, these domains contribute to the diversity of mathematical subjects treated in school and help to implement dialectic relationships between mathematical domains – which is one of the main principles of his reform curriculum’s structure. He says combinatorics and probabilities can be studied on the basis of very concrete, material experiences and so can give a good example of the process of mathematical abstraction very early, using a diversity of representational tools, and without the need of complex theoretical background. These domains can also give occasion to many playful activities. More particularly the teaching of probabilities represents a “different kind” of mathematics: the mathematics of uncertain things, which is especially important to describe real world phenomena. Furthermore, in the frame of tasks related to probabilities, and especially through estimations, student’s autonomous thinking and the expression of students’ various opinion can be easily encouraged. The quotation below shows also that this last question is closely related to more general pedagogical considerations concerning the teacher’s and student’s role in the learning process or students’ education to democracy.

My own view is that estimating, guessing, predicting, mentally representing, the future and expressing our opinion about it is a human ability which should play a greater role in education than it does now. All these activities [...] get kids personally involved in learning. [...]

Reasons must be strong, maybe not unrelated to sentences from “a child should not have an opinion” to “a child should have not will.” If this is a correct conjecture, then the issue is a more general one about education, not necessarily school education or school math in particular. (Varga, 1982, p. 30)

All the arguments resumed above are important characteristics of Varga’s conception on mathematics and its teaching (Gosztonyi, 2016a, b). Thus, one can understand that the emphasis made on the teaching of combinatorics and probabilities is closely related to the general educational goals of Varga’s reform, and these domains’ curricula and tasks can serve as efficient examples to understand the realization of these goals in Varga’s reform.

In Brousseau’s examined experiment, there is no question of a general curricular reform: probabilities are not included in the official curriculum of primary school, and Brousseau’s experimentation is realized in the frame of general activities (“activités d’éveil”) and not during the mathematics lessons. However, Brousseau underlines also some general arguments to explain the interest of teaching probabilities. The idea of “another kind of mathematics” appears also in his work (Brousseau, Brousseau & Warfield, 2002, p. 397). Beyond that, students’ autonomous work and the repartition of responsibilities between the teacher and the students is in the center of his theoretical thinking, and as he admit in the quoted paper (e.g. p. 384, p. 411), the experiments on teaching probabilities played a crucial role in the development of his didactical theory.

### **Some tasks of Varga on probabilities**

In his articles, Varga describes several probabilistic tasks developed in the frame of his experimentations (see e.g. Varga 1970, 1982). In the case of the subtraction game,

Each kid draws boxes for the digits [of two two-digit numbers] the way they are used in writing subtractions. The goal is to make the difference as great as possible. They can fill the boxes in any order, but only with random numbers produced by rolling dice. (Varga, 1982, p. 28)

In another game, the “game with three disks” (Varga, 1970, p. 424), three discs are in a box, one of them has a cross in each side, one has a cross on one side only and one is blank in both sides. The teacher draws a disk at random and shows one of its faces at random to the students. They have to guess the other face.

In each of these situations, there is a competition between students, which motivates the development of a strategy. The comparison of these strategies, their test during further experiments contributes to the development of probabilistic thinking. According to Varga’s description, frequentist approach, based on repeated experiments and the observation of relative frequencies is alternated with a classical approach to probabilities, based on logical arguments concerning models with equally probable events. However, the frequentist approach is rarely developed in deep details: it seems more to serve as an experimental basis to develop classical models which are then confirmed by logical and combinatorial arguments.

In the situations described by Varga, teacher and students are in permanent dialogue: Varga gives several examples how to guide these dialogues in order to help the development of mathematical notions, but to give also important autonomy to the students in this process.

Beyond the description of tasks and problem situations, Varga describes also the conception of long-term teaching processes. Even if some texts help to understand the long-term conception of probability-teaching, the clearest descriptions on the construction of long-term teaching processes concern the domain of combinatorics. We study this in the next section.

### **Varga’s series of problems to teach combinatorics**

In Varga’s conception, ordered series of problems play a crucial role in the construction of long-term teaching processes (Gosztonyi, 2015b). A particularly interesting example concerning combinatorics is described in the first grade teacher’s handbook associated to Varga’s reform (C. Neményi et al., 1978, pp. 243–258). It is interesting not only because it is particularly clearly structured (compared to other parts of the handbook), but also because it gives quite explicit explanation about the principles of ordering problems. This ordering is not completely given in advance: teachers have to conceive (and reconceive) it depending on the particularities of the class, and on the reactions of the students.

The series contains activities with different materials: the students build towers with coloured cubes; thread beads, draw flags or build houses with three parts of different colour; write ‘words’ (letter series) with a given number of characters or play music with a given number of notes. One organizing principle is the variety of experiences, apparently far from each-other, and stimulating a diversity of senses. But there is also certain progressiveness in their order, namely in the level of abstraction: starting from the manipulation of physical objects, through drawing and until the manipulation of symbols.

The activities with one material follow also a progressiveness, which is explained in detail on the example of building towers: after a free game with the material (elements with, for example three different colours), students are asked to build towers with a given height; then different towers with

the same height; and then come the question of the number of possibilities. The handbook suggests variations of the mathematically important variables as the number of levels or colours, but also the mathematically neutral elements as the type of the material or the colours of the elements. It suggest also some additional restrictions (as for example two neighbouring levels cannot have the same colour; or a given colour can have on the top level, etc.).

A similar process is described for different materials. The handbook indicates the analogies between the corresponding phases of these different activities, and explains also their differences which make them problems of different nature in the eyes of students: for example, in the case of building houses, the order of the elements is not immediately given, contrarily to the building of towers or the colouring of (three-stripe) flags. Students have to recognize progressively the links and the analogies between these different problems: that is what will lead to a progressive generalization of methods and solutions.

The process is planned for several years: the object at the first grade is mostly the collection of experiences in structuring possible cases and in looking for the number of all possibilities, in concrete situations. The systematic variation of conditions and the formulation of rules for calculating the number of cases come some years later. In a later article, Varga (1982) describes in detail a process on the long-term, based on the example of building coloured towers: there he also explains how the progressive construction of representation tools (as tables and trees) leads in his conception to creating proofs and general formulas in combinatorics.

### **Brousseau's experimentation**

In his experimentation on the teaching of probabilities, Brousseau also conceives a long and coherent teaching process, although the structure of this process is quite different from those of Varga, as we will see below. The whole process emerges from one situation: the teacher fills three opaque sacks with black and white balls, five in each sacks but the proportion of blacks and whites is unknown. The students have to find out the exact composition of each sack by drawing balls one by one from the sacks. The process goes through several phases that the authors describe as follows:

- i. "An introduction to hypothesis testing" (5 sessions)
- ii. "Modelling and experimenting" (3 sessions)
- iii. "Graphic representation of long series" (8 sessions)
- iv. "Convergence and statistical decision" (4 sessions)
- v. "Decision intervals" (5 sessions)
- vi. "Events and their probabilities" (7 sessions)

After a number of drawings and hypotheses made on the compositions, they decide to model the sacks with transparent bottles where they put five balls in different compositions, in order to compare the outcomes of these bottles with those of the sacks. Students work almost autonomously during the first two phases, only with some "regulative" interventions of the teacher: that's what Brousseau calls later an *adidactic situation*. The teacher intervenes more directly during the third phase, in order to stabilise the method of students' experimentation. A difficulty emerge in this phase, as even after long series of drawings, students are still not able to prove a decision between the possible compositions and they start to loose motivation. The teacher refuses to open the sacks but suggest proving the compositions by elaborating a methodology which allows students to do predictions. That is what

happens during the fourth and fifth phases using computers for simulations and different tools and methods of representation (as tables and graphics).

The described process represents a typically frequentist type of approach to probabilities, with the use of complex statistical methods and tools, and with a long process of repeated experimentations. The first five phases emerge from one initial problem. The classical approach as well as other problem situations appear in the sixth phase but, considered more conventional as the precedent ones, this phase is not developed in the article (p. 405)

### **A comparison of Brousseau's and Varga's projects**

Comparing Brousseau's and Varga's teaching projects briefly described above, one can observe some common points but also several interesting differences.

Although both frequentist and classical approach appears in both of the authors' projects, Brousseau puts more emphasis on the first one while Varga emphasize more the second one. This difference can be explained by different things, as by the coherence with other parts of the curricula (links with statistics on one hand, with logic and combinatorics, privileged domains of Varga on the other; the use of decimal numbers, privileged by the French curriculum of the period, or the use of fractions, emphasized in Varga's curriculum), but also by some pedagogical questions.

One of the common motivations to introduce probabilities into the primary school mathematics education is, in both of the cases, the opportunity offered by this domain to work with students guessing and estimations, and develop mathematical thinking with an important responsibility provided to students during the learning process. However, the repartition of responsibilities between teacher and students does not happen in the same way by the two authors. For Brousseau, this repartition has to be provided by the alternation of *adidactic phases*, where students work fundamentally autonomously and teacher does not intervene on the level of mathematical knowledge, and phases of *institutionalization*, where teacher intervenes essentially in order to transform students' context-dependent discoveries into stable, decontextualized and institutionally accepted knowledge. As Brousseau underlines, the experiments on teaching probabilities contributed essentially to develop these key-notions of his later theory. In Varga's case, although students' responsibility in the learning process plays also a key role, the teaching situations are more based on a permanent dialogue between the teacher and the class: the teacher acts as an experimented guide to develop progressively collective knowledge.

In both cases, we can see sophisticatedly constructed long-term teaching processes. But the structure of these processes is quite different. Brousseau's experiment is developed starting from one problem situation. This is something that he calls later *fundamental situation*: a problem situation which is rich enough to lead to the emergence of a whole theme. The process goes through the alternation of adidactic situations and institutional phases. According to him, the transmission of knowledge constructed by students in the context of a particular situation is not possible without the decontextualisation realized during the institutionalization (Brousseau, Brousseau, & Warfield, 2002, p. 407). Indeed, in the examined experiment, other problem situations appear only in the last sixth phase. Varga's approach is quite different to the construction of long-term teaching processes. He suggests starting from a diversity of problem-situations, with a big variety of contexts. The

construction of *series of problems* offer occasions to recognize similitudes, analogies between these different problems, and leads to a progressive generalization of the solutions.

Behind this difference of the two authors' conception on long-term teaching processes we can recognize a fundamental difference concerning their conception on the mathematical abstraction. As for Brousseau, abstraction is *decontextualisation*, for Varga, the abstraction process does not mean the elimination of the context, more a *progressive generalization* on the basis of a diversity of contexts.

## Conclusion and discussion

The comparison of Brousseau's and Varga's experimentations led in the 1970s showed several common points and also some important differences. This comparison can help to understand better the conceptions of the two authors on mathematics and its teaching, and also the relationship of these conceptions to their special context. Both of the two authors' projects inscribe clearly in the context of the international New Math movement, with the reforms of the content of the curricula, the debates on the nature of the mathematics and on the psychology of mathematics education. For both of them, Piaget's constructivist theory represents an important reference, but they are both critical with it: the alternation of the didactical situations with institutionalization in Brousseau's case, and the dialogic relationship between the teacher and the student in Varga's case can be interpreted as two different answers to the limits of constructivism considered by these authors. Moreover, Brousseau's notion of *didactical situation* seems to be related to the discourses about the French reform, more precisely to the notion of *situation* and its role in pedagogical practices and students' learning processes (Artigue & Houdement, 2007). Varga's choices seem also to respond to several elements of local discourses in mathematics education as well as in pedagogy and psychology (Gosztonyi 2015a).

An interesting relationship can also be observed with the dominant epistemological background of each countries reform movement, concerning the author's conception on mathematical abstraction: Brousseau's decontextualisation approach seems to be related to the "bourbakian" conception on abstract mathematical notions, as Varga's ideas on the progressive generalization can be find in the writings of several Hungarian mathematicians supporting his reform (Gosztonyi, 2015a, part II).

This case study reveals how a didactical theory, like Brousseau's one, may depend on the particular context in which it emerges. Thus, further studies on the history of didactical theories are susceptible to contribute to their understanding, and enrich also projects connecting and comparing didactical theories as the "Networking Theories" project (Bikner-Ahsbahr & Prediger, 2014).

The comparative analysis presented above contributed importantly to the original objectives of my research, namely to a reconstitution of Varga's missing didactical theory. But it can also contribute to recent didactical discourse in several further ways, as to the research on the teaching of probabilities or to the recent reflections on the notion of mathematical abstraction.

# Historical methods for drawing anaglyphs in geometry teaching

Rainer Kaenders and Ysette Weiss

Rheinische Friedrich-Wilhelms-Universität Bonn, Germany: [R.Kaenders@uni-bonn.de](mailto:R.Kaenders@uni-bonn.de)

Johannes Gutenberg-Universität Mainz, Germany: [weisspid@uni-mainz.de](mailto:weisspid@uni-mainz.de)

*The historical anaglyphic method was in use for more than hundred years to create spatial illusions of mathematical objects and for technical constructions. While algebraisation is predominant at school, students lack experience in understanding the causalities of technical tools. Modern technical devices rarely allow for direct investigations on underlying technical principles. Here we use the historic anaglyphic method to enable the students to produce high-standard 3D illusions just by using coloured pencils, a ruler and glasses with colour filters. We developed an approach to the anaglyphic method that uses nothing but similarity and especially surpasses projective geometry. The presented approach relates plane and spatial geometry, and can be grasped by all students that have some understanding of the similarity of triangles.*

*Keywords: Anaglyph, binocular geometry, historical methods of visualization, 3D-representations.*

## Introduction

Concept development in high school mathematics – in particular A-level subjects in many countries – is characterized by predominant algebraisation. This seems to match successful and effective heuristics, attitudes and problem-solving strategies in modern everyday lived experience. Out of school it fosters the learning of pattern recognition, algorithmic procedures and trial and error. The progressive digitalisation of most fields of experience and actions of contemporary students seems to make the search for causalities and functional principals superfluous and unnecessary. Modern technical devices rarely for allow direct investigations on underlying technical principles. However, approaches and attitudes aiming only for the use and not the understanding of technical devices involve the risk of simple manipulation of the user and restrict creative developments of the tools by their users. In order to help our students to become autonomous, mature individuals, we need in mathematics (and also as a foundation for technical sciences) teaching designs where students start to wonder: How does it work? How can I accomplish it on my own?

In the following we present materials for discovery learning, supporting the described educational goals. The design of teaching and learning materials allows for the implementation of the history of engineering and technical drawing in different ways and with different aims. A historical investigation using original sources can be conducted as an introductory part of a workshop on 3D presentations. Historical investigations can also be undertaken as a part of an individual student's presentations after the workshop on anaglyphs and binocular geometry. We start with a short historical introduction into anaglyphs as well as into the literature and original sources, which are applicable by the students at school or by student teachers in teacher education.

We then give a short summery of how binocular geometry can be related to the mathematics curriculum and discuss a textbook presentation of the topic. The following section deals in detail with

the geometrical properties of central projections, which enable the drawing of anaglyphs without using three-dimensional analytic geometry.

We tried out the developed set-up and the material in four workshops at an international Kangaroo Camp, each with 15-20 high school students between the ages of 15-18, and in a day course at the Hausdorff Center with local high school students in Bonn, with a lecture and problem sessions with about 60 high school students.

## Historical background

Sir Charles Wheatstone invented the earliest type of stereoscope in 1838 (Wheatstone, 1838). However, as David Brewster writes in (Brewster, 1856, p.27) a certain Mr Elliot was led to the study of binocular vision ... as early as 1823. Wheatstone and Elliot used mirrors, whereas Brewster invented lenses. The mathematician Wilhelm Rollmann (1853) invented the anaglyph stereographic method. The Greek word *Anaglyph* is derived from *ἀνά*(aná), meaning “on” or “on each other” and *γλύφω*(glýphō) “to carve”, “engrave”, or “represent”. In his method, two pictures in the mutually different colours blue and yellow are superposed onto each other. The observer in Rollmann’s method separates these pictures by using glasses with colour filters, i.e. a red glass for the left eye and a blue one for the right eye.<sup>1</sup> All cited sources are digitalised and available online. The descriptions of the methods are mainly verbal. The few calculations can be performed and understood using elementary middle school mathematics. This makes the cited literature a good and suitable source for historical investigations in the classroom.

Rather than being a goal as such, the anaglyph method was already used by Rollmann to illustrate mathematical facts and insights in a three-dimensional fashion. Another impressive example of this kind of illustration is the Imre Pal’s beautiful book (1961). Although the books of Rollmann and Pale describe the three-dimensional model of spatial seeing, nevertheless they do not instruct how to draw two-dimensional anaglyph stereographic pictures. For the latter we designed a special workshop, which can be related to schoolbook exercises in analytic geometry (Körner et al., 2010, p. 92) or can serve independently for project work.

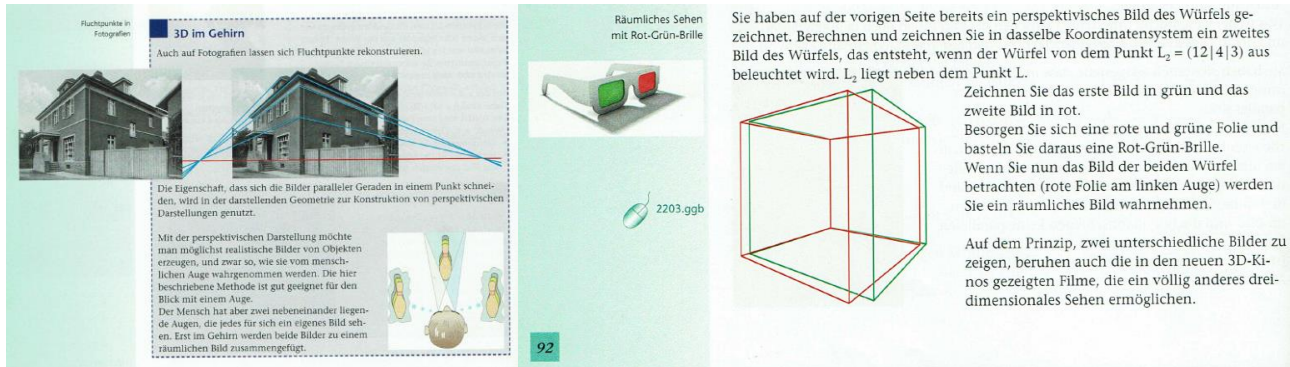

## Anaglyphs in teaching

Binocular geometry is not a canonical topic for mathematics lessons. So we were rather surprised to find a set of exercises related to the anaglyph method as well as materials for teacher training courses. The following excerpts in Figure 1 are taken from a German school textbook for grade 11 (one year before A-levels). The book is one of the five most widely used textbooks in high schools in Germany. The excerpts stem from a chapter in analytic geometry dealing with the calculation of intersections of lines and planes given in Cartesian coordinates. In addition to perspective drawings of a house and bowling pins, some general properties of perspective drawings are given (left). In preparation for the work with perspective mappings, the textbook authors posed the exercise to compute the image of the shadow of a cube illuminated by a lamp given in Cartesian coordinates. The shadow has to be calculated in a given plane using the formulas for intersection points of lines

---

<sup>1</sup>In our case, we use a red glass for the left eye and a blue or better turquoise one for the right eye.

with planes. The green image (right) is the cube shadow in the given plane. The red image is the result for the same calculation but with a slightly shifted illuminant. The students are asked to make red-green glasses themselves and to look at the picture through these glasses. Among the textbook materials for computer-based learning, there are 3D dynamic geometry applets with the green and the red calculated images corresponding to different dynamic light sources. Even though the exercises deal with a geometrical context – perspective drawings – the proposed approach is purely algebraic.

**Figure 1: Erecting a stick of thumb size by lifting a point.**

The pictures are visualizations of the results of algebraic calculations. In (Färber, 2016) the author proposes designing the excursion on the anaglyph stereographic method as discovery learning in groups. Nevertheless, the lesson planning only involves algebraic manipulations. As we already discussed in (Kaenders & Weiss, 2016), the high degree of abstraction and technical complexity of algebraic symbolic language gives students few opportunities to question the underlying rules, to introduce their own situated notations and notions reflecting their individual understanding of a problem and its context or to develop their own mathematical questions. To deal with this problem we develop a geometrical context for discovery learning of the anaglyph stereographic method.

### A simple approach: Lifting plane figures

When we considered using the historical anaglyph method for teaching, we expected a couple of difficulties. First, we were convinced that we would have to give a quick introduction to projective geometry and then apply it to the anaglyph method. We were then surprised to discover an approach to the fabrication of such binocular illusions that does not use projective geometry at all. It is the technique of *lifting a point*. Well understood, it allows not only for the lifting of points but also the lifting of any figure from the plane as long as it is supposed to become an illusion of a congruent figure in a plane parallel to the initial plane. We give a description of the course of action in the workshops.

### Practical preparation

Before the students are given the task of creating their own anaglyphs, we show them some exemplars. By looking through the red-green-glasses they begin to get a feeling for what such a painting could look like and which type of effects are generally possible. It turned out to be a helpful practical hint to let the student put their fingertip on the spatial spot where they expect the figure to be. A few students do not succeed in recognizing the intended illusion. The reason for this might be problems like shifted eyesight, where one eye has a stronger visual faculty than the other, or a red green deficiency. Nevertheless, these students could successfully participate in the workshop.

## Erecting a little stick

The first exercise is to erect virtually a little stick of thumb size to an illusion that appears to be an orthogonal stick on the paper. In a second step, we can also let the stick appear slightly levitated. In order to find such a representation of the desired illusion, the students can turn the question around: the stick is given and we seek the red-green drawing on our paper. If we put a stick (like a pencil) orthogonally on the paper, we can conceive the red and the green drawing as the shadow we obtain when we imagine our eyes to be light sources.

**Figure 2: Erecting a stick of thumb size by lifting a point.**

Almost all students draw a short red and a short green line segment that produce two lines that intersect at the point that is ought to be the orthogonal projection of the stick on the paper. By discovering this, two questions arise:

- What is the angle between the red and the green line segment? The students relate it to the position of the eyes and some conjecture that the lines prolong to the pedals of the eye points.
- How far do we have to draw the line segments for a perfect illusion? After having explored the situation, the students give two conjectures: The ratio of the red and green line segment is the same as the ratio of line segments between the pedal points of the eyes and the point where the stick touches the paper. They indicate that because of similarity, both assertions are equivalent.

## Analysis of the exercise

To analyse the situation, we assume the position of the eyes  $A$  and  $B$  on fixed height  $h$  over the table. We assume the eyes  $A$  and  $B$  to be parallel to the table plane and to have a distance of 7 cm, which is about the average eye distance for adult human beings. When we project the eyes  $A$  and  $B$  orthogonally onto the table, we obtain two pedal points  $A'$  and  $B'$ . We consider an arbitrary point  $P'$  in the plane. Now we want to find points  $P_A$  and  $P_B$  in the plane with the effect that they create the illusion of a point  $P$  in space, that *lifts* our point  $P'$  to some height  $h$ .

In Figure 3 we see that this illusion arises when the lines  $AP_A$  and  $BP_B$  cross in the point  $P$ . Then  $ABP$  forms a plane. Then the three planes  $A'B'BA$ ,  $A'B'P$  and  $ABP$  have three intersection lines, two of which are parallel. Then the third one is parallel as well. The reason is what one can call the *Theorem of the Tent*: Given three planes  $E_1, E_2$  and  $E_3$  that intersect in three lines  $g_{12} = E_1 \cap E_2$  and  $g_{23} = E_2 \cap E_3$  as well as  $g_{13} = E_1 \cap E_3$ . When two of these lines are parallel to each other, the third is

parallel to both as well. The proof of this proposition is an occasion to show the efficiency of the set theoretic language: Assume that the lines  $g_{12} = E_1 \cap E_2$  and  $g_{23} = E_2 \cap E_3$  are not parallel; they then intersect in a point  $P$ , since both lie in a plane. Then  $\{P\} = g_{12} \cap g_{23} = E_1 \cap E_2 \cap E_3$  and  $g_{23} = E_2 \cap E_3$  intersect in  $P$  as well.

**Figure 3: The basic principle of point lifting.**

Hence, we can *lift* the point  $P'$  to an illusionist point  $P$ , when we draw the lines  $A'P'$  and  $B'P'$  and end up at points  $P_A$  and  $P_B$ , such that  $P_AP_B$  is parallel to  $A'B'$ . In order to find out how far the point will be lifted, we use the point of view of similarity as the students uttered it. We consider one of the two triangles  $A'P_AA$  or likewise  $B'P_BB$  (see Figure 4). We especially want to understand the relation between the height  $h$  and the distance  $d := P_AP_B$ .

**Figure 4: One of the triangles of the basic figure.**

In Figure 4 we read off the following ratios:  $\frac{a}{h} = \frac{A'P_A}{A'P'}$  and  $\frac{a-h}{h} = \frac{AP}{PP_A}$ . Combining this with the ratio between the triangles  $ABP$  and  $PP_AP_B$ , we conclude  $\frac{7}{d} = \frac{AP}{PP_A} = \frac{a-h}{h}$ . Thus  $d = \frac{7h}{a-h}$  or  $h = \frac{ad}{7+h}$ .

Note the remarkable fact that the distance  $d$  does not depend on the special position of  $P'$ . Hence, we have one method to lift not just one point but also a whole figure to a certain fixed height  $h$ . For instance, we can lift a square by lifting its vertices on the same height and then connect the corresponding red and green points. If we do that twice, we can construct the illusion of spatial box.

### Similarity as key concept

Finally, we want to understand how we can lift a figure that does not consist of line segments, e.g. a circle. For this, we need to understand how to lift an arbitrary figure to a fixed height  $h$ . For this fixed  $h$ , we consider the map of the plane to itself, that maps  $P'$  to  $P_A$  and likewise the map that

maps  $P'$  to  $P_B$ . We know already the answer, since  $\frac{A'P'}{A'P_A} = \frac{a}{h}$ . Therefore, both are central dilations with the factor  $\frac{a}{h}$ , one with centre  $A'$ , and the other with centre  $B'$ .

**Figure 5: Central dilation with factor  $\frac{a}{h}$ .**

These considerations on similarity can be used to construct tasks for instructional scaffolding as well as materials for explorative learning.

## Observations during the workshops and development of research questions

In our workshops, we developed most of the tasks and drawings together with the students on the blackboard. This gave us the possibility of choosing between small-step guiding tasks and rather open activity-oriented tasks corresponding to the work of the students. The groups in the four workshops at the international Kangaroo Camp were very inhomogeneous regarding their English language skills as well as their mathematical preparation. These groups had students interested in mathematics but without any training for competitions or mathematical extracurricular experiences and participants of the International Mathematical Olympics. None of the participants had ever dealt with binocular geometry. In spite of their age (15-18 years old) there was no problem to get the students to draw pictures with crayons. It became also evident that the problem ‘How to draw an anagram’ is extremely suitable for inhomogeneous groups. The students worked in small groups and were quickly fascinated by their own experiments and pictures. Our objective that was reached in all four workshops was to get the students to search for the underlying principles of constructions and to produce their own drawings by using the principles. As soon as the students are acquainted with the technique of point lifting, there are many possible projects to tackle.

The day course in Bonn was organized differently. The workshops were held by mathematics teacher students. We gave introductions into anaglyphs first for the tutors than for the students, attended the different workshops and moderated the presentations of the results. For the day course in Bonn, we prepared a script for the tutors with problems they were supposed to solve. Before the day course there were several meetings where the tutors could ask questions and discuss the concept. There was a noticeable difference between tutors who tried to grasp on their own the concept of drawing anaglyphs by lifting points and curves using the script more to look up some of the details and tutors who first read the script and tried to solve the problems by using the methods described there. The first type of tutors led their workshops in a more explorative experimental way; some of the second type tutors had inserted into their workshops small lectures on the basis of the script. The students

asked questions from different perspectives: from a phenomenological perspective (What are conditions for two points to create the illusion of a floating point?), from the perspective of geometrical invariants (Which properties do not depend on the position of the centre of the projection?), from the perspective of geometric transformations (How to place the figure to support its three-dimensional illusion?).

**Figure 6: Examples of student products: a box with concave top, a house, a tetrahedron.**

Nevertheless, the students of all groups of the day course were very motivated to understand how to draw a 3D picture, experimented with pencils, lifted points and produced their own 3D images (Fig.6). During our reconsiderations of the first repeated workshops, we tried to describe the atmosphere when the students started to construct central projections and calculate distances. At the beginning - may be because of our technical explorations into the past - we called it the mind of engineers and inventors. During the next workshops non the less we realized that a substantial part of workshops the students were engaged with thought experiments: projections through transparent tables, cutting up spheres, building houses out of cubes and tetrahedrons, rotating trefoil knots. This led us to think about the role of thought experiments in physic and mathematic lessons. May be it was so easy to inspire so different students for experiments because there were not real experiments? Students meet nowadays in their everyday life not often people who both are said to be cool and decompose technical devises in order to understand basic functional principles. Choosing advanced courses in science for A-levels does not imply one has grown up with a soldering iron or a chemistry box.

One could think that our students good performance and experiences in virtual worlds could give the historical extremely important thought experiment a new place in physics lessons in order to develop interest in functional principles even if there are only very limited prior technical experiences. But at least in German physic lessons, it seems to be rather the other way around: Many computer based visualisations and experiments transform the very nature of the thought experiment and replace it by a confirmation experiment of a virtual programmed reality (as it is also done in the earlier discussed mathematics textbook task using the applet to compute the anaglyphs).

May be it became rather a task for mathematics educators to integrate thought experiments and virtual engineering into mathematics teaching to support the perspective: How does it work?

## Conclusion

The fact that the participants in our workshops were able to pose independent research questions in geometrical terms with geometrical meaning is for us an indication of their development of a geometrical language and concept. The students gave their proofs by construction and in different geometrical notions using invariants and similarity mappings. We were especially impressed by the ability to switch between plane and spatial perspectives on the stereographic pictures developed by the participants during the workshops.

# Teaching kinematics using mathematics history

Alfredo Martínez, Olimpia Figueras and François Pluvinage

Centro de Investigación y de Estudios Avanzados del IPN, México

[alfymago@hotmail.com](mailto:alfymago@hotmail.com); [figueras@cinvestav.mx](mailto:figueras@cinvestav.mx); [fpluvinage@cinvestav.mx](mailto:fpluvinage@cinvestav.mx)

*This article describes a proposal for teaching kinematics using mathematics history; recognizing that history, mathematics, physics and language share similar knowledge structures that must be articulated to achieve teaching-learning processes. To account for this, we discuss how mathematics and physics has historically contributed to describe motion representations. A learning unit is described based on the experimental technique that probably Galileo used to measure times and distances and is not well known by textbooks' authors. This experimentation with intervention tries to interrogate students' alternative ideas. We intended to provoke a conceptual change using several mathematical and physical representations that have been constructed throughout history and have allowed describing the nature in a better way. A qualitative study of the experience in a physics class was carried out. Forty students aged about 13-years-old from a public secondary school in Mexico City participated in the study. The learning unit described in this article was the first stage of a broader study constituted by five stages. It was important to work with students to establish the relationship between the variables involved in the description of uniformly accelerated motion, so as the ratio between the distances travelled and the time elapsed.*

*Keywords: Conceptual change, alternative conceptions, acceleration, uniformly accelerated motion, mathematics and physics representations*

## Introduction

The role of the history of mathematics in teaching and learning mathematics has been discussed in several workshops (Fauvel & Van Maanen, 1997). However, Fried (2007) has pointed out a major problem: Where do teachers find time to teach the history of mathematics? It isn't easy to answer this question, but given that both history of mathematics and mathematics themselves embrace genuine ways of knowing, it may be possible to make a didactic design that combines mathematics with valuable elements of history of mathematics without investing too much time.

It is important to recognize that mathematics, history and language are ways of knowing related to semiotic systems that are used to understand or interpret any kind of knowledge. Therefore, we consider the problem presented above as our own, that's why we propose an approach that has been tested with 13-year-old high school students, to give an example with the intention to contributing to answer the previous question.

Acceleration concept is an example of the relationship between our ways to understand nature and to interpret it. It is well known, since ancient times, that interpretations had been made to explain acceleration as a physical phenomenon without being able to describe it fully. Unfortunately, the nature interpretations that human beings do are determined by common sense, this situation causes obstacles to describe it correctly in Bachelard and Viennot's sense (cited respectively in Jankvist (2009), and Bastián, Mora & Sánchez, 2013). Obstacles to understand sciences have been called in several ways associated with different epistemological origins, however, authors of this paper agree

with Halloun & Hestenes (1985), Hierrezuelo & Montero (1989/2006), Laburú & Carvalho (1992), Duit & Treagust (1998), and others who have contributed to define obstacles as alternative conceptions. Ideas that are related to common sense, which are persistent, shared by many persons and can be adapted and modified in such a way that one can believe that those ideas are adequate to explain the reality of the physical world.

Some ideas in science history have been considered satisfactory because they explained, at least in part, a field of reality, but others, much more powerful, creative and audacious, have emerged to break paradigms and challenge common sense. Such are the ideas of those who have not been satisfied with the accepted description of reality at a certain historical moment.

The so-called scientific revolutions allowed the advance of science and a changing in our understanding of the universe. An analogy of these scientific revolutions is found in the processes of teaching and learning, as well as alternative conceptions that are compared, but if those ideas cannot be used to explain reality, they lose their validity. Anomalies then arise, which will open the way to new explanations, often more complex, but those ideas could be used to explain a situation apparently in a better way. This process has been called conceptual change (Posner, Strike, Hewson & Gertzog, 1982).

If ideas are images and representations of reality, then in so far as representations are tested, the validity of the ideas is proved. Mathematics makes possible the testing of diverse representations of distinct levels of complexity, so concept formation can be achieved in an increasingly structured way (Pozo & Flores, 2007).

Considering that it is necessary to challenge the ideas of the common sense, Galileo made experiments on the acceleration leaving aside the causes of its origins. Galileo in his *Discorsi e Dimostrazioni Matematiche* (Hawking, 2013) explained some experiments and his description about uniformly accelerated motion, but he did not explain his efforts and trials to obtain satisfactory results or how he accurately measured time or displacement. Drake (1975) researched these problems by reviewing Galileo's notes and pen strokes to discover clues as to how he did his research.

This article deals with the description of a didactic intervention using a teaching experiment in which Galileo's technique is used to describe uniformly accelerated motion. The didactic activities allow the students to interrogate some alternative conceptions, such as the idea that, in a uniformly accelerated motion equal distances are travelled in equal times (Laburú & Carvalho, 1992). Relationships between experiments have also been established, data organized in tables and qualitative diagrams to propose a mathematical expression that allows to relate distances and times; with the intention to promote a conceptual change.

## **Historical development of the kinematical concept**

The first ideas about motion came from Aristotle who in his dialogue *On Philosophy* uses the term *proton kinoun* as the first motor, the cause of every motion in the Universe (Düring, 1990, p.188). According to Aristotle, the velocity of a moving object is directly proportional to the thrust force and inversely proportional to the media resistance (Düring, 1990, p.477).

It was not until the 14th century, when mathematicians from Oxford (most of whom came from Merton College), took up again the study of motion of bodies. This was mostly done in the decade between 1330 and 1340, as explained by Farmaki, Klaudatos & Paschos (2004).

William Heytesbury (1313-1400), Richard Swineshead (1340-1354), and John Dumbleton (1310-1349), mathematicians and logicians of Merton College at Oxford, known as “Calculators”, introduced the idea of functional relationships in attempt to describe magnitudes with quantitative measurable features. They defined several kinds of motion, proposed theorems concerning motion and proved them mathematically, using Euclidean geometry. Swineshead defined uniform motion, and Heytesbury the uniformly accelerated motion (Farmaki, et al., 2004, p. 506).

Nicole Oresme in 1362, in the *Configurationibus qualitatum* represented the variations of qualities (see Figure 1), such as velocity and time, by means of geometrical figures, in which the line AB represents the time and the perpendicular lines the speed or its increasing value (Farmaki et al., 2004, p. 507).

**Figure 1: Oresme representation of a qualitative magnitude**  
(Adapted from Farmaki et al, 2004)

There were many efforts to solve the problem of the unequal velocities that appear in a uniformly accelerated motion, however they were not concretized. It was not until Galileo's deduction presented in the *Discorsi*, where he artfully simplifies the free fall of a ball rolling down along a plane with a few degrees of inclination.

**Figure 2: Theorem I, Proposition I, Third journey in**  
**Discorsi e dimostrazioni matematiche (Hawking, 2013, p. 468)**

In Theorem I, Proposition I, Third Day of the *Discorsi*, Galileo states the relationship between velocity and time, using schemes such as those used by Oresme, but replacing uniform motion with uniformly accelerated motion (Hawking, 2013). In Figure 2, time is represented as a quality by the line AB and velocities are represented as intensities by perpendicular lines.

The schemas used by Oresme and Galileo suggests that the relation between time and velocity could be drawn in a Cartesian coordinate system, but in Galileo's scheme there is also a line

representing an external magnitude, the distance. In the Proposition II, third day of *Discorsi*, Galileo explains the proportional relationship between time and distance travelled in a uniformly accelerated motion, including the relation between time and velocity. But the method reported by him to measure time was not considered practical, in accordance with Drake, who estimated that Galileo achieved more accuracy with another method than would have been possible with the clepsydra. So, there is a controversy about how Galileo found these results. Galileo just wrote:

For the measurement of time, we employed a large vessel of water placed in an elevated position; to the bottom of this vessel was soldered a pipe of small diameter giving a thin jet of water, which we collected in a small glass during the time of each descent, whether for the whole length of the channel or for a part of its length; the water thus collected was weighed, after each descent, on a very accurate balance; the differences and ratios of these weights gave us the differences and ratios of the times, and this with such accuracy that although the operation was repeated many, many times, there was no appreciable discrepancy in the results (Galileo Galilei, 1633/1914, p.179).

### Stillman Drake's proposal

In “The Role of Music in Galileo's Experiments”, Drake (1975) described an experiment that probably took place in 1604. The experiment was part of a series of investigations that led Galileo to obtain finally the correct rule of times-squared being proportional to the distance an object falls from rest during the time elapsed. Ben Rose reconstructed the experiment according to specifications supplied by Drake (see Figure 3).

**Figure 3: Reconstruction of Drake's experiment (Drake, 1975)**

The objective of this modernized test was to measure as precisely as possible the distances travelled from rest by a ball rolling down on an inclined plane taken at the end of eight equal time intervals. The grooved inclined plane used in the reconstruction was 6 ½ feet long (198.2 cm) and was set at an angle of 1.7 degrees. The time intervals were established at a tempo almost two notes per second. At one note the ball was released, and the positions of the ball at subsequent notes were marked with a chalk; for comparison the exact 0.55 second positions were also captured by multiple-flash photographs. A rubber band was then put around the plane at each chalk mark. The positions of the rubber bands were adjusted so that the audible bump made by the ball in passing each band would always coincide exactly with a note; the bumps were visualized by leaving the camera shutter open during an entire run. Finally, the distances between pairs of adjacent bands were measured. The

ratios of the successive intervals were found to agree closely with a set of figures logged by Galileo (Drake, 1975).

## **Methodology**

In Mexico as in other countries, the role of textbooks is very important for the teaching-learning process from primary school to the first university-level courses. The first Physics course is offered in secondary education to 13-year-old students, where conceptual approach prevails. We decided to work with a group of forty students who attend a high school physics class in Mexico City to make a qualitative study of their reactions to a teaching sequence proposal. This group had no teacher, so the learning unit did not conflict with the daily activities related to the ongoing study of curriculum contents.

After having done an analysis of a Mexican textbook (Gutiérrez, Pérez & Medel, 2012) of the secondary school on the proposed activities to study the topic of acceleration, it was decided to make a design of a learning unit complemented by a physical experimentation. First, the students had to perceive with their senses how the ball falls that is rolling down on an inclined plane and, as it rolls, rings bells placed at equal distances.

Students were asked how distances were covered by the rolling ball between successive rings of the bells, how time between each ringing of the bell varied, and to make a personal description of the rhythm they had heard. They modified the height of the inclined plane and the distances between bells to find out if they perceive changes in the phenomenon.

At the end of this experiment, students wrote their observations in a notebook. The following student's activity was designed with had the purpose of recalling the meaning of proportionality in a context of a recipe to make a three-layered cake. They had to find the proportion of the ingredients with respect to the amount of cake that had to be prepared. Students were asked how they found the proportion and what the proportionality constant for each quantity was. The amounts of ingredients provided were given in kilograms.

Finally, students were asked to carry out a different measuring process to find the times and distances travelled by a ball that rolls down on an inclined plane. The instructions for assembling the device in the laboratory were given to the students. The teacher previously tested the assembly to control the time in which distances were covered by the rolling ball. The material used consisted of an aluminium rail, a steel ball, a universal holder, burette clamps, bells and clips.

The learning unit took place in a week. All sessions were video recorded. Students wrote their answers in a booklet guide prepared by the researcher, those answers were later analysed.

## **Description of physical experimentation**

The material was placed on working tables in the laboratory for each team. The teacher had a digital metronome on the computer connected to an amplifier so that all students could hear loudly the rate of 60 beats per second.

The experiment started when the teacher activated the metronome; then the students had to synchronize the beat of the metronome with their mental count. A student in each team then had to drop the iron ball from the top of the aluminium rail upon hearing a beat (of the metronome) and

stop it upon hearing the next beat. The first distance should be considered as a unit. This action is repeated several times to determine the distance travelled in a second, which has to be marked each time with a permanent marker pen. The process continued in basically the same manner; students must drop the iron ball from the beginning of the rail, just when hearing a beat and stop it after having heard two beats making a mark on the rail. The same has to be done with three, four and more beats.

Once the distances travelled per second by the rolling ball were determined, students had to put a bell in each marked position. To verify that the travelled distances were correct, they dropped the iron ball while the metronome marked the time, so that at each beat of the metronome a corresponding bell rang.

## Results

With the help of the written guide, students took notes on what they had observed. In the first activity, 17 out of 40 students answered that the distances travelled between successive bells were equal while the time intervals were getting shorter and also described that the ringing of the bells during the journey of the ball were getting faster and faster. In the activity to review the proportionality issue only three out of 40 students could find the factor to determine the correct amount of ingredients for each cake.

A small exercise was included, which consisted in completing some arithmetic progressions, specifically a succession of integers, odd, even, and finally squares. The purpose of this exercise was to serve as a heuristic to conjecture that in a uniformly accelerated motion the distance travelled increases as the square of the time intervals do.

<p>Esto quiere decir que para una unidad de tiempo le corresponde una unidad de distancia, para dos unidades de tiempo le corresponden cuatro unidades de distancia, para</p> <p><i>Para tres unidades de tiempo le corresponden 9 unidades de distancia</i></p> <p><i>para cuatro unidades de tiempo le corresponden 16 unidades de distancia</i></p> <p><i>para cinco unidades de tiempo le corresponden 25 unidades de distancia</i></p> <p>¿En qué proporción aumenta la distancia con respecto al tiempo? Discutir en plenaria</p> <p><i>la distancia está en proporción al tiempo al cuadrado <math>d = \propto t^2</math></i></p>	<p>This means that for a unit of time corresponds a unit of distance, for two units of time corresponds four units of distance, for . . .</p> <p><i>For three units of time correspond to 9 units of distance.</i></p> <p><i>For four units of time correspond to 16 units of distance</i></p> <p><i>For five units of time correspond 25 units of distance</i></p> <p>In what proportion does the distance increase with respect to time? To discuss in plenary with the wholegroup.</p> <p><i>The distance is in proportion to square time <math>d = \propto t^2</math></i></p>
--	---

**Figure 4: Relationship between distances and time: a student's conclusion**

Then with the intention of analysing the information provided by the previous activity, the teacher asked the students in a plenary session, what relationship was observed between elapsed time and distances travelled. Students answered for each unit of time elapsed, that the distance travelled increased as the square time intervals, thus establishing a proportional relation between both magnitudes associated with uniformly accelerated motion.

The teacher introduced for the first time the algebraic symbol ( $\propto$ ) to denote the correspondence rule which is used in physics when the proportionality constant is not fully determined. Finally, it was found that 16 out of 40 students gave incomplete arguments about time measurement and distance travelled, but 24 of 40 answered that the rhythm of time was constant while distance increased faster and faster as square of the time intervals (see Figure 4).

## Conclusions

The learning unit described in this paper was important as a starting point of a larger study involving several phases of experimentation, because it allows a perceptual approach to uniformly accelerated motion.

The activity provides a simple way to engage students with the task of describing uniformly accelerated motion. They associated the problem with Galileo's experiments and were able to identify how nature is scrutinized in order to describe and understand it.

Experimentation allowed students to be challenged by the alternative conception which assumes that in a uniformly accelerated motion the velocity is constant.

This procedure avoids the problem of synchronization with several timers placed simultaneously at equal distances, an impractical measure option that is often suggested in textbooks. Another advantage is that students can listen to a metronome carefully and measure time mentally, as is done in music.

The students realised some difficulties Galileo may have faced in order to measure time and determine their relationship with the distances travelled, providing both experimentation and the learning unit design, a learning context that is much more meaningful than any anecdotal knowledge.

Finding the proportionality relationship between elapsed time and distance travelled may be enough as a first approach to describe a uniformly accelerated motion for being used when necessary to determine more precisely the proportionality constant of a uniformly accelerated motion.

The results shown in this research give an account of how the obstacles attested by history for the understanding of scientific concepts help overcome the obstacles that students face.

Our didactic proposal was enriched with the development of ideas in the history of mathematics and physics by adapting them to provide a different way of accessing to physics and mathematics knowledge. In this didactic design, we consider the genesis of the concept of uniformly accelerated motion throughout history as an example of the inductive thinking that human being does in the construction of their own knowledge, so it has been tested with students, getting encouraging results.

# The concept of infinity – different meanings through the centuries

Regina D. Möller<sup>1</sup> and Peter Collignon<sup>2</sup>

<sup>1</sup>University of Erfurt, Germany; [regina.moeller@uni-erfurt.de](mailto:regina.moeller@uni-erfurt.de)

<sup>2</sup>University of Erfurt, Germany; [peter.collignon@uni-erfurt.de](mailto:peter.collignon@uni-erfurt.de)

*The concept of infinity and its use is one with different meanings through the centuries within various contexts reflecting mathematical historical development. This development is scarcely clear to pupils during school time and rarely stressed in teacher education although it offers a lot of potential to understand mathematics. The field of arithmetic is one example in which to study infinity within a range that student teachers are able to understand and that is useful for and in their future teaching. The paper focusses on the potential of this concept within the arithmetic field using an original article of Cantor and on examples, also from Hilbert, that stress different counting methods and various illustrations of infinity.*

*Keywords: Infinity, countable set, denumerable set, very small/large numbers.*

## Introduction

Like many other mathematical concepts ideas of infinity developed and diversified through the centuries. Well known is its appearance within the Elements of Euclid within the ninth chapter: There are more prime numbers than any given number of prime numbers, cf. Euclid (1997, IX, §20). This statement answers the question, if there is an end of prime numbers. The proof uses the fact that the product of arbitrary prime numbers added by 1 has a new prime number in its prime factorization. That is, to conceptualize the concept of infinity of prime numbers Euclid uses the idea that there is always another one apart from the given ones which has a somewhat operative aspect.

Also within geometric contexts there are ideas about infinity regarding the extensions of space, planes and lines as well as the number of points on lines and figures. There are considerations of the behavior of parallel lines regarding infinity, like for example the parallel axiom states.

Already these examples show that there exist different meanings of infinity depending on the various mathematical objects. Also, the meanings are verbalized without formulization. Doubtless does the use of very large numbers within everyday experiences come close to a sense of infinity. For example, the addition of two numbers, one of which is very much larger than the other, form a sum that does not differ very much from the large number in terms of the relative error concept.

Infinity and the use of it deserves a closer look because terms like “infinite”, “endless” and “unlimited” have a colloquial meaning that sometimes provides a reasonable starting point for the understanding of abstract patterns and sometimes not. In some instances infinity incorporates the imagination of a very large extension, endlessness is for many just a word for a very large but still finite set of objects or a very large extension like the ocean.

First-year students often show a vague notion of the term “infinity”, an observation that was done also by Woerner (2013). She even points out that a thorough understanding of infinity is neither a goal nor is it a step towards understanding mathematics. Dötschel (2011) even finds that the

understanding of infinity does not vary much between teacher students and pupils of secondary level. In school they learned the lemniscate symbol “ $\infty$ ” and used it associated with the limit of sequences, series and – at the best – the differential quotient. At least in principle they know that it is not allowed to use this symbol like a number or a variable in all respects (like it was used partly in the 18th century), but one can observe a high degree of uncertainty. For instance, what does it mean when the differential quotient is interpreted in terms like “zero divided by zero”? And what is the outcome? Standard lectures like the ones for Analysis and Linear Algebra usually do not change the perspective and are continued with refined conceptions of limits and the definition of concepts like that of an infinitely dimensional space. Concerning the cardinality of sets there remains often the sketchy notation  $|A| = \infty$  or the like.

Precisely because counting, the determination of a number, is a fundamental concept at all school levels, it is surprising that the issue of cardinality seems to be somewhat neglected. Nevertheless, it is not too difficult to provide a base of knowledge due to Georg Cantor. In many cases original mathematical treatises are definitely unsuitable within teacher education, but there are notable exceptions. One of these is the article of Cantor (1895), which is understandable in large parts. The reason for this is that students are able to acquire understanding with supporting examples on the side of the teacher which will be shown later in the paragraph.

Our paper describes the used examples during the seminar held in the summer term 2016 together with some details around the concept of infinity.

### **Various ways towards an understanding of infinity**

The mathematical education of future elementary math teachers at the University of Erfurt includes among mathematical survey lectures a seminar on the basic principles of arithmetic and algebra. One of the goals of this seminar is to improve the student's understanding of (natural) numbers and their properties since this field will constitute one of the bases of their future teaching. During the seminar students are often encountering the question in how far they have an understanding of the set of natural numbers being infinite. The upcoming discussions circle around the question how one could find out “what is true”. And the discussion ends with the question why. The phenomenon of infinite many natural numbers very often brought about an astonished attitude on the part of the students who pondered about the reasoning of Aristotle: There will be always one number that can be added.

In our seminar there was a focus on aspects of numbers, especially of the natural numbers. Apart from the Peano axioms, the aspect of ways of counting provides a reliable foundation, especially since the cardinalities of sets may be included. This approach promotes a formalization due to the concept of bijective mappings, which is of value in its own. The natural numbers can be regarded as cardinal numbers of finite sets. But what do students know about the cardinality of the set of the natural numbers? Being asked, students claim “infinite” and denote the lemniscate symbol which they know from limits of sequences or functions. In interviews they show an obvious uncertainty about the arithmetical behavior of the object “infinite”. In case of doubt they often suggest treating it like a “usual” number.

We feel responsible for giving a brief insight into the cultural heritage of the different approaches dealing with “infinity”. In particular we seek to show with what kind of caution Euclid, and Cantor

too, got closer to proper descriptions, depending on the actual contexts. Especially we are interested in giving insight into the richness of mathematical thoughts and ideas: "It is possible to regard the history of the foundations mathematics as a progressive enlarging of the mathematical universe to include more and more infinities" (Rucker, 1982, p. 2). With regard to Cantor, we know that "... soon obtained a number of interesting results about actually infinite sets, most notably the result that the set of points on the real line constitutes a higher infinity than the set of all natural numbers. That is, Cantor was able to show that infinity is not an all or nothing concept: there are degrees of infinity." (Rucker, 1982, p. 9)

There are a lot of ways how to understand mathematical statements. Some point out their proof, some stress their genetic development, some point out their formal argument. Our actual understanding of infinity allows us to give statements like: the set of natural numbers or the set of natural numbers between 0 and 100. The first is an infinite set, the second is a finite one. Stressing the idea of a potential infinity which we could not grasp as a solid concept, we help ourselves by a stepwise approach knowing that we will never succeed. This very constructive standpoint or procedure permits a very simple activity and that is adding one, again and again: |, ||, |||, ... In this manner one can distinguish finite and infinite sets. For the first set the procedure ends with a certain number, for the second one there is no certain last number and it becomes clear that the procedure never ends. In both cases the counting is mathematically a 1-1-correspondence.

The different meanings of the term infinity show the richness of mathematics and its historical development. Needless to say that mathematical history does not develop in a regular and uniform way (Dieudonné, 1985, p. 16). Some epoch does not show any development in a field, in some there is a continuous change because of new developments. The fact that we use the word infinity the way we do with numbers goes back to Cantor (1895). It was the upcoming of new ideas, e.g. the idea of a set that changed the understanding of infinity.

How very much different this meaning is in contrast to the "old" Greek meaning shows when student teachers learn about it in their first mathematical lectures: infinity is hard to grasp and the use of it shows that school mathematics does not at all build a proper foundation. Because of its lack it is even more important to build a solid understanding during mathematical studies especially for student teachers as there are many potential links to basic notions of counting in their future teaching.

German mathematical education often refers to three basic experiences ("Grunderfahrungen"), by Winter (1996):

- perceiving phenomena of nature, society and culture;
- knowing (and appreciating) mathematical issues, represented by language, symbols, images and formulas;
- acquiring heuristic competencies.

We like to refer to Winter (1996) because he stresses a connection between everyday life experiences, heuristics and beginning formalization. In order to get aware of basic experiences and deepen the understanding there is a strategy necessary that gets students involved. Kattou et al. (2009) points out:

In particular, academic programs offered to teachers should include mathematical knowledge regarding to infinity in combination with instructional approaches related to the concept. A proposed teaching approach could include the following steps: presentation with several typical tasks aimed at uncovering teachers' intuitions about the concept, discussion about infinity's applications in real life, introduction of the formal definition of infinity and the two aspects- potential and actual- and attempt to distinguish them in examples. (Kattou et al.2009).

Within this this context we pinpoint the following aspects:

1. The notion of infinity changed its meaning through the centuries. In the late 19<sup>th</sup> century the notion of aleph 0, aleph 1 and so forth came up.
2. The way infinity appears in mathematical textbooks follows the idea of Freudenthal's anti-didactical inversion. It is common to introduce infinity by using the lemniscate symbol, mostly just informing about it. The mathematical developments are neglected.
3. Some examples of infinite sets can be solved with simple steps used with finite sets. This presents an approach with a low barrier to student teachers and enhances their understanding of infinity.

Our didactical approach is influenced by Vollrath (1987) who proposed a phase model showing the process of understanding mathematical concepts:

intuitive and content-related → formal / integrated → critical

We therefore stress the finding of variations of standard examples and of counting strategies on the side of the students. The integration of Cantor's text provides some formalism and fostered discussions about the historical circumstances which were not controversial, that is the conflict between Cantor and Kronecker e.g.

The following paragraph presents examples that proved useful within elementary school teacher education.

## Methods of counting

In many cases it turns out difficult to provide an original text to students with the expectation of an adequate comprehension. But just mathematical topics that lead to very fundamental issues may prove appropriate in order to their connection with intuition and imagination. Cantor (1895) develops a concept of elementary set theory, which includes transfinite cardinalities and their arithmetic properties. During teaching it became evident, that important parts of this text are quite understandable and can be an opportunity to discuss an historical treatise and express own reflections.

Before we start investigating into various ways of counting infinite sets we observe that there is no uniform definition of the concept infinity. The word occurs as an adjective to characterize sets especially. We concentrate therefore on the arithmetic field.

The following sections present a couple of examples that may foster the understanding of infinite sets.

### Counting as one-to-one correspondence

The concept of a set, as introduced from Cantor (1895), surely fits into these frameworks. To him we owe the so-called “naïve” definition of a set.

By an “aggregate” we are to understand any collection into a whole  $M$  of definite and separate objects  $m$  of our intuition or our thought. These objects are called the “elements” of  $M$ .

A counting or numerating of a finite set  $M$  with exactly  $n$  elements means, that every number 1, 2, 3, ...,  $n$  is assigned to exactly one element of the set. This is linked to the concepts of maps and functions and more over bijectivity.

### The set $\mathbb{Q}$ is countably infinite

This follows out of a scheme in which every positive rationale number shows one time and is arranged like this:

1/1	1/2	1/3	1/4	1/5	1/6	...
2/1	2/2	2/3	2/4	2/5	2/6	...
3/1	3/2	3/3	3/4	3/5	3/6	...
4/1	4/2	4/3	4/4	4/5	4/6	...
5/1	5/2	5/3	5/4	5/5	5/6	...
6/1	6/2	6/3	6/4	6/5	6/6	...
...	...	...	...	...	...	...

**Table 1: Cantor’s first diagonal method**

The way the scheme is counted goes back to Cantor and is called the “diagonal method”.

Following the presentation of the scheme students were invited to vary it and write down their proposals. Are there other suitable paths? What do they have in common? Furthermore, how could repetitions of numbers be avoided? In the scheme above every positive rational number is repeated infinitely. Does this cause problems? What options do we have to be represented by a reduced table of fractions? Is this already an indicative of the countability of even “larger” sets? After all most students could design various methods for counting even all rational numbers, for instance by designing spiral paths or the like.

### The set $\mathbb{R}$ is uncountable

Suppose that there is an enumeration

$$\alpha_1, \alpha_2, \alpha_3, \alpha_4, \dots$$

of the interval  $[0, 1[$ , which is a subset of  $\mathbb{R}$ , and the numbers are represented in the decimal system, i.e.

$$\alpha_1 = 0, \underline{\alpha_{11}}\alpha_{12}\alpha_{13}\alpha_{14}\alpha_{15}\dots$$

$$\alpha_2 = 0, \alpha_{21}\underline{\alpha_{22}}\alpha_{23}\alpha_{24}\alpha_{25}\dots$$

$$\alpha_3 = 0, \alpha_{31}\alpha_{32}\underline{\alpha_{33}}\alpha_{34}\alpha_{35}\dots$$

$$\alpha_4 = 0, \alpha_{41}\alpha_{42}\alpha_{43}\underline{\alpha_{44}}\alpha_{45}\dots$$

.....

with digits  $\alpha_{i1}, \alpha_{i2}, \alpha_{i3}, \dots \in \{0, 1, \dots, 9\}$  for every positive natural numbers  $i$ .

Now one can define a number  $\beta = 0, \beta_1\beta_2\beta_3\dots \in [0, 1[$  such that

$$\beta_i = \begin{cases} 1, & \text{if } \alpha_{ii} \neq 1 \\ 7, & \text{if } \alpha_{ii} = 1 \end{cases}$$

for all positive integers  $i$ . Obviously, the representation of  $\beta$  possesses at least one decimal digit that differs from  $\alpha_i$ , namely, the  $i$ -th digit. Therefore  $\beta$  cannot occur in the enumeration above, which is inevitably incomplete. Now, if the given interval is already uncountable, then all the more the real numbers are. This scheme originates from Cantor, too, and is called the second diagonal method.

To promote an adequate understanding, students did vary this scheme in a written form, also regarding other  $b$ -adic representations. At this point, the fundamental significance of place value systems in general is to be clarified. During teaching lessons students were encouraged to replace the digits by other symbols such as letters or notes from sheet music etc., and it has become clear, that the relating interpretations (“the entity of ‘texts’ is uncountable”) can foster an adequate understanding in the sense that students are able to make a transfer.

### Hilbert’s Hotel

The cardinality of the set of the natural numbers is denoted by  $\aleph_0$ . In set theory several properties of this first transfinite cardinality are elaborated, as there are

$$1 + \aleph_0 = \aleph_0,$$

$$n + \aleph_0 = \aleph_0$$

for any  $n \in \mathbb{N}$ , as well as

$$2\aleph_0 = \aleph_0$$

and

$$n\aleph_0 = \aleph_0,$$

again for any natural number  $n$ . To illustrate this, the thought experiment of Hilbert’s hotel is helpful: Suppose that there is a hotel with an unlimited number of single rooms, which are numbered according to the natural numbers. The hotel is fully occupied and one other person is knocking on the door. Will the hotel be able to accommodate this person, too? In the classical version each present guest moves up to the room that is numbered one greater as yet. In this way the

first room (numbered by 0 or 1) becomes available and no one has to leave the hotel. The situation is very similar if two or a finite number of new guests ask to come in: The present guests move up in the rooms that are numbered  $n$  greater than now.

A bit more challenging is the arrival of a “Hilbertian bus” with an infinite number of passengers, named or numbered due to the natural numbers. In this case a constant moving up will not be successful. But the past guests could double their initial room number, and every passenger gets an oddly numbered room. This is not the only option available, students should contribute alternatives. More general, if there are two or a finite number  $n$  of “Hilbertian busses”, one can multiply every original room number with  $n + 1$  and assign the passengers of the first bus those rooms, which numbers are congruent  $n + 1$  modulo 1. The occupants of the second bus move into the rooms that are numbered by natural numbers congruent  $n + 1$  modulo 2 and so on. Students are expected to formulate a proper mapping rule and to come up with their own ideas relating alternatives.

Where is the border line? Even a “Hilbertian bus-fleet” of infinite number of “Hilbertian busses” numbered according the natural numbers, is still not able to overstrain the hotel. For example, one can assign a double index to every passenger due to his bus number and his seat number within this bus. Now Cantor does the work by applying his first diagonal method to this matrix structure. Also here students could consider a formula or a formal description of an algorithm.

Students varied the above solutions in several and diverse ways. For example, prime numbers were used and alternating methods of simultaneous counting. Of course, the most important task is the clarification of the impossibility of lodging an uncountable amount of recent arrivals.

The above considerations go along with the equation

$$\aleph_0 + \aleph_0 + \aleph_0 + \dots = \aleph_0,$$

where the number of the summands on the left side is countable.

The given examples above, which were part of the studies of our futures teachers, have certain potential to support understanding.

## Conclusions with respect to understanding the concept infinity

We referred to Cantor especially when we stressed the 1-1-correspondance (or mapping) and some insights of arithmetic rules including infinity. Since all examples are rather basic but initially unknown to most of the students they gained competencies with counting and the notion of bijectivity. It is important to realize that the arithmetic rules known from the basic arithmetic operations may vary, depending on the context. Another example, but in a different relationship is the “double distributivity” in case of unions and intersections of sets. The phenomenon “infinity” holds in itself ambiguities which contradict common sense at first glance. It is of great educational value to become acquainted with some of them, namely in two respects: in terms of general education, which should be a concern of mathematics education and for the purpose of educating “good” teachers. The well-educated primary teacher is then in the position to react properly when children ask smart questions or questions that show insight but do not use proper wording. Pupils occasionally may achieve even philosophical significance – so long as the teacher recognizes its meaning.

*The use of symbolic language and the resolution of equations are of great curricular importance and often cause difficulties to our students who find several obstacles. These obstacles can be of different nature and epistemological obstacles can sometimes be traced back to ancient mathematical texts. In this paper, we will focus on one of the first texts with algebraic content that was published in Spanish, the *Arithmetica practica, y specvlatiua* by Juan Pérez de Moya. In particular, we will present the mistakes made by the author when solving equations of the form  $ax^m = bx^n$  and we will analyze and give explanations for some of them. Furthermore, we will observe how 10th grade students face these types of equations and if some of the old arguments are still present among our students.*

*Keywords: Algebra, mistakes, obstacles, history of mathematics education, 16th century.*

## Introduction and objective

Obstacles to learning can be (Brousseau, 1983) of different types according to their origin. They can be ontogenetic, didactical, epistemological or cultural. An obstacle is epistemological if it is independent from the teaching practice. Brousseau suggested (Chorlay & de Hosson, 2016) that a distinctive characteristic of epistemological obstacles is their appearance in mathematics “from the past”. It might be true that in ancient texts we barely find traces of the errors, difficulties and failures associated to mathematical creation (Cid, 2000). However, in some kind of texts, devoted to teaching or to the introduction and dissemination of knowledge it is sometime possible to find non-trivial errors<sup>1</sup>.

The use of symbolic language and the resolution of equations are of great curricular importance and often cause difficulties to our students (Socas, 2010). Consequently, it can be of interest analyze ancient algebraic texts searching for possible mistakes or misconceptions.

The first algebraic texts written in Spanish appeared during the second half of XVI century. The first one was the *Libro primero, de Arithmetica Algebratica* (Aurel, 1552) written by a German living in Valencia (Puig & Fernández, 2013). The first text with algebraic content written by a Spanish author was (Meavilla, 2005) the *Arithmetica practica, y specvlatiua* (Pérez de Moya, 1562).

In this work will identify some mistakes in Pérez de Moya book. For some of them we will try to give plausible explanations and furthermore, we will see how present 10th grade students face the type of equations where those errors arise.

---

<sup>1</sup> By non-trivial errors, we mean errors that imply cognitive difficulties of some degree; i.e., we do not take into account small arithmetical mistakes, typos, etc. that are also usually found in this kind of texts.

## Juan Pérez de Moya mistakes

In his book, Pérez de Moya discusses the possible solutions of equations of the form  $ax^m = bx^n$  by considering four different cases. In table 1 we summarize the information given by the author in his text:

Case 1	$a = b$ and $m = n$	Unique solution, $x=1$
Case 2	$a \neq b$ and $m = n$	No solution
Case 3	$a = b$ and $m \neq n$	Infinite solutions
Case 4	$a \neq b$ y $m \neq n$	Unique solution (not given)

Of course, this information is clearly incorrect from a modern mathematical point of view. It is interesting to point out that the same mistakes can be found in different text printed during the same period. For instance, in the *Arithmetica* by Rocha (1565) we find the exact same errors, while in Marco Aurel's previously mentioned work we can find a fragment where the author considers cases 1 and 2 above in the same way as Pérez de Moya.

This fact can of course be explained because many of these authors used the same sources and they read each other. However, it is noteworthy that none of them noticed or corrected them. This leads us to the hypotheses that they did not see them as incorrect and some deeper explanation for them must exist. In this work, we will focus on cases 1 and 2.

### Analyzing case 2

In this paper, we are going to focus on case 2 above. From our modern point of view it is rather straightforward that this type of equations have the unique solution  $x = 0$ . In any case, straightforward as it is, we can try to make some kind of aprioristic analysis of how a hypothetical solver can face one such equation.

Consider, for instance, that we want to solve the equation  $4x = 2x$ . We can conceive, at least, the following possibilities:

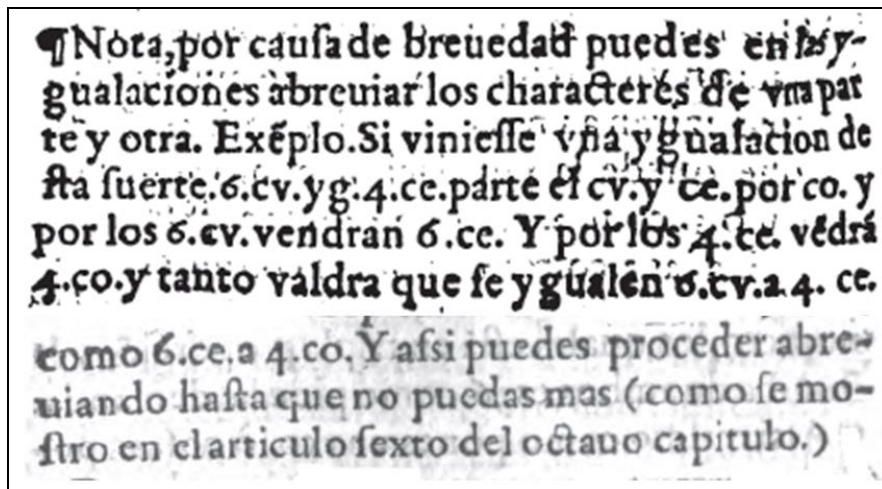

1. The “canonically correct” procedure. Transform the equation into  $2x = 0$  subtracting  $2x$  from both sides of the equation and then divide by 2 to obtain the unique solution  $x = 0$ .
2. A procedure which is “syntactically correct” but “semantically incorrect”. Divide both sides by  $x$  to obtain that  $4 = 2$  and conclude that there is no solution to the original equation.
3. A “materialistic procedure”. Four objects of some kind cannot be equal to two objects of the same kind. Hence, the equation has no solutions.

Of course, at that time it was natural not to consider zero as a number so it is reasonable that a XVI century algebraist thought that this equation has no solution at all. Hence, from this point of view, the answer given by Pérez de Moya would not be a mistake at all.

Anyhow, it can be of interest to identify which of the three previous possibilities, if any, was chosen by XVI century algebraists.

In principle, point 1 above was well-known at that time. In fact, this was the procedure used by Pérez de Moya throughout his work as soon as the considered equation had a constant term. On the other hand, Pérez de Moya also used point 2 in his work. For instance (see Figure 1) we can read

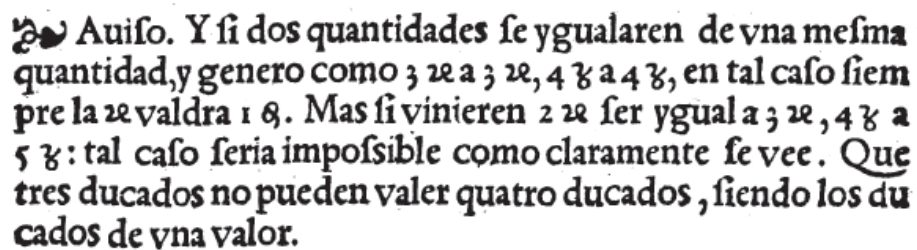

(pp. 546-547): “if you were given an equation like  $6x^3 = 4x^2$ , divide  $x^3$  and  $x^2$  by  $x$  [...] and the equation  $6x^3 = 4x^2$  will be the same as  $6x^2 = 4x$ . And thus you will continue until you can no more”.

¶ Nota, por causa de breuedad puedes en las y-  
gualaciones abreviar los caracteres de vna par-  
te y otra. Exemplo. Si viniere vna y gualacion de

uiando hasta que no puedas mas (como se mo-  
stro en el articulo sexto del octauo capitulo.)

Figure 1: Dividing by  $x$  during XVI century

But, in spite of his constant use of point 1 and 2 above throughout his algebraic work, Pérez de Moya did not use any of those arguments when facing equations described in case 2. Instead, he appeals to that “materialistic procedure”. In particular, we read (p. 544): “if  $3x$  were equated to  $4x$  or  $5x^5$  to  $2x^5$ , in such case, those equations will be impossible and they cannot be done because two reals cannot be the same as three, provided they have the same value”. Moreover, this exact same idea, with nearly the same example can be found in Marco Aurel’s work (fol. 78 v): “three ducats are not worth the same as four ducats since ducat have one only value” (Figure 2).

¶ Auiso. Y si dos quantidades se y gualaren de vna mesma  
quantidad, y genero como 3. d. a 3. d., 4. d. a 4. d., en tal caso siem-  
pre la d. valdra 1. d. Mas si vinieren 2. d. ser y gual a 3. d., 4. d. a  
5. d.: tal caso seria imposible como claramente se vee. Que  
tres ducados no pueden valer quatro ducados, siendo los du-  
cados de vna valor.

Figure 2: Materialistic argument in Marco Aurel’s work

As we already pointed out, the first possibility led to the solution  $x = 0$ . It is very likely that these authors conceived ‘0’ just like a figure and not like quantity. Since ‘0’ is not a quantity, it cannot be the solution of the equation. Hence, a reasoning like the described in the point 1 above was flawed and could not be used.

Regarding the second possibility, we have seen that Pérez de Moya in fact used this technique. Nevertheless, he is quite imprecise saying that it must be used “until you can no more”. It is possible that, since in this case this technique leads to non-sense expressions, was also considered flawed and abandoned.

Therefore, from this point of view, the third possibility was the only hope to give an answer to this type of equations and so they used it. As we will see, this idea is still present among our students and it has an interesting explanation (Booth, 1984). The use of this argument implies that the

unknown is conceived as an object itself and not as the representation of a number. Clearly Pérez de Moya and Marco Aurel have this in mind when they talk about “*two reals*” or “*four ducats*” when referring to  $2x$  and  $4x$ , respectively.

### Back to case 1

After the previous analysis, we have a more or less clear idea of why XVI century authors could not manage correctly equations of the form  $ax^m = bx^m$  with  $a \neq b$ . Moreover, we understand why they said that they had no solution. Then, we might want to apply a similar reasoning to equations of the form  $ax^m = ax^m$ ; i.e., to case 1 above.

These equations, from a modern point of view, have – trivially – infinite solutions. They are, in fact, what some people call identities. Pérez de Moya, Marco Aurel and other authors provide  $x = 1$  as the only solution and, unlike in the previous case, they provide no argument supporting this claim. If we try to apply the three aforementioned possibilities to the case of, say,  $2x = 2x$  we would get:

1.  $0 = 0$ .
2.  $2 = 2$ .
3. 2 euros are always equal to 2 euros.

All three cases lead to some kind of tautology. To some kind of essential identity of an object with itself as opposed to an accidental identity of the form  $2x = 3x^2$ . When dealing with aspects regarding these topics we can turn to Aristotle’s *Metaphysics* which suggests a genealogy or rational grounding for this answer. In particular, in the chapter IX from Book V we read (Taylor, 1801, p. 122): “*But some things are said to be the same essentially, in the same manner as things which are essentially one. For things of which the matter is one, either in species or number, are said to be the same*”. Thus, when facing an essential identity “*the matter is one*” and the answer is the unity as our XVI century authors claim. In any case, as to the historical question of the impact of Aristotle’s *Metaphysics* on our XVI century algebraists, this paper is no place to discuss it.

### Dealing with cases 1 and 2 today

We worked with 57 students of 10th grade during a 50 minutes class session. By 10th grade, Spanish students should be completely familiar with algebraic language and notation (introduced in 7<sup>th</sup> grade). They have not systematically solved polynomial equations of degree higher than two, but they know how to use techniques such as taking common factor, etc. We designed a questionnaire (Table 1) that included the four cases treated by Pérez de Moya in his work. In particular, items (1) and (2) corresponded to the cases 1 and 2 discussed above.

Solve the following equations:

(1)  $x + 1 = 1 + x$

(2)  $x = 2x$

(3)  $4x^7 = 4x^5$

(4)  $8x^2 = x^5$

**Table 1: Questionnaire**

Among other aspects, we wanted to analyze how the students faced identities like the one presented in item (1) and equations like item (2) that lead to the materialistic procedure described above.

### Item 1

For this equation, Pérez de Moya proposed  $x = 1$  as the only solution. The answers given by the students can be classified according to the following categories (Table 2):

- NS: The student says that there is no solution.
- US: The student says that there is a unique solution.
- IS: The student says that there are infinite solutions.
- N: The student does not give an answer.

NS	16 (28%)
US	5 (8.7%)
IS	19 (33.3%)
NDS	17 (29.8%)

**Table 2: Answers for item 1**

It is clear that answers from the categories NS and US are incorrect. Moreover, 15 answers from the category IS are also incorrect. Thus, only four (7%) students gave a correct answer to this item. From these correct answers, two are worth mentioning:

1. *“Infinite solutions. Because the order of the factors does not change the result and if you sum one to a number is the same as if sum the same number to one”.*
2. *“It has infinite solutions, because any value that you give to the  $x$  is the same. For instance,  $x = 5$ ,  $5 + 1 = 1 + 5$ ,  $6 = 6$ ”.*

The first answer shows that the student has observed the structure (Linchevski & Livneh, 1999) of the algebraic expression and has identified it with the commutative property of addition. In the second answer, we see that the student has the idea that the solution of an equation is a number that leads to an identity when  $x$  is substituted by this number.

Among the students in the category US, only one gave  $x = 1$  as the unique solution to the proposed equation. His answer was the following:

$$x + 1 = 1 + x \rightarrow x - x = 1 - 1 \rightarrow x = 1$$

The most plausible interpretation for this answer is that the student compared both sides of the second equality and assigned to the symbol on the left hand side ( $x$ ), the corresponding symbol on the right hand side (1). Of course, we could not expect any XVI century-like reasoning.

In addition to this answer, some other mistakes were found that are worth mentioning:

1.  $0x = 0$  ;  $x = 0/0$ . *“It has no solution. Dividing by zero gives an irreal [sic] number”.*
2.  $x - x = 1 - 1$  ;  $0x = 0$ . *“It has no solution because it gives  $0x = 0$ , that is, there is no”.*
3.  $x - x = 1 - 1$  ;  $0x = 0$  ;  $x = 0$ . *“No solution”.*
4.  $x - x = 1 - 1$  ;  $x = 0$ . *“Infinitely many solutions”.*
5.  $1 - 1 = x - x \Rightarrow 0 = 0 \Rightarrow x = 0$ .
6.  $x + 1 = 1 + x \Rightarrow x - x = 1 - 1$ . *“No solution, that is, infinite solutions, because if we find zero, it means that there can be many solutions”.*

The first mistake comes from the use of the “canonical” procedure to solve linear equations. As we pointed out before, this procedure lead to “non-standard” situations, the student cannot manage. The second mistake arises when the student tries to give a meaning to the expression  $0x$ . The student understands this expression as “*there is no  $x$* ”. Since there are no  $x$ , there is no value to assign to it. Finally, the last four mistakes show different ways to face the expression  $0 = 0$ . Some are wrong, some are arbitrary and the last one shows how the student fails in remembering what he is supposed to say when he gets  $0 = 0$ .

## Item 2

Pérez de Moya states that this equation has no solution. The answers given by the students can be classified according to the following categories (Table 3):

- CS: The student correctly solves the equation.
- WS: The student gives a wrong answer but with a unique solution.
- NS: The student is unable to give a numerical solution (either correct or incorrect).
- N: the students gives the wright answer without any explanation.

CS	18 (31.6%)
WS	20 (35%)
NS	15 (26.3%)
N	4 (7%)

**Table 3: Answers for item 2**

In this case, we mainly focus on the categories NS and CS, especially on the last one. Students belonging to the category WS usually make mistakes when operating and manipulating algebraic expressions. The following steps give a rather paradigmatic example:

$$x = 2x ; x / x = 2 ; x = 2.$$

Regarding those students not providing a numerical solution, it is noteworthy that one of them gave an answer that essentially reproduces the XVI century reasoning: “*No solution.  $x$  cannot be equal to  $2x$* ”. The most interesting other mistakes that we have found in this item are:

1.  $x - 2x = 0 ; -x = 0$ . “*It has no solution because  $x$  cannot be negative*”.
2.  $0 = 2x - x ; 0 = x$ . “*No solution*”.
3.  $2 = x / x ; 2 = 1$ .

The first two answers show a good knowledge of the algorithmic procedure used to solve a linear equation but both students fail in the last step, which involves some kind of interpretation. The third answer again involves dividing by the unknown.

In this case, 18 students provided a correct answer. One of these answers, in some sense, completes and corrects the original XVI century mistake: “ *$x = 0$ . Because  $x$  cannot be equal to  $2x$  unless the solution is 0*”.

## Some final comments

Leaving apart problems regarding algebraic manipulation and notation, we find a main difference between the student who correctly face the analyzed situations and those who do not. In the case of item 1, for instance, we see that most of the correct answers involve a clear idea of the notion of

solution to an equation, while wrong answers always involve the mechanical and algorithmical search of the solution using the steps of some kind of canonical procedure. This thoughtless application of a procedure implies that the student is not usually able to manage non-standard situations like  $0 = 0$  or  $0/0$ . Then they sometimes try to use some memoristic knowledge or just do not know how to give an answer. This algorithmical conception also leads very often to divide by the unknown, even if this assumes that  $x$  is not 0. Most of the students work at a syntactical level and they simply do not care about the meaning of the symbols and the operations among them.

Consequently, we think that the mechanical manipulations and rules to solve equations, if presented, should never be the starting point of our teaching. Rather, the solution of equations should be introduced starting from particular problematic situations. After all, algebra was initially a method to solve some arithmetical problems involving unknown quantities. It might be possible that such an introduction implied what we have called “materialistic procedures”, which can also lead to mistakes as we have seen, but at least statements like “ $x$  cannot be equal to  $2x$ ” can be the basis for interesting discussions in the classroom.

Finally, in the light of our results, it seems clear that we should devote plenty of time to work with equations leading to identities and to expressions of the form  $0 = 0$  and  $0/0$ . They will consistently appear throughout the mathematical life of our students and a good understanding of the meaning and implications of these expressions will be a great benefit for them.

# Multiple perspectives on working with original mathematical sources from the Edward Worth Library, Dublin

Maurice O'Reilly

CASTeL, Dublin City University, Ireland; [maurice.oreilly@dcu.ie](mailto:maurice.oreilly@dcu.ie)

*In the spring semester of 2016, the author worked with twenty undergraduate (BA) students on original sources from the Edward Worth Library (1733), in Dublin. The end goal was to produce an online exhibition of the mathematical works from that library. The approach to this collaborative work is given, set in the context of a more general framework of the pedagogical value of working with original sources for teaching the history of mathematics. Examples of feedback from the students are given, as is an outline of how the exhibition itself was eventually shaped. The conclusion reflects on the learning gained by all involved in the collaboration.*

*Keywords: History of mathematics, original sources, cooperative learning*

## Introduction

This paper outlines the process and product of working, with twenty students and two other collaborators, on the mathematical works in the Edward Worth Library (EWL). This collection opens a window on two centuries of the development of mathematics in England from the 1530s to the 1730s, a period of momentous cultural change in Ireland – with the expansion and consolidation of English political power and the emergence of an Anglo-Irish Protestant elite – and scientific blossoming, culminating in the work of Isaac Newton and his circle, with very strong influences from continental Europe, especially from France and the Netherlands. The work, on original sources from EWL, of the author with his students and the librarian is outlined, as is the subsequent work in preparing an online mathematical exhibition, launched in November 2016.

## The Edward Worth Library and my encounter with it

The Edward Worth Library was founded in 1733 by its benefactor, Edward Worth (1676-1733), a medic who had a passion for fine books and who left some 4500 volumes to Dr Steevens' Hospital, in Dublin. Unusual in Ireland for this period, about one third of his collection comprise texts of medical and scientific interest. Of these, in turn, about 9% are mathematical. The collection is housed in a single room with glazed cabinets designed specifically for that purpose. The books themselves are in impeccable condition due, in no small way, to the fact that they were used very little during the 283-year history of the library (Mc Cormack, 2005).

I have taught a one-semester module on the history of mathematics every two years since 2008. A few weeks after completing teaching such a module in 2012, I visited EWL on 15<sup>th</sup> June, for the first time, in the company of Professor William (Bill) F. McComas, visiting Fulbright Professor (to Dublin City University, DCU) from the University of Arkansas. Combining his interest in the history of science and mine in the history of mathematics, EWL gave the impression of an Aladdin's cave of early modern European learning. We were enthusiastically welcomed by the librarian, Dr Elizabethanne Boran. With a permanent staff of one (the librarian herself) and some visiting scholars and interns from time to time, it is challenging to open the doors to the public, although small specialist conferences are accommodated as much as possible. The librarian has overseen the

publication of online exhibitions that enabled the treasures of the library to be appreciated by a wider readership (Edward Worth Library, n.d.).

On 6<sup>th</sup> May 2014, the librarian welcomed the first group of my students (undergraduates in their second or third year of a three-year BA) to visit EWL. She had put on display works I had chosen by Viète, Harriot, Descartes, L'Hospital, Wallis, Ward, Huygens and Newton, dating from 1615 to 1732. The reaction of the students to viewing the original sources was very positive, however it was too late in the academic year for this cohort of students to engage with these original sources in any meaningful way. Their reaction, together with my own growing familiarity with scholarship in the HPM community on the importance of working with original sources, prompted me to seek an opportunity to work with EWL in a more significant way in 2016. The librarian was keen to extend the scope of the online exhibitions at EWL, and it seemed realistic to build a mathematical exhibition around the work of the next cohort of students (twenty, including two visiting from the USA). Necessary preparatory work on my part was to become familiar with the online EWL catalogue and derive from it a (provisional) list of the mathematical works in the collection. From this list (of 109 works), I identified for which ones the author had a biographical entry in MacTutor (O'Connor & Robertson, 2016), and found online versions of about a third of the texts, using EROMM, for example. Searching for so many original sources was time-consuming, yet very rewarding; it was an exercise I had previously no reason to undertake on such a scale. At this stage, I considered myself ready to lead the students in the EWL Project. This paper gives an overview of how the project itself was conceived and implemented.

## **Original sources and teaching History of Mathematics**

Much is said in the literature about the use of original sources in teaching the history of mathematics, and this is not the place to provide a comprehensive overview. Kiernan identifies the challenge facing both teacher/lecturer and students:

The task of presenting original works of mathematics to a class of undergraduates may seem like a daunting task. It requires much preparation. How does one become confident that one can do this? Well, you must remember that you are not alone in this task. Attending any conference with themes on the history of mathematics will remind you that there are many others who have the same interest as you. (Kiernan, 2010, p. 412)

Because I, the author, am also the lecturer and so a crucial player in the work described in this paper, it is appropriate to describe, in the first person, how I engaged with the tasks involved. Glaubitz is quite clear that working with original sources is quite a different kind of work from that which students usually think of when they 'do' mathematics:

Of course, on the part of the teacher it involves quite some preparation, but this is always the case when you are going to try something new. What is more, the study of original sources requires teachers and students to be prepared to dive into some strange and unknown realm of thinking, to appreciate cultural and historical contexts and – last but not least – to deal competently with written text that is more extensive than the word problems they are used to in mathematics. (Glaubitz, 2010, p. 351)

If working with original sources is, indeed, ‘something new’, it “[provides] context, motivation and direction for students’ mathematical endeavours” (Barnett, 2012, p. 336). Thus, such work has a strong potential to open up new perspectives for students:

By reading historical sources students can be acquainted with episodes of past mathematics where other meta-discursive rules governed the discourse. (Kjeldsen, 2010, p. 52)

Even when students do not make explicit reference to unfamiliar ‘meta-discursive rules’, appreciation of such rules can often be noticed indirectly in the ‘surprise’ they express in their reflections on working with original sources.

## Designing the EWL project

The EWL Project was designed as an integral part of a 5-credit (ECTS) module on the History of Mathematics (having a strong, but not exclusive, emphasis on the development of algebra). Credit for this module comprised two main components: 70% for a terminal examination and 30% for continuous assessment (CA). Roughly one third of the examination and 17 marks of the 30 allocated to CA were associated with the EWL Project. Thus, in effect, a substantial 40% of the total credit for the module was assigned to this project. What were the salient aspects of the project and how was it presented to the students?

The semester began on 1<sup>st</sup> February (2016) and it was important to arrange a visit to EWL early in the semester to allow the students to become familiar with material that would be very foreign to their experience. In advance of the visit, I prepared a one-page overview (with web links, **indicated in bold**, below):

It is a great privilege to be invited to view a selection of the mathematical works at EWL of which there are about 109 in total. These span a period of almost two centuries, from Cuthbert Tunstall’s *De arte supputandi libri quatuor* (1538) to Isaac Newton’s posthumous *Arithmetica universalis* (1732), published the year before the establishment of EWL and the death of its founder.

According to the entry in MacTutor, **Tunstall** (1474-1559) had a prominent career as a diplomat (at the court of Charles V in Aachen, for example) and bishop (eventually of Durham). His *De arte supputandi* (1522) was the first printed work published in England devoted entirely to mathematics. This was not an original work, but was based on Luca Pacioli’s *Summa* (1494).

Newton (1643-1727), arguably the greatest English mathematician, worked in a broad range of disciplines including theology, optics, mechanics, algebra and (especially) the calculus. EWL has no fewer than 16 works attributed to Newton. There are several other works in EWL by others associated with Newton (such as Barrow, ‘sGravesande and van Musschenbroek), all of whom (along with Newton himself, of course) are presented in the EWL online **exhibition on Newton**.

The 109 books are written in four languages: English (21), French (15), Latin (64) and a combination of Greek and Latin (9). The authors of 74 of these (and some of the authors, such as Newton, have more than one book in EWL) have **biographical entries in MacTutor**. EWL

expects to prepare an online exhibition on Mathematics at EWL in summer 2016. You are invited to contribute to this by writing a page on one of the mathematical works in EWL.

In advance of the visit to EWL on 25<sup>th</sup> February, take a look at one of the seven ‘big’ exhibitions already online at EWL (**Newton, Botany, Alchemy & Chemistry, Infectious Diseases, Astronomy, Dr Steevens’ Hospital and Aldines**) or one of the eight smaller exhibitions (e.g. **Looking at the Moon** or **Surgery**). Think about the following:

1. How do you find navigating these webpages?
2. What features of the exhibition (you chose) do you find attractive?
3. What do you find exciting/daunting about the prospect of writing a page for the Mathematics at EWL exhibition?

This page set the scene for the project. Its subsequent development required much attention to detail, taking on board, to a greater or lesser extent, the reactions of the students as observed in their submitted work, contributions to a forum (in a virtual learning environment), and queries by email or verbally.

On the day of the visit, 16 of the twenty students made it, along with a colleague (Fionnán Howard) who played a crucial role later in editing work for the online exhibition. The students were given hard copy of the following:

- A list of the twelve works of which nine were put on display by the librarian
- A page of text or an illustration from ten of these
- Chapter 3 (“How are mathematical ideas disseminated?”) from Stedall’s *The History of Mathematics – A very short introduction* (Stedall, 2012)

Students were asked for their reflections on visit, and responded enthusiastically and on a wide range of aspects. Different perspectives on the library itself included (with student identifiers given in [square brackets]):

On arrival to the Edward Worth Library (EWL) it was just how I would have pictured it. Not only had the books all been perfectly preserved but so had the library itself. [8]

I expected the library to be quite big and look similar to any other library. My expectations were quite incorrect. [15]

I felt as if I went back in time [12]

In each case, the student’s surprise, even sometimes delight, is evident. On the nine books put display, comments included:

I was surprised that we were allowed to view some texts up close given their iconic meaning. [16]

The books themselves were written in a number of different languages, mainly Latin and French, with only a small amount in English, which again highlights how things have changed. [10]

The most astonishing thing I saw was the quotient rule in a book from 1696. It was bizarre seeing it in such an old context. [2]

There is a real sense here of situating a rule, familiar from school, now in the ‘exotic’ period of the calculus textbook (L’Hospital, 1696). In her introduction the librarian had made a very reasonable conjecture on the relative plainness of the binding of almost all of Worth’s mathematical books, and one student picked up on this:

Worth didn’t seem to pick these books for their binding or appearance alone, but their content [7]

Some students were thoughtful, as if for the first time, about how mathematics emerges and is communicated:

It quickly became apparent to me that to study any subject during this time period you would need a huge amount of devotion and intellect. You would need to be fluent in various languages to even access three quarters of the books, you would need to travel to find the books and you would need an in-depth knowledge of the subject to comprehend them. [2]

I was curious about the various languages used in the books and wondered whether every mathematician needed to be fluent in order to understand and broaden their mathematical knowledge. [6]

The visit gave me a much better and clearer insight into the HoM module, it put into context how the maths we do and formulas we take for granted did not just fall from the sky, but were sought after and achieved by great minds. [12]

Other students articulated hermeneutical sensibilities about the foundations of mathematics:

Seeing some of the diagrams and equations that were printed in the math books we viewed (though in a different language and confusing at times) made me very aware of how long math has been around. That may sound childish at first, but it was extremely eye-opening to realize that though we may now solve problems using different methods, the foundational concepts and ideas are similar. [9]

I suppose because these books were collected such a long time ago, we assume that they had a complete different idea of maths, but in fact this is where our understandings stemmed from. The visit to the Edward Worth library made me completely believe and understand that. [15]

Others again drew attention to the language in which the works were written:

I was also reminded how much I take it for granted that English is the principal language of science today. [7]

I was taken aback by how easily I could comprehend what was in the books even though they were written in different languages. [18]

Overall the response to viewing original sources close up and in the ‘intense’ atmosphere of EWL was strong and clearly expressed. After giving these initial informal impressions of their visit, students were asked to work on the detail of the EWL Project in two phases. The first phase was introduced as follows:

The overall aim of this project is to produce material that will contribute to an online exhibition of the Mathematical works at EWL. Specifically, you are asked to choose one mathematical book from the collection and explore it in whatever way you can.

Several approaches that students might have adopted were suggested, without being prescriptive. These included (along with many others): finding out about the author (from the web), about the historical context in which they lived and about who influenced their mathematical development. Students were encouraged to make plenty of rough notes, to be explicit about why they had chosen a particular work, and to relate it to their prior knowledge and readings. Moreover, the librarian sent a message of encouragement with some notes on the availability of English translations of books in other languages using the British Library's English Short Title Catalogue (ESTC). She also recommended paying attention to the preface of their chosen book (if available in English) so as to get an idea of the context of the book and what the author considered important, and to identifying the most striking illustrations in the book (if any).

The four students who could not make the visit had the opportunity to read the feedback of those who did, and compose questions for them. In this way, they were integrated into the work of the EWL Project alongside their peers.

Not surprisingly, some books were chosen by more than one student: seven chose Wilkins (1691), three chose L'Hospital (1696) and 2 chose Tunstall (1538). Having reviewed the work of phase one and given feedback, I nudged students to choose unique books, so that, in the end, 19 distinct books were 'chosen' (with two opting for Wilkins).

In phase two, students were required to review and polish their work, taking my feedback into account, reviewing features of the existing EWL online exhibitions and distilling their work to produce an engaging, informative and reliable piece of between 800 and 1200 words.

Later, in a short 'capstone' exercise, students were asked to identify the two readings they found most helpful for insights into the history of algebra, and give reasons why? Many of them chose readings related to their work on the EWL Project, indicating its strong significance in their view.

## **Preparing the online mathematics exhibition**

Once the students' work was complete, the next challenge was to devise the structure for the online exhibition. The librarian, Elizabethanne Boran, had much experience in this matter and, together, we decided to use the headings (Arithmetic, Algebra, Geometry, Conic Sections and Infinities) in Ward's *The Young Mathematicians Guide* (1719) as categories for five sections, and to augment these by four more, namely Probability, Applications, Notation and Communities. These nine sections were then to be introduced by an opening section entitled 'What is Mathematics?' A decision was made to incorporate the students' project work to the greatest extent possible (within an appropriate editorial rubric). Each of these thematic sections included links to the works of featured mathematicians. A full list of these mathematicians is given in Table 1 (presented chronologically, with reference to the life of Edward Worth himself).

<b>Number represented in EWL who died (or were born) in a particular period</b>	<b>List of those chosen for the EWL Exhibition</b>
7 died before 1000	1. Euclid of Alexandria 2. Archimedes of Syracuse 3. Apollonius of Perga
16 more died before 1640	4. Tunstall (1474–1559) 5. Commandino* (1506–1575) 6. Cardano (1501–1576) 7. Viète (1540–1603) 8. van Ceulen (1540–1610) 9. Clavius (1538–1612) 10. Harriot (1560–1621) 11. Marolois (1572–1627)
13 more died before 1678 (before Worth's birth in 1676, roughly)	12. Descartes (1596–1662) 13. Pascal (1623–1662) 14. Wilkins (1614–1672) 15. Barrow* (1630–1677)
<b>of the remaining 37:</b>	
16 were born before 1640 (and were living during Worth's lifetime, but were much his senior)	16. Kersey (1616–1690) 17. Wallis (1616–1703) 18. Brouncker (1620–1684) 19. Dechales (1621–1678) 20. Leybourn (1626–1716) 21. Huygens (1629–1695)
15 more were born before 1676 (and were contemporaries of Worth, and senior to him)	22. Ozanam (1640–1717) 23. Ward (1648–1730) 24. Fontenelle (1657–1757) 25. Gregory* (1659–1708) 26. L'Hospital (1661–1704)
6 were born after 1676 (and were younger than Worth)	27. Montmort (1678–1719) 28. Steell (1690–1726)

**Table 1: List of those chosen for the EWL Exhibition**

In this table, three (indicated by \*) are included for their editions of Euclid. The exhibition itself can be seen online (O'Reilly, et al., 2016).

## Conclusion

This paper has outlined the design and implementation of collaborative work within a module dedicated to the history of mathematics, drawing significantly on original sources. The result of this work has led to the production of an artefact external to the module, the online mathematical

exhibition at EWL. It is evident that much was learned by all those involved, students, librarian and lecturers, giving clear testimony to the value of engaging deeply with original sources, in this case the mathematical works collected by the medic, Edward Worth, in the late 17<sup>th</sup> and early 18<sup>th</sup> centuries. It is hoped that many will view the exhibition and thereby enjoy the work of those who created it.

### Acknowledgment

I acknowledge the work of collaborators, Dr Elizabethanne Boran, Fionnán Howard and the twenty BA students (named on the online exhibition). I would like to dedicate this paper to Professor Jan van Maanen who was the first to alert me to the wealth of insight to be enjoyed through working with original sources.

# **Inquiry-based teaching approach in mathematics by using the history of mathematics: A case study**

Areti Panaoura

Frederick University, Cyprus; [pre.pm@frederick.ac.cy](mailto:pre.pm@frederick.ac.cy)

*The use of the history of mathematics during an inquiry-based teaching approach is expected to multiply the positive effects on students' learning. The present work investigated a "typical" teacher's difficulties while trying to use the history of mathematics as a teaching tool during inquiry-based teaching activities. Two examples which were presented in the textbook of the 5<sup>th</sup> grade of primary education were used to observe the teaching practices. Results indicated that the teacher had difficulties in understanding how students could investigate a mathematical concept by integrating the history of mathematics and how the study of the history would enable them to construct the new-acquired knowledge. The respective knowledge of the domain seemed to be a prerequisite in order to be able to use the history of mathematics fluently and flexibly in a learning environment which asked students to explore or investigate the mathematical concepts.*

*Keywords: Case-study, inquiry-based teaching approach, history of mathematics.*

## **Theoretical background**

Mathematics education aimed to develop pupils' abilities to think logically, critically and creatively by recognizing that mathematics permeates the world around and by recognizing the power and the beauty of mathematics. We believe that a central key for those aims is the appreciation of the multicultural and the historical perspective of mathematics which faced the tendency to understand it as a formal science which has already been discovered. Using authentic problems from the history of mathematics provides experiences for students to actively engage in classroom discourse (Gulikers & Blom, 2001), and to realize the role of the construction of the science of mathematics.

Since 2009, in the context of the CERME we have the appearance of the specific group which discusses the role of using the history of mathematics, the theoretical framework, the teaching practices and the respective learning results. In a meta-analysis, Butuner (2015) included 56 researches in Turkey and abroad in order to reveal the influence of using the history of mathematics on success. By the same way numerous articles have been published in scientific journals and many conferences have been done, without exhausting the discussion on how to use in a more productive way the history of mathematics in order to fulfill the aims of mathematics education. Recently there was a special thematic issue of the Menon Journal of Educational Research about the use of the history of mathematics in mathematics education. The emphasis concentrated on the educators' experiences, beliefs and practices on using the study of the historical aspects of many different concepts for the teaching of mathematics in different ages. There are many studies on the level of higher education (e.g. Weng-Kin, 2008) and on the level of secondary education (e.g. Kaygin, et al., 2011, Lim & Chapman, 2015) and fewer about the primary education.

The present work joined the use of the history of mathematics at a specific grade in primary education, with the aim of using the inquiry-based approach as a teaching method which was supposed to enable students explore and investigate the new mathematical concepts. At the Curriculum of Mathematics which was constructed in 2011 for the primary education in Cyprus, the

use of the history of mathematics was suggested in order to develop students' positive beliefs about mathematics and the usual use of inquiry-based teaching was proposed as the main teaching approach. The two central concepts for the inquiry-based teaching approach which were proposed were "investigation" and "exploration". A case study of a "typical teacher" was used in order to investigate the two specific research aims: a) to examine his knowledge and beliefs on using the history of mathematics in an inquiry-based framework and b) to reveal the teaching practices which are used and the teaching difficulties which are faced during the implementation of the innovation.

### **The history of mathematics as a teaching tool**

In 2000 the International Commission on Mathematics Instruction has set up a study on the role of the history of mathematics in the teaching and learning of mathematics. The main intention was to study the role of the history of mathematics in relation to the teaching and learning of mathematics to the teacher training. Jankvist (2009) explains the use of the history of mathematics both as a tool and as a goal and suggests that introducing the history of mathematics in school curricula enhances learners' motivation, promotes favoured attitudes, and draws attention to possible obstacles faced in the generation and evolution of mathematical concepts. As a pedagogical tool it can serve as a guide to understand the difficulties students may encounter as they learn a particular mathematical topic (Haverhal & Roscoe, 2010). History of mathematics enables teachers to present to their students how mathematical ideas develop and to guide them appreciate mathematics as a creative disciplinary activity. Schubring and colleagues (2000) also posit that programs based on the history of mathematics could increase self-confidence in working with mathematical tasks and develop learners' ability to apply mathematical methods. A journey through the history of mathematics can also enable learners to construct mathematical meanings and support new conceptions about mathematics by changing learners' existing beliefs and attitudes (Dubey & Singh, 2013).

Jahnke (2000) suggests three general ideas which are suited for describing the special effects of studying a source on the teaching of mathematics: (a) the notion of replacement according to which mathematics is seen as an intellectual activity, (b) the notion of reorientation according to which history reminds us that the mathematical concepts were invented and (c) the notion of cultural understanding. As Siu (1997) claims, using the history of mathematics in the classroom does not necessarily increase students' cognitive performance, but "it can make learning mathematics a meaningful and lively experience, so that learning will come easier and will go deep" (p. 8). As Panasuk and Horton (2013) underline the learning of mathematics can be facilitated by studying the cultural significance of mathematics and understanding that "in the earliest stages of invention, many of the mathematical concepts were extremely difficult to define, understand and accept for even the most gifted mathematicians" (p.38).

Although the mathematics teachers in the study by Lit and Wong (2001) were very supportive in using history in their teaching, Siu (1997), in an invited talk given at the working conference of the 10<sup>th</sup> ICMI study on the role of mathematics in mathematics education, offered a list of thirteen reasons why a school teacher hesitates to make use of the history of mathematics in classroom teaching such as "I have no time for it in class", "Students don't like it", "There is a lack of teacher training on it", "Students do not have enough general knowledge on culture to appreciate it", etc.

## **The inquiry-based teaching approach**

The inquiry-based approach in mathematics education is supposed to promote engagement and ownership and a “human view” of science as knowledge in the making (Savelsbergh et al., 2016). It requires teachers to use pedagogical methods which actively engage students in developing conceptual understanding of mathematical concepts (Chapman, 2011). The challenge for educational systems is to enable its teachers to adopt the values of the inquiry-based pedagogy. The scientific journal of *ZDM in Mathematics Education* has published a special issue in 2013 with nine papers focusing on inquiry-based mathematics education and their implementations, indicating that many questions remain unanswered.

Teachers need to develop their ability to foster student decision-making by balancing support and independence in thinking and working (NCTM, 2000). Classroom management is a crucial aspect of instructional quality (Taut & Rakoczy, 2016). Chin and Lin (2013) claim that there are obstacles and difficulties such as: (i) teachers did not experience inquiry-based learning in mathematics in their own school years, (ii) they do not have complete understanding of the inquiry-based teaching, (iii) there are practical constraints such as that the allocated teaching hours are not enough, (iv) the influence of teaching for success in tests.

Maab and Artique (2013) examine the implementation of the inquiry-based approach and look at its implementation through resources and professional development. They indicate that there is a need to promote a widespread uptake of inquiry-based approach in day to day teaching. One of the main emphases of the new proposed teaching model of Mathematics in the centralized educational system of Cyprus which is presented at the New Curriculum (NCM, 2011), is the use of “exploration” and “investigation” of mathematical ideas, as two dimensions of the inquiry-based teaching and learning approach. The whole idea is to introduce a mathematical concept by using an inquiry-based activity through which the teacher asks students to express their ideas and arguments, to communicate by using the language of mathematics. The emphasis is on using authentic and open-ended problem solving activities without only one correct answer and by respecting the value of inter-individuality.

## **Methodology**

The emphasis of the present study was to examine the teaching practices used during the implementation of the inquiry-based activities by using the history of mathematics in authentic classroom situations. We chose to observe two lessons where the use of the history of mathematics was proposed by the textbook, at the 5<sup>th</sup> grade of primary education. We are referred to a centralized educational system where the Curriculum, the textbooks and the teaching materials are proposed by the Ministry of Education. A “typical” teacher was chosen after the first phase of the study which is not presented at the present paper. The criterion for the selection was his medium performance concerning his knowledge and beliefs about using the history of mathematics and the inquiry-based teaching approach in mathematics. He took part at a first phase of the project which collected data about teachers’ knowledge and beliefs (details about the questionnaire are presented at Panaoura, 2016). We aimed to make the link between what he might say during an interview and what he actually did during the teaching. By using the case-study approach we emphasized the analysis of the teaching conditions in real-life classroom situations and the interpretation he proposed during a

follow up interview. Firstly the teacher at the 5<sup>th</sup> grade was observed by the researcher and then semi-structured interviews were conducted in order to discuss the lessons. The lessons were chosen because an activity of using the history of mathematics for introducing a concept during an investigation was suggested by the school textbooks. The proposed activities are presented at the Figure 1.

**Figure 1: The activities as presented at the textbook (in Greek and in translation)**

A protocol for the observation was constructed and used in order to concentrate the observer's attention on: a) teacher's guidelines at the introduction of the activity and his interventions while students were working and b) teachers' feedback on students' difficulties and mistakes. The semi-structured interviews with the teacher were concentrated on the practices he used and the difficulties he faced.

## Results

The teacher's observation enabled us to concentrate our attention on the teaching practices he followed in order to use the inquiry-based approach during the teaching of numbers and operations, by using a historical perspective.

In the first case the teacher asked students to study the page, then they had to write few numbers by using the hieroglyphs and finally they were asked to transform other numbers into the decimal arithmetic system. After they presented a few numbers, their teacher asked them to discuss with the members of their group the similarities and differences of the two systems. The specific activity lasted for 10 minutes and then a whole class discussion was conducted. Teacher insisted by posing questions to guide them understand the limitations of the ancient Egyptians' numeric system. Many correct answers were given by the students and only one unexpected question was posed by a girl:

“Today in Egypt people use these symbols or something which remind them the attempts of their progenitors?” The teacher explained why the ancient systems were not survived by repeating arguments which were presented previously by the students, such as the complexity of the symbols. Nevertheless he admitted that he was not able to answer whether there is something in Egypt today which is related with the specific system. He continued by showing his clock and the roman symbols on it, he explained that there were residues of arithmetic systems and symbols which were used in the past. He then asked students voluntarily to look in their free time for more information about the arithmetic system of the ancient Egyptians in order to be able to answer their classmate’s question in three to four days. As he admitted during the interview there were some students who tried to find out more information about the numeric systems. They had not found anything about Egyptians; however they discover the Babylonians’ impact on the way of measuring the time and the Latin numbers on buildings such as the German Parliament.

In the second case, it was the use of the ancient Egyptians’ algorithm of multiplication. The teacher asked students to study individually the method which was presented and applied it at the multiplication  $35 \times 17$ . Few students were not able to continue after the  $32 \times 17$ . One of them continued by writing  $3 \times 17$  and then she added the two products. Teacher said that it was a wrong solution because “Egyptians did not know how to find  $3 \times 17$ ”. The follow up dialogue is interesting:

Student: How is it possible to know  $2 \times 17$ ,  $4 \times 17$ ,  $32 \times 17$  and they didn’t know  $3 \times 17$ ?

Teacher: They knew only to double the product.

Student: Why they did that?

Teacher: It was their algorithm.

Student: But the guideline at the book asked to use the distributive property to find the product. I had used it,  $32 \times 17$  and  $3 \times 17$ .

Teacher: It is right today, but not for the ancient Egyptians.

Student: They were not clever.

It is obvious that the student did not understand that the method of the Egyptians depended on the property according to which when a factor is duplicated the whole product is duplicated and she was not able to understand why this method was easier for them rather than the algorithm which is used today. However it is important that she understood the use of the distributive property in mathematics. Actually this was the objective of the specific course and probably the teacher did not know that the history of mathematics was proposed in the specific case in order to enable students investigate and understand the use of the distributive property in multiplication. When the teacher was asked about the teaching aim and the respective learning aim he said:

Teacher: The history is used in order to understand that mathematics was created by humans.

Researcher: Yes, but they could understand this at the previous lessons, with the arithmetic systems.

Teacher: Here they can understand that complicated processes were used as well.

Researcher: Which was the impact of those processes on the development of mathematics?

Teacher: I don't know. However it is important for humans to study their past.

Researcher: Do you know which were the ancient Egyptians' occupations and where did they use mathematics?

Teacher: No, I am not sure, probably for their transactions.

The teacher used only naive teaching arguments for studying the history of mathematics without understanding that students by investigating the way the arithmetic properties were used, they could understand the use of those properties in order to simplify the used processes. He seemed to not have adequate knowledge about the cultural, political and economic framework of using the specific processes in order to be able to judge their utility.

## Discussion

Teachers will continue to be expected to actively engage students in inquiry-based experiences. At the same time most of the Curriculum will continue to ask teachers to use the history of mathematics as a teaching tool in order to enable students to understand the continuity and the development of mathematics in respect to the cultural circumstances. The current study provided evidence that although probably a teacher may express positive beliefs about the importance of the history of mathematics for the introduction or the understanding of mathematical concepts, he or she may face serious difficulties in implementing an inquiry-based teaching approach. Teachers need experiences during their school life or even during their pre-service training in order to be convinced for the results of the inquiry-based learning and the positive results of exploring and investigating the mathematical concepts through a historical perspective.

The historical approach is supposed to encourage and enable students to regard mathematics as an intellectual process and an on-going activity of individuals (Grugnetti & Rogers, 2000). The prerequisite is to enable them to understand how mathematics thinking and applications developed in different cultures, in response to the needs and thinking of different societies. As it is obvious from the present qualitative study, there are fundamental problems in the implementation of this objective in relation to other main objectives such as the use of the inquiry-based teaching approach. In the case of the New Curriculum in the educational system of Cyprus the history of mathematics is proposed to be used as a tool in teaching the students topics or concepts within the curriculum (Jankvist & Kjeldsen, 2011).

The present study is just a part of a project which investigates the use of the inquiry-based approach. Much more research has to be developed in order to relate the teachers' knowledge and beliefs about the use of the history of mathematics with their beliefs and knowledge about the inquiry-based approach in different grades. Teachers' knowledge and beliefs are the official targets of educational reform (Uwe, Espinoza & Barbe, 2013). Emphasis has to be given on studying further teachers' difficulties in implementing the inquiry-based teaching approach in general and in the case of using the history of mathematics in particular, by examining the results of intervention programs in real classroom actions, with an emphasis on facing the teachers' difficulties.

[Bernardo.gomez@uv.es](mailto:Bernardo.gomez@uv.es)

*This paper reports on a study about word fraction problems. These kind of problems have been transmitted by the school tradition. Nowadays, they have disappeared because the education model has changed. A classification of the problems is given and the historical resolution methods are presented here because they may be useful in creating knowledge for teaching.*

*Keywords: Descriptive, historical, fraction problems, resolution methods.*

## Introduction

In textbooks, there are a variety of descriptive word problems. Swetz (2012) mints *descriptive* and it refers a story or pseudorealistic situation that is not meant to address any practical real situation (some of them are known as recreation or puzzle problems).

Until recently, these problems were used as an essential part of the teaching of mathematics. However, the educational model and the design of mathematics textbooks began to change. Then, many problems disappeared from the current books, because the confidence in the educational power of these problems had declined.

Nowadays, descriptive problems have emerged with renewed interest because the curriculum proposals consider problem solving as a core competency in the development of arithmetical and algebraic thinking. In this context, they become relevant because the historical record of the development of mathematical ideas and methods is useful to produced knowledge valuable for teaching. Particularly, to support an alternative pedagogical approach different to those that use problems as sub-product of other specific content learnings (as an exercise and practice).

When we have reviewed descriptive problems that appear in textbooks, we have found them under different headings which are related with Methods and Rules or with Context, Actions and Agents. For example,

- Methods and Rules: Rule of Three, Compound Proportion (or Double Rule of Three), Conjoined Proportion, Fellowship, Allocation, Interest, False Position (single and double), proportional distribution, etc.

---

<sup>1</sup> This paper has been done in the framework of the research projects of Ministerio de Ciencia e Innovación, references: GVPROMETEO2016-143 and EDU2015-69731-R (MINECO/FEDER)

- Contexts: Fountains or Pipes filling or Holes Emptying the Cistern, Inheritance, Clock Problems, God Greet You or Heap problems, Passing Through Tax passes, Water in wine, Division of Casks, etc.
- Agents: Ass and Mule, Hound and Hare, Hundred Fowls, Couriers or Mobiles, The Epitaph of Diophantus, Animals eating a Sheep, Men Buy a Horse, Men Find a Purse, Lazy Workers, Posthumous Twins, Dishonest Butler, Apple-sellers', Snail Climbing out of Well, Broken Bamboo, Monkey and Coconuts, A travelling Merchant, Lotus, etc.
- Actions: Overtaking and Meeting, Giving and Taking problems, Selling Different Amounts at the Same Prices (to yield the same amount), Co-operative work, etc.

This way of showing problems is the result of historical motivation and it does not allow an overall vision of the problems. For example, there is usually not a single resolution method for the same problem. Also, problems with different appearance may have the same characteristics or structure. This is the reason why the problems can be not organized according to the context, the actions or the agents, or even method of resolution.

Our goal in this research is to build the classification of descriptive fractions problems, with a criterion that contributes clarity and generality, for an overall view of them. At the same time, we want to recover the different resolution methods, as authors have been reflected in textbooks.

The remainder of the paper is organized as follows. First, sample problems are presented and their classification is explained. Also, the relation between quantities is shown with a generic statement. Second, different resolution methods are shown. Finally, the conclusion of the research and some suggestions for future research are proposed.

## The problems

The problems, which are studied in this research, seem similar because they are multi-step fraction problems.

*Dying man.* A dying man gave 6000 escudos to distribute in this way: the half will be given to the monastery of the Jacobites; the third part will be given to the convent of San Agustin; the fourth of the escudos to the monastery of the Friars Minor; and the fifth will be given to the order of the Carmelites". Question: if the whole is 6000 escudos, how many escudos will each monastery have? (Silíceo, 1996, p. 266)

*The Cloth.* A certain man buys 4 pieces of cloth for 80 bezants. He buys the first for a certain Price, and he buys another for  $\frac{2}{3}$  the price of the first. He truly buys the third for  $\frac{3}{4}$  the price of the second. Moreover, the fourth he buys for  $\frac{4}{5}$  the price of the third. It is sought how much each piece is worth. (Sigler, 2002, pp. 274-275)

*Lotuses.* From a bunch of lotuses,  $\frac{1}{3}$  are offered to Lord Siva  $\frac{1}{5}$  th to Lord Visnu,  $\frac{1}{6}$  th to the Sun,  $\frac{1}{4}$  th to the goddess. The remaining 6 were ofered to the guru. Find quickly the number of lotuses in the bunch (Bhāskarācārya, 2001, pp. 57-58, ex. 3)

*The Eggs.* A country woman carrying eggs to a garrison, where she had three guards to pass, sold at the first, half the number she had and half an egg more; at the second, the half of what remained and half an egg more; and the third, the half of the remainder and half an egg more when she arrived at the market place, she had three dozen still to sell. How was this possible without breaking any of the eggs? (Ozanam, 1884, pp. 207-208)

Nevertheless, they presented two main differences. First, the whole may be known or not. The whole is the amount that will be split up in parts. Second, the different parts of the whole are interrelated or not.

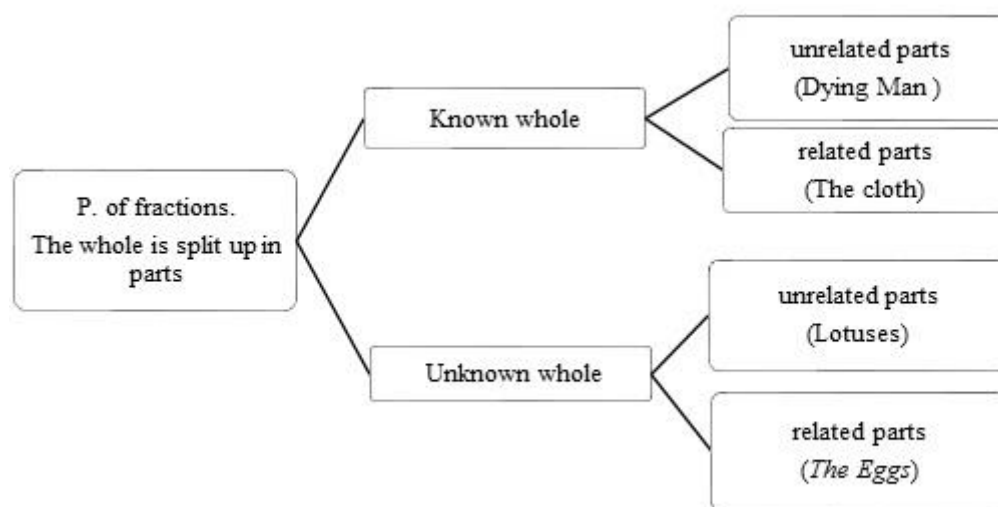

*The Dying Man* is a problem in which the known whole is split up in unrelated parts, i.e., we know the whole ( $T$ ) and for example we have two parts:  $p_1 = \alpha_1 T$  and  $p_2 = \alpha_2 T$ , where  $\alpha_1 + \alpha_2 \geq 1$  and  $\alpha_i \in \mathbb{Q}$  with  $i \in (1,2)$ . We want to know each part.

*The Cloth*, is a problem in which a known whole is split up in related parts, i.e., the known whole ( $T$ ) is divided in, for example, three parts,  $p_1 = a_1 + \alpha_1 p_1$  and  $p_2 = a_2 + \alpha_2 p_2$ , where  $a_i$  and  $\alpha_i \in \mathbb{Q}$  with  $i \in (1,2)$ . We want to know each part.

*Lotuses* are problems in which the unknown whole is split up in unrelated parts, i.e., we do not know the whole ( $T$ ) and it is divided in three parts:  $p_1 = \alpha_1 T$ ,  $p_2 = \alpha_2 T$  and  $p_3 = A$  where  $\alpha_i \in \mathbb{Q}$  with  $i \in (1,2)$  and  $A$  is a known quantity. We want to know the total amount.

*The Eggs*, are problems in which the unknown whole is split up in related parts, i.e., we do not know the whole ( $T$ ) and we want divided it in, for example, three parts:  $p_1 = a_1 + \alpha_1 T$ , and  $p_2$  is  $a_2$  and  $\alpha_2$  of the remaining, the third part is known  $A$ , where  $a_i, \alpha_i, A \in \mathbb{Q}$  with  $i \in (1,2)$ . We want to know the total amount.

These differences permitted us to classify the problems and show a global vision about descriptive word fraction problems (Figure 1).

**Figure 1: The classification of the problems**

Note that it is possible to which the draft of the classification according to the relations between the parts: additive (one part is the sum of another or others), multiplicative (one part is a multiple or a fraction of another or others), combinations of both, ...but the research focuses on a classification without subcategories because of the allowed extension.

## Resolution methods

Different Textbooks, from different periods or historical moments, has been reviewed to select problems. The resolution methods observed are the following.

### Method of inversion

The method of inversion method is explained by Colebrooke (1817, p. 21) in these words, “To investigate a quantity, one being given, make the divisor a multiplicator; and the multiplier, a divisor; the square, a root; and the root, a square; turn the negative into positive; and the positive into negative.”

In this method, the problems are solved by the inverse operations, i.e., if the problem name the product, the division is used to solve, or in the case of addition, the subtraction is used. Note that, the resolution process begins with the last operation, and continues up to the first operation indicated in the problem definition.

The next problem of “unknown whole and related parts” shows the method:

*The Eggs solution.* It would appear, on the first view, that this problem is impossible, for how can half an egg be sold without breaking any? The possibility of it however will be evident when it is considered, that by taking the greater half of an odd number, we take the exact the half  $+\frac{1}{2}$ . It will be found therefore that the woman, before she passed the last guard, had 73 eggs remaining, for by selling 37 of them at that guard, which is the half  $+\frac{1}{2}$ , she would have 36 remaining. In like manner, before she came to the second guard she had 147; and before she came to the first, 195 (Ozanam, 1884, pp. 207-208).

### False position

False position is related with the algorithmic process where an assumed value is chosen. The operations are done with this number so the result is not correct because the value is not the real value. Then, a rule of three or a proportion is done to obtain the correct result<sup>2</sup>.

We can see this method in a lot of fraction descriptive problems, for example in this known whole and related parts problem,

---

<sup>2</sup> The conditions of the statement can be modeled with a first-degree equation with one unknown:  $b = ax$ . The rule commands that the equation be solved by giving an assumed value to the unknown  $x = x_1$ , which gives rise to the error  $b_1$ ,  $b_1 = ax_1$ . From these two equalities:  $b = ax$  and  $b_1 = ax_1$ , we obtain the ratio  $= \frac{b_1}{x_1}$ , from which the value of  $x$  is followed.

*The Cloth solution.* Put the first piece worth 60 bezants (False position), because 60 is the least common multiple of 5 and 4 and 3. Therefore, if the first is worth 60 bezants, then the second is worth  $\frac{2}{3}$  of it, 40 bezants and the third worth 30 bezants, that is  $\frac{3}{4}$  of the price of the second. The fourth worth 24 bezants, that is  $\frac{4}{5}$  of 30. Then you add 60, 40, 30 and 24, i.e., sales prices of the four pieces; They are 154 and should be 80; says, got 60 for the price of the first piece and 154 bezants result that the sum of the four pieces; How much will I put to the sum of the parts it is 80 bezants? Multiply 60 by 80; and there will be 4,800 which is divided with the rule by 154, i.e.,  $1/2 \ 0/7 \ 0/11$ ; the ratio is  $6/7 \ 1/1131$  bezants. And this is the value of the first piece. Also in order to obtain the price of the second, multiply 40 by 80, then divide again by  $1/2 \ 0/7 \ 0/11$ ; the ratio is  $20 \ 4/7 \ 8/11$  the price of the second piece. Also, to know the price of the third, it multiplies 30 by 80, and divide by  $1/2 \ 0/7 \ 0/11$ ; the ratio is  $3/7 \ 6/11 \ 15$  bezants; in the end, the price of the fourth, multiply 24 by 80, and divide by  $1/2 \ 0/7 \ 0/11$ ; the ratio is  $1/7 \ 5/11 \ 12$  bezants, and you realize that in each of the four products is canceled  $1/2$ . (Sigler, 2002, pp. 274-275)

Or in these other two problems of “unknown whole and unrelated parts”:

*The Tree solution.* Because the least common denominator of  $\frac{1}{4}$  and  $\frac{1}{3}$  is 12, you see that the tree is divisible into 12 equal parts; three plus four parts are 7 parts, and 21 palms; therefore as the 7 is to the 21, so proportionally the 12 is to the length of the tree. And because the four numbers are proportional, the product of the first times the fourth is equal to the second by the third; therefore if you multiply the second 21 by times the third 12, and you divide by the first number, namely by the 7, then the quotient will be 36 for the fourth unknown number, namely for the length of the tree; or because the 21 is triple the 7, you take triple the 12, and you will have similarly 36 (Sigler, 2002, p. 269).

*Lotus solution.* Suppose the total number of lotuses is 1. Then the number of lotuses left is

$$1 - \left( \frac{1}{3} + \frac{1}{5} + \frac{1}{6} + \frac{1}{4} \right) = 1 - \frac{20+12+10+15}{60} = 1 - \frac{57}{60} = 1 - \frac{19}{20} = \frac{1}{20}. \text{ So [if } \frac{1}{20} \text{ th is 6]} \text{ the total number of lotuses is } \frac{6 \times 1}{\frac{1}{20}} = 120 \text{ (Bhāskarācārya, 2001, pp. 57-58, ex. 3).}$$

In both examples, the value of one part is known and the other parts are fractions of the whole unknown. If  $T$  is the unknown whole and  $A$  is the known part, in these problems  $T = p_1 + p_2 + p_3$ , where,  $p_1 = \alpha_1 T$ ;  $p_2 = \alpha_2 T$ , where  $\alpha_i \in \mathbb{Q}$  with  $i \in (1,2)$ . Consequently, we add the fractions  $\alpha_1 + \alpha_2$ , and an equation is drawn between the difference of this sum with  $T$  and the known value. To solve this equation is arithmetically run as in the false position. For this, one can proceed by avoiding the fractions, by taking an assumed value for  $T$  that is a multiple of the denominators of the fractions (*The Tree*); Or, taking as value the whole unit (*Lotuses*), and then with a rule of three.

### Direct method

In this resolution method, the arithmetic operations with fractions are performed as the statement says. We present a “known whole and unrelated parts” problems to show this method:

*Dying Man Solution.* For Jacobite the half of 6000 escudos; for St. Augustine a third of the 6000 escudos, i.e., 2000; for Friars Minor the fourth part 6000 escudos that is 1500; and for Carmelites the fifth of the 6000 escudos, i.e., 1200. All of these parts add up 7700, but it is not possible

because the man only has 6000 escudos. The divisor is considered 7700, and the multiplier is the money that would must be distributed, i.e., 6000. Then, each part is multiplied by this ratio. Therefore, if the part of the Jacobites is multiplied by the multiplier and is divided by the divisor, they get 2337 escudo 23 duodenos and 2 turonos and  $1400/7700$  parts of turon. Then, this is the amount that corresponds to the Monastery of the Jacobites. In other cases, we proceed similar and get the amount corresponding to each of them. Note that 1escudo = 35duodenos; 1duodeno = 12turonos. (Silíceo, 1996, p. 266)

In *Dying Man*, once the arithmetic operations with fractions are performed directly as the statement says, is needed an unequal distribution.  $T$  is distributed according to the rates  $\alpha_1 : \alpha_2 : \alpha_3$ . Then the required distribution of  $T$  is:  $p_1 = \frac{T}{\alpha_1 + \alpha_2 + \alpha_3} \alpha_1$ ;  $p_2 = \frac{T}{\alpha_1 + \alpha_2 + \alpha_3} \alpha_2$ ;  $p_3 = \frac{T}{\alpha_1 + \alpha_2 + \alpha_3} \alpha_3$ .

The direct method appears in the “known whole and related parts” problems too. In this kind of problems, the parts of the whole are considered in different ways. The next examples illustrate it,

*A walker.* A certain man walking in the street saw other men coming towards him, and he said to them: “O that there were so many [more] of you as you are [now]; and then half of half of this [were added]; and then half of this number [were added], and again, a half of [this] half. Then, along with me, you would number 100 [men].” How many men were first seen by the man? (Hadley & Singmaster, 1992)

*Solution.* We can suppose that the half of half is a part; then the half would be two parts; The group of men would be four parts and the others are four parts. Therefore, if you divide 99 into eleven parts, the result will be half of the half, then the solution is 36 men in the group. Testing:  $36+36+18+9+10=100$ . (Sánchez Pérez, 1949, p. 58)

*Day laborers.* Three laborers charged for one hour 610 pesetas. The oldest earned  $1/8$  more than the median and this  $1/5$  more than the youngest. How many pesetas are each?

*Solution.* Supposing that the youngest earned 1, the median would earn  $1 + \frac{1}{5} = 1.5$ , and the oldest would earn  $1.2 + \frac{1.2}{8} = 1.2 + 0.15 = 1.35$ . If we divide 610 in proportional parts 1:1.2:1.35, the youngest earn  $\frac{640}{3.55} = 171.83$  pesetas... (Solís y Miguel, 1893, p. 52)

*The hours.* You know the hours, could you say me how many hour have passed since this morning? There remain twice the two thirds of the hours that have already passed. (Jacobs, 1863, p. 42)

*Solution.* You must divide the length of the day in 12 parts, the question is divided this number in two parts, such that the  $\frac{4}{3}$  of the first are equal to the second, it is  $\frac{51}{7}$ , consequently, for the rest of the day, 6 hours and  $\frac{6}{7}$ . (Ozanam, 1844, p. 192)

*The work.* In one work, 25 men, 12 women and 30 children are employed. A woman's salary is  $\frac{2}{3}$  of a man's salary, and a child earns  $\frac{3}{4}$  of a woman salary's. The work has cost 403.20 pesetas. What is the salary of each?

*Solution.* The 12 women earn as much as  $12 \cdot \frac{2}{3} = 8$  men. A child earns  $\frac{3}{4}$  of a woman's salary, i.e. or  $\frac{2}{3} \cdot \frac{3}{4} = \frac{1}{2}$  of a man's salary. The 30 children earn  $30 \cdot \frac{1}{2} = 15$  men. The 403.20 pesetas are

the salary of  $25 + 8 + 15 = 48$  men. Each man earns  $\frac{403.20}{48} = 8.40$  pesetas. Each woman:  $8.40 \cdot \frac{2}{3} = 5.60$  pesetas. Each child:  $\frac{8.40}{2} = 4.20$  pesetas. (Aritmética razonada, 1940, pp. 151 & 660)

### Algebraic method

This method is where the problem is reduced a list of quantities and the relation between them gives rise to an equation (Puig, 2003). The equation is obtained as a result of matching two algebraic expressions that represent the same amount.

The next example of “known whole and related parts” illustrated this resolution method (Aurel used the cossic sign, not  $x$ )

*Three men want to share 100 ducats.* Three men want to share 100 ducats. The first person has  $\frac{2}{5}$  of the second person; and if the ducats of third person are divided by the ducats of the first person, the number is  $4\frac{5}{6}$ . So, how many ducats are there?

*Solution.* Three men want to share 100 ducats. The first person has  $\frac{2}{5}$  of the second person; and if the ducats of third person are divided by the ducats of the first person, the number is  $4\frac{5}{6}$ . So, how many ducats are there? Solution. I suppose the second person have  $1x$  ducats so the first person have  $\frac{2}{5}x$ ; and the third will have the remainder,  $100 - 1\frac{2}{5}x$ . The ducats of the third person are divided by the ducats of the first person and the result is  $\frac{100 - 1\frac{2}{5}x}{\frac{2}{5}x}$ , it is  $4\frac{5}{6}$ . Reduce the equation,  $100 - 1\frac{2}{5}x = \frac{29}{15}x$ . Calculating,  $1x$  is equal to 30, then the first and third person have 12 and 58 ducats, respectively (Aurel, 1552, fol. 102v, ex 88; Aurel used the cossic sign, not  $x$ ).

### Conclusion

With this research, we try to use the historic descriptive problems to produce useful information to the mathematics education.

Firstly, the descriptive word fraction problems, which are in the ancient textbooks, have been studied. Secondly, a classification of them is built and is focused in the whole and the parts. With this, four different types of problems have been obtained and a generic statement of each problem is proposed. Thirdly, some resolution methods have been explained and analyzed: method of inversion, false position, direct method and algebraic method. Note that this is a classification that supports subcategories, and they are been studying in this moment.

This research allows us to offer students a range of methods to choose the most appropriate method in each problem to solve it correctly.

In a future, we will design a questionnaire to carry out a cognitive analysis to obtain the students achievement in this kind of problems. That is, an empirical analysis that will try to find out the difficulties faced by students in each of the determined types. The difficulties will be related with the essential elements studied in this research.

# Mathematics at the Royal Danish Military Academy of 1830

Asger Senbergs

Roskilde Katedralskole, Roskilde, Denmark; [asger@senbergs.dk](mailto:asger@senbergs.dk)

*This paper takes its starting point in the question concerning why mathematics was chosen as the most important subject in the education of Denmark's new officers when the Royal Military Academy was founded in 1830. To answer this question, source material from the period is researched. From the source material, three educational aims in the mathematical education can be derived: mathematics as a goal in itself; mathematics as a tool; and the mathematical method. These educational goals can be seen as a desire to educate officers in three skills: theoretical knowledge; vocational knowledge; and general education. Together these two sequences of each of the three elements are connected in pairs, thereby creating a link between the officers to be educated and mathematics as a taught subject. It is concluded that mathematics was chosen as the most important subject, because it supported the needs an officer educated at the Academy was required to possess.*

Keywords: Military schools; officer's mathematics education; societal elite.

## The Royal Danish Military Academy

In 1830 a new military education was created in Denmark – an education that was very different compared to similar educations that existed in Denmark at the time and even very different compared to the modern officer's education in Denmark. This new education was called The Royal Military Academy, and it played a central role in the history of Denmark due to the establishment being an expression of the emerging nationalism that was forming in the country. It also marked the start of a professionalization of the military, which consequently formed a new social class: the educated officers. With this institutionalization of military training there was a desire to organize the knowledge believed necessary to become an officer. This created a need for both skilled teachers and teaching material of a certain quality that could support this new institution.

In particular a need for educated mathematicians arose, since mathematics was chosen as the main subject for the entire education regardless of which field of study, the students were subjected to. At the Royal Military Academy officers could study the following fields: general staff officer; engineer officer; artillery and rocket officer; and road officers. For all four fields of study, mathematics was the subject that had the highest number of modules throughout the 4-year education. The education was split into two classes – referred to as the youngest class and the oldest class – both having a duration of two years. Students in the youngest class followed courses classified as being “purely scientific”, which included mathematics, chemistry, physics and languages. In the oldest class the students had courses classified as the “applied” subjects, which included war history, mine teachings, and field maneuvers.

The split mentioned above seems consistent with the general view of mathematics as a teaching subject at the time, i.e. in Denmark as well other countries in Europe mathematics was viewed as an entity made up by two parts: a pure and an applied (Kragh et al., 2005, pp. 297–298). Pure mathematics was perceived as the theoretical part, which was considered beneficial to the ability to think logically and connect structures in a certain way – important aspects of what was described as

the “general education”. The applied part of mathematics was perceived as a tool for solving various problems, often in a very practical context.

Out of all the subjects taught at the academy, mathematics made up half (49%) of the total number of lessons taught during the youngest class. In total during the four years, mathematics made up one fourth (25%) of the lessons taught making it by far the largest single subject taught during the entire education. Not only was mathematics the largest single subject, it was also taught at a very high level in particular in comparison to mathematical knowledge of the average population of Denmark at the time. The students at The Royal Danish Military Academy were taught descriptive geometry, mathematical analytics and rational mechanics, which consisted of both complicated proofs and assignments varying from very abstract situations to practical use. Even compared to the current officers’ education in Denmark at The Royal Danish Defense College, this prioritization of mathematics is notable. An article brought in a Danish military magazine present the fact that 40% of all permanent military employees have difficulties even with 9<sup>th</sup> grade level mathematics suggesting that the mathematical knowledge of today’s military education has been somehow downsized (Frovin, 2014, p. 16).

In a central source material book from 1855, which is concerns the creation and subsequent operation of the Royal Danish Military Academy, the following is stated:

The Danish academy is modelled on the French educational institutions. [...] the organization, the teaching methods (first theory taught by a teacher and then repetition), the exams, which are supervised by other officials than the teachers – these main points with minor details are directly copied from the French educational institutions, only with smaller modifications which are caused by the economic situation and the smaller scale of the Danish educational system. (Caroc, Bjerring, Reich, & Købke, 1855, p. 31, my translation)

This strong inspiration was most likely due to the fact that several of the officers in the planning commission of the Royal Military Academy in Denmark had themselves studied at the Ecole Polytechnique. A key difference between the Ecole Polytechnique, created in 1794, and the Royal Military Academy was however that the Royal Military Academy did not train civil engineers, which was the case at the Ecole Polytechnique.

The prioritization of mathematics in a military context, as in the case of the establishment of the Royal Danish Military Academy is not only a Danish phenomenon, it is closely linked to similar trends which started years before in central Europe with France as a starting point (Bradley, 1976, p. 165). The French Revolution and the European wars throughout the 1700s led to developments in both weapon technology and construction work. This again increased the need for better educated mathematicians and hence teaching in more advanced mathematics.

Still, the question remains, how mathematics was considered to help cadets become better soldiers? According to Karp and Schubring (2014) not much research has been carried out on mathematical education in a military context. In fact, they describe how this field is only just beginning to take shape alongside the methodology. Nevertheless this relatively new research field can contribute to our historical knowledge about the development of a society, because mathematical education have often been prioritized in historical periods, where society was in need of engineers, technical and scientific personal (Karp & Schubring, 2014, pp. 9-10). Hence, an understanding of how the mathematical education was constructed at military academies can provide us with an indication of

what kind of work tasks the military personal was meant to fulfil, thereby also explaining the general perception of mathematics at the given time. This sums up the focus of this paper, which may be condensed into the following research question: *Why was mathematics chosen as the most important subject, when the Royal Danish Military Academy was founded in 1830 as the new national officer's education program?*

## Methodical approach

The answer to the above question shall be based on a carefully selected sample of source material from that period alongside a variety of secondary literature, which will form the historical background for the source material. The historical source material falls in two categories: books concerning administrative aspects; and teaching materials.

In the first category, two very central works from the period are used. The first book is *Plan to the Royal Military Academy* (my translation) and was written by a committee in 1830. The committee consisted of eight officers from the Danish army. Lieutenant general Franz Christopher Bülow oversaw this committee, and he was also the official author of the work. This book formed the official establishment of the Royal Military Academy and described all relevant matters for the creation and operation of the academy. The content covered everything from the overall structure and economic frame to detailed descriptions of the teaching subjects and lesson tables for all fields of study spanning over all four years. This book makes up the main source, since it contains several descriptions about why mathematics is important and what role mathematics was to play in various connections. The second central book is *Overview over the education in the special corps before 1930 and the Royal Military Academy's operation from its creation to 1855* (my translation), written by three officers and a professor from the University of Copenhagen: F. C. V. Caroc, V. J. Bjerring, C. E. Reich and J. P. Købke. This book was released on the occasion of the Academies 25-year anniversary. The book makes up an important piece of source material, because it is one of the only available books from the period that describes the development of military education and does so in a critical manner.

In the second category, the teaching materials, there are seven books in total. All seven are teaching materials in mathematics: three of these are textbooks in mathematical analysis; two are textbooks in descriptive geometry; and the last two are figure books in descriptive geometry the purpose of which were to serve as support for the textbooks. One textbook by Bendz (1831) was in particular used to support the conclusions about the role of mathematics at the Royal Military Academy. The book is in mathematical analysis describing differential and integral calculations, and an analysis shows that it contains practically no tasks related to extra-mathematical circumstances, which supports the interpretation of the text by Bülow (1830).

To set the historical frame for the Royal Military Academy, several books have been used, of which *Danish history of Natural science, Volume II* edited by Helge Kragh, and *Private Schools through 200 years, volume I* edited by Christian Larsen, are some of the more important books. These works provide an overall understanding of the educational level of young men from the higher levels of society in Denmark, who would be the students at the Royal Military Academy.

In order to set the European historical frame, both regarding military education in general and mathematics as a teaching subject and as a research profession in particular, several articles and books have been used. Here it is important to mention: Boyer (1968); Barnett (2015); and Bradley (1975). These works provide the study presented in this paper with background knowledge on how the

development of the Royal Military Academy might have been influenced by similar institutions in other European countries, in particular France.

## **Mathematics as the cornerstone**

In the main source (Bülow, 1830) there are several descriptions and explanations about the various teaching subjects which were taught at the Royal Military Academy. The description of mathematics is rather interesting in this context. The following quote from the introduction became the starting point for the research described in this paper:

Mathematics, especially its analytical part, including rational mechanics, is considered the cornerstone in education as a whole. Thus it should give the students the means to understand a series of other important subjects. (Bülow, 1830, p. 38, my translation)

Through careful readings of this material several other interesting quotes were found and eventually they came to form the analysis. Through this archival based analysis I found evidence to suggest that the commission, who planned and designed the Royal Military Academy, were subject to three central educational aims, all having mathematics as the cornerstone: mathematics as a goal in itself; mathematics as a tool; and mathematics as a method. These aims were never explicitly uttered in the source material and could therefore make up a separate question for discussion. In the present analysis, however, they came to structure the reading of the source material. In the following I present carefully chosen excerpts from the source material in order to support the finding of the three underlying educational aims of the commission.

## **Mathematics as a goal in itself**

There are several quotes that put emphasis on the importance of “mathematics as a goal in itself” without mentioning a specific purpose of the mathematical knowledge, which might lead one to think that there was another purpose besides the more direct usage of mathematics. A central quote on this is from the descriptions of the teaching subject of physics, where the proper way of learning is explained:

The dual way to realization; the experimental and the mathematical, which here make up the right teaching method, which also has an exceedingly significant influence on the entire development of the mind; because the mind gets used to neither neglecting the simplicity of the real world nor making us lose ourselves in these details, thereby forgetting the general principles. (Bülow, 1830, pp. 39–40, my translation)

Here mathematics is mentioned as one of the two ways to true realization, whereas an experimental or practical way is mentioned as the other. In fact we touch upon a very central aspect. As mentioned earlier, several publications state that mathematics in this historical period is seen as a unity consisting of two parts, namely pure and applied mathematics. The distinction between these two is noticeable in the way the mathematical subjects were structured during the education at the academy. For example, descriptive geometry was divided into a theoretical and an applied part, with a vast difference between what kind of theory and assignments the students were to do. The following quote is a description of what kinds of assignments the students should be able to accomplish during a lecture in the theoretical part of descriptive geometry.

For a given curve, draw a tangent, which has a horizontal projection that is parallel to a given line.  
(Bülow, 1830, p. 76, my translation)

This assignment is purely mathematical without any trace of an extra-mathematical scenario, which was very important since the purely mathematical way was thought to be one of two parts in the learning process. This central point can be further validated by looking at the teaching material used in descriptive geometry, which are two textbooks both authored by L. S. Kellner. The first book (Kellner, 1830a) – which consisted of only one booklet – described a theoretical approach to geometry, whereas the second book – consisting of six booklets – described different ways to use the given theory in a wider range of subjects, spanning how to construct different buildings to how shadows fall on objects (Kellner, 1830b). From reading the source material it seems clear that students were believed to be able to understand the basic sciences to the fullest before they could apply them in other connections. Since mathematics was a subject that had its usage in other scientific disciplines and a large part of the applied disciplines, mathematics appears to be a subject that students should learn and master before applying it in extra-mathematical connections.

However, the mathematical curriculum exceeds the need in other subjects, which indicates that the students were meant to learn beyond the point of what they were actually going to use in these subjects. This suggests that mathematical knowledge was an educational goal in itself, because it was thought to be beneficial in various ways.

## Mathematics as a tool

The second identified educational aim was that it was essential that the students learned how to apply mathematical equations and a logical approach to problems, because it was a required tool in both the purely scientific and applied subjects taught in the youngest and oldest class at the academy. Especially in the applied subjects mathematical knowledge was necessary, since these applied subjects were the ones to make a student capable of fulfilling his later duties in a specific position within the military.

For that reason it was important that the students knew how to use mathematics as a tool, which according to the source material forms the experimental way to realization. This practical use of mathematics can be seen in a description of an assignment from descriptive geometries in the applied part, which the following quote illustrates.

Explain the various timber connections in roof- and stair constructions. (Bülow, 1830, p. 79, my translation)

This example forms a clear contrast to the other assignments from descriptive geometry in the theoretical part, where there is no connection to the real world. In this short assignment, the student should be able to construct very specific structures according to a set of requirements.

This vast span from theoretical knowledge to the ability to use it practically is closely linked to the term “general education”, which is commonly referred to by Bülow (1830). Hence, this term is vital for this analysis, and needs to be explained in this paper as well. The term “general education” (in Danish “*almendannelse*” similar to the German “*Allgemeinbildung*” or “*Bildung*”) was a common term in the Danish society in the beginning of the 1800s, and the exact meaning of the term was greatly influenced by the first Danish professor in pedagogy, L. C. Sander. The “general education” term was also seen as a unity with two parts: the general part and the professional part. The

professional part was a person's ability to carry out a certain profession or job, which required some specific skills and knowledge. The general part was a person's ability to engage in and contribute to different levels of the society, which required overall knowledge about culture, history, behavior, science, manners and language (Slagstad, Korsgaard, & Løvlie, 2003, pp. 9, 245). Both of these rather different parts should be in place before the general education was complete. And this was one of the central goals at the Royal Military Academy. Hence, in order for the students to gain this general education, they should be educated to be good soldiers and loyal officers with insight in every relevant subject in their field.

## **The mathematical method**

This brings us to the last identified educational aim, namely the mathematical method. The mathematical method is mentioned several times in *The Plan to the Royal Military Academy* and was described as something that benefitted the general ability to think and to conclude logically, not only in a mathematical context but also in other circumstances. Actually, it was believed that once a student had acquired the mathematical method, this student would be able to transfer this knowledge and approach to other fields of study and everyday scenarios (which we of course know from mathematics education research often is not the case).

This idea becomes clear through the following quote, which is taken from a paragraph that describes the Danish language as a subject, taught at the Royal Military Academy.

The incessant desire for clarity and definitiveness of expression leads to clarity and definitiveness in concepts of the person, whose thinking has become sharpened by the mathematical study of the natural sciences. Thought and language are in close contact with each other; they constantly excite and control one another. (Bülow, 1830, p. 41, my translation)

Not only is the mathematical study seen as something that sharpens the minds of the students, which makes them more precise in their choice of words, it is actually seen as something that makes the students more likely to draw the right conclusion based on logical assumptions. This is further supported by the following quote.

The verdict is always most correct, when it can be constructed with numbers, or, and even more perfect, with specific algebraic symbols that simultaneously provide idea and form, the common and the special, the abstract and the concrete. (Bülow, 1830, p. 38, my translation)

The above suggests that the mathematical method played several important roles in the education at the Royal Military Academy. Not only was mathematics a central subject in order to acquire the other subjects taught at the academy, it was also believed to develop the mind and the communication of those who mastered the mathematical method to its fullest extent.

## **The officer: Gentleman and soldier**

In the following, I compare the above described three educational aims, which were condensed from the source material, and connect them with the three levels of knowledge that might make up some of the main reason why mathematics was chosen in the first place. These three levels of knowledge could be described as: theoretical knowledge; practical knowledge; and general education.

*Theoretical knowledge:* It is the idea that an officer must be trained in the basic sciences that are used in various parts of his work as a soldier. Courses in this type of knowledge are taught at the youngest

class, which is certainly not a coincidence, but part of a basic philosophy that these basic sciences must be mastered in full, before the student will be able to apply the knowledge in other contexts. This explains why several of the mathematical topics were not connected to any applications. The point was to learn the theoretical basis without any applied context.

*Practical knowledge:* This type of knowledge is gained through the courses taught at the oldest class, because these subjects are related to the different fields of study, i.e. the “applied” subjects. For example, it was in the oldest class that artillery and rocket students had training in artillery, mine teaching and statistics, as well as practical exercises in artillery shooting and marching. This tendency is present in all fields of study. Many of the courses for students in the youngest class served as basis knowledge for the applied subjects in the oldest class.

*General education:* Here the underlying idea is that an officer in addition to knowing his profession to his fingertips also should be a well-educated gentleman. That meant that an officer trained at the Royal Military Academy should be a person with a broad insight into the culture, history and language of Denmark as well as other European countries. The students should also have a wide knowledge of the natural sciences and their mutual connections, but also with sensible ethics, a good appearance, attitude and solid behavior.

It may seem odd that an officer was taught about Danish literature, since this does not immediately suggest itself as a useful subject for an officer. But at the time an officer was also a person who should be able to be part of Denmark's highest layer of society. In fact, officer was one of the best educated professions in all of Denmark at the time. Therefore, it was indeed expected that the officers were well-educated in many subjects and trained in the spirit of the time.

## Conclusion

My starting point was a question about why mathematics was chosen as the cornerstone subject, when the new officer training institution in Denmark, the Royal Military Academy, was founded.

In this paper the reasons for choosing mathematics as the main subject are examined through source materials and mathematical teaching materials from the academy and the given period. The analysis of these contemporary sources was structured around three educational aims, which were supported by a close reading of the source material linked to other similar institutions of the time, e.g. the Ecole Polytechnique. These educational aims could be thought to show three distinct levels of knowledge, which were desirable for a recent graduate student to possess from the Royal Military Academy, i.e. theoretical knowledge, practical knowledge, and general education.

Besides these two sequences being findings in their own right of the present study, yet a finding is that they belong together in pairs. That is to say, the aim of mathematics as a goal in itself was to support students' development of theoretical knowledge; the aim of mathematics as a tool that of practical knowledge; and the aim of acquiring the mathematical method served a purpose of general education. Hence, it seems fair to say that mathematics was chosen as the cornerstone for the education at the Royal Danish Military Academy, because it supported the objective – namely to educate good officers.

# Design research with history in mathematics education

Bjørn Smestad

Oslo and Akershus University College of Applied Sciences, Norway; [bjorn.smestad@hioa.no](mailto:bjorn.smestad@hioa.no)

*This paper describes a research project analysing design research projects with history of mathematics. As a background, the theory of design research is invoked. For the purpose of this paper, preliminary analyses of three publications have been made. In later phases, interviews will supplement text analyses to enable a discussion on both explicit and implicit considerations involved when designing materials with history of mathematics in mathematics education.*

**Keywords:** Design research, history of mathematics, mathematics education.

## Introduction

The study of how history of mathematics (HM) can contribute to mathematics education has been ongoing for a long time. From time to time, major efforts have been made to design materials for teaching mathematics with history of mathematics. Parallel to this, design research has emerged as an area of study in its own right. The purpose of this research project is to use the insights that recent literature of design research provides to study how design have been done with HM.

## Design research

In a recent ICMI Study on task design in mathematics education, Kieran, Doorman and Ohtani (2015) outlines the history of “design-related work” in mathematics education. Design efforts have had many forms and names, but I will take as my starting point Malcolm Swan’s encyclopaedia article on design research (Swan, 2014). He defines design research in this way:

[Design research] is a formative approach to research, in which a product or process (or “tool”) is envisaged, designed, developed, and refined through cycles of enactment, observation, analysis, and redesign, with systematic feedback from end users. In education, such tools might, for example, include innovative teaching methods, materials, professional development programs, and/or assessment tasks. Educational theory is used to inform the design and refinement of the tools and is itself refined during the research process. Its goals are to create innovative tools for others to use, describe and explain how these tools function, account for the range of implementations that occur, and develop principles and theories that may guide future designs. Ultimately, the goal is *transformative*; we seek to create new teaching and learning possibilities and study their impact on teachers, children, and other end users. (Swan, 2014, p. 148)

I choose to lean on Swan’s definition and use the phrase “design research” here. Others use “task design” for similar efforts – task design is not to be understood as merely designing tasks:

[...] designing a task or task sequence in isolation from consideration of the design of the instructional culture in which the task is to be integrated may be of quite limited value – somewhat analogous to expecting a bird to fly with just one wing. (Kieran et al., 2015, p. 61)

Based on a selection from the literature on design research (including task design), I will focus on four dimensions: the goal; theories, values and design principles; testing; and end result.

First, what is the goal of the project? As seen in the quote above, the goal is to improve something (a product, process or tool) – for instance it could be to create materials (based on history of mathematics) that will improve how geometry is taught.

Design can be seen as an art or as a science (Kieran et al., 2015, p. 62) or as both. Seen as an art, creativity is an important factor, seen as a science, design will be based on previous theories. In addition, values will always play a role: “the frames and principles used in task design are intimately related to aims of mathematics education” (Kieran et al., 2015, p. 65). The role of theories is debatable, for instance Burkhardt (2013) stresses that “strong theories” are often overestimated in education, and argues for “phenomenological theories for specific areas” (p. 233). Kieran et al. (2015) distinguish between three levels of theoretical frames: Grand Theoretical Frames (such as the constructivist), Intermediate-Level Frames (such as the Theory of Didactical Situations) and Domain-Specific Frames (such as theoretical frames concerning specific parts of mathematics). Based on such theories, as well as on values, design principles are often developed for the research project. Thus, the second dimension is which theories, values and design principles are involved.

Kieran et al. (2015) also makes a further distinction: “*Design as implementation* focuses attention on the process by which a designed sequence is integrated into the classroom environment and subsequently is progressively refined, whereas *design as intention* addresses specifically the initial formulation of the design” (p. 28). In design as implementation, the testing in “cycles of enactment, observation and redesign” (Swan, 2014, p. 148) has a key role. Moreover, Burkhardt (2013) states that there is a “crucial difference” between exploration of teaching possibilities by a researcher and testing “what can be achieved in practice by typical teachers with available levels of support” (p. 207). He claims that impact on practice at least requires involving “typical teachers” in testing. The third dimension is therefore what the role of testing is in the project, who is doing it, in what way and in how many cycles.

The fourth dimension concerns the results of the project. The result may be the designed product that can be used by others. Often, local theories about the designed material are also developed:

Potential users of a curriculum should know what conditions are necessary for its successful implementation, so they can make sure the conditions are in place [...]. It is the development team’s job to discover and provide this information in the later stages of development and from use in the field. (Burkhardt & Schoenfeld, 2003, pp. 6–7)

In addition, researchers also want to contribute to more general theories of mathematics education: “Design experiments [...] are about improving both theory and practice” (Schoenfeld, 2014, p. 404)

For several reasons, design research studies do not always conform to the definition. For financial reasons, testing cycles are often reduced to a minimum. There are also political factors; theories seem to be valued more than practical solutions. When publishing or applying for grants, theoretical results may be stressed more than design results. However, this may be changing, as signalled by the introduction of the ICMI Emma Castelnuovo Award – an award “for excellence in the practice of mathematics education”. Burkhardt (2013) contrasts the situation in education with medicine, where the development of new medicines and treatments are valued as much as new theories.

Kieran et al (2015) concluded with a note that “knowledge about design grows in the community as design principles are explicitly described, discussed, and refined” (p. 73–74). This is exactly my motivation for looking at how design is conducted when history of mathematics is concerned.

### **History of mathematics in mathematics education**

Jankvist (2009) shows that the literature on history of mathematics in mathematics education was for a long time dominated by “publications advocating [...] for history in mathematics education” and “publications describing either concrete uses by teachers or developments of teaching materials” (p. 13). Some publications in the latter category can be seen as small design research studies, but were mostly based solely on reflections by the teacher-researcher. By adding systematic testing and data collection, the projects can become empirical studies on the “effectiveness” of history of mathematics. Recently, there have been a number of these, and they are often focusing on generating theory rather than the development/design of material (although design nonetheless plays an important part). Alternatively, putting more weight on the development part, they can become fully-fledged design research studies. There does exist a small number of large-scale design research projects, for instance the Historical Modules project (Katz & Michalowicz, 2005).

### **Research questions**

The main research question of this study is: What are characteristics of the design projects that include history of mathematics?

The design research perspectives are used to analyse the projects to shed light on what is considered important by researchers and the community. I will base the analyses on the four dimensions discussed above: the goal; theories, values and design principles; testing; and result.

As not all these dimensions are likely to be described explicitly in written articles about the projects, there are two sub questions: a) How is this process presented in writing? b) What considerations are involved which are not explicitly included in the written results?

In addition, this project may give suggestions on ways in which the literature on design research can contribute to HPM design projects and vice versa.

### **Methods**

The project has three phases. In the first phase (reported in this article), I analyse three publications describing efforts in designing materials for teaching mathematics with history. The analysis is twofold, the texts are analysed in accordance with the categories of the design research literature, and also to find additional considerations not included in the design research literature that I have surveyed. The first phase can be regarded as a “pilot” to see if the approach seems worthwhile. In the second phase, a more thorough literature review is done and more texts are included, whereupon a more thorough analysis is done. In the third phase, interviews are conducted with researchers from selected design projects to identify considerations absent in the published texts.

For the first phase, three texts were chosen: Weng (2008), Barnett, Lodder, Pengelley, Pivkina, & Ranjan (2012) and Jankvist (2009). They were chosen because they are different in scope, target group and context, and could therefore be expected to provide diversity. Two of them are not design

research studies on the face of it, thus the analysis can give me a clue as to whether including such other design-related studies in my analyses are worthwhile.

## Preliminary results

### Weng: Using history of mathematics in Singapore

Weng (2008) gives an overview of the use of history of mathematics in Singapore, while section 6 of the article describes “an action-research based case study” in which the author developed and gave a course using history of mathematics.

**Goal:** The stated goal of the study was “integrating history of mathematics into the teaching and learning of mathematics” and “investigate whether such a methodology help the students develop (or even enhance) a positive attitude” (p. 18). The article also includes a ten-page appendix giving examples from several projects, suggesting that the examples are assigned a value of their own.

**Theory, design principles, values:** The article refers to several potential effects of employing history of mathematics, but advocates the use of history of mathematics “to inculcate positive attitudes of the learner, as well as the teachers, towards mathematics” (p. 3). Weng proposes a “didactical framework”, based on the thought that “the learner must make *intellectual leaps*” while mankind make “*historical leaps*”. “[The] relationship between the mechanisms which are responsible for each of these leaps” (p. 13) is important. The intellectual leaps should be identified, “psychogenetical mechanisms” to help should be found, historical mechanisms associated to these should be identified, and historical points found which the historical mechanisms were employed to tackle. Identifying the historical points is called “sourcing”, and concerns searching the literature and discussing with colleagues.

In the appendix, seven kinds of “implementation methods” are given – these could perhaps be seen as seven sets of design principles. The seven are historical snippets; primary sources; worksheets; historical packages and enrichment programmes; experimental activities using ancient instruments and artefact; outdoor experiences; integration into modes of assessment.

**Testing:** The course was taught (once) by the researcher himself. The article includes results from students’ and teacher’s logs and a student survey.

**Results:** The stated result of the case study was that the historical approach was effective concerning belief and perseverance. However, as mentioned earlier, some of the materials created are given as examples in the appendix, and there are also examples of “evaluations” connected to the concrete examples: “[...] students appeared motivated since this approach *replaced* the usual, *re-orientated* their mathematical perspective and promoted *cultural understanding*.” (p. 35)

There is no discussion of which contexts the examples given could be suitable in, but there is discussion on the Singaporean context, including data on teachers’ attitudes and a lament on lack of teacher training in history of mathematics, lack of curriculum time and lack of assessment rubrics. This could perhaps be helpful for others to see whether their context is similar to the Singaporean.

### Barnett et al.: Designing student projects via primary historical sources

**Goal:** The project described in Barnett et al. (2012) builds upon an earlier design research project (a “pilot program”) in which “over a dozen historical projects for student work in courses in discreet

mathematics, graph theory, combinatorics, logic, and computer science” (p. 189) were developed. In the new project, “additional projects based on primary sources are being developed, tested, evaluated, revised and published” (p. 189). The goal was thus to develop these resources, with the aim “to recover motivation for studying particular core topics by teaching and learning these topics *directly* from a primary historical source of scientific significance” (p. 190). The article was written while the authors were in the second year of the four-year project.

**Theory, design principles, values:** The article does not give an overview of the theory it is building on, instead just stating that “Much has already been written about teaching with primary historical sources”, and then referring to chapter 9 of the 10<sup>th</sup> ICMI Study. Some design principles are given:

each historical project is built around primary source material which serves either as an introduction to a core topic in the curriculum, or as supplementary material to a textbook treatment of that topic. Through guided reading of the selected primary source material and by completing a sequence of activities based on these excerpts, students explore the science of the original discovery and develop their own understanding of the subject. Each project also provides a discussion of the historical exigency of the piece and a few biographical comments about the author to place the source in context. (p. 190)

In addition, fifteen “pedagogical goals guiding the development” are given. They include “students’ verbal and deductive skills”, “moving from verbal descriptions [...] to precise mathematical formulations”, “the organizing concept behind a procedure”, “understanding of the present-day paradigm [and] standards”, “attention to subtleties”, “students’ ability to equally participate”, “offer diverse approaches”, “provide a point of departure for students’ work”, “more authentic (versus routine) student proof efforts”, “a human vision of science and of mathematics”, “a framework for the subject”, “a dynamical vision of the evolution of mathematics”; “greater understanding of its roots” and “engender cognitive dissonance (dépaysement)” (p. 190).

**Testing:** The testing is done “by faculty at twenty other institutions” (p. 189), but no more detail is given in the article on the procedure, number of iterations and so on.

**Results:** The projects are published online at <http://www.cs.nmsu.edu/historical-projects/>, including “notes to the instructor” and comments from users of the projects. The article includes some experiences from the implementations (p. 199–200), including some comments from students and some possible ways of using the materials. This approach to using history to teach mathematics “is effective in promoting students’ understanding of the present-day paradigm of the subject” (p. 200).

### **Jankvist: Using history as a ‘goal’ in mathematics education**

Jankvist (2009) is a dissertation, and therefore has more room for (and demand of) a clear theoretical underpinning than the articles. Moreover, Jankvist’s project is not design research as such – to the contrary, the project is an empirical research study whose stated goals are to answer general questions, with materials only as “a byproduct” (p. 8). The three research questions are

RQ1. In what sense, to what extent, and on what conditions is it possible to have upper secondary students engage in meta-issue discussions and reflections of mathematics and its history in terms of ‘history as a goal’?

RQ2. In what sense and on what levels may an anchoring of the meta-issue discussions and reflections in the taught and learned subject matter (in-issues) be reached and ‘ensured’ through a ‘modules approach’?

RQ3. In what way may teaching modules focusing on the use of ‘history as a goal’ give rise to changes in students’ beliefs about (the discipline of) mathematics, or the development of new beliefs? (p. 45)

However, for two reasons it makes sense to regard this project as having a design research project at its core. Firstly, his way of answering his research questions is by designing and testing two modules. Secondly, the developed materials are interesting results in their own right, as evidenced by their being published in full (Jankvist, 2008a, 2008b). Thus, in this analysis, I will look at the design parts of Jankvist (2009) as an example of design research.

**Goal:** The goal of the design research part follows directly from RQ1–3; to design teaching modules engaging students in meta-issue discussions and reflections of mathematics and its history, anchored in in-issues, changing students’ beliefs about mathematics in the process.

**Theory, design principles, values:** The theories are treated systematically and in detail. First, he gives his categorization of the whys and hows. Then, he discusses Meta-Issues (inner and outer driving forces; pure and applied mathematics; epistemic objects and epistemic techniques; discovery versus invention; multiple developments), In-Issues (in particular Sfard’s theory of commognition) and Student Beliefs (stressing students’ beliefs about mathematics as a discipline and the role of reflection in changing beliefs). As Meta-Issues and In-Issues are part of what the students are supposed to reflect on, a thorough theoretical treatment of them is of particular relevance.

Design principles are not treated as systematically; they are found throughout the dissertation:

Obviously, original sources have to be chosen with great care, depending on the educational level in question, in order to make sure that the students have a realistic chance of actually working with them. (p. 33)

The historical cases chosen for [a modules approach] should [...] be exemplary, e.g. in such a way that they embrace as many general topics and issues related to the history and historiography of mathematics as possible. (p. 89)

[cases should be chosen] for which the in-issues could be built up in front of the eyes of the students in parallel with the explaining of the related meta-issues. (p. 94)

Other design principles are “using modern notation in the presentation of the mathematical in-issues” (p. 95), “setting the text of the teaching material with two different fonts; one for in-issues [...] and one for meta-issues” (p. 95), and “Following their group discussions, the groups were to write essays on the topics in question and hand these in” (p. 95).

Jankvist also offers some of his “personal viewpoints”, such as that it is “important to provide students with a ‘picture’ of what mathematics in time and space is” and that “one must have some kind of understanding of the involved mathematics also” (p. 7).

**Testing:** The actual teaching was done by “a typical upper secondary mathematics teacher” (p. 96), being “coached” by the researcher (p. 115), but no teacher’s manual was written (p. 95). There was

just one cycle, but the testing of the first module led to some changes in the second module. Most importantly, “[instead] of the introductory essay assignments, so-called historical exercises were introduced” (p. 157). Moreover, discussions with the teacher also led to at least one change, in that the researcher agreed to discuss the final essays with the class (p. 127).

An immense amount of data was collected: videos of the teaching and of focus group discussions, interviews with teachers and students, lots of hand-ins, including essays, and several questionnaires.

**Results:** The modules have been published, but not (as far as I know) in a new version informed by the results of the testing, although there are examples of details that were “ill-suited” (p. 150) and examples of new ideas; including role play (p. 202) or using the wording “on the shelves” (p. 203).

There is no attempt in the dissertation to describe conditions necessary for using the modules, except that “In other countries with different types of curricula, the possibilities for doing this may be somewhat limited” (p. 108). It is pointed out that although this “typical” teacher was coached by the researcher, she felt she lacked historical knowledge (p. 275). This makes it doubtful that other teachers with the same level of confidence would use the modules on their own – suggesting that having teachers collaborating with researchers to develop materials might be better (p. 304).

On the questions that the dissertation set out to answer, however, there are ample answers: Students were able to have discussions on meta-issues, anchored in in-issues. The essay assignments “appear to be a suitable setting for having the students engage in meta-issues” (p. 201). “[S]ome of the effects of choosing a newer history over an older one appear to be that it may be easier to relate to” (p. 281). Changes in students’ beliefs/views were observed.

## Preliminary discussion

The three publications include the theoretical background to very different degrees – probably partly because of context and space restrictions. Therefore, I will not discuss this in detail here. Design principles, however, are detailed in all three publications. Some of these concern the parts of history to be chosen. In Weng’s case, specific “historical points” are found that will help students make “intellectual leaps”, while in Jankvist’s case, the historical cases should be “exemplary”, but without concern for whether the mathematics covered is already a central part of the curriculum. Barnett et al., on the other hand, does not discuss the choices of topics but seem to choose topics already central to the curriculum.

All three projects include testing to some degree, although they include different levels of detail. While Barnett et al. explicitly states that testing will be used to revise the materials, Jankvist gives examples of revisions that could be made but he does not make them. None of the publications give very detailed (testing-based) pointers on what “conditions are necessary for its successful implementation”, to quote Burkhardt and Schoenfeld. However, both Jankvist and Weng are concerned about the teachers’ attitudes and knowledge, raising the question of whether the materials could be used by “average” teachers at all, without significant support.

For two of the publications, the materials produced are not presented as the main result of the studies. If this emerges as a pattern, it would be interesting to investigate whether this is because of the authors’ opinions or because of external factors such as the expected format of research texts.

## Conclusion of the first phase (“pilot”)

The first phase of this project establishes that there are significant differences in the goals, theoretical underpinnings, design principles, testing and results in the three chosen texts. Bringing such differences into the foreground may contribute to a discussion which can, in turn, benefit future design research projects.

# “Sickened by set theory?” – About *New Math* in German primary schools

Tanja Hamann

University of Hildesheim, Germany; [hamann@imai.uni-hildesheim.de](mailto:hamann@imai.uni-hildesheim.de)

*Keywords:* *New Math, primary, Germany, set theory, reform.*

## Purpose and question of the study

In the Federal Republic of Germany, public remembers so-called *New Math* mostly as a curious episode during which set theory has preceded numbers in primary mathematics education, a reform that has been controversially discussed and finally taken back, having been branded a failure. Thus, a closer look at the history of this reform is required.

As in any educational reform, changes concerned all different components of the educational system. Keitel (1980, p. 449) summarizes three levels that are crucial for the course of any reform, namely a subject’s educational scientific community, educational administration and curricula alongside their implementation in textbooks. Neglecting practical classroom experience, this list sticks to a more theoretical view, whereas Fend (2008) constitutes a multi-layer model of educational system upon the levels administration (politics and curriculum), school (teachers) and lesson (pupils and parents), putting more emphasis on practice and social reception. In both concepts textbook production is seen as being closely linked to curricular decisions, nevertheless it is also stated that – particularly within the German *New Math* movement – schoolbooks served as “instruments of innovation” inside the classroom (Keitel, Otte, & Seeger, 1980, p. 73). For these reasons, the project is based on a multi-layer model of schooling comprising the following levels: scientific theories of education, curricula, textbooks and implementation in classroom. Former analysis of the reform in Germany has mostly emphasized on curricular aspects (Damerow, 1977; Keitel, 1980; Zumpe, 1984), has mainly been focused on secondary education and dates back from when *New Math* curricula were still mandatory, causing those accounts to criticize the concepts and implementations rather than bringing them in line with long-term historical development.

From this derives the main purpose of the project, which is to describe ideas and concepts (with regard to aims, contents, principles, methodical suggestions) leading to the reform of mathematics education in West German primary schools and compare them to how they were implemented into methodical concepts. Three different 1st grade textbooks and associated teacher handbooks from the 1960s and 1970s were chosen as exemplary key sources: *alef* by Bauersfeld et. al., which developed from the country’s only long-term classroom project (*Frankfurter Projekt*), *Wir lernen Mathematik* by Neunzig & Sorger, which was the first *New Math* textbook for primary level being published and which is explicitly based on the concept of Z. P. Dienes, and *Mathematik für die Grundschule* by Fricke & Besuden, which originated from a former numeracy textbook based on the operative principle and therefore on the results by J. Piaget.

## Results

It shows that the courses differ when it comes to basic curricular decisions as well as to the relation between mathematics, sets and arithmetic. Bauersfeld et. al. have created a non-linear course that is

based on fundamental logical (relations, sets, transformations) and geometrical concepts. Here, arithmetic is founded on mathematics; sets serve as one example of a basic mathematical notion. Fricke & Besuden subordinate all their subject matter decisions to the learning of operative thinking. Thus, mathematics becomes a means for this, and arithmetic as well as set theory, logic and geometry serve as examples for mathematical thinking. Neunzig & Sorger's course, however, is aiming at a mathematical foundation of arithmetic, which is solely based on sets.

Especially the latter, which largely narrowed the original idea – namely to replace pure arithmetic by propaedeutic mathematics from the start – to teaching set theory in advance of numbers and numeracy, was widely disseminated and thus influential for the course of reform. The question occurs what might have caused this development. One result of further investigation of concepts of numeracy education up to the 1960s at the German *Volksschule* is that such an approach could be brought in line with long-term tradition of German primary arithmetic education.

# **The role of genetic approach and history of mathematics in works of Russian mathematics educators (1850-1950)**

Ildar Safuanov

Moscow City University, Russia; [safuanov@yahoo.com](mailto:safuanov@yahoo.com)

*Keywords: Russian mathematics education, history, genetic approach.*

## **Introduction**

The aim of this poster is to present the study of the history of the development of genetic and, in particular, historic-genetic approach in works of Russian mathematics educators of the second half of the 19<sup>th</sup> century and first half of the 20<sup>th</sup> century. It is important because the genetic approach and the history of mathematics are used in mathematics teaching nowadays (e.g., Fauvel & van Maanen, 2000). The role of genetic approach and history of mathematics for mathematics teaching is important today and it has been investigated by many authors (e.g., Furinghetti & Radford, 2008). The role of genetic approach and history of mathematics in works of Russian mathematics educators also needs a systematic research. In our study (work in progress), we use books and articles written by Russian mathematics educators of the past, notes of their lectures, and proceedings of Congresses of mathematics teachers held in the beginning of the 20<sup>th</sup> century.

## **Genetic and historic-genetic approach to the teaching of mathematics in works of Russian mathematics educators**

Progressive Russian mathematics educators developed ways of using history and genetic approach in mathematics teaching since the middle of the 19<sup>th</sup> century.

Russian mathematics educator Petr Semyonovich Guryev (1807-1884) was acquainted with works of F.W.A. Diesterweg. As early as in the middle of the 19<sup>th</sup> century he insisted on the use of elements of genetic and concentric (Safuanov, 1999) teaching. He wrote (Guryev, 1857, p. 176):

It is necessary that theory would develop like concentric circles... It is more appropriate and in accordance with the progress of development, that the definitions should be given at the end rather than in the beginning of the teaching of elementary arithmetic and geometry.

Viktor Viktorovich Bobynin (1849-1919), in his report on the 7<sup>th</sup> All-Russia congress of scientists and doctors he explicitly argued that it is necessary to use genetic method in geometry teaching and, in particular, to base the methods of teaching on the history of mathematics (Bobynin, 1886, p. 31).

At the end of the 19<sup>th</sup> century and in the beginning of the 20<sup>th</sup> century, one of the leading figures in the development of Russian mathematics education was Semyon Shokhor-Trotsky, author of mathematical textbooks for elementary mathematics. He invented the "Method of expedient tasks" which was essentially similar to genetic method. He wrote in one of his methodical guidebooks for mathematics teachers (Shokhor-Trotsky, 1935, p. 9):

The true method consists in that we should put a child in conditions at which human mind started inventing arithmetic, we should make him a witness of that invention. But it is not sufficient today. Nowadays we should aim at putting a child in conditions at which she/he would become not only a witness but rather the active participant of that invention.

Most interesting was the development of didactic ideas of Nikolai Izvolsky. Beginning with the method of “combination of mathematical representations” (Reports of the First Russian Congress of Mathematics Teachers, 1913, pp. 148-157), he eventually came to the profound expression of the genetic approach (not reduced to the historical one) to geometry teaching: “...A view of geometry as a system of investigations aiming at finding answers to the consequently arising questions” (Izvolsky, 1924, p. 9). He elaborated an original version of the genetic approach.

## Conclusion

Thus, we see that in Russian mathematics education many researchers, mathematicians, as well as mathematics educators, strongly contributed to the development of the genetic teaching of mathematics. N. Izvolsky articulated the idea of indirect genetic teaching prior to O. Toeplitz. We think that ideas of Russian mathematics educators, especially those of S. Shohor-Trotsky and N. Izvolski, would be useful for the further elaboration and improvement of the genetic approach in future. The development of ideas of Russian mathematics educators will be presented in the poster via the use of images and schemes.

### Introduction

The working group on Early Years Mathematics was established at CERME 6. The aim of this working group has always been to share scholarly research concerning mathematics for children aged 3-8. In this age group, the transitions within preschool, and from preschool to the early grades of primary school are important areas of attention. The working group on early years mathematics has also considered that in different countries preschool education has different objectives and children in different countries begin primary school at different ages (e.g., in Sweden there is one preschool curriculum for children aged 1-6 followed by primary school, and in UK there are different curricula for with nursery, preschool and primary school: 0-2, 3-4 and 5-8 years). These differences have always stimulated fruitful discussions and CERME 10 was no exception.

The 15 papers were each allocated 30 minutes of attention during the TWG 13-sessions; 12 minutes for presentation, 8 minutes where a different participant prepared a response or query, and 10 minutes for open discussion. The five posters were allocated 15 minutes each for a brief presentation and open discussion. One 30-minute slot was reserved for group work where participants from different countries were grouped and discussed quite openly topics of common interest (such as, e.g., the role of aesthetics in mathematics and the use of manipulatives in mathematics), and another 30-minute slot was reserved for discussing the plenary by Lieven Verschaffel on children's number sense. It was very fortunate to have him as a participant in TWG13..The final 90-minute session on Saturday was used to collaboratively prepare the report for Sunday, which together with what was presented and discussed in the other sessions, formed the basis for this introduction.

One of the Friday sessions included a 60-minute presentation and discussion of the Early Years Mathematics chapter draft for the soon to be published ERME book, where one of the editors of the book (Kenneth Ruthven) was present. Participants had been asked to read and send their questions and comments to the chapter in advance of the conference, and these inputs, as well as comments during the session, contributed important input to the ongoing discussion in the group.

The number of participants in TWG13 has been quite stable over the past five conferences, and each time the group has benefitted from a quite broad attendance when it comes to the area of Europe. Twenty-nine participants from 11 different countries attended the working group in Dublin (see the table below).

Country	Number of papers	Number of posters	Number of Participants
Belgium			1
Denmark			1
Germany	1	1	3
Greece	2		2
Israel	1		1
Norway	3	2	8
Poland	1	0	1
Portugal	0	1	1
Sweden	3	1	4
Spain	2	0	4
UK	2	0	4
TOTAL	15	5	29

## General summary of presentations

Seventeen of the 20 papers and posters concerned preschool children aged 3-6 years, preschool/kindergarten teachers' professional knowledge and competence development or teaching materials for activities in preschool. The remaining three contributions focused on children aged 6-7 years, which in most countries means Grade 1 in school. Compared to previous years, there was an increased attention given to preschool compared to early schooling.

Broad attention was given to the roles of preschool teachers' competencies in promoting early years mathematics learning. Vanegas, Gimenez and Samuel studied school mathematics narratives in early childhood teacher education, focusing on how the future preschool teachers recognized the potential of two professionally designed geometrical tasks to promote mathematical processes. Palmér and Björklund considered how preschool teachers characterize their own mathematics teaching in terms of design and content, while Hundeland, Erfjord and Carlsen analysed preschool teachers' orchestration of researcher-designed mathematical activities. They used this analysis to discuss what can be learned about teachers' knowledge by adopting the Knowledge Quartet by Rowland and colleagues for kindergarten level. Tirosh, Tsamir, Levenson and Barkai studied preschool teachers' variations when implementing a patterning task, where they investigated the impact of the various implementations on children's success in extending repeating patterns. Gifford, Griffiths and Back presented a theoretical paper concerning the use of manipulatives with young children, while Skoumpourdi presented a framework for designing inquiry-based activities for early childhood mathematics. Silva, Costa and Domingos offered an interdisciplinary approach to linking science and mathematics in early mathematics. A new issue presented and discussed during our WG was

mathematics for special needs children during the early years. Gasca, Clemente and Colella outlined and discussed the design of mathematical instructional activities to foster achievements in mathematics for children with Trisomy 21 (Down's Syndrome). Peter-Koop and Lüken considered the role of inclusive compared to exclusive settings for the learning of mathematics for children with special needs.

In total, eight papers and posters focused on the learning and development of mathematics for preschool children. The paper by Tzekaki and Papadopoulou was based on a teaching intervention for developing generalisation in early childhood. Björklund's paper considered the importance of adults challenging two year old toddlers' evolving concepts of numbers in their play. Her paper stimulated a discussion as to whether 3 years of age should be the lower limit of attention for our group as it was in the past. Sundström and Levenson reported on an exploratory study of young children's aesthetic development in the context of mathematical explanation, while Pettersen and Volden presented a poster considering the use of maps in kindergartens and children's development of spatial orientation and navigations. Bjørnebye reported from a multi-case embodied design study on early learning of numbers, while the paper by Schöner and Benz studied preschoolers' perception and use of structures in sets, adopting eye-tracking as a tool. Breive studied preschool children's argumentation as part of an inquiry approach in reflection symmetry and Rinvold investigated children's learning of numerocity. Both Breive and Rinvold adopted Radford's theory of knowledge objectification to kindergarten settings.

Regarding the first year of primary school, Maj-Tatsis and Swoboda reported on an intervention study on first grade school children's ability in noticing and using regularities in three-dimensional geometrical objects while using playing blocks. Van Bommel and Palmer focused on 6 years old children's representation of the semi-concrete and semi-abstract, as connections between concrete (objects) and abstract (signs) representations. Finally, Thoules presented a self-study action research study on the role of gestures in supporting mathematical communication for first grade students with language delays.

## **Main characteristics and issues in focus**

The group had ongoing discussions about the importance of fostering children's early development of mathematics for later success. As such, the group experienced presentations and discussions of several intervention and exploratory studies, teacher development and ways of fostering children's mathematics learning. The role of play and the term "playful learning" was given great attention. This proposed term takes into account that distinguishing between play and learning at this age-level makes little sense. The argument offered was that an activity designed, planned and guided by the teacher may indeed promote learning among children, but can be considered as play by the children.

As usual, the group presented a mixture of small scale studies (case study design), large scale studies and several pilot studies for larger studies. These different studies contributed valuable insights. We also experienced a broad range of theory in discussions of papers and posters, including the theory of objectification, variation theory, socio-cultural theories, the use of Clements and Sarama's framework, the core knowledge system, as well as development of conceptual frameworks. The theoretical discussions of the group were supported by Lieven Verschaffel's perspective and contributions, generating fruitful discussions of theory use and development.

The most prominent “news” for our group came from presentations discussing the following issues: ways in which special needs children can engage with mathematics, toddlers and mathematics, and young children’s appreciation for the aesthetical dimensions of mathematics. The group was also introduced for the first time to the possibility of using eye tracking as a tool in early years mathematics research. We encourage researchers to continue with their important work regarding early years mathematics and hope to see new insights in the next CERME meeting.

# Aspects of numbers challenged in toddlers' play and interaction

Camilla Björklund

University of Gothenburg, Sweden; [camilla.bjorklund@ped.gu.se](mailto:camilla.bjorklund@ped.gu.se)

*The aim of this pilot study is to explore when and how toddlers discern aspects of number in exploratory play and communication. Data for analysis consists of video-observations of 23 1–3-year-olds' mathematical activities in preschool, revealing occurrences where toddlers' conceptions of number are challenged. A qualitative analysis informed by Variation theory of learning provides important clues for early mathematics education: toddlers encounter many aspects of number on a daily basis, but their conceptions are rarely challenged. This study will work as a basis for intervention and further studies of the possibility to enhance early mathematics education.*

*Keywords: Early childhood education, mathematics, number concept, toddlers.*

## Introduction

There is a diversity of pedagogical approaches and theoretical understanding of young children learning mathematics. Palmér and Björklund (2016) discuss in a recent review of contemporary preschool mathematics research that what children are actually offered to learn in preschool differs to a great extent, even though there is a consensus among the research community that early math matters. Consensus is however not reached when it comes to what and how mathematics should be taught. Some argue that basic understanding, which some children already have acquired, is enough and preschool should offer a space for children to use and master these skills. Others find it necessary to challenge children's knowledge and set goals for learning that the majority of the children in a group have not yet mastered (Claesson, Engel, & Curran, 2014).

Many researchers have made efforts to describe developmental trajectories in mathematics learning and what to expect from children at different ages or in what order skills develop in general. Consequently, there is a large body of research departing from different theoretical approaches (see Baroody, Lai & Mix, 2006; Sarama & Clements, 2009 for overviews). A contemporary theory – Variation theory of learning (Marton, 2015) – proposes a bold conjecture that the understanding of whole numbers originates from experiences of different aspects of number, rather than a predictable development trajectory. Focus is here shifted from descriptions of children's competences and learning trajectories towards the content to be learnt, and particularly what it takes to learn that content. Based on this conjecture, this study directs attention to what aspects of numbers are discerned by toddlers in play and interaction in preschool. The theoretical framework furthermore provides analytical tools for interpreting *why* children express different ways of experiencing numbers and what is possible to learn in different interaction. The study will therefore have impact on education and further research. There are many aspects of mathematics that could be made object for this study, but in this particular pilot project the interest is demarcated to number concept.

## Aspects of number as learning object in the early years

The concept of number is complex and research shows that many competences seem to be necessary for children, to develop their numerical reasoning and arithmetical skills. By the time children turn three years, most of them already know the beginning of the sequence of counting words and are

acquainted with nursery rhymes with number words. To develop an advanced understanding of the different meanings of number in different contexts is however a process that continues until children are about eight years old, according to Fuson (1992). In the early years, the sequence of counting words is best described as a continuing string of words that lack numerical meaning. During their preschool years, children's understanding of number words includes also a numerical meaning, but how this process happens is an issue raised by Wynn already 25 years ago (Wynn, 1992). There is of today no consensus how this development occurs or what seems critical for learning to handle numbers in arithmetic tasks. Some (c.f. Carpenter & Moser, 1982; Fuson, 1992) claim that counting is the foundation for arithmetic competence, while others argue for the necessity of perceiving the part-whole relationship of numbers (Baroody & Tiilikainen, 2003). One way of finding a path to understand the development of number sense and arithmetic skills could be to direct more attention to the features of numbers and how numbers may be perceived in different ways, as proposed by Marton (2015). A controlled study by Benoit, Lehalle and Jouen (2004) has for example shown that the perception of numbers as parts and whole simultaneously, supports children in acquiring the meaning of small numbers. This builds on the ability to perceive numbers as exact sets of items without counting, referred to as "subitizing" (Kaufman et al., 1949). Subitizing is limited to small amounts of three or four, but the ability can be enhanced to larger numbers, so called conceptual subitizing (Clements, 1999). When items are arranged in ways that make them possible to recognize as patterns or collections of sets, it is easier to compare and estimate both exact number and larger magnitude. However, the sequence of counting words and the meaning of numbers as descriptions of sets of objects (a sense of "manyness") probably has to be considered as two necessary aspects of numbers that children presumably learn during their first years.

Even though young children seem to have the ability to perceive exact number, there is no guarantee that all children make use of this ability. Studies (Hannula, Mattinen & Lehtinen, 2005) show that far from all three-year-olds take initiatives to focus on numerical features of their surroundings or use number words in routine situations and play. Spontaneous attention to number among young children has nevertheless shown to predict later mathematical achievements (Hannula-Sormunen, Lehtinen & Räsänen, 2015) and this can be enhanced by social interaction and directed attention towards number relations, with long-lasting effects.

From earlier research we have reasons to believe that certain aspects of number are necessary to discern in order to develop number sense and arithmetic skills. Neuman (1987) argued, based on a study of 6-7-year-olds that children who suffer from math difficulties cannot experience the first ten natural numbers as magnitudes nor the relations between them. This lack hinders them in perceiving that 7 may be a part of 9 and the difference between them is 2. Most children develop strategies to deal with numbers and arithmetic tasks, but those who cannot discern the part-whole relationship have to turn to cumbersome strategies of counting up and down and even double-counting. Neuman further described how children's strategies for problem solving are related to their conception of numbers and what aspects of numbers that the children can differentiate. The following aspects are known from the vast literature in the field, confirmed as aspects necessary for arithmetic computation in Neuman's study: a) numbers can be *represented in different ways*, b) numbers constitute a *part-part-whole relationship*, c) number words refer to *cardinality* (or manyness), and d) number words refer to *ordinality* (or sequence).

In an on-going project (Björklund et al., 2016) we found these aspects present in some, but not all, 5-year-olds' conceptions of number. It is thereby of interest to further investigate how younger children perceive numbers. Thus, the question raised in this pilot project is: What aspects of number are discerned by the youngest preschoolers and how are their conceptions of number challenged?

## Theoretical framework

The theoretical framework used in this study is Variation theory of learning (Marton, 2015). The theory states that variation is central for learning and patterns of variation constitute necessary conditions for learning (Marton & Tsui, 2004). When learning new concepts, there is in particular one pattern of variation that is essential – contrast. By contrast means that what is to be learnt is held constant but some critical aspect of the learning object has to be contrasted to enable discernment. In other words, to learn the meaning of “five”, sets of five (items constituting the sets) may vary (five flowers, five dogs, five children) but the “fiveness” will appear only when *five* in a set is contrasted with for example *four* in another set. Only then, can the numerical meaning of five be discovered and thereafter generalized to the different sets of five. Generalization, differentiation of aspects that are potentially necessary to discern in order to better understand the concept, and simultaneous attention to several aspects are the other patterns of variation that the framework holds as necessary for learning (Marton, 2015). This theoretical framework provides tools for analyzing empirical data to describe the process of learning by focusing on how necessary aspects of the learning object are presented to the learner. For example, the child needs to differentiate that numbers have both ordinal and cardinal meaning to be able to operate with numbers in arithmetic tasks, but if the child has not discerned numbers' cardinality they cannot make use of numbers as a representation for sets of objects.

Children's conceptions of a phenomenon constitute, according to this theoretical framework, of those aspects that the child can discern in a particular situation (either due to earlier experiences of similar phenomena or due to what the situation offers the child to experience). Conceptions can thereby be interpreted as the way a child encounters a phenomenon. Lack of discerned aspects is thereby also expressed in children's use of numbers in problem solving (Neuman, 2013) and in particular when they are encouraged to communicate their understanding of numbers to peer or adults.

## Methods

The aim of this study was to get an overview of toddlers' conception of number and in what ways their conceptions of number are challenged. This is done through an analysis using Variation theory of learning as analytical tool, which directs attention to the content of learning and in particular how a phenomenon (number in this case) is perceived by the children in a specific situation. The unit of analysis is interaction that provides opportunities to discern necessary aspects of number.

The participating children attend two randomly selected preschools in Finland, where they take part of a pedagogical practice with their peers in both planned activities and self-initiated play. 23 toddlers altogether (aged 13 months – 3 years 9 months) are observed in their common activities in these preschools. The data consists of 45 hours of video-documentations originally collected for a larger study with a broader mathematics focus (see Björklund, 2007). Of these, episodes where

number concepts are focused on are analyzed more thoroughly in this particular study. Written consent for children's participation in video-recorded documentations is given by the children's parents. Children's and teachers' names are anonymized in all public presentations.

The analysis concerns the opportunities children are given to develop their conceptions and learn to use numbers and is conducted in two steps: 1) the children's conceptions of number is characterized, 2) the analysis focuses what aspects that are emphasized when children express a certain conception including if and how this conception is challenged. The theoretical framework provides analytical tools to study such situations where the number concepts are challenged and what constitutes the development opportunity. We are in accordance with the theoretical framework looking for situations where children or adults "open up dimensions of variations" (Marton, 2015), meaning that a certain aspect of the learning object is emphasized and thereby made possible to explore and learn the meaning of. It is in particular *contrast* that we look for and how it enables different dimensions of variations to be opened up.

## **Results – Acts that challenge toddlers' number concepts**

We know from studies with older children that some critical features of number are necessary to discern to use numbers successfully in arithmetic problem solving. In this study we see the same aspects' importance and can describe how the lack in discerning necessary aspects results in different conceptions of numbers. The sequence of counting words is quite common in different activities, but the sequence is mostly used for naming items or as any nursery rhyme. The number concept is then limited to an ordered string of words without relation to numerosity. It is more seldom found that the children use the sequence of counting words to find out how many objects there are in a set (in a cardinal sense). However, there are examples of children using number words to describe sets and quantities and thereby expressing a conception of number as quantitative relations. The following presentation will discuss how toddlers' conceptions of number are challenged in their interaction with peer and adults, with analytical focus on which aspects that are made possible to explore for the further development of number concept.

### **Describing objects or sets**

Number words are by many toddlers used as a rhyme that is fun to recite. Some relate the reciting to groups of objects, one-to-one, and a few children use number words to describe sets of objects. The difference between these ways of using number words is in the conception of numbers as ordered names (emphasizing an ordinal aspect) or numbers as describing a set (a cardinal aspect brought to the fore). To challenge number concepts' meaning it is then necessary to open up these dimensions of variation to the child:

Harry (2:0): (looking in a picture book) Wow, horses.

Nancy (3:9): Yes. It's two horses.

Harry (2:0): (browsing through the book) There they are. There are also two.

The short but clear comment from the peer opens up for numbers' "manyness" and numerical relationships to be explored. Harry shifts his attention from "horses" to numbers, "two". However, numbers are not further challenged, such as by comparing two horses with more or less or generalizing to other sets of two.

Expressions of numbers as names of items are common in the literature and frequently observed in this study. This conception of number (or rather the number words) is characterized as a way to enumerate by giving each counted item a number name, attaching the name to the physical object. This means that number words do not refer to quantity - they are rather an ordered list of names applied to some items. In the short excerpt below the child Lou is counting stars in a book, over and over again, pointing her finger at one star at a time while saying the number words:

Lou (2:7): One, two, three, four, five, six, seven, eight, nine.

Arthur (3:1): That one is not nine!

Lou points at the stars while counting out loud. The second time she points at different stars than before, making Arthur react to the break in the pattern of named stars. Arthur acts as the counting rather is about “naming” the stars with number words, not differentiating any cardinal meaning. The order of naming them is then closely related to the physical objects, emphasizing ordinality.

### **Extending the setting**

Mathematics is useful due to the transferability of notions and the abstract relationships that mathematics concepts describe. It is in this sense natural to think that generalization is a key to learning the meaning of abstract numbers. This is not uncommon in teacher-child interaction:

Elsa and Ann (adult) are sitting at the breakfast table.

Elsa (2:6): There's two (pointing at two plates on top of the other).

Ann (adult): There's another two (pointing at two other plates) and there's two pieces of bread, and there's also two (pointing at two spoons on a plate).

The teacher makes efforts to pick up the child's initiatives and generalizes the idea of sets of two. However, the observation does not reveal whether the child discerns the cardinal meaning of “two” applied to other settings as well or if the directed attention to other kind of objects takes away attention from the number's meaning of “twoness”.

### **Comparing more-less**

When numbers are used to describe sets, a possibility to explore number words' cardinal meaning opens up if sets of different quantities are made possible to compare. Subitizing enables children to compare and estimate small number of items, but this builds on the above mentioned condition, that focus is already directed towards numerosity.

Lou (2:7): (brings three different cat toys to a table) Here's two kitty cats.

Arthur (3:1): No, it's not like that, it's this many (showing three raised fingers on one hand).  
One, two, three (raising one finger for each said counting word).

Cardinality is undoubted critical for operating with numbers. It seems that comparison of different quantities, contrasting numbers as sets, makes this possible. Merely counting will promote ordinality as the primary aspect in focus, shorter or further on the sequence of counting words, but does not necessarily emphasize the “manyness” of the numbers.

### Attention to the cardinal *and* ordinal meaning of number words

Observations show that many children, and teachers, express a rather strong focus on the aspect of ordinality, while the cardinal meaning of numbers is an aspect that is rarely opened up for exploration. The following excerpt is thereby an exception but important in our investigation of learning opportunities in preschool mathematics:

Alan (3:5): (has been asked to check how many children there are in the cloakroom) There is *one* and *one* and *one* and *one* and *one* and *one* and *one* and *one* and *one* and *one* and *one* there.

Gloria (adult): That's quite a lot. Or was there only one?

Even though the child is not using number words to express himself, he expresses number as an addition of ones. The teacher picks up the word he uses and opens up both the aspect of ordinality by referring to the number word “only one” and in the same occurrence also the aspect of cardinality when confirming that the boy had described a large number of objects.

The idea of directing attention to ordinality, as in the following excerpt, is however not always critical for a task and may thereby not be taken into consideration by the child:

Alice (2:4): (sits with a jig-saw puzzle with pieces shaped as fish and a number of dots on the board and corresponding number of dots on the fish) Just one dot and then just two (tries to fit a piece in the board).

Mary (adult): No, you have to look at the dots, here's three, then you have to see how many dots there are there [on the board]. Where should it go?

Alice (2:4): There! (pointing at the board where there are three dots)

Mary (adult): (pointing at each dot on the fish) There's one, two, three, where?

Alice (2:4): (pointing again at the board and the three dots)

Mary (adult): There's one, two, three.

Alice (2:4): It will go there (putting the rest of the pieces with 1–3 dots on their right places on the board). Here's only one dot (pointing at the last empty place on the board).

Alice's attention is directed towards the features of the fish that will not fit on the board. This conflict directs her attention to find clues or strategies to ease the task of finding right pieces. She discovers the dots and describes their difference in number “just one dot and then just two”. The teacher supports her discovery but offers a counting strategy to make sure she finds sets of dots that are equally large. However, the attention to different aspects does not seem to meet, nor are they simultaneously considered as aspects of numbers. Alice did not count the previous two dots, she also seems to perceive equal number of dots if they are three, since she does not make any attempts to count in the same way as the teacher instructs her to do. It is thereby uncertain if the aspect of ordinality is necessary to emphasize since the child masters the task by focusing on the “manyness” of the sets. The number of dots is within the subitizing range, which has to be considered as a reason for not needing another strategy to compare the number of dots on the fish and on the board.

## Discussion

This pilot project brings to the fore that children's conceptions of number seem to be characterized by partly numbers as names and sequence, parallel to using numbers to describe a set of objects. In some rare occasions these conceptions are emphasized simultaneously, enabling the fusion of ordinal and cardinal meaning, which is presumably an important condition for number concept development. An advanced use of number words includes both of these aspects and enables a child to solve arithmetic problems. Wynn (1992) raised this issue when presenting findings of 2–3-year olds' sense of numerosity in contrast to their emerging understanding of the counting system. The current study confirms that toddlers experience number in different ways, but provides insight to the activities and interactions where ordinality, cardinality and the fusion of them are put to the fore and thereby enable children to develop number concepts. According to Variation theory (Marton, 2015) such analyses are essential for understanding what constitutes the learning object (numbers in this case) and consequently how to support concept development by offering necessary aspect to be discerned by the child. Forthcoming studies will thereby shed more light on how the conception of numbers as names and rhyme can be challenged and related to numbers' "manyness". Critical is what role the different aspects play in number concept development; is cardinality superior to ordinality (c.f. Benoit et al., 2004), and perhaps more important, how are the aspects related in toddlers' number concept development?

It is of high pedagogical value to consider what activities toddlers encounter in preschool and what opportunities to explore ordinality and cardinality there are – the examples presented here show that it occurs in both planned and spontaneous situations. Further studies will also direct attention to teachers' acts to engage toddlers in such stimulating activities and how it can be made possible for children to extend their conceptions of numbers, as this pilot study indicates is possible.

*Research on how neuroscience and knowledge of human's endowment can inform educational practice is a young field. With reference to contemporary research and models that hold the idea that humans possess non-verbal inborn cognitive systems for estimating sizes and processing quantities, empirical data from a multi-case embodied design study on early learning of numbers is discussed. Based on observational data and on a discrepancy in the results of traditional and modified Give-N-tasks for determining the cardinal knower level, it is contended that designs which embrace innate spatially organized representations of numerosity through body-based metaphorical mappings, could guide the development of tools for measuring the cardinal concept.*

*Keywords: Cardinality, cardinal concept, measurement, embodied design, core knowledge systems.*

## Introduction

Recent research and discoveries in the field of cognitive development suggest that the individual's concept of cardinality in terms of fluency with exact enumeration constitutes a particular predictive factor for the development of mathematical skills (Aunio & Niemivirta, 2010). Furthermore, mastery of cardinality as a culturally-achieved word principle is regarded as a fundamental skill for later development of arithmetical abilities (Dowker, 2005). However, children find it challenging to understand the meaning of cardinality (Fluck et al., 2005). Some cognitive psychologists who develop models of numerical cognition posit a close relationship between the spatial and the numerical domains, and see the existence of spatially organized representations as the core of number meaning (e.g. Dehaene & Brannon, 2011). However, there is a dearth of research focusing on the underlying cognitive structures that support mapping between non-symbolic and symbolic representations of numbers (Mundy & Gilmore, 2009), and in particular inquiries into children's mathematical performances in naturally occurring testing scenes (Reikeras et al., 2012).

The aim of the study is to explore how the cardinal concept is measured, perceived and conceptualized in an educational design incorporating early learning of numbers. In the following, we introduce the conceptual framework of the study which is theories of core knowledge system.

## The core systems of number representation and conceptual mapping

In the literature, there is a consensus that cognition is based on at least four domain-specific core knowledge systems for representing objects, actions, numbers and space, each mechanism being deeply rooted in human evolution with shared ontogenetically and phylogenetically abilities (Spelke & Kinzler, 2007). Two of these core systems are dedicated for representing numbers, i.e. the *Approximate Number System* (ANS) and the *Object Tracking System* (OTS), accounting for humans

basic numerical intuitions, and serve as the foundation for acquiring symbolic and cultural aspects of the number concept (Feigenson et al., 2004). Whereas the ANS supports rapid analog estimated representation of large magnitudes, the OTS is a cognitive system for tracking up to four objects in parallel (Burr et al., 2010). Subitizing, which is an immediate perceptual insight of the cardinal value of a small set of objects “without having to engage in conscious counting” (Wynn 1995: 36), is thought to emerge from the OTS-system. However, the exact nature and origin of subitizing is still in dispute (Piazza, Fumarola et al. 2011). Moreover, these core systems of object representations center on the spatio-temporal principles of cohesion and continuity, positing that objects maintain their connectedness and boundaries across movement in space and time (Spelke et al., 2007). Hence, from a core knowledge standpoint, this suggests that infants have an innate ability to grasp the ontological aspects of wholeness, numerosity and invariance of the cardinal concept.

A *conceptual mapping* concerns neural connections in the brain including core knowledge systems, and is described as a systematic set of relations between constituting elements where a target domain is understood in terms of a source domain (Lakoff & Johnson, 1999). Based on this model, the level of meaning in the transfer is determined by what the two domains have in common. This set of shared features or similarities is termed the “ground”. For example, cardinal word knowledge within the subitizing range is thought to reflect a mapping between number terms or metaphorical expressions (e.g. “cat-four”) in the semantic domain and the OTS (i.e. the cardinal value 4 is the ground). In a similar manner, approximate number word knowledge is supposed to reflect a projection between the ANS and cardinal labels such as “all”, “many”, “a part” or “about 20” (Gunderson et al., 2015). Thus, linguistic expressions that reflect estimated values or exact enumeration share the feature of pointing back to the collection of items as a part or as a whole, but these types of number representations are posited to be processed in different neural structures. Next, in order to illuminate how the core knowledge system is put into play in the design, a brief epistemological and ontological clarification of the cardinal concept is presented.

### **The concept of cardinality**

The cardinality refers to the number of objects in a set, also denoted as the set size, magnitude or the quantity of a set. Formally, there are two main approaches to determining the cardinality of a set. The first method, which is associated with the cardinal word principle (Gelman & Gallistel, 1978), uses enumeration, that is the transitive meaning of counting to align the cardinal value to the set. The last number-word in a counting sequence points back to the group of tagged items, and hence ontologically reflects an aspect of the set as a whole. The second method compares sets directly using one-to-one correspondence. For example, a gestalt using two hands, two knees and two feet to tag an array of six leaves, is an embodied way of confirming that the quantity of the set of grounding limbs and the collection of leaves is the same. The non-verbal transitive relation emphasizes that the pair of knees is a part of the entire collection of six body-parts across movement in space and time. Thus, the aptitude to treat sets as wholes and parts of wholes reflects spatial and temporal features of the cardinal concept, and rests on the ability to grasp the idea that the value of the set is an invariant property across the form and shape of the boundary and the configuration of the items.

## Methodology

### Selection and intervention

Four 4-year olds were enrolled in a six-week program outdoors comprising ten one-hour sessions using direct methods to determine the cardinality. The cases were selected based on results on a Give-N-task for assessing understanding of cardinality (Schaeffer et al., 1974), as outlined below. Cardinal-four knower, Fia (3:9), was selected as a prototypical case, and cardinal principle-knower, Kate (4:2), and the two cardinal-one-knowers Chris (3:11) and Ted (4:1) to ensure maximum variation in the cases competences in representing numbers.

Situated in the vicinity of the kindergarten and contextualized by different N-dotted matrixes on the asphalt, the participants were guided to articulate their body-based mappings using corresponding number-metaphors (see Figure 1). For example, on a four-dotted matrix, they could embody and articulate the metaphorical expression “frog-four” performing a gestalt of four body parts tagging the dots.

**Figure 1: Embodiment of spatial-structures using body parts**

### Data collection

The empirical data was assembled as video-recordings of intervention episodes and assessment tasks.

**Figure 2: The modified small-scale (left) and large-scale (middle and right) Give-N-tasks**

Pre- and post- Give-N-task. The children were asked to select a certain number of blocks from a set of fifteen blocks (e.g. “Can you give me three blocks?”). When the child had responded, the experimenter asked “Is that *N*-blocks?” If the child confirmed, a new task was given. Otherwise, the initial question was repeated. No suggestion was made to use a counting procedure to check incorrect responses. The knower level (c.f. Lee & Sarnecka, 2010) was determined by the highest number of correct responses given by the child in two out of three times (i.e. the criteria set by

Wynn, 1992), given that all preceding numbers had met the same criteria. Knower-levels above four are labeled cardinal-principle-knowers, and reflects the group that knows how counting works.

The “Create A-Metaphor-N-task” (only post-test, see Figure 2, left). The same procedure as the Give-N-task described above was applied but the question comprised the use of “number-metaphors”. For example: “Can you find a cat-four?” and the experimenter asked “Is that a cat-four?”

The “Embodiment-Metaphor-N-task” (only post-test, see Figure 2, middle). A circle ( $d = 2.0$  m) on the ground with 16 arbitrary distributed dots ( $d = 0.1$  m). The experimenter asked can you jump or find a “Metaphor-N” in the matrix; for example, “Can you find a kangaroo-two and then a dog-four?” (Coded as 2+4, see Table 1). The question was repeated only if the child did not respond. No confirmatory question was posed after the child had completed the articulated embodiment. The initial position outside the circle was determined by the movement trajectory of the previous task.

### **Qualitative data analysis**

A qualitative multi-case study approach using pattern matching and cross-case analysis as analytic techniques (Yin, 2009) was adapted to our purposes. The first step of the analysis identified unique patterns in the data material for each case, and meaningful units conveying information of non-verbal and verbal representations of numbers across testing scenes and activities were transcribed and coded in the qualitative analysis tool NVivo. A cross-case analysis was conducted in order to identify diversities, gaps and shared patterns across the cardinal-knower-level. Based on this, general patterns and discrepancies emerged and were synthesized.

### **Findings and discussion**

Five hours of video produced 700 references in NVivo capturing situations where the four cases were engaged in bodily-spatial mappings of numerosity. Elaborated, the data shows 1182 occurrences of the seven most frequently used metaphors of articulated body-based mappings of numbers. For example, the use of the “cat-four” metaphor was reported 316 times. Moreover, the assessment shows that the cases skills in verbal production tasks span from cardinal-one-knowers to cardinal-principle knowers. With the exception of Ted who progressed to a cardinal-two knower-level, the results from the pre- and post-Give-N-tasks suggest that the intervention had no “effect”. However, during intervention and on the two modified assessment-methods, the three subset-knowers showed domain-specific cardinal knowledge in terms of an ability via metaphors to map non-verbal and verbal cardinal knowledge above their assessed level in the ordinary Give-N-test. Subsequently in order to ensure an in-depth-analysis comprising the lower bound of the performances in the design, the examination will mainly focus on the behavior of Chris, this being the case with the lowest measured competence. Table 1 comprises a summary of his Give-N-results.

Give-N-Task			Create A-Metaphor-N-Task	Embody-Metaphor-N-Task	
Asked: "Can you give me N blocks?"			Asked: "Can you make a Metaphor-N?"	Asked: "Can you embody a Metaphor-N?"	
Task	Pre	Post	Only post	Task	Only post
One	1,2*	1,1,2	1	Rooster-One	1
Two	3,2,5	2,4,15,2	3,2,2	Kangaroo-two	2,2,2,2,2,2,2
Three	2,6,6,9,9	5,15	3,3,3	Monkey-three	3,3,3
Four	5,4,3	6	4,4,4	Dog-four	4,4
* A follow up test established Chris as a cardinal-one-knower				3+1 (e.g. "Monkey-three and Rooster-one")	3+1
				2+3	2+3, 2+3
				2+4	2+4, 2+4
				4+2	2+4, 2+4
				3+3	3+3, 3+3
				4+4	4+4

Table 1: Results for Chris on traditional and modified Give-N-tasks

### The traditional Give-N-task and the "Create a Metaphor-N-task"

According to the notion of conceptual mapping, the dissimilarities between the two things being compared in the Give-N-tasks might create an epistemic "tension" in terms of instability between two cognitive domains. Thus, and applied to the core knowledge systems, the question of discrepancy in the results narrows down to an explanation as to why the tension was resolved in a conventional manner in the projections involving ANS and OTS in the modified Give-N-tasks. Overall, the results of tasks above the three subset-knowers level of competence as measured by traditional Give-N-tasks suggest that the semantic mapping from a number word (i.e. the source) onto an unstructured collection of items (i.e. the target), did not share the cardinal value as a common feature (i.e. the ground). For example, the behavior for cardinal-one-knower, Chris, shows that the semantic expression "Give me *three* blocks" is frequently associated with verbal expressions such as "*many*" or "*all*", and in a concrete manner mapped as 2, 6, 6, 9, 9, 5 and 15 blocks respectively. Hence, the transfer gives no meaning as the mappings are reflected in arbitrary, unstructured and inconsistent distributions of blocks. Moreover, this suggests that the semantic label "three", with the exception from the first response, is mapped via ANS. However, on the two correct responses of post-testing of the two-knower-level (2,4,15,2), Chris accompanies his behavior with articulation of the metaphor "kangaroo-two" showing via the OTS an emergent ability to lean on figurative support in the mapping of the number-word "two". In contrast, on the "Create a Metaphor-N-Task", the tension of the mappings initiated by the contextualized metaphorical questions was resolved in a conventional manner showing that he is on a cardinal-four-knower level in a domain specific way. For example, on "find a monkey-three"-tasks, Chris consistently produced spatial structured assemblies of three blocks (see Figure 2, left). Hence, this suggests that the mapping from the number word "three" is processed via the OTS to produce structured configurations of sets. Furthermore, this chain of reasoning rests on the assumption that no counting procedure was employed. This premise lends support from previous research that suggests that subset-knowers seldom use any counting procedure on Give-N-tasks (Le Corre et al., 2006). Hence,

the verbal twist in the small scale “Give-N” question, from “Give-me-two-blocks” to “Can you find a kangaroo-two”, suggests that the discrepancy in “knower-level” is on a linguistic level and that the knowledge assessed in the modified task is domain-specific and contextualized.

### **The “Embodiment-Metaphor-N-task” and behavior that reflects aspects of the cardinal concept**

Below, we focus on the two core knowledge structures for representing numbers to examine the responses that cardinal-one knower, Chris, gave to the kangaroo-two and the cat-four task in the “Embodiment-Metaphor-N-task”. Allowing the use of the commutative property of addition, the results in Table 1 show that Chris responded correctly to all four tasks, and the behavior was observed as articulated bodily-spatial representations “Kangaroo-two, Cat-four”. Since Chris is standing outside the marked boundary of the matrix, we suggest that he cognitively represents the whole assembly of 16 dots using ANS. Based on the verbal instruction “kangaroo-two”, Chris had to visually identify a configuration of dots that matched the metaphorical expression (see Figure 2, right). Although it is a difficult task to account for when the two systems for representing numerical information are activated, verbal- and non-verbal empirical data in combination with experimental findings of the signatures of the OTS and ANS, could provide supporting evidence to the various hypothesis (Barner et al., 2008). For example, one hypothesis posits that the first “container” was visually identified via a metaphor-word-mapping onto OTS, and the rest of the dots were cognitively processed as an estimated quantity through ANS. This suggests that the whole assembly of dots was decomposed in two subsets, one part being exact enumeration via OTS, the other being a constellation of the whole, i.e. an estimated number representation via ANS. Another explanation is that Chris subsequently processed the two dots via the OTS as a part of a whole estimated set. Either way, these lines of reasoning finds support in the claim that ANS interacts with OTS (Piazza, 2010), and moreover the suggestion that ANS constitutes a support in basic numerical processes of small numbers (Feigenson et al., 2013). Moreover, the findings of Burr et al. (2010) show that subitizing (OTS) rather than estimating needs attentional resources. Thus, a third hypothesis, which also lends support to the claim that ANS is defined for large and small sets (Cantlon et al., 2006), suggests that the two-dotted configuration was initially identified as an estimated value via the ANS, and as a result of an increased use of attentional resources, was subsequently processed as an exact numerical magnitude via the OTS.

Overall, the four cases demonstrated flexibility in their non-verbal and linguistic-metaphorical representations of numbers, and the diversity of embodied strategies was shared across cardinal knower-level and counting skills. However, the quality of the cases use of cultural skills for exact enumeration differs. While Kate as a cardinal-principle knower provided exact enumeration of embodied additive structures such as  $4+4+4$  and  $1+2+3+4$ , the subset-knowers could represent the same arithmetic structure via articulated bodily-spatial mappings, for example three times “Cat-four” or “Cat-four, dog-four, bear-four” and “Rooster-one, kangaroo-two, monkey-three, cat-four”. Hence, this gap in competence might inform of a potential learning trajectory.

### **Concluding remarks**

The results reveal a discrepancy in sub-set knowers’ behavior across representational tasks of numbers. In particular, the data show that subset-knowers possess an ability to map non-verbal and figurative expressions of cardinality in modified small-and large-scale Give-N-tasks above their

knower-level as assessed in traditional Give-N-tasks. We suggest that the most promising explanation concerns the suggestion that the formation of the cardinal concept rests on the core knowledge structures for representing numbers synchronized via direct methods to determine the cardinality. Based on this, the full bodily-spatial metaphorical mappings of the matrixes provided coherence and meaning to the cases ideas of invariance, wholeness and numerosity. Hence, the results correspond to a growing body of evidence suggesting the existence of a fundamental link between the non-verbal and verbally-created system for processing numbers (Feigenson et al., 2013). Furthermore, the consistency of the results in the modified Give-N-tasks suggests that the participants managed to transfer their metaphorical number knowledge across testing scenes. Thus, the design follows contemporary views on cognition that see mathematical ideas and reasoning as “embodied” and “imaginative” (Niebert et al., 2012), suggesting the use of metaphors and imageries as powerful “thinking tools” (English, 2013). Hence, the examination emphasizes that the cardinal value is a linguistic surfacing manifestation of a deeply grounded spatial structured concept, and that the use of metaphors might merge these two domains in a complementary manner. In conclusion, the examination shows that authentic assessment during intervention and the adapted Give-N-tasks provides a fine-grained picture of the multiple dimensions that proficiency of the idea of cardinality reflects.

# Kindergarten children's argumentation in reflection symmetry: The role of semiotic means

Svanhild Breive

University of Agder, Norway; [svanhild.breive@uia.no](mailto:svanhild.breive@uia.no)

*In this paper I investigate the characteristics of children's argumentation when they work with reflection symmetry. Using Toulmin's (2003) model for substantial argumentation, I illuminate structural aspects of the ongoing argumentation. In addition, I analyse the children's argumentation with respect to their use of semiotic means. Results show that children are able to argue for a claim in a quite complex manner. The study also illustrates the extensive use of semiotic means in children's argumentation. In every element in the argumentative structure, children use gestures and other semiotic means to mediate their ideas. It is actually impossible to make sense of the ongoing argumentation without considering the use of semiotic means.*

**Keywords:** Argumentation, kindergarten, gestures, semiotic means.

## Introduction

How children communicate their mathematical ideas is an important aspect in the attempt to understand children's reasoning in mathematics. In kindergarten children experience mathematical concepts through play and interaction with others. In their communication they justify and explain their mathematical ideas and in return they need to consider other's ideas and arguments. Thus argumentation can be seen as important for fostering children's mathematical learning.

This study is situated within a research and development project called the Agder project<sup>i</sup> (AP). One of the aims in the project is to investigate how researcher designed mathematical activities, developed in the project, stimulate mathematical competences. In this case study I observed one kindergarten teacher (KT) and a group of six 5-year-old children engaged in mathematical activities about reflection symmetry. The aim of this paper is to examine the characteristics of children's argumentation when they work with reflection symmetry. Furthermore, I examine what role 'semiotic means' (e.g. objects, linguistic devices and signs) play in the ongoing argumentation.

Following Toulmin (2003) and Krummheuer (1995), I regard argumentation as the practical business of choosing statements that serve the purpose of making an initial assertion reasonable and accountable for others. Argumentation is the production of an argument. An argument is then "the final sequence of statements accepted by all participants" (Krummheuer, 1995, p. 247). In addition, several arguments can serve as units in an expanded argumentation which again constitutes a new and extended argument. Toulmin also recognises that single statements can contain argumentative features. Just by making a statement you put yourself in a position of potentially being questioned.

Argumentation, acknowledged as an important means for enabling young children's mathematical reasoning, can be promoted through a dialogic approach to teaching (Mercer & Sams, 2006; Yackel & Cobb, 1996). Despite the increased focus on the role of mathematical argumentation for enabling young children's mathematical reasoning, little research has focused explicit on the role and characteristics of mathematical argumentation at kindergarten level. Pontecorvo & Sterponi (2002) found that children's reasoning in preschool activity unfolded "through complex argumentative

patterns” (p. 133). They emphasised that teachers should pay attention to the different ways children argue in order to facilitate children’s “possibilities to practice, enrich and refine argumentative resources they have already acquired” (p. 139). Tsamir, Tirosh, and Levenson (2009) investigated different types of justification given by children between five and six years old, working with number and geometry tasks. Their study shows that young children are able to justify their statements by using appropriate mathematical ideas. Some children, in contrast, used their ‘visual reasoning’ as a way to justify their statements. When the researcher asked how they could know which bunch of bottle caps had more they answered “because we see”, and they felt no further need to justify their answer or did not know how to do it. Dovigo (2016) investigated how argumentation promoted collaboration and problem solving in preschool (age 3-5). By comparing different ways of how argumentation took place in teacher-talk and peer-talk they found that peer-talk contributed very positively for promoting collaboration and problem solving. But at the same time they emphasised that if the teachers were able to guide the debate in a careful and exploratory way the teacher guidance could be a positive contribution to the development of the argumentation.

## **Theoretical framework**

My theoretical stance is rooted in a sociocultural paradigm where interaction is regarded as the very engine of learning and development, (Vygotsky, 1978). As a consequence of adopting this theoretical stance, I regard argumentation as a cultural and historical activity. Children are not naturally born with the ability to argue. Argumentation is a communicative pattern which they learn through interaction with more knowledgeable others.

Interaction, specific for human beings, is characterised by the use of tools and especially by the use of language (Vygotsky, 1978). In recent years there has been a growing interest to study the interplay between gestures, language and thought both in mathematics education and in other domains. McNeill (2005) developed a theory where he regarded gestures as an integral part of language, not merely as a support for language. He regarded gestures as having an active and inseparable role in language and thought.

Not only gestures have been recognised as important for human reasoning. Radford, Edwards, and Arzarello (2009) talk about the importance of the multimodal nature of cognition; how different sensorial modalities – tactile, perceptual, kinesthetic become integral parts of our cognitive learning processes. Radford’s (2002; 2003) theory of knowledge objectification emphasises how gestures, bodily actions, artifacts, (mathematical) signs and speech in cooperation affect mathematical reasoning. A special category of semiotic means of objectification that Radford (2002) considers is deixis. Deictic terms are words that have the function “to point at something in the visual field of the speakers” (p. 17), and cannot be fully understood without additional contextual information (e.g. “here”, “there” “that”, “this” etc.). All semiotic means play a significant role in mathematical mediation and reasoning. “Each semiotic means of objectification puts forward a particular dimension of meaning (signification); the coordination of all these dimensions results in a complex composite meaning that is central in the process of objectification” (Roth & Radford, 2011, p. 78).

The concept of argumentation used in mathematics and mathematics education is often related to the production of proofs. It is nevertheless important not merely to connect the concept of argumentation to formal logic as found in mathematical proofs. Toulmin (2003) distinguishes

between analytic argumentation, which is used in production of mathematical proofs, and substantial argumentation which is informal argumentation used in everyday practices. Substantial argumentation does not necessarily have a strict logical structure. Substantial argumentation gradually supports a statement by presenting relationships, explanations, background information, etc. (Krummheuer, 1995). Toulmin (2003) strongly emphasises that substantial argumentation should not be regarded weaker as or less important than analytic argumentation.

Toulmin (2003) developed a model for analysing structural and functional aspects of substantial argumentation with the aim to illuminate how statements are organised for the purpose of constituting an argument, and how a conclusion is established through the production of an argument. In Toulmin's model the core of an argument is based on three elements: claim (C), data (D) and warrant (W). The claim is an initial statement, for example an assertion or an opinion about something. To support the claim, the arguer needs to produce data. Data are facts or statements on which the claim can be grounded. A warrant is a justification of the data with regard to the claim. The warrant holds the argument together. It points to the relation between the data and the claim.

In addition, Toulmin's (2003) model contains three other elements, backing (B), qualifier (Q) and rebuttal (R). A backing is a statement that supports the warrant. It is like a special case of data that is provided as evidence for the warrant. The purpose of a backing is to answer "why in general this warrant should be accepted as having authority" (Toulmin, 2003, p. 95). A qualifier says something about the extent to which the data confirm the claim. Words like 'probably', 'presumably' etc. are often used as qualifiers. Rebuttals refer to exceptions or conditions under which the claim is true, often used subsequent to a qualifier, exemplified as "The claim is true except/unless/only if ...".

## **Method for data collection and data analysis**

In this case study I observed one KT in the focus group of AP and his group of six 5-year-old children engaged in mathematical activities about reflection symmetry. The activities had been developed in the AP, and as part of an in-service program for the focus group the KTs were asked to implement a number of activities with their children. I visited the kindergarten on two occasions with a one week interval. It was the KT himself that decided to work with reflection symmetry activities on both occasions. The method for data collection was observations and the sessions were video recorded and field notes were made.

I regard argumentation as a sequence of statements (both verbal and non-verbal) that serve the purpose of supporting an initial claim. Thus one criterion for selecting episodes from the transcript was that they should contain verbal communication and have more than one utterance from the children. Another criterion was that the episodes I selected should contain mathematics, and they should be linked to the lesson aim (reflection symmetry). In total I found 11 episodes from the transcript using these criteria. Ten of these episodes had more or less an argumentative structure. Six of the episodes had more than two turns and more than two argumentative utterances from the children. These episodes were analysed in depth according to Toulmin's (2003) model to identify the argumentative structures. In addition, I analysed each of the six episodes from a multimodal perspective. In fact, I *had* to look at multimodal aspects in order to be able to differentiate between the elements in the argumentative structure. I did not focus on any specific semiotic means and their significance for children's reasoning. Rather I focused on what kind of semiotic means children

used with respect to the different elements in the argumentation, and what role they played in constituting the argument.

## Results

In this section I will present the analysis of one of the six episodes to illustrate the structure of children's argumentation, and what role semiotic means play in the ongoing argumentation.

In advance of this episode the children have been asked, by the KT, to find things in the room which they think are symmetric or as the KT says "equal on both sides". Each child is then asked to explain why they think the toy they have chosen is equal on both sides. In this particular episode one of the boys (John), who has chosen a trolley, is being asked to explain why he thinks the trolley is equal on both sides (or more precise; he is being asked if he think the trolley *is* equal on both sides).

- KT: Maybe we should start with John, since he has a very large thing. John, is this equal on two sides?
- John: Mmm (2)<sup>ii</sup> There (2) ((He lifts his trolley up from the table, and holds it in a straight forward position. Then he says "there" and nods his head)).
- John: and there... ((He rotates the trolley 90 degrees, showing the side of the trolley and then nods his head while saying "there")).
- KT: Aha!
- John: and (2) there. ((He rotates the trolley 180 degrees, showing the other side of the trolley and nods his head again while saying "there")).
- Elias: And there and there. ((Elias has already paid attention to the situation)).
- KT: Can you see if this is equal Elias?
- Elias: Look...
- Elias: There, there (.) there, there (.) there, there and there, there. (.) And there and there, and (1) everywhere. ((He is pointing with his index finger to show where he thinks the trolley is equal. When he says "everywhere" he is letting his whole hand swipe over the trolley)).
- KT: ((The KT lifts up the trolley and tries to show the symmetry line and explaining how the trolley is equal on both sides of that line)).
- Elias: Everything is equal on both sides, even the wheels.

### The structure of children's argumentation

Before this episode each child was asked by the KT to choose a thing that they thought was equal on both (two) sides. In this episode John has picked a trolley and just by doing so he has implicitly made the claim that the trolley is equal on both (two) sides. When the KT asks John; "John, is this equal on two sides?" John's claim is being challenged. The KT actually asks a yes-no question, but the question is still a quest for explanation or justification.

To argue for his claim, John lifts the trolley up in the air, like he wants to make it visible to the others. The first "there" and the first nod is also a part of this visualization which together constitute

the *data* he presents. It is important to notice that at this moment he holds the trolley in a straight forward position from his own point of view. He is not referring to any particular equal points on the trolley. The trolley itself is being presented as the data that supports the claim.

Then he is trying to present a *warrant* for his data by rotating the trolley 90 degrees while saying “there” and then back again 180 degrees while saying “there” again. Each time he is saying “there” he is nodding his head. John is presenting the warrant as two particular sides that are equal, and exemplifies the equality. The warrant (the example) relates the data (the presentation of the whole trolley) to the claim (the trolley is equal on two sides). Considering the time John is using while presenting the warrant and the way he utters the second and third “there”, John does not seem very confident in his presentation of the warrant. Nevertheless, when John was walking around in the kindergarten trying to find a thing that had two equal sides, he considered the trolley for some seconds before he took it back to the table. This indicates that his choice was not completely random. John seems certain that the trolley is equal, but he is not quite certain how to justify it.

After John has presented the second “there”, the KT utters “aha” (with a rising intonation at the end). By this utterance the KT gently appreciates John’s contribution, even if the two sides that John presented thus far were not equal. While presenting his data and his warrant, John waits several seconds, and it seems that the KT thinks that John has finished his explanation after the second “there”. From the children’s point of view, the KT’s “aha” gives John’s contribution authority and can be regarded as a backing of John’s warrant-attempt. But from the KT’s point of view, the “aha” was not meant as a backing, only as a gentle appreciation of his contribution.

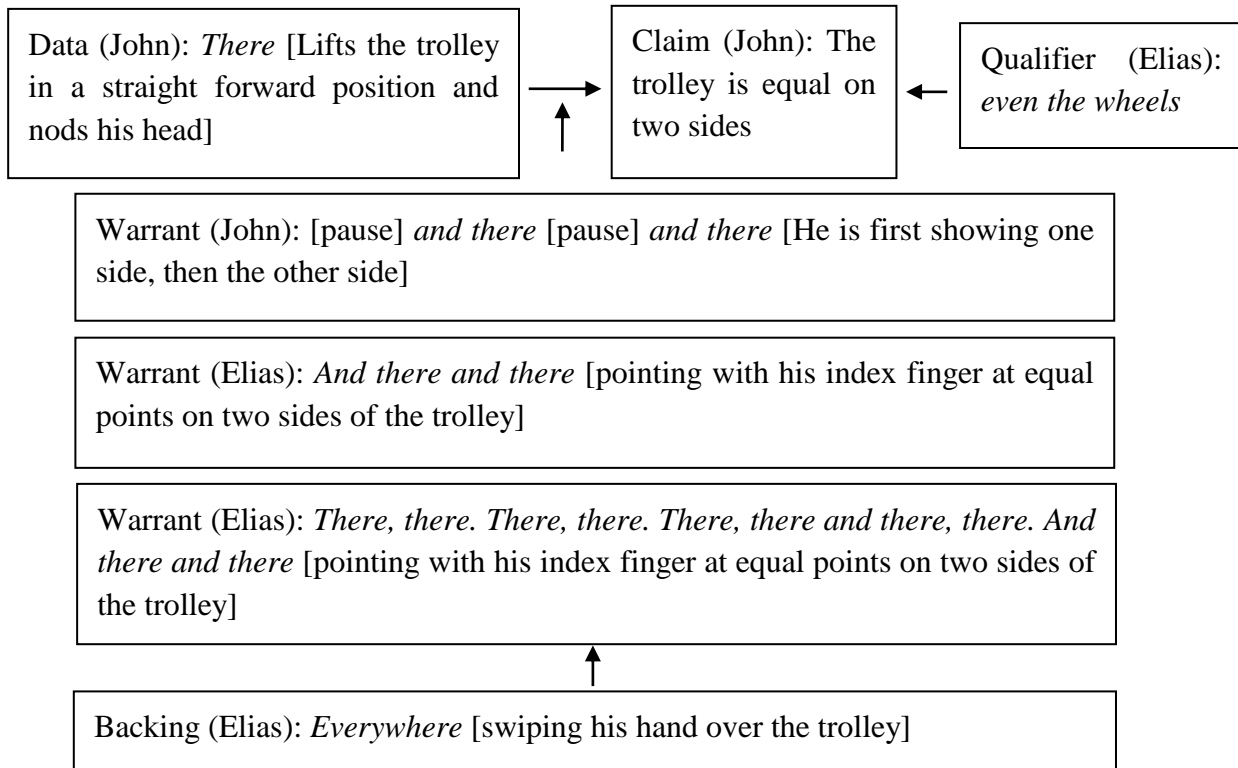

Elias then contributes to the argumentation. By the utterance “and there and there” and a pointing gesture he is presenting another warrant for John’s data. Elias is talking faster and more concisely than John. Because he is using his index finger rather than nodding he is also more precise in his communication and is able to point on specific points on the trolley, like the joints and the handles. The way Elias communicates indicates that he is more confident and has more knowledge about reflection symmetry. Elias is actually presenting several warrants for the data. Every time he says “there and there” and points at different corresponding points, he gives a new warrant. By presenting particular corresponding points, each warrant is exemplifying exactly where the trolley is equal. By repeating several almost identical warrants (presenting several examples) it seems that he is trying to communicate that *every* point on one side has a corresponding point on the other side.

After presenting several warrants Elias says “everywhere” while he is swiping his whole hand over the trolley. I interpret this as a generalisation of his previous statements (warrants), and thus a backing for the warrants because it answers “why in general this warrant should be accepted as having authority” (Toulmin, 2003, p. 95). The warrants are not independent examples of equality rather examples of a more general property of reflection symmetry.

When the KT shifts his attention to Elias in the middle of this episode, Elias answers by saying “look”. The intonation of the utterance indicates that he is only introducing his coming explanation. I interpret his utterance as synonymous to “let me explain”.

At the end of this episode, Elias says “everything is equal on both sides, even the wheels”. The use of the word “even” in this sentence is very interesting. The word “even” I interpret as a qualifier for the claim. It says something about to what degree the data confirm the claim. Usually words like

“probably” or “presumably” are used as qualifiers, but in this case Elias is indicating that he is *very* certain that everything is equal on both sides, by saying “even the wheels”. It seems that the probability for everything being equal increases since ‘the critical points’, the wheels, are equal. Why Elias regards the wheels as important points is hard to tell.

**Figure 1: The structure of children's argumentation**

This example illustrates the complexity of children's argumentation. They are able to present more than only the core of an argument. In this episode I found that some children are able to present both data, warrant, backing and even qualifier for a claim. In another episode that is not provided in this paper (because of the limited space) Elias was also able to present a rebuttal. He was able to modify his claim by giving examples of exceptions.

## Discussion

This study shows that young children are able to argue for a claim in a quite complex manner. Using Toulmin's (2003) model to illuminate structural aspects of the children's argumentation, the results show that some children are able to use several of the elements in the model in their argumentation.

This study also illustrates the extensive use of semiotic means in children's argumentation. In every element in the argumentative structure, children use gestures and other semiotic means to mediate their ideas. This illuminates the significant role that gestures and other semiotic means play in children's communication and especially in their argumentation. (cf. McNeill, 2005; Radford, 2002; 2003; Roth and Radford, 2011). Deixis, in particular, are extensively used in the argumentation above. Both the data that John presents and the warrants that John and Elias present are based on the deixis “there” and the related pointing and nodding gestures. Even if John and Elias use different signs for mediating their ideas, both the nodding and the pointing gestures serve the same purpose,

namely to give contextual information to the deixis “there”. It is actually not possible to get the whole meaning of the words “there and there” without including the pointing and nodding gestures.

The deixis and the related pointing and nodding gestures are not the only significant semiotic means in this argumentation. To be able to distinguish between the data and the warrant that John provides I had to interpret his related actions. When he presents the data he holds the trolley in a straight forward position, he is not referring to any particular equal points, only presenting the trolley as a whole, as if he wants to show the equality. The way he presents his claim corresponds with one of the findings in Tsamir, Tirosh and Levensons (2009), that some children based their justification on ‘visual reasoning’. The trolley itself is being presented as the fact that supports the claim. In the warrant he is presenting two corresponding sides, as if he wants to give an example of the equality. Without interpreting these actions, it is impossible to distinguish between the data and the warrant, and thus fully understand the structural aspects of the ongoing argumentation.

The repetitive presentation of Elias’ warrants and the swiping hand that generalises the repetitive warrants are other important semiotic means in the argumentation. By repeating “there and there” with corresponding pointing gestures Elias indicates that *every* point has a corresponding point on the other side of the symmetry line. When Elias says “everywhere”, he swipes his hand over the trolley. This swiping gesture plays a significant role in the generalisation process of the points.

The results from this study point to significant features of children’s argumentation and give important insights into *how* children argue. I think teachers could benefit from paying attention to the different ways children argue and being aware of the structural aspects in children’s argumentation in order to provide opportunities for improving children’s mathematical communication and reasoning (cf. Dovigo, 2016; Pontecorvo and Sterponi, 2002). But to be able to do so, the KT’s also need to pay attention to how children make use of semiotic means in their argumentation. The Toulmin model revealed structural aspects of children’s argumentation, but these structural aspects would not have emerged without considering the use of semiotic means. In line with Roth and Radford (2011) I would argue that all the different semiotic means play a significant role in the constitution of meaning.

In the example above we saw that Elias was able to use several elements in the model and demonstrated more confidence in his argumentation than John. A possible explanation could be that Elias is further in his appropriation of the properties of reflection symmetry than John. Maybe there is a correspondence between how far children have appropriated a certain subject and their ability to use several elements in the Toulmin model. This is thus a suggestion for further research on this interesting topic.

*The Making Numbers research Project, funded by the Nuffield Foundation, has developed guidance for teachers of 3 to 9 year olds on the use of manipulatives in the teaching of arithmetic. The project, which consisted of a literature review, survey of teacher use and small-scale teaching investigations, identified key principles and issues for the use of manipulatives. This paper gives a brief overview of project findings, which are reported elsewhere, and discusses issues relating to the early years from the literature review.*

*Keywords: Early childhood mathematics, finger counting, patterns, representations, manipulatives.*

## Background to the project

Making Numbers is a Nuffield Foundation funded project to develop research-informed guidance for teachers of three to nine year olds on the use of manipulatives to teach arithmetic. The project has run for two years and includes a literature review, a survey of current practice and the development of exemplars of good practice through observation and small-scale teaching investigations. The resulting guidance has been published as a fully illustrated book for teachers with accompanying animations for use with children (Griffiths, Back, & Gifford, 2016). The findings of the project are reported in full elsewhere (Griffiths, Back, & Gifford, in press): this paper gives a brief overview, highlights some issues concerning the use of manipulatives with young children and exemplifies key pedagogical principles.

Our definition of manipulatives is “objects that can be handled and moved and are used to develop learners’ understanding of a mathematical situation” (Gifford, Back, & Griffiths, 2015, p.1). This includes the use of everyday and structured materials, characterized by a pedagogical intention, which concurs with recent studies (Swan & Marshall, 2010; Carbonneau, Marley, & Selig, 2013). The project focus was on number sense, prioritizing for this age range counting, cardinality, comparison and composition of numbers. Hence the project title, ‘Making numbers’, emphasises flexibly decomposing and recomposing numbers, which was identified by Boaler (2009) as key to mathematical achievement.

From the survey and interviews with teacher groups, we found that manipulatives were mainly used in the early years and with older low achievers (Gifford et al., 2015). The most common were counters, interlocking cubes and Numicon 10-frame based number plates (Wing, 2001), followed by place value apparatus. Teachers’ choice was influenced by commercial availability and past government policy, but for some it was serendipitous. Most expressed a lack of confidence about how to use manipulatives to teach different aspects of number.

The methodological approach of the literature review was to consider studies and theories from a range of perspectives, in order to gain insights into factors affecting children’s learning. Sources included the history of pedagogy, cognitive and social constructivist theories of learning and quantitative and qualitative empirical studies. We found that experimental studies were contradictory

and inconclusive, identifying only crude factors, such as length of the study or the amount of instructional guidance, as shown by Carbonneau et al.'s (2013) meta-study.

The conclusion was that the effective use of manipulatives depended on some key pedagogical principles (Gifford et al., 2015). These included:

- the careful matching of both manipulatives and activities to the mathematical focus
- the identification and assessment of children's prerequisite understanding
- activities involving comparison, equivalence, analysis and generalisation
- discussion, requiring children to use manipulatives to justify reasoning
- linking manipulatives to abstract symbols
- creating an inclusive mathematics learning community.

Here we identify some issues from the literature review about teachers' use of manipulatives with young children. These concern fingers as manipulatives, discrete and continuous models for number and the learning potential of pattern activities. The pedagogical principles above are exemplified in a small case study from a teaching investigation.

### **Fingers as manipulatives**

The benefits of drawing from a range of perspectives are evident in the consideration of fingers as manipulatives, which are of particular relevance to teachers of young children. Their significance has been underlined by neurological research: brain areas representing fingers and numbers are closely related, according to Wood and Fischer (2008). Young children use mental finger representations for numbers more than adults, suggesting that finger use is significant for the development of number understanding. Gracia-Bafalluy and Noel (2008) found that young children's finger awareness was predictive of their mathematical competence and that training in distinguishing fingers resulted in improvements in subitising, counting and comparing numbers. However, the way that fingers are used for counting varies in different cultures, including counting three to a finger, or counting hands as fives. Bender and Beller (2012) argued that the resulting number concepts also vary according to different languages, some of which support 10s structures more transparently. Jordan (2003) also found that children from low-income families tended not to use fingers to solve problems. This suggests that home practices differentially support children's number understanding and need to be taken into account by teachers.

How should children be taught to use fingers? Sarama and Clements (2009) advised teachers not to discourage children from using fingers until they were confident with mental strategies, in order to prevent reliance on finger counting. Marton and Neuman (1990), using a phenomenological approach, found that older higher attainers, who used recall and derived facts, showed numbers of fingers 'all-at-once', whereas low attainers continued to rely on using fingers to count on and back. 'Finger numbers' encouraged children to analyse numbers, developing subitised images and part-whole number understanding. This model therefore represents key number concepts more effectively. Sinclair and Pimm (2015) reported that using the app 'Touchcounts' rapidly resulted in three year olds showing 'all-at-once' finger numbers. This seems an important skill which young children might also learn in other ways, for instance, when singing number rhymes.

## Discrete and continuous models of number

One current issue relating to young children is about the relative merits of discrete and continuous models of number, for instance using either counters or colour rods which represent numbers as lengths. Usually in England numbers are introduced by counting separate items. However, when children are later introduced to number lines, numbers are represented by intervals on a continuous line and children often count the numerals or marks, rather than the intervals between them. Sarama & Clements (2009, p. 119) recommended caution in using the number line “as a representation for beginning arithmetic”, raising the issue of when and how to introduce it. However, neuroscientific evidence suggests that people intuitively see some kind of mental number line (Wood & Fischer, 2015). This supports renewed interest in teaching young children about number based on measuring lengths, as proposed by Bass (2015) following the approach of Davydov (1975). Bass pointed out that number “arises from measuring one quantity by another, taken to be the ‘unit’” (2015, p. 100). He argued that introducing numbers as chosen units for measuring quantities provides a more coherent model of numbers which can also include fractions. It supports multiplicative and proportional reasoning and early understanding of algebraic principles such as inverse and commutativity. This argument also supports the use of colour rods.

Fuson (2009) argued that number paths or tracks are more comprehensible for young children, as they present adjacent squares which are more obviously countable than intervals on a line. Laski & Siegler (2014) found that children who regularly played number track games, reading the numbers aloud as they counted moves, improved their awareness of number magnitude and arithmetical achievement. It has subsequently been argued that children’s engagement with ordinal number has been overlooked as a means of developing understanding. Sarama & Clements (2009, p. 93) suggested that children were linking the distance model with counting moves and numbers spoken:

connections between the numerical magnitudes and all the visual-spatial, kinaesthetic, auditory and temporal cues in the games (i.e., all the magnitudes increase together: numerals, distance moved, number of moves, number of counting words etc.) may provide a rich mental model for a mental number line.

It therefore seems that we may underestimate children’s capabilities to combine the various models to construct complex networks of numerical understanding. According to Clements and Sarama (2009), four year olds may be in the process of developing a mental number line connecting different ‘quantification schemes’, including discrete number ideas based on subitising and counting with continuous ideas about duration and length.

Some manipulatives have attempted to integrate discrete and continuous models of number. For instance, bead strings present countable beads, usually coloured in groups of five or 10, along a line: Beishuizen (2010) reported that teaching children to find a number on a bead string and then on a number line helped them to develop mental calculation. Some older apparatus, such as Montessori’s numeric rods and the Stern counting board, present rods arranged as ‘staircases’ of discrete cardinal numbers, with numerals alongside. These afford a clear image of the value of numerals in sequence increasing by one, but are not common in schools, having been replaced by rods made of interlocking cubes. An approach we have developed is to use centimetre cubes alongside a ruler: this has the advantage of providing countable objects, while demonstrating that the individual items counted are

in the intervals between the numerals. This not only shows the numbers increasing by one and but also that each successive number includes all previous ones, the idea of hierarchical inclusion or ‘nested numbers’ (Clements & Sarama, 2009, p. 20). Combining both models also provides opportunities for children to discuss what is the same and what is different, as advocated by Harries, Barmby and Suggate (2008). This is an area where teachers need to be aware of the complexities involved in the differences between continuous and discrete models and further investigation is needed of how children reconcile these.

## **The potential of pattern**

There is a range of possible factors affecting young children’s understanding of manipulatives used to represent number relations. From Piagetian theory young children are seen as needing sensory experiences in order to learn, and from Vygotskian theory as being able to use symbols, such as fingers, from an early age. Recent theories suggest differences in young children’s spontaneous and intuitive appreciation of number and pattern. Hannula and Lehtinen (2005) found that some very young children displayed a tendency to spontaneously focus on numerical features of a situation (SFON), while others did not, and this predicted later achievement. Mulligan and Mitchelmore (2009) found that children varied considerably in their awareness of mathematical pattern and structure (AMPS) and that this was also linked to mathematical achievement. They identified different stages of AMPS: some children focused on non-mathematical surface features of patterns, some children noticed one or two mathematical elements in a pattern and others could reproduce and continue patterns, by identifying the components and relationships. Mulligan and Mitchelmore also found that pattern awareness could be taught to young children, suggesting that this facility is learned from experience: Papic, Mulligan and Mitchelmore (2011) reported a successful intervention with four year olds, which improved awareness of pattern and mathematical structures. This presents a potentially powerful approach, both in building on young children’s strengths with visuo-spatial memory and in developing pre-algebraic understanding.

## **Staircase patterns**

One of our teaching investigations, into the learning of numbers to 20 with a class of 30 six year old children, exemplified the importance of pattern awareness as well as some of the key principles identified in the literature review. In a series of small group teaching sessions, we aimed to teach children about the numbers from 10 to 20, sometimes referred to as the ‘teen numbers’ (Gifford & Thouless, 2016). We used a ‘staircase’ pattern of ‘teen numbers’ made of rods of interlocking cubes arranged in number order. The rods for one to 10 were of different colours, with the rod for ten consisting of a stick of green cubes; the rods for 11 to 19 then had 10 green cubes with the rods for numbers 1 to 9 attached, repeating the same colour sequence. Numerals were presented alongside the rods 1 to 9. We invited the children to find a single rod, such as 18. We found that children used a variety of strategies to do this: most picked a rod at random and counted the cubes from one. Magda counted in ones along the 20 rod and then along the 18 rod and explained “I knew one less would be 19 and one less would be 18”. Only one child identified rods by counting on from ten. Some children made errors in counting, either in the word sequence, or in matching words to cubes when pointing.

This activity demonstrated the pedagogical principle of carefully selecting manipulatives to match mathematical concepts and showed how this affected the accessibility of those concepts. We wanted

the children to recognize the sticks as representing the teen numbers as composed of ten and another number, but it was not easy to see there were ten green cubes and recognize the ‘ten’, unlike with Numicon plates which children had previously identified as ‘ten’. However, the staircase arrangement enabled some children to recognize the ‘one more than’ pattern, which would not have been so evident with Numicon. When trying to find the ‘thirteen’ rod, six year Lucasz, who was not yet fluent in English, said, ‘because after 2, 3. Because it’s like ten, 1, 2, 3.’ In doing this he made a sweeping gesture across the 11, 12 and 13 rods, then across to rods 1, 2 and 3. Later, Magda, whose home language was Czech and who was more fluent in English, said, ‘It’s a bit like counting up stairs. Like counting 1, 2, 3 but 11, 12, 13.’ The children thereby implicitly identified two types of pattern, a repeating units pattern and the stair pattern of equal intervals of one, which is the most basic arithmetic sequence. This was evidence of early algebraic thinking, in that they noticed mathematical features, identified the relationship between elements and observed regularities (Blanton et al., 2015, cited by Kieran, Pang, Schifter, & Ng, 2016).

This activity thereby also demonstrated the principle of prompting analysis, by simply asking children to say how they identified a number. In our teaching investigations we have been impressed by the way patterns can fascinate children. On one occasion, when children were rushing by our table outside a classroom on their way to lunch, two six year old boys halted in their tracks in order to gaze at the staircase pattern and one child sat down to join us. We found that patterns like these engaged a range of children, who had differing expertise with numbers, in solving problems and noticing relationships. While some children may have had high levels of AMPS (Mulligan and Mitchelmore, 2009), the striking pattern made with manipulatives helped all children to focus on number relationships. Presenting number patterns in this way contrasts with other approaches which advocate that early years mathematics pedagogy should be based on realistic “context situations” (van den Heuvel-Panhuizen, 2008, p. 20).

The activity also prompted discussion, stimulating both Lucasz and Magda to express themselves creatively using language and gesture, as shown above, making connections and elaborating ideas. Lucasz may have been an example of a child using gesture to express emergent mathematics learning, as described by Garber, Alibali and Goldin-Meadow (1998) or he may have already been familiar with this pattern and been able to articulate it in Polish: we do not know. However, this showed that a lack of fluency did not prevent a child in the early stages of learning a language from trying to express a mathematical relationship, and also the importance of gesture in supporting mathematical discussion between children who are not using their home languages. The manipulatives pattern thereby supported the linking of different modes of representation, not only verbal and visual, but also kinaesthetic and, through the use of numeral cards, abstract symbols.

This activity also exemplified the need to identify and assess prerequisite understanding. Some children could not reliably count objects to 20, despite having been assessed as doing this the previous year. Most of the children counted from one instead of counting on from 10, even when it was pointed out to them that there were always 10 green cubes. This may have been because they lacked skills of counting on or were not yet able to unitise ten as an item. As Cobb (1995) pointed out, if children do not have a concept of ‘a ten’ they will not be able to ‘see’ it even when demonstrated. Similarly, some children could add 10 and 3 and instantly say “13”, but seemed not to understand the inverse relationship sufficiently to apply this to decomposing 13 into 10 and 3 and did not use this knowledge

to identify 13 as 10 and 3. Therefore some children may have lacked the prerequisite understanding and skills to access what the manipulatives were intended to represent.

The final principle shown by this example, is that of an inclusive learning community. The children were not in ‘ability’ groups, as is common in English early years classrooms, in which case Lucasz and Magda would not have been in the same group. We do not know if Magda would have articulated the pattern in this way, if she had not first listened to Lucasz, who was able to hear his idea expressed differently. Latoya, in her second session, identified the 15 rod by counting on from 10, saying, ‘10, 11, 12, 13, 14, 15’; this was a skill she had not used previously but had observed another child using in the previous session. Both the lack of grouping and the open activity, allowing for a range of solution strategies, facilitated children in learning from others.

In our study we also observed successful practice, particularly with colour rods, which similarly showed children engaged by patterns and stimulated to discuss mathematical relationships. These experiences imply that developing children’s focus on patterns is a promising avenue for mathematical pedagogy in the early years.

## Implications

The issues discussed here suggest some potentially profitable avenues for future research with mathematical manipulatives and young children and some implications for practice. Firstly, we might build on home practices in finger counting and develop young children’s use of ‘all at once’ finger numbers. We also might investigate how children reconcile differences between discrete and continuous models of number, through comparing and discussing representations. These issues highlight the need to consider carefully exactly how manipulatives might foster learning of particular aspects of mathematics. There are promising avenues for early years mathematics pedagogy in using manipulatives to build on children’s interest in patterns and to develop children’s own expressions of mathematical relationships. However, an important prerequisite for all of these is a focus on children’s understanding of mathematical relationships rather than on performing calculations, as suggested by Ma (2015), which also has implications for early years mathematics curricula.

## Acknowledgements

Helen Thouless was our co- researcher in the classroom-based research described here. The *Making Numbers* Project is based on ‘Using manipulatives in the foundations of arithmetic’, a Nuffield Foundation funded research and development project.

# A kindergarten teacher's revealed knowledge in orchestration of mathematical activities

Per Sigurd Hundeland, Ingvald Erfjord and Martin Carlsen

University of Agder, Norway; [per.s.hundeland@uia.no](mailto:per.s.hundeland@uia.no), [ingvald.erfjord@uia.no](mailto:ingvald.erfjord@uia.no),  
[martin.carlsen@uia.no](mailto:martin.carlsen@uia.no)

*The aim of this study is to employ the Knowledge Quartet, proposed by Rowland, Huckstep, and Thwaites (2005), in order to characterise the kindergarten teacher's competence when orchestrating researcher designed mathematical activities for 5-year-olds. We are drawing on design research as a methodology in which design principles such as playful learning and inquiry are implemented in the activities. Our analyses show that knowledge-in-action and knowledge-in-interaction are revealed in the orchestration. Hence, the Knowledge Quartet is applicable in the kindergarten context – however, with some modifications due to kindergarten particularities.*

*Keywords: Design research, kindergarten, Knowledge Quartet, mathematics, orchestration.*

## Introduction

For about a decade, mathematics has been part of the Norwegian curriculum for kindergarten, a curriculum situated within a social pedagogy tradition. In a kindergarten setting in Norway, a kindergarten teacher (KT) is supposed to empower the children's mathematical explorations. However, the curriculum is not explicit as regards how KT's are to facilitate the children's mathematical explorations. In this study we characterise one KT's orchestration of mathematical activities for 5-year-olds in terms of knowledge employed by the KT. The following research questions are formulated for the study:

In what ways may the Knowledge Quartet be employed in order to characterise the kindergarten teacher's competence?

What knowledge-in-action and knowledge-in-interaction does a kindergarten teacher reveal in her orchestration of a mathematical activity on geometrical shapes?

The activities were designed by researchers in mathematics education (the authors of this paper among others), as part of an ongoing research and development project called "The Agder project"<sup>i</sup>, in order for the participating children to engage with mathematical concepts and ideas.

In this study we use the metaphor of orchestration. By this metaphor we mean that it is the KT who is in charge of and leads the mathematical activity. She has to plan, think forward, act in the moment, follow up children's questions and comments, adapt questions for each of the children, etc. – an important and by no means easy role to fulfil. Our admiration of this complexity is thus considerable when we set out to design the mathematical activities and study how the KT's orchestrate the activities.

## Theoretical lens: The Knowledge Quartet

In order to analyse in depth how the Knowledge Quartet may be employed in order to characterise the kindergarten teacher's competence and the revealed knowledge-in-action and knowledge-in-interaction on behalf of the KT, we draw heavily on the Knowledge Quartet coined by Rowland,

Huckstep and Thwaites (2005). The Knowledge Quartet was developed by Rowland et al. (2005) as a theoretical construct drawing on the profound and substantial work of Shulman (1986). Rowland and colleagues drew on videotapes from mathematics classroom lessons where pre-service teachers utilised their mathematical and pedagogical knowledge in their teaching. This quartet is used as a theoretical lens through which we analyse video data of one KT's orchestration of one of the developed activities. We limit ourselves to one KT taking into account that "the quartet is comprehensive as a tool for thinking about the ways that subject knowledge comes into play in the classroom" (Rowland, Huckstep, & Thwaites, 2003, p. 97).

The Knowledge Quartet differs from the framework of Ball, Thames and Phelps (2008), mathematical knowledge for teaching (MKT), in that the former focuses on situations in the mathematics classroom through which the teacher's mathematics-related knowledge may be observed. Ball et al.'s (2008) framework describes different kinds of mathematics teachers' knowledge. Mosvold, Bjuland, Fauskanger, and Jacobsen (2011) used the framework of Ball et al. (2008) to analyse mathematics teaching at the kindergarten level. Mosvold et al. (2011) found that the MKT framework needs to be adjusted to the kindergarten context in order to be appropriately used. This is because (1) the work situation of orchestrating mathematical activities for a Norwegian kindergarten teacher is very different from the teaching situation of a U.S. mathematics school teacher; and (2) the tasks of teaching in the kindergarten setting are significantly different from that of the school setting. It is pedagogical activities which is the basis for learning activities in Norwegian kindergartens, not mathematical activities as such. These differences have been emphasised by Erfjord, Hundeland, and Carlsen (2012), through the lens of the didactic triangle.

In adopting a grounded approach to the analyses of data, Rowland et al. (2005) identified what they labelled the Knowledge Quartet, four dimensions along which mathematics teachers' "mathematics-related knowledge" (p. 255) may be analysed. These four dimensions are termed *foundation*, *transformation*, *connection* and *contingency*. Foundation encompasses the knowledge background of the KT; transformation and connection encompass how and to what extent knowledge is revealed in action as the KT implements and orchestrates the activity, hence dimensions described as knowledge-in-action. Contingency encompasses the KT's knowledge as this unfolds in interaction with the children, hence knowledge-in-interaction.

Foundation is a dimension of *propositional knowledge* used, adapted to our case, to address the KT's mathematical knowledge, the KT's knowledge of mathematics education, and the KT's view upon the purpose of mathematics education and how children learn mathematics. Analytically, we use this dimension to characterise both the mathematics and the didactical insights revealed by the KT in her orchestration of the activity.

Transformation is a dimension of *knowledge-in-action* which addresses the KT's choices of representations, demonstrations, and use of examples in her orchestration of the activity. The dimension focuses on the KT's ability to transform the mathematics "in ways designed to enable students to learn it" (Rowland et al., 2005, p. 265). Analytically, we use this dimension to describe the KT's orchestration of the activity on characterising two-dimensional geometrical shapes.

Connection is a dimension of *knowledge-in-action* as well, addressing to what extent the KT draws connections between various mathematics concepts and connections between various mathematics

procedures, alternative meanings for these concepts and different ways of carrying out procedures. Analytically, we use this dimension to characterise how the KT makes connections between the geometrical shapes and their features, as well as various ways of deciding what shape is what.

Contingency is a dimension of *knowledge-in-interaction*, a dimension that addresses how the KT interacts with the children through appropriately responding to children's contributions, to what extent she takes advantage of learning opportunities that emerge, and to what extent she makes the activity her own and deviates from the goals and foci of the activity. Analytically, we use this dimension to characterise how the KT responds to the children's ideas, the questions and comments she uses, whether she draws the children's attention towards particular mathematical ideas, and whether she makes the geometry activity her own and are unbounded by its original foci.

## **Design principles and context**

In our design of the mathematical activities we drew on two main principles, *playful learning* and *inquiry approach* to the teaching and learning of mathematics. The design principle of playful learning emphasises that for children play and learning is one and the same thing. Playful learning encompasses both free play (child-initiated and child-directed play) and guided play (adult-initiated and child-directed play), where guided play is the principle used here. In guided play the KT orchestrates and literally guides the play in an adequate direction in order to reach pre-formulated aims for the children's play and to nurture the children's interest, curiosity, engagement, and (mathematical) sense-making (Weisberg, Kittredge, Hirsh-Pasek, Golinkoff, & Klahr, 2015). The design principle of adopting an inquiry approach to the teaching and learning of mathematics stems from Jaworski's (2005) inquiry as "a way of being in practice" (p. 103). That is, the KT and the children collaborate in order to achieve meaningful answers to prompts and questions, the children's curiosity is taken advantage of, and the children are guided into mathematical inquiries through the use of questions, being curious and excited about mathematical issues.

The KT that takes part in our study is a participant in the Agder Project, and by that also a participant in a professional development program. The professional development program within this project was based on four workshops of two days duration, focusing on Number, Measurement, Geometry and Statistics, combinatory and probability. In the third workshop, the KTs participated in lectures and group discussions on Geometry. Our data collection took place during the period when the KTs tried out two geometry activities. The observed KT is in her forties, educated for three years (180 ECTS) at university level, and is a well experienced kindergarten teacher.

## **Context**

We as researchers are interested in scrutinising the KTs' processes of orchestrating our designed mathematical activities. Moreover, the KTs have been participants in a professional development program where we have contributed with lectures and feedback on previous orchestrations of mathematical activities. We study the case of Wilma and videotaped her orchestration of a geometry activity. Wilma had received a written instruction note for the geometry activity a couple of weeks in advance of our data collection.

## Analysis and results

In order to employ the Knowledge Quartet (KQ) on empirical data, one has to go into the code level from which the four dimensions are extracted (Rowland, 2016, personal communication). Our analytical process started with a first phase of collectively reflecting on our collected data in total, consisting of two days with data collection in each of four different kindergartens. In doing that, we had the KQ in mind, seeking to use KQ terminology and codes to analyse our data. The second phase consisted of us collectively looking at video excerpts from the different kindergartens, resulting in our choice of the case of Wilma. The reason for choosing one of the sessions of Wilma was that this session, from our collective looking at the video, turned out to be the most promising in addressing our research questions. The KT observably revealed her knowledge in action and interaction, the children contributed with oral statements and questions, and interaction amongst the children was taking place. The third analytical phase consisted of transcribing the video from Wilma's session. The fourth phase consisted of us conducting collective in-depth analyses of the natural talk-in-interaction adopting the codes developed in the Knowledge Quartet.

The activities were presented in written form by us with the three headings *Equipment*, *Intention*, and *Implementation*. The particular activity we consider here, is the first part of an activity focusing on two-dimensional geometrical shapes. Under *Equipment* we wrote: Geometrical shapes: triangles, squares, rectangles, circles, trapezium, rhombus, while for *Intention* we wrote: The children are supposed to get experience in recognizing properties of different two-dimensional shapes. Furthermore, the children are supposed to practice mathematical argumentation with respect to features of the various shapes. As regards *Implementation*, we wrote: Let the children investigate the shapes and their characteristics. Let the children discover the shapes' differences.

### Excerpt 1: Foundation

The following excerpts are taken from the initial phase of Wilma's orchestration of the geometry activity. Wilma shows and shakes a box containing two-dimensional paper shapes. One of the children responds that "It's shapes". Upon this, Wilma continues their conversation. The analytical contributory codes are: "awareness of purpose; identifying errors; overt subject knowledge; theoretical underpinning of pedagogy; use of terminology; use of textbook; reliance on procedures" (Rowland et al., 2005, p. 265).

- Wilma: Yes, that's correct. And with mathematical terminology we call them geometrical shapes. Are you able to pronounce that?
- Sam: I think it is cookies (Smiles as he says it).
- Wilma: John, are you able to pronounce that? Geometrical shapes?
- John: Geometrical shapes. (Several children simultaneously say "Geometrical shapes")
- Wilma: Yes, that is what they are called with mathematical terminology. Inside this box there are several of such shapes (She opens the box and shows it to all the children so that they may look inside the box).
- John: It looks like a puzzle.
- Wilma: Yes, it looks like a puzzle. That's true.

- Sam: Yes. Are we going to puzzle with them?
- Wilma: At least we are going to work with them, yes we are.
- Ken: Can you pour them out?
- Wilma: I was thinking of pouring them out. Then I want you to take a look at them. Currently, there are quite a few shapes and some of them are almost identical. Now you may take a look at them. (She pours the shapes out on the table; the children take some shapes each and say “that is small” and “a triangle”.)

In this excerpt we argue that Wilma’s orchestration is characterised by her foundation, both with respect to mathematics insights and didactical insights. The mathematical insights are revealed through Wilma’s emphasis on the mathematical terminology through the twice expressed term “geometrical shapes”. Furthermore, her mathematical insights are revealed through her choice of shapes that are congruent, shapes that are similar, and the variety of shapes included (various triangles, various quadrilaterals, circles of various sizes, ellipses, hexagons and octagons). The written material made by us suggested “triangles, squares, rectangles, circles, trapezium, rhombus” as shapes to work on in the activity while Wilma introduced many more shapes and terminology. Thus, we argue that the foundation here is Wilma’s and not just her use of external provided foundation from us in the written form.

The didactical insights of Wilma are revealed through her way of establishing interest and curiosity among the children by shaking the box. The children’s interest and curiosity about the shapes are nurtured further by her showing of the various shapes in the box. Wilma confirms that the shapes look like pieces of a puzzle and by that she makes a link between these shapes and the apparently well-known activity of puzzling. By establishing that link, Wilma also communicates a playful way of engaging with the shapes. Finally, in this excerpt, Wilma’s didactical insights are revealed when she asks the children to inquire into the various shapes. By orchestrating the activity as playful, Wilma signals that she appreciates inquiry as a tool in order to learn mathematics. Additionally, the children’s interest, curiosity, engagement, and mathematical sense-making are nurtured.

### **Excerpt 2: Transformation and Connection**

Approximately ten minutes later, the following dialogue occurred, exemplifying the dimensions of transformation and connection. Relative to transformation, the analytical codes are: “choice of representation; teacher demonstration; choice of examples” (Rowland et al., 2005, p. 265). Relative to connection, the analytical codes are: “making connections between procedures; making connections between concepts; anticipation of complexity” (Rowland et al., 2005, p. 265). Some of the children had picked up quadrilaterals that they found interesting since they did not know their names and they were different from rectangles and squares. Then the KT said:

- Wilma: Do you know what? These two quadrilaterals actually have other names with mathematical terminology. They have four edges (She counts “one, two, three, four” aloud while simultaneously pointing at the edges).
- Susie: But what are they called then?
- Wilma: That one is called a rhombus (she points at the rhombus while speaking).

Susie: Rhombus.

Wilma: Rhombus. And that one, do you notice that two and two edges are equal (she points at the parallelogram she shows). That edge and that edge (slides her finger along the two opposite, parallel edges), are equal, and that edge and that edge are equal (slides her finger along the two other, opposite, parallel edges). Its name is actually a parallelogram.

Sam: A paragram?

Wilma: Yes, a parallel o gram.

In this excerpt we see that Wilma carefully introduces two new shapes for the children. She gets everyone's attention by holding up and showing one shape at a time. She emphasises that both shapes are conceptually associated with quadrilaterals, by overtly counting the edges. At the same time she makes it obvious that the two shapes are particular kinds of quadrilaterals. This is pinpointed by saying that they have "other names", implicitly distinguishing these shapes from the familiar quadrilaterals square and rectangle.

Wilma's orchestration in this excerpt exemplifies transformation in that she uses one example of each of the two new shapes. She points at each of them in accordance with what she is saying, and she demonstrates how to classify geometrical shapes by counting their edges. Her orchestration also exemplifies contingency due to the deviations from the agenda set by the researchers in the designed activity.

The dimension of connection is also exemplified in this excerpt as Wilma draws the children's attention towards the particular features of one of the shapes. Wilma carefully focuses at the two pairs of edges that are parallel, one pair at a time, by sliding her index finger along the edges. She neither uses the mathematical concept of parallel nor equal length at this occasion. She only uses the feature "equal". The feature of parallelism is thus only implicitly focused. However, by sliding her index finger along the two edges, her gesture signals that they are of equal length.

In the end of the dialogue we also notice that Wilma is particularly focused at offering opportunities for the children to learn the name of the new shape. On two occasions, Wilma uses the name "parallelogram" for the shape. Both times she puts emphasis on the expression "parallelogram". We see that Sam tries to pronounce the name, but only partly succeeds. Wilma then slows down the pace in her pronunciation of the word, in order for Sam, and the other children, to pay attention to the new word. Hence, we observe that Wilma is eager to name new objects mathematically correct. Naming is an important element in these children's mathematical learning process. However, both in this example and in other examples the naming of shapes comes at a late stage, after the children have presented their sorting of shapes and the KT has orchestrated a discussion of the properties of the shapes. We consider this as evidence of her taking an inquiry approach in her orchestration.

### **Excerpt 3: Contingency**

To exemplify this dimension of the KQ in Wilma's orchestration, we include examples of single moves which illustrate how she responded to the children's ideas, the questions and comments she used to make the children pay attention to various mathematical ideas. Even though she occasionally addressed her questions to one particular child, the other children still paid attention.

The analytical codes used were: “responding to children’s ideas; use of opportunities; deviation from agenda” (Rowland et al., 2005, p. 266).

Wilma drew the children’s attention towards the mathematical concept of sorting. Sam said: “Can we sort them?” (19). Then, some moves, but only a few seconds later, Wilma said: “Sam, what does it mean to sort?” (27). Wilma also drew the children’s attention towards mathematical features of the various shapes. One example was found when Sam said: “Yes, but these are small (points at the short edges of the rectangle). These two are equally long” (144). A few seconds later, Wilma responded to this utterance and asked all of the five children: “Does anybody know what the shape is called when two edges are quite long and two edges are shorter?” (147). With this question, she seeks to establish interest and curiosity, and thus to nurture playfulness in her orchestration.

Wilma likewise focused their communication around the similarities between the shapes. Susie talks about the fact that two shapes, two congruent triangles, may be joined in order to make a rectangle. She says: “Jack’s shapes have such..., but Ken’s do not have such when he puts them together” (196). Upon this statement of observation, Wilma responds immediately: “What happens when you put them together?” (197). Furthermore, Wilma addressed the children’s mathematical reasoning through questions like: “How did you figure out that one (points at one of the hexagons)?” (72); and “Do you want to tell the other children?” (227). These examples show that Wilma adopts inquiry as a way of being (cf. Jaworski, 2005) and responds to the children’s ideas and uses the opportunities that unveil in their interaction.

## Discussion

In this study we have considered the following questions: In what ways may the Knowledge Quartet be employed in order to characterise the kindergarten teacher’s competence? and What knowledge-in-action and knowledge-in-interaction does a kindergarten teacher reveal in her orchestration of a mathematical activity on geometrical shapes? From what is possible to include in this relatively short paper, we are able to discern instances of all four knowledge dimensions through which her orchestration of the mathematical activity is informed. As such, the Knowledge Quartet (Rowland et al., 2005) has proven to be analytically useful when seeking to wrap up how a KT is able to orchestrate researcher-designed mathematical activities. At the same time, we observe that the KQ unfolds slightly different in the kindergarten context than in the school context, the context from which the KQ was originally elaborated and developed. In the Norwegian kindergarten context, it is highly rare, even inappropriate to orchestrate mathematical activities through long introductions and demonstrations. Concerning the issue of time, we see that the periods where the KT has the word are quite short, often only 5-10 seconds. Furthermore, in the kindergarten context it is unusual to give children extensive time to inquire into the mathematics without KT interference. This is however a usual case in the school context. KQ contributory codes, such as use of textbook, reliance on procedures, teacher demonstration, and making connections between procedures, are partially inappropriate and inapplicable in the kindergarten context. Thus, our modification of the KQ materialised as not taking these codes into consideration.

It is challenging to separate the dimensions from each other in the dialogues. In the dialogues the dimensions are intertwined, where one move may simultaneously exemplify several dimensions. The excerpts above are thus not mutually exclusive when it comes to the four dimensions of the

KQ. For the purpose of this paper, however, the excerpts are deliberately chosen to illustrate how the KT reveals her knowledge-in-action and knowledge-in-interaction with respect to this particular mathematical activity.

*Mathematicians routinely report that beauty is both a reward and a motivation for the work they do. However, how and to what extent children can appreciate mathematical beauty is an open question. This exploratory study looks at young children (ages 6-12, with a focus on the younger years) as they evaluate different explanations of claims about even numbers and triangular numbers. While our results are fairly speculative, we provide case studies which illustrate possible kinds of aesthetic reactions, and some of the factors which might impact on those reactions.*

*Keywords: Aesthetics, explanation, even numbers, triangular numbers, affect.*

## Introduction

There is little doubt that mathematicians have rich, aesthetic lives (Sinclair, 2004). While recent research has attempted to characterize what exactly this aesthetic life consists of (Raman-Sundström, & Öhman, 2016) or what is meant by aesthetics in mathematics in the first place (Rota, 1997), evidence suggests that aesthetic reactions are common in, and perhaps even central to, the working lives of mathematicians. According to some, aesthetic reactions include pleasure, tension, surprise, and a sense of being compelled (or repelled) (Marmur & Koichu, 2016). Interestingly, neuroscientists suggest that the same region of the brain is involved for judging mathematical equations and works of art (Zeki et al., 2014).

Recently, there has been interest in studying aesthetics in mathematics education. While some of those studies have investigated school children's aesthetic reactions while working on mathematical problems (e.g., Sinclair, 2006), few have focused on young children. Yet, research has shown that young children are capable of sophisticated proof-like reasoning (Maher & Martino, 1996), justification, and argumentation (Tatsis, Kafoussi, & Skoumpourdi, 2008). Thus, it seems reasonable to ask whether young children could be capable of aesthetic experiences, and if so, at what age. Are young children able to experience the satisfaction of finding a good explanation? Do they find pleasure in coming to understand an explanation?

This paper presents an explorative study of the possible aesthetic experiences of young children. Mathematics, like other aesthetic subjects, provides experiences that have the potential to draw people in. It also provides a reward or a sense of satisfaction (Sinclair, 2004). What makes the experience "complete" is the presence of *both* a startup phase and a reward phase. We study the presence or absence of aesthetic reactions of young children (age 6-7) by comparing their behavior to an older cohort (ages 9-10). We find that the younger children, while lacking some of the insight of the older children, have what we might call "aesthetic dispositions" that allow them to enjoy and to be curious about fairly complex mathematical tasks.

## Theoretical background

One of the central questions of aesthetics is whether beauty is objective or subjective. According to Marmur & Koichu (2016), those that consider mathematical beauty as objective (such as Dreyfus and Eisenberg, 1986) list characteristics such as clarity, simplicity, brevity, and conciseness when judging theorems and proofs. In other words, beauty is an intrinsic property of the mathematical object. Those that consider beauty to be subjective, claim that mathematical beauty is in the eye of the beholder and that experience, age, knowledge, and culture contribute to aesthetical views. Marmur and Koichu (2016) integrate both views, concluding that when discussing school mathematics, we may hypothesize that a mathematical problem might elicit an aesthetic experience among students because of its simplicity or surprising result. Ultimately, however, students may or may not have an aesthetic experience depending on, among other things, the pedagogical setup of the problem.

In their study of university students, Marmur & Koichu (2009) found that surprise was integral to experiencing mathematical beauty. They found that students who referred to a solution as beautiful had first struggled with the problem, had put significant effort into finding the solution, and ultimately were surprised at the simple and unexpected solution. Struggle was also a factor in Brinkmann's (2009) study of middle and upper school students' appreciation of mathematical beauty. A problem was considered to be beautiful if it had a certain degree of complexity, yet felt solvable. Eberle (2014) investigated students' (ages 8-10) aesthetic attractions when evaluating geometric tessellations. Students referred to several characteristics of the geometric objects which contributed to their appreciation, such as real world connections, color, complexity, and uniqueness. Eberle (2014), as well as Sinclair (2001) also noted the generative role of aesthetics when students were involved in inquiry-based tasks. In both studies, aesthetics led students to engage and play with the mathematics, guiding them when deciding which direction to pursue.

The above studies related to aesthetics with regard to problems, solutions, and geometric objects. In our study, we focus on mathematical explanations and young children's appreciation of those explanations. Previously, Levenson (2010) found that fifth-grade students have preferences regarding different types of explanations. Students' preferences were based on clarity, brevity, relatedness, and because the explanation was perceived as fun. Although some of the reasons students mentioned for their preferences are reminiscent of aesthetic evaluations given by older students, and even mathematicians, the focus of that study was not specifically on aesthetic appreciation or satisfaction from an explanation. In this study, we draw on a theory of explanation developed by Gopnik (2000), which helps explain what makes certain explanations satisfying. Gopnik suggests that an explanation consists of two parts, the *why?* (the 'hmmm....' phase) and the *because!* (the *aha!* or *wow!* phase depending on how surprising the result is for the individual). An exploration can have a *why?* without a *because!* and vice versa. Both phases are needed for an explanation to be found satisfying. Moreover, Gopnik suggests that both the seeking and the satisfaction from finding a good explanation are part of our human nature.

The aim of this study is to begin an exploration of young children's appreciation of mathematical beauty. Specifically, we ask: Do young students' aesthetic reactions (or non-reactions) to mathematical inquiry and explanation differ from that of older students? Are younger and older

students capable of an experience that contains both the hmmm... and aha! phase of a mathematical explanation?

## Methodology

Data was collected using semi-structured interviews with two cohorts of children, one aged 6-7 years old, and one aged 9-10 years old. The older children worked with explanations about triangular numbers, namely that the number of dots in the  $n^{\text{th}}$  triangular number is  $n(n+1)/2$ . This cohort included four fifth grade girls, all from the same class, who sat together in a group with the interviewer in one of the girl's houses. The discussion began with introducing the girls to triangular numbers, discussing the number of dots in the first five triangles, and then asking them to come up with the number of dots in the 100<sup>th</sup> triangle. After giving them time to work on the problem, the girls were shown two solutions and asked to evaluate each solution.

The younger cohort of three children worked individually with the interviewer with explanations of the claim: the sum of two even numbers is always even. Two interviews were conducted in the house of the child and one was conducted in the house of the child's grandmother. Each interview began in the same way, asking the child to say if he or she could give examples of even numbers and to say why those numbers were even. After confirming that the children were familiar with even numbers they were given the following question: what would happen if you add two even numbers, would the answer be even or odd? Children were given time to think and reply. Although the interviewer had several explanations on hand for the children to evaluate, as will be shown in the next section, only one child was asked to evaluate explanations.

One of the difficulties of studying aesthetics in children, or even with mathematicians, is how to detect an aesthetic experience. While there may be bodily clues, such as changes in eye-dilation or neural correlates (e.g., Zeki et al., 2014), a natural place to start is by simply listening to what people say (see Wickman, 2006) and watching for engagement (or disengagement) during the experience. In this study, we take this approach as a first approximation, using key words (taken from the background studies) such as "Wow!" and "Funny!" as markers for a general aesthetic experience.

## Findings

Below we present four episodes, one with older girls and three with younger children. What is striking about the young children is that there is no sense of surprise. The children seem to lack the 'hmm....' needed to build the wow! or to even warrant an explanation.

### Fifth-grade girls, age 11

Trying to figure out how many dots will be in the 100<sup>th</sup> triangle proves challenging to the girls. When they realize that they would have to sum all of the numbers from 1 to 100, the interviewer gives them some time to work this out and then explains to the girls the Gaussian method for summing an arithmetic sequence. She lines up the numbers from 1 to 100 in one row and on top of that row, lined up the numbers from 100 to 1 (see Figure 1), explaining that this shows how many dots are in each row of the 100<sup>th</sup> triangle.

**Figure 1: Summing the numbers from 1 to 100****Figure 2: Combining two triangles**

To explain why one multiplies 100 by 101 and then divide by 2, the following discussion ensues:

Esther: Two triangles of 100, right? Now look what we have here. (Esther circles the 100 and 1 and the 99 and 2).

Girls: Ahh!

Esther: 1 and 100, 2 and 99, 3 and 98.

Trina: Wow! It's great. It's the same thing.

The girls are surprised that the sums all add to the same number, 101. Their remarks of "Ahh" and "Wow" indicate their pleasure in this simple conclusion. After showing the girls this explanation, the interviewer shows them a second method, that of drawing two congruent triangles, inverting one and placing it next to the first, thus creating a rectangle. The number of dots in the triangle is then equal to the area of the rectangle divided by two (see Figure 2). After establishing that the girls understand both explanations, the girls are asked to compare the two methods.

Esther: Which explanation of the method gives you more satisfaction?

(All of the girls point to the second explanation with the dots.)

Amanda: You simply see that you do this times this, and then divide by 2 because you have 2 triangles.

Hailey: Because instead of computing it all, this is easier and simpler and in front of your eyes.

Amanda: Also, it draws attention more. It's more fun, but not just more fun, it's like, it goes more into your head.

In the second segment, the girls claim to like the second explanation better because it is simpler and because they can "see it." This hints at their appreciation for the aesthetic value of efficiency, which might have been enhanced by their struggle to find the solution.

### **Zev, age seven**

Zev is seven years old, attends first grade in Israel, where learning about even and odd numbers is part of the curriculum in school. Zev is able to list several even numbers as well as several odd numbers. When asked why eight is an even number he says, "because four is even and ... because four is even and it's... and also... the second four is even." Note that he does not stress that 8 could be written as the sum of two equal whole numbers, but rather that both of the addends, in this case fours, were both even numbers. When asked why 10 is an even number, the following discussion ensues:

Esther: OK. Is ten an even number?

- Zev: Yes.
- Esther: How do you know that ten is even?
- Zev: Because odd plus odd is even.

Here Zev was probably thinking that 10 results from  $5 + 5$ , both odd numbers. Realizing that Zev seems already familiar with summing odd numbers, the interviewer asks about the sum of two even numbers:

- Esther: And what about an even number plus an even number?
- Zev: Even.
- Esther: Always?
- Zev: Yes.
- Esther: Can you tell me how you know that even plus even is always even?
- Zev: Four plus four, eight. Eight plus eight, sixteen.
- Esther: How do you know that sixteen is even?
- Zev: Because ten is even, and six is even.

For Zev, it seems that his working definition of an even number is of a number that can be written as the sum of two other even numbers. Although this is a recursive definition, it does not seem to bother him and the outcome of this conception is that Zev does not even recognize the question of what might be the sum of two even numbers. Zev has no sense of *hmm....* When Zev is shown another explanation for why the sum of two even numbers is always even (that every even number can be written as the sum of twos and thus the sum of two even numbers can also be written as the sum of twos), Zev says that the explanation is boring because he already knew that.

### **Anna, age six**

Anna is six years old and attends kindergarten in Israel. Although even and odd numbers are not part of the kindergarten curriculum, Anna was able to list several even and odd numbers and claimed to have learned about them from her teacher. When asked why eight is an even number she responded, “Because each one has a partner.” When she was asked to explain what an even number is, she said, “That the two of them have a partner. That each of them has a partner.” What Anna is alluding to in her own language is that an even number may be written as the sum of twos. After talking about even numbers for a few minutes, we discuss the sum of two even numbers:

- Esther: What would happen if I added an even number with another even number?
- Anna: It would be even.
- Esther: How do you know?
- Anna: Because both of them are not separate, it never separates from the second.
- Esther: What do you say! Are you sure that this is always this way?
- Anna: Yes. It will never be that, uhmm, a partner doesn't run away from the pair.

Anna has a very specific conceptualization of even numbers, that an even number represents an inseparable pair. She draws on this conceptualization to explain why the sum of two even numbers

must always be even. Engaging further with the problem, Anna takes out a bunch of wooden blocks from a basket (without counting) and proceeds to pair up blocks. When the interviewer asks if she can say if she took out an even or odd number of blocks she readily says that she took out an even number of blocks because on the table, every block is paired off. To summarize, Anna is drawn in to the problem, has an explanation, but she does not struggle with the claim.

### **Leila, age seven**

Leila is from Sweden, has just turned 7, and attends kindergarten. Although learning about even and odd numbers is not part of the curriculum, she is able to list several even numbers (perhaps hearing about them from her parents or friends). Although prompted to think about the possible sum of any two even numbers, Leila shows no interest and instead, with the use of colorful cubes, begins to explore a self-generated conjecture involving pairs of twos. She puts together six pairs of cubes to represent an even number and then wonders if seven pairs will still be even.

- Leila: I have a question. You can't have an odd number of twos.
- Manya: How are you thinking?
- Leila: Like, if I have these (pointing to the six pairs of cubes), you can never have an odd number. Look here. I have 1, 2, 3, 4, 5, 6. If I have this many (she takes another pair), now I have enough.... odd numbers of twos... because there's seven... does it get an odd number or an even? I think it is actually funny. If you have an odd number of twos, it even gets an even number. That I think is really funny.
- Manya: I see. Why is that?
- Leila: I don't know, because it feels like it's actually pretty funny.
- Manya: Do you think it's funnier to have an even number made of an odd number of twos than an even?
- Leila: What do you mean – an even number of odd number ...? Yeah. It gets an even number if you have an odd number of twos. Because I figured it out of these.

This discussion suggests that autonomy might play a role in having an aesthetic experience. Leila generates her own question (What is the sum of two odd numbers?) and the resolution of the question (that an odd number of twos can be even). She thinks that this conclusion is funny. While she might have had a similar reaction to a given statement, the affect seems to be closely correlated to ownership of ideas. In the last two lines, the researcher asks her to compare two statements. Leila replies “what do you mean”? The statement is funny to her because she “figured it out of these.”

### **Comparing the older cohort to the younger cohort**

The following table summarizes the observations from the data presented above and the children's aesthetic experiences (AE). A full circle represents that an AE took place, a dotted circle reflects a partial experience, and an empty circle that no AE was detected. In all of these cases, we can see that the path to having an aesthetic experience consists of several distinct phases. One needs to be engaged; there should be some build-up, some crucial moment, and then some release. Only the 10 year olds seem to have a complete experience.

Children	Age	Task	AE	Behavior
Trina, Hailey, Amanda	10	Triangular numbers		Have an aesthetic experience, marked by both surprise and satisfaction. They appreciate a solution which is simple and “goes into their head”.
Zev	7	Even numbers		Has a conception of even numbers, but is uninterested in explaining why the sum of evens is even. He “already knows that”.
Anna	6	Even numbers		Has a conception of even numbers which goes along with the claim about the sum of even numbers. Is engaged and involved, but is lacking a “hmmm....”
Leila	7	Even numbers		Takes control. Explores her own hypothesis. Tests if an odd number of twos can be even. Finds the result “funny”.

**Table 1. Types of aesthetic experiences for the triangular number and even number tasks**

Build-up takes place when they explore the question, and their interest increases as the interviewer shows the explanation involving pairs of numbers. After having time to digest this information, the interviewer shows another explanation which further increases their interest. Each time a new explanation is understood, the girls say words like “wow!” and “aha!”. The fact that they have this kind of reaction, we claim, is because they had time to explore and to start generating their own explanations. We also cannot rule out that there might be some developmental issues, such as the children being old enough to abstract and/or take in the explanations given.

In contrast to the fifth-graders, the younger students had limited or no aesthetic experience. Zev is strikingly uninterested in any explanation at all. We suspect that his disinterest came from the fact that he had been told in school that even + even is even, so there was no tension left to resolve. Leila has some interest in explanation, but not for the question given to her. Rather, she generates her own question about whether an odd number of pairs can result in an even number. She finds this result funny, indicating some level of surprise, which she quickly believed despite her initial expectation. Anna is drawn in to the explanation activity, but did not seem to have a full aesthetic experience. Unlike the fifth graders who could “see” why the explanations held, Anna simply states her conception of even numbers in terms of pairs or partners, and claims that any sum of pairs will still be even. She does not give an actual reason, which might be because she did not experience the hmmm... phase of explanation. She is not bothered by any alternative, so no relief or satisfaction is expressed.

## Conclusion

One of the challenges of this study was to find tasks that might elicit an aesthetic reaction. We attempted to find tasks that would be suitably challenging, yet accessible to each of the age groups. In the end, the older children worked on a new task, presented not only in general manner, but with an iconic illustration, while the younger children worked on familiar (at least for two children) general characteristics of numbers. Thus, it might be that the different conditions affected the aesthetic experiences. Taking these limitations into consideration, there is still the possibility of developmental differences in aesthetic experiences. In the naïve view, children have and rely on concepts, but are not yet puzzled. Because of this lack of puzzlement (an essential ingredient

according to several researchers (e.g., Gopnik, 2000; Marmur & Koichu, 2009)), there is no tension in their mathematical exploration, nothing to be resolved, and so no aesthetic experience is possible. In contrast, in the mature view, children are engaged and puzzled. They are more open to explanations because they themselves have struggled with the questions. This kind of behavior is possible among quite young children (Leila, at age 7, has a very small amplitude aesthetic experience when she generated her own conjecture), but might be more likely to occur the more autonomy is given to the students, the more challenging the task, and the more supported the students are to not to give up when they think they already have the answer. As an exploratory study, this paper has begun a discussion regarding young children's possible aesthetic experiences when working on mathematics. Additional research is needed to continue this discussion.

# Discovering regularities in a geometrical objects environment

Bozena Maj-Tatsis and Ewa Swoboda

University of Rzeszow, Poland; [bmaj@ur.edu.pl](mailto:bmaj@ur.edu.pl); [eswoboda@ur.edu.pl](mailto:eswoboda@ur.edu.pl)

*We present the analysis of a research conducted with first-grade pupils with a focus on their ability to notice and use regularities in three-dimensional geometrical objects by using playing blocks. The results show that children had difficulties in reconstructing the figure and retaining the regularities in the invisible part of it.*

*Keywords: Early years mathematics, patterns, regularities, geometrical objects.*

## Introduction

Discovering regularities is considered one of the most important processes involved in mathematics. Actually, developing an awareness of patterns is a significant step towards generalisation. Children are expected to be able to recognise, describe, duplicate and extend patterns, even at a young age. These assumptions are expressed in the Polish curriculum (Podstawa Programowa, 2011), in which the use of patterns and regularities appear in the first grades of primary schools; for example, the pupils are expected to be able to draw a particular pattern. However, much often the attention of the teacher is focused on the manual abilities of the students and not on mathematical thinking. In the next classes the topics do not play a significant role, according to the Polish curriculum.

In our study we designed a series of lessons for the first grade pupils using playing blocks. By observing constructions presented at pictures the children were asked to construct the same figures. In order to do so, they had to recognize a geometric pattern and/or a repeating pattern (Zazkis & Liljedahl, 2002), and then use their observations to their work. Our analysis was focused on children's ability in noticing regularities and in continuing them in their constructions. In our paper we describe a particular task in which the children had to reconstruct a three-dimensional figure and build an invisible part, which could be done by using the same pattern. We try to investigate to what degree the children subordinated their actions connected to building the invisible part of the construction to regularities of the visible part of the construction. Our theoretical framework is presented in the next section, followed by our methodology, the results and analysis, and finally our conclusions.

## Theoretical framework

### Discovering regularities in the primary school

In mathematics teaching exploring patterns is closely related to the development of mathematical thinking and reasoning: "Patterns are the heart and soul of mathematics" (Zazkis & Liljedahl, 2001, p. 379). This is underlined in many studies (e.g. Clements & Sarama, 2009; English, 2004; McGarvey, 2012; Threlfall, 2005). It is thus very important for every child from a young age to have contact with patterns; it is considered a way "to make connections to the world around them" (McGarvey, 2012, p. 310). As Frobisher and Threlfall (2005) state, in their first years of schooling students should develop abilities to describe, complete and create patterns. Tasks that involve patterns encourage students to verbalize their ideas, thus improve their communicational ability (Garrick, Threlfall & Orton, 2005). Moreover, searching for a regularity is an extremely effective method during solving

mathematical problems. English and Warren (1998) suggest a patterning approach as a way to introduce the concept of variable. Mulligan and Mitchelmore (2013) introduce the construct “Awareness of Mathematical Pattern and Structure” in order to study the development of structural understanding; moreover, they claim that this development is related to the big mathematical ideas of generality and equal grouping.

Although patterns and regularities are considered vital, in some cases they do not stand on their own in the curricula and teachers see such activities as merely an enrichment to more “traditional” activities. On the contrary, we believe that “algebra, and indeed all of mathematics is about generalizing patterns”. (Lee, 1996, p. 103) Therefore, patterns should be observed and studied in many different manifestations in mathematics.

### **Three-dimensional geometry in the early mathematics classroom**

Although small children have many experiences with handling three-dimensional objects within their play, early geometry curricula usually place three-dimensional geometry to higher educational levels (Swoboda & Vighi, 2016). In Polish primary schools, space geometry is almost absent in the first three grades. According to the National Curriculum (Podstawa Programowa, 2011), the only relevant topics are recognising and naming basic geometrical two-dimensional figures. Generally, the tasks proposed in the textbooks have a reproductive character and are directed into building the concept of geometrical object. Much often the tasks impose scientific terminology. There is lack of tasks which could be a cognitive challenge connected to geometric problem solving. The tasks in which the pupil has to use some geometrical properties of objects or some observed relations are also missing in the first years of school mathematics. Moreover, there are very few tasks related to three-dimensional geometry. Such tasks have a significant influence on development of thinking and imagination of a child who is surrounded by three-dimensional objects.

### **Context of the study and methodology**

The starting point for our research was a general question concerning the degree that 6-7-year-old children can grasp regularities formed in a three-dimensional environment. The research was conducted by a preservice teacher (Falger, 2016) – a master student supervised by the second author of the paper – among 16 first grade pupils (6-7-year-old). It consisted of a series of four lessons of around 45 minutes and it was realized in the period of February – April 2016 every two weeks. The preservice teacher was known to the pupils. The research tools were series of tasks, which were based on creating a construction by wooden playing blocks of dimensions 3 cm × 3 cm × 3 cm in three colours: red, blue, and yellow. The classes comprised a sequence of activities which started by building “towers” and “snakes” (considered as one-dimensional figures) then by “walls” of different shapes and regularities (considered as two-dimensional figures) and continued by three-dimensional constructions which were also based on some regularities. During the classes the children were asked to build some constructions presented on a picture; sometimes this was accompanied by building the figure by the teacher. All the lessons were video recorded; additionally, photos were taken. All the phases of pupils’ work were reconstructed and analysed by using the video; the process of analysis was supported by the photos and the notes of the preservice teacher.

For the purpose of this paper we will focus on the last lesson which consisted of two different activities. The first task was to build a construction which was presented to the children on a picture

(Figure 1, shape on the left) and then the pupils were asked to continue the figure. The second task was to build the construction presented on a picture (Figure 1, shape on the right) and built by the preservice teacher by using the blocks. For a short time the pupils could observe it in order to familiarize with it (still a part remained invisible to the pupils) and after that the building was destroyed. The children were expected to rebuild it. At the end of the activity the teacher asked them individually: “Which blocks did you use where it was not visible? Why?”. In this paper we will analyse the second activity.

**Figure 1: The first and the second construction during the fourth lesson**

Both constructions were classified as visual geometric patterns (Zazkis & Liljedahl, 2002) in which we can observe two types of regularities: the colour repetition (“repeating pattern”, Zazkis and Liljedahl, 2002) and the heights of the “towers” which increase by one block (“geometric growth pattern that can be quantified”, McGarvey, 2012). The first figure can be considered a two-dimensional one and the second figure three-dimensional. In the second construction there is an “invisible” part which has to be built by the children.

Our analysis was mainly based on the videotaped process of building the constructions of every child; additionally, we collected data from a discussion with the pupil at the end of the task. All aspects of pupils’ works emerged during the process of analysis, according to a grounded theory approach (Strauss & Corbin, 1998). We focused on answering the following research question: To what degree children will subordinate their actions for building the invisible part of the construction to regularities existing in its visible part? In particular, we have formulated the following research questions:

- a) Were the pupils able to reproduce regularities in the visible part of the construction?
- b) Did the invisible part of the construction retain any regularities during the students’ work?  
Which student activities led to the retain of the regularities?

## Results and analysis

In this section we will present the results of the second activity during the fourth lesson. Firstly, we present a detailed analysis of the works of three pupils as characteristic cases. All pupils’ names are pseudonyms.

### Ania’s work (Figure 2)

The girl started her work from constructing a “tower” which contained four red blocks. Then she created a blue “tower” of three blocks and located it next to the initial one. The next step was one red two-blocks “tower” which she put next to the blue one. The wing was finalised by one blue block. After that, she started building another “tower” from four blue blocks. Next to it she located a red two-blocks “tower” and one blue block. She had left one blue block which she put at the top of the construction, half at the red and half at the blue “tower”.

**Figure 2: Ania's work**

Ania used a different regularity of colours than in the picture; her “towers” were the same colour and occurred by turns. She consequently kept that rule. She built her “towers” decreasingly, the first part of her work retained the regularity of heights but in the second “wing” she made a mistake. Her work started from the invisible part and that somehow determined the rest of the construction. The only visible element of the highest “tower” was red, which could cause the decision of the colour choice for the whole “tower”. Ania built the whole “tower” in one colour and that influenced the fact that the rest of “towers” were also one-colour. The process of creating one “wing” with her own ad hoc rule could pull her back from analysis of the regularity at the picture. During building of the second part of the construction she repeated her own rule and she changed only the first colour into a blue one. She also forgot that the four-blocks “tower” appeared only once in the construction. By putting the last block she probably tried to keep the regularity of the heights of the “towers” and to balance the two contradictions of the right and left “wings”.

#### Kuba's work (Figure 3)

He firstly built the “right wing” and then the “left wing” of the construction, according to the template. Then he connected the two separated “wings” with the edges of the cubes. He completed the construction by a “tower” of four blocks: blue, red, blue, and red. He continued the regularity created by the second “left wing”.

**Figure 3: The phases of Kuba's work**

Kuba worked very precisely and systematically; all his movements were intentional. He created the construction correctly. He recognised and used the regularity of colours and heights. The last part of the figure – the invisible “tower” – was an effect of continuation of the regularities previously created and connected to the construction of the “left wing”.

#### Julia's work (Figure 4)

The girl started the construction from the invisible “tower” in the order: blue, red, blue and red block. Then she continued the “left wing” by constructing the “towers” of three blocks: red, blue and red, then two blocks: blue and red. She finalised the “left wing” by a red block. In that way she created a regular wall, concerning the colours and heights. Then she constructed the “right wing” by a “tower” of three blocks, then two-blocks “tower” and the last blue block.

**Figure 4: Julia's work**

Julia was the only one who fully succeeded in the task by starting her construction from the invisible part. That part was a result of her imagining the continuation of one of the walls (the left wing). She applied the observed pattern without testing it on the visible parts of the figure. Thus, she started from realising the imagined part and then she reproduced the pattern in the opposite order. Her building of the “wing” was done by lower “towers” of alternate colours, thus we can conclude that the base of her first decision was determined by firstly ascertainment of the height (four blocks) and calculation back: red – blue – red – blue. Even the contradiction between the left and the right “wings” did not affect her self-confidence.

The analysis of the process of building the second construction (Figure 1) of all 16 pupils, led us to the following aspects. We have to note that one work may contain more than one aspects:

1. Regularity of colour – a pupil puts red and blue block in a staggered manner;
2. Grouping colour – a pupil is grouping the colours by building short series of same colour blocks;
3. Regularity of shape – the figure's shape is reconstructed correctly;
4. Partial regularity of shape – a pupil reconstructs only one part of the figure (one “wing”); s/he has difficulties in building the second “wing”.
5. Student's own shape – a pupil builds a construction which is not related to the template.
6. The invisible part built first – a pupil starts the work from the invisible “tower”;
7. The invisible part built as last – a pupil starts from the visible parts and at the end of work s/he completes the invisible “tower”;
8. Colour regularity of the invisible part – a pupil uses the same rule of the colours which was observed in one of the “wings” of the construction;
9. Lack of colour regularity of the invisible part – a pupil does not use the rule of the colours.
10. Proper height of the invisible part – a pupil builds a “tower” by using 4 blocks;
11. Improper height of the invisible part – a pupil uses less or more than 4 blocks.

Table 1 presents the pupils' ways of work in relation to the aforementioned aspects. We may notice that 15 works contain more than four aspects; each aspect present in a particular work is marked by x. Only Bartek's work does not contain any aspect: this boy did not build anything during that activity; he was just repositioning the blocks. He justified this in the following way: “I don't want to build anything. I have already built something before (referring to the previous task)”.

No.	Pupil's name	Characteristic aspects of the pupils' works										
		1	2	3	4	5	6	7	8	9	10	11
1.	Kuba	x		x				x	x		x	
2.	Zosia	x		x				x	x		x	
3.	Dawid	x		x				x	x		x	
4.	Julia	x		x			x		x		x	
5.	Maciek	x		x				x		x	x	
6.	Franek	x			x			x	x			x
7.	Borys	x	x		x		x		x			x
8.	Paula	x			x		x		x		x	
9.	Ania		x			x	x			x		x
10.	Wiki	x	x			x		x		x	x	
11.	Staś		x			x				x	x	
12.	Leon		x			x	x			x	x	
13.	Kamila		x			x	x			x		x
14.	Basia		x			x	x			x		x
15.	Jola		x	x			x			x	x	
16.	Bartek	-	-	-	-	-	-	-	-	-	-	-

**Table 1: Characteristic aspects of the pupils' works**

Only four children managed to build the correct construction by using the observed patterns: Kuba, Zosia, Julia and Dawid. They all used the regularity of colour (aspect no.1) and preserved the regularity of the heights of the “towers” (aspects no.3 and 10). They created the “invisible tower” which retained the colour regularity of one “wing” (aspect no.8). In Kuba, Zosia and Dawid’s constructions the highest “tower” was a consequence of their work on the “wings” and was created as the final element. Julia started her construction from the “invisible” element. The remaining eleven children (without Bartek) tried hardly to complete the task. They used the experience from previous lessons by putting the red and blue blocks in a staggered manner (aspect no.1) or grouping them according to the colours (one “tower” red, then blue or bases of the “towers” are blue and the next level of the “towers” are red, etc. – aspect no.2). Five of the mentioned children used the regularity of colour (aspect no.1) and three of them transferred their observation into the invisible part, where they applied that regularity (aspect no.8). Two pupils out of eleven were able to reconstruct the shape by using the shape regularity together with space imagination (aspect no.3) but failed to keep the colour regularity (aspects no.1 and 9). Five children did not notice that the invisible “tower” is the highest one and contains 4 blocks (aspect no.11; usually the “tower” was built from three blocks, in one case it was five blocks). During reconstructing the processes of the pupils’ works it can be noticed that the buildings were changed when the children reached the invisible “tower” and then they usually lost their regularity. It seems that the invisible part of the figure dominated the pupils’ trials of constructions and most of their difficulties were caused by the fact that it was hard to imagine what is behind of the figure. Four examples of the constructions are shown in Figure 5.

Figure 5: The works of Staś, Leon, Kamila and Jola (from left to right)

Although almost all children did not have any problem in building the first construction (Figure 1) in which they used the observed visual geometric patterns: the repetition of the colours and increasing the heights of the “towers”, building the second construction seemed to be very difficult. While in the first task all children were able to use their experience from the previous lessons, in the second task the experience was not enough for some of them. We may claim that working with geometrical patterns in a three-dimensional environment is much more difficult than in a two-dimensional one and that patterning skills obtained in a two-dimensional environment are not easily transferred.

## Conclusions

In early years mathematics it is expected that children will easily recognise patterns, particularly they should impose regularities on visual images and describe the rules that help to extend or predict those regularities (McGarvey, 2012). Many researchers express the opinion that recognising patterns is one of the most important skills which are necessary for algebraic thinking (e.g. Lee, 1996). On the one hand, research has shown that “perceiving a pattern is not difficult. Students successfully recognize patterns by imposing structural regularities onto visual and symbolic phenomenon” (McGarvey, 2012, p. 313). On the other hand, our study has shown that many children failed to construct the presented pattern. Only four out of sixteen pupils performed the task correctly and, additionally, retained the regularities in the invisible part. Although the teacher did not mention that the hidden “tower” should follow the rule of the whole figure, they felt the need to continue it. The task turned out to be difficult; however, many children presented their trials in keeping the regularities they observed. They demonstrated their good intuitions and imagination. In most works we could find a rule which was dominant and influenced the final performance.

Our data shows that even if the children had difficulties in reconstructing the figure, they were motivated and their work was intentional. The combination of two regularities and the three-dimensional geometrical object was challenging and such activities brought new experiences to the pupils. The tasks using three-dimensional geometric patterns unveiled that the children in early years need such stimulations. Such activities engage pupils in discovering regularities but also in experiencing and “touching” geometrical objects.

*How can we design mathematical instructional activities that reveal children's early mathematical competence in an analogous way as school activities that exploit children's mother language competence? We put forward a list of mathematical conceptions young children may have been taught previously and some subsequent actions developed to observe them and guide their first steps in mathematics in an instructional context. The list has been developed on the basis of insights from modern axiomatic presentation of arithmetic and geometry contrasted with historical results and epistemology of mathematics. We discuss the application of the list in a singular context, a group of eight 3 to 8 year-old Spanish children with Trisomy 21, to show the suitability of this tool for revealing early mathematical competence.*

*Keywords: Experiential learning, early years education, special needs, mathematical skills.*

### The central issue: Enhancing young children's competence in mathematics

The starting point of our research was a situation of stagnation in two different and singular educational contexts: the encounter with mathematics of Italian primary first graders and the special needs of children with Trisomy 21(or Down syndrome).

Actual current praxis in Italian first grade classrooms<sup>1</sup> and the available research and teaching materials regarding mathematics for children with Trisomy 21 show a remarkable similarity in two aspects. Firstly, from the point of view of contents, there is a focus on numeracy and especially on teaching and learning of numerals and written arithmetic and a clear exclusion of geometry. Secondly, from a wider cultural point of view, we witness a marked lack of confidence in the relationship between mathematics and children's feelings and mind. (Millán Gasca & Gil Clemente, 2016). Both aspects are interrelated. As mathematics is socially viewed as a key component of our modernity, school is forced to cope with the difficulties of its teaching and learning. Consequently, teachers must concentrate on the traditional hardcore, that is, numeracy and practical tasks,

---

<sup>1</sup> A quite homogeneous didactical praxis was identified thanks to the relationship of the Roma Tre University Department of Education with schools (private, state, urban and rural, and with students from different social backgrounds) in the Lazio area in 2006-2014. Although compulsory mathematics teaching or initiation for 3 to 5 years old children is not laid down, in some Italian preschools, including the wide number of state Montessori schools, mathematics is a part of the curriculum and goals. A sharp contrast is experienced between the good results obtained in these latter schools, where pupils usually show a deep interest and curiosity towards number and geometry, and a general situation of difficulty, anxiety and fear of primary school first graders starting in the first months of first grade where schoolwork is focused on exercises about the writing of the numerals from 1 to 9 and moving on to addition and number symbols with two digits from 11 to 20 after 3-4 months.
