Introduction
• Different behaviour and effects of metal-bearing nanoparticles (NPs) have been found compared to their corresponding metallic ions [1,2].
• Toxicity of metal-bearing NPs isn’t easily predicted when comparing to corresponding ionic form
• It is unclear whether toxicity of metal-bearing NPs is dependent on particle size.

The aim of our study is to exam effects at the individual level by measuring typical endpoints in two organisms (i.e., a marine polychaete, Capitella teleta and a marine bivalve, Macoma balthica) after exposure to sediment amended with different forms and particle sizes of Ag.

Hypothesis:
Toxicity and biota is metal form/particle size dependent? (Here are their relative differences in size)

Ion Nano-particle Micron-sized particle

Result – Macoma balthica

Toxicity
No negative effects were detected on mortality, condition index or growth of exposed clams for any Ag form (data not shown).

Bioaccumulation
Bioaccumulation of Ag in M. balthica decreased significantly with increasing particle size (One-way ANOVA, p = 0.03) (Figure 1).

Result – Capitella teleta

Toxicity
No significant effects on either mortality or specific growth rate were detected for any Ag form or nominal concentration (data not shown).

Bioaccumulation
There was no significant effect of Ag form on Ag accumulation in C. teleta, although body burden increased significantly as a function of nominal concentration (One-way ANOVA, p = 0.001) (Figure 2).

Conclusions
• No significant effects on mortality and growth of C. teleta and M. balthica.
• All Ag forms are bioavailable to both organisms.
• Metal form/particle size dependence of bioavailability is species specific, possibly due to differences in:
  • gut structure, thus
  • particle sorting mechanisms

Such differences in the bioavailability of metal-bearing particles warrant further investigation and consideration in terms of the impact of them in sediment environments.
